

**Handbook of Nonprescription Drugs** > Chapter 1. Self-Care and Nonprescription Pharmacotherapy**Self-Care**

*Self-care* is the independent act of preventing, diagnosing, and treating one's illnesses without seeking professional advice. Preventive self-care involves maintaining well-being and appearance through exercise and a healthy lifestyle. For many individuals, a healthy lifestyle includes controlling their diet; taking vitamins, minerals, and herbal supplements; participating in regular exercise and keeping fit; and maintaining their appearance by using dental, skin, and hair care products. However, sickness self-care for individuals involves diagnosing their conditions and obtaining products for the goal of mitigating illness and relieving symptoms. Examples of sickness self-care include use of dietary options (e.g., warm soup for a cold); use of devices for both disease assessment (e.g., home blood glucose meters and pregnancy tests) and treatment (e.g., ice packs, first-aid bandages, vaporizers, and nasal strips); and use of nonprescription medications. The use of sickness self-care products is limited to mild illness or short-term management of illness, and most products warn users to contact a health care provider if conditions do not improve within a short period of time.

For the provision of sickness self-care, one individual from each household usually plays a leading role in adopting a course of action. This individual must determine whether a health care provider should be consulted or whether the use of home remedies and self-care will suffice. Furthermore, the number of individuals involved in choosing the most appropriate self-care option is increasing because of the growth of the U.S. geriatric population, whose members are known as high users of nonprescription medications.<sup>1</sup>

Individuals responsible for providing self-care for themselves or family members rely on knowledge and experience to guide their decisions. For better or worse, there is no shortage of information, given the wealth of health-related self-help books, newspaper feature articles, magazine and television advertisements, magazine articles, radio programs, instructional tapes and CDs, DVDs, and Internet sites—all of which provide self-care advice. The availability of coupons indirectly provides information and encourages cost savings for trying a product. The abundance of available health-related information, especially from the Internet, helps individuals become more "self-empowered" to address their health care issues and leads to aggressive marketing and use of self-care alternatives. The quality of the information ranges from excellent to very poor. Although it is more accepted today for individuals to attempt to manage their health-related issues rather than to consult a health care provider, the concern is whether they are making appropriate and informed decisions. Furthermore, all this health information can become overwhelming, driving some individuals to seek advice from family and friends. This well-intentioned advice can be problematic because it is often biased, and most individuals are not sufficiently informed or qualified to consider another's health conditions or medications before making a recommendation. They simply state what has worked best for them and fail to consider how their approach might apply to someone else.

Commercial products used for preventive or sickness self-care are often classified together as health and beauty care (HBC) products. Staggering numbers of HBC products are available. Although access to quality HBC products is crucial to the goal of self-care, the vast number of similar, competing products makes appropriate selection difficult. Yet, in one consumer poll in which 66% of adults believed that the wide range of competing products made selection difficult, less than half (43%) said they consulted a pharmacist before making a purchase.<sup>2</sup> The pharmacist plays a crucial role in assisting patients who are seeking both preventive and sickness self-care products. The practicing pharmacist has the expertise to screen patient health information and apply his or her knowledge and training to select products according to individual health care needs. Therefore, for pharmacies to provide pharmacist-assisted self-care, only quality HBC products should be stocked, and a pharmacist should be readily available for patients seeking assistance. More and more pharmacies are changing their floor layout and design and staffing to ensure that a pharmacist is available and easily accessible to patients seeking advice in the nonprescription drug aisles. At times, this change coincides with the implementation of a retail clinic staffed by a nurse practitioner or a physician assistant as a primary care provider.

**Self-Medication**

Self-medication is often the most sought-after first level of self-care. As self-care has increased, so has the practice of self-medication with vitamins (i.e., nutritional dietary supplements), natural products (i.e., herbal/botanical and nonherbal dietary supplements [e.g., glucosamine]), and nonprescription medications. Factors that help drive reliance on self-medication include (1) growth of the aging population, (2) decreased availability of primary care providers, (3) increased costs of health care, and (4) high proportion of underinsured or uninsured people in the United States. Easy accessibility, convenience, and cost-effectiveness of self-medication products ensure their essential role in the U.S. health care system.

Results of a 2002 survey conducted for the National Council on Patient Information and Education (NCPPIE)<sup>3</sup> illustrate how ubiquitous the use of nonprescription medications has become. According to the survey, 59% of Americans had taken at least one nonprescription medication in the preceding 6 months. [Table 1-1](#) illustrates some of the conditions that are self-treatable with nonprescription medications. Conditions and symptoms commonly treated with nonprescription medications include the following:

- Pain (78%)
- Cough/cold/flu/sore throat (52%)
- Allergy/sinus problems (45%)
- Heartburn/indigestion (37%)
- Constipation/diarrhea/gas (21%)
- Minor infections (12%)
- Skin problems (10%)

Approximately 20% of Americans believe that they are consuming more nonprescription medications and taking them more frequently than they did 5 years earlier.<sup>3</sup> This increase in nonprescription drug use may reflect a consumer belief that self-medication is safe.

Additional data collected in the survey “Your Health at Hand: Perceptions of Over-the-Counter Medicine in the U.S.” supports the view that consumers and physicians are confident in their use of nonprescription medications.<sup>4</sup> These survey results show the following:

- 93% of physicians believe it is important that medications for minor ailments be available over the counter.
- 96% of consumers believe nonprescription medications make it easy to care for minor medical ailments.
- 87% of physicians and 89% of consumers believe nonprescription medications are an important part of overall and family health care.
- 93% of adults prefer to treat minor ailments with nonprescription medications before seeking professional care.
- 88% of physicians recommend patients address minor ailments with self-care, including nonprescription medications before seeking professional care.

**TABLE 1-1 Selected Medical Disorders Amenable to Nonprescription Drug Therapy<sup>a</sup>**

Abrasions	Cold sores	Gastritis	Ostomy care
Aches and pains (general, mild-moderate)	Colds (viral upper respiratory infection)	Gingivitis	Ovulation prediction
Acidity, stomach	Congestion (chest, nasal)	Hair loss	Periodontal disease
Acne	Constipation	Halitosis	Pharyngitis
Allergic reactions (mild)	Contact lens care	Hangover relief, morning	Pinworm infestation
Allergic rhinitis	Contraception	Head lice	Premenstrual syndrome
Anemia (after diagnosis by a health care provider)	Corns	Headache	Prickly heat
Arthralgia	Cough	Heartburn	Psoriasis
Asthma (after diagnosis by a health care provider)	Cuts (superficial)	Hemorrhoids	Ringworm
Athlete's foot	Dandruff	Herpes	Seborrhea
Bacterial infection (dermatologic, mild)	Decongestant, nasal	Impetigo	Sinusitis
Blisters	Dental care	Indigestion	Smoking cessation
Blood pressure monitoring	Dermatitis (contact)	Ingrown toenails	Sprains
Boils	Diabetes mellitus (insulin, monitoring equipment, supplies)	Insect bites and stings	Strains
Bowel preparation (diagnostic)	Diaper rash	Insomnia	Stye (hordeolum)
Burns (minor, thermal)	Diarrhea	Jet lag	Sunburn
Calluses	Dry skin	Jock itch	Teething
Candidal vaginitis	Dyslipidemia	Migraine	Thrush
Canker sores	Dysmenorrhea	Motion sickness	Toothache
Carbuncles	Dyspepsia	Myalgia	Vomiting
Chapped skin	Fever	Nausea	Warts (common and plantar)
	Flatulence	Nutrition (infant)	Xerostomia
		Obesity	Wound care
		Occult blood, fecal (detection)	

<sup>a</sup> The pertinent nonprescription medication(s) for a particular disorder may serve as primary or major adjunctive therapy.

Source: U.S. Food and Drug Administration. Status of OTC rulemaking. February 17, 2011. Accessed at <http://www.fda.gov/Drugs/DevelopmentApprovalProcess/DevelopmentResources/Over-the-CounterOTCDrugs/StatusofOTCRulemakings/default.htm>, June 2014.

A major 2012 survey of more than 3200 individuals provides information regarding the value of nonprescription medications and their contribution to cost savings and quality care in our health care system.<sup>5</sup> These data showed the following:

- Availability of nonprescription products provides \$102 billion in annual savings relative to alternatives and increased access to medications.
- Each dollar spent on nonprescription medications saves \$6-\$7 for the health care system.
- In the previous 12 months, 79% of consumers (or approximately 240 million people) took a nonprescription drug in the categories of allergy, analgesics, antifungals, cough/cold/flu, lower gastrointestinal, upper gastrointestinal, and medicated skin.
- 180 million individuals would seek treatment from a primary care provider if nonprescription medications were not available.

Self-medication plays an increasing role as adjunctive therapy for chronic diseases that are managed with prescription medications. Examples include low-dose aspirin for reducing heart attack risk, fish oil (omega-3 fatty acids) to help manage certain dyslipidemias, and glucosamine with chondroitin to help relieve symptoms of osteoarthritis. However, the use of nonprescription products as adjunctive therapy comes with potential risks associated with incorrect product selection. For example, many patients who require daily low-dose aspirin do not fully understand the differences between the many aspirin products. There are various strengths (low dose, regular, and extra strength) and products (chewable, buffered, and enteric coated). Selection of the wrong product could result in adverse reactions (e.g., gastritis or ulcer) or drug-drug interactions (e.g., warfarin and blood pressure medications). The pharmacist plays an important role in helping patients select the correct products for their condition.

### Options for Self-Medication

Three general categories of products are available for self-medication: (1) nonprescription medications, (2) nutritional dietary supplements, and (3) natural products and homeopathic remedies.

#### Nonprescription Medications

Nonprescription medications are regulated by the Center for Drug Evaluation and Research, a division of the U.S. Food and Drug Administration (FDA)—the same agency that regulates prescription drug products. As such, nonprescription medications are held to the same drug product formulation (e.g., purity and stability), labeling, and safety (benefits outweigh risks) standards as those for prescription medications. A complete discussion of the monograph system can be found in [Chapter 4](#). It is worth noting that, although nonprescription medications are regulated in a manner equivalent to that of prescription medications, the sales of nonprescription medications are not limited to pharmacies. They are also available in retail establishments such as discount stores, supermarkets, and gas station quick stops and on a plethora of Internet sites.

The provisions of the 1951 Durham-Humphrey Amendment to the Food, Drug, and Cosmetic Act of 1938 gives FDA the final authority to categorize a medication as prescription or nonprescription. FDA deems nonprescription medications safe and effective when they are used without a prescriber's directive and oversight. In addition, these products have the following characteristics: they have a low potential for misuse and abuse; patients can use them for self-diagnosed conditions; they are adequately labeled; and they do not require access to a health care provider for safe and effective use.<sup>6</sup> The estimated number of available FDA-approved nonprescription drug products is 100,000, including more than 1000 active ingredients that cover more than 80 therapeutic categories. *Your Health at Hand Book: Guide to OTC Active Ingredients in the United States* provides an extensive list of active ingredients, therapeutic categories, and examples of brand name products.<sup>7</sup> Sales of nonprescription medications in 2011 were estimated at \$17.4 billion dollars.<sup>8</sup> Sales of the top 15 therapeutic categories of nonprescription medications for 2011 are shown in [Figure 1-1](#).<sup>9</sup> Not surprisingly, the dollars spent, as shown in this figure, correspond to what consumer surveys have reported as the most common conditions managed with self-care. For example, in a survey in which consumers were asked what health problems they had experienced in the preceding 6 months, the most frequent responses were muscle/back/joint pain and cough/cold/flu/sore throat (both categories at 48%), with headache and

heartburn/indigestion trailing at 43% and 32%, respectively.<sup>10</sup> The correlation between common types of illnesses and dollars spent implies that many Americans provide self-care for those conditions using nonprescription medications.

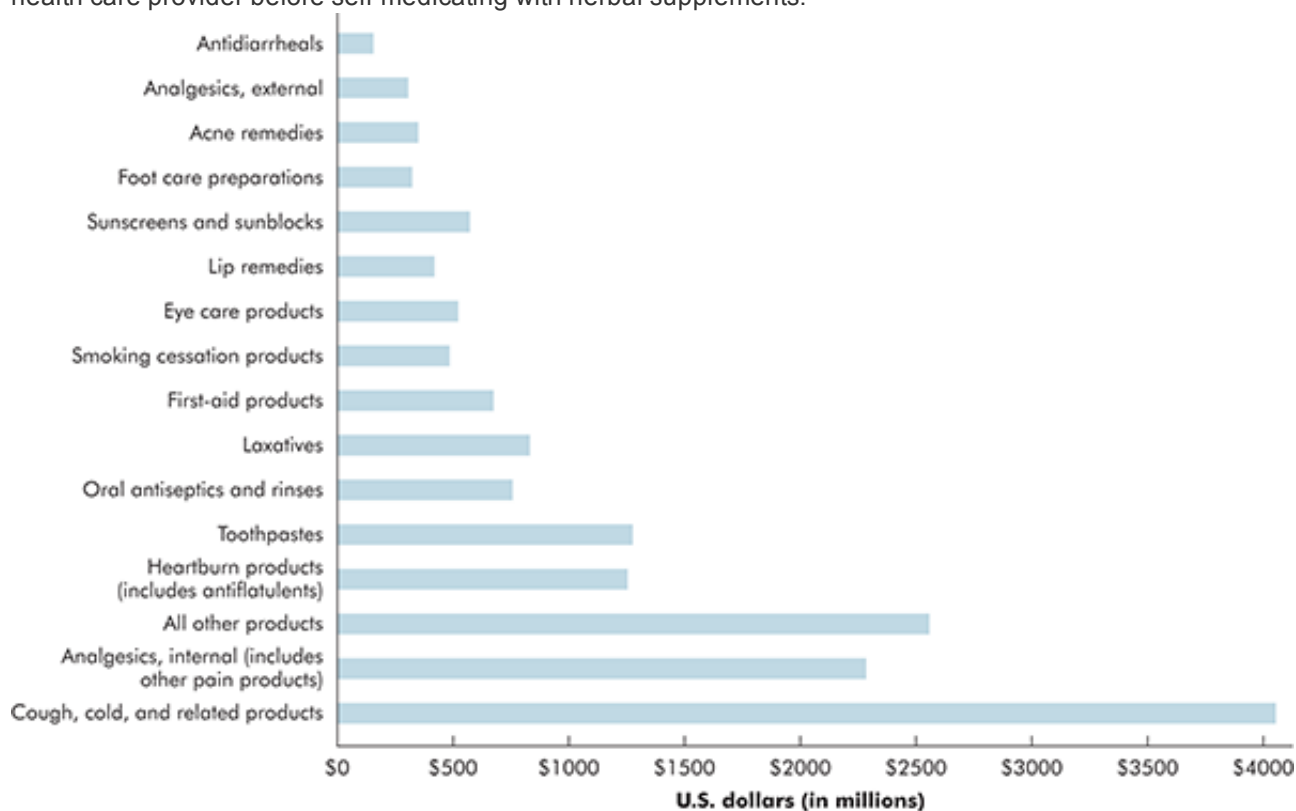

### Nutritional Dietary Supplements

The Dietary Supplement Health and Education Act of 1994 amended the 1983 Food, Drug, and Cosmetic Act to establish standards with respect to dietary supplements. The amendment defined dietary supplements as products that are intended to supplement the diet and that bear or contain one or more of the following dietary ingredients: (1) a vitamin, (2) a mineral, (3) an herb, or (4) an amino acid. Results from a recent National Health and Nutrition Survey indicate that more than 50% of adults used one or more dietary supplements between 2003 and 2006.<sup>11</sup> A survey of college students found that almost three-quarters (71%) had used an herbal or nutritional supplement and that 61% had used both a nonprescription product and a nutritional or herbal supplement within the past year.<sup>12</sup> (See [Chapters 50, 51, and 52](#) for further information on dietary supplements.)

### Natural Products and Homeopathic Remedies

Because of factors such as high health care costs and restricted access to conventional health care providers, many patients seek care from providers of complementary and alternative medicine (CAM). The National Center for Complementary and Alternative Medicine and the National Center for Health Statistics reported survey results on Americans' use of CAM.<sup>13</sup> Approximately 38% of adults and 12% of children reported receiving some form of CAM therapy in 2007. Some of the most common forms of CAM therapy were natural products (18%), deep breathing (13%), meditation (9%), chiropractic and osteopathic care (9%), massage (8%), and yoga (6%). Adults spent approximately \$34 billion out of pocket to visit CAM providers and purchase products.<sup>14</sup>

Self-care is a component of many CAM therapies. By definition, the term *dietary supplement* includes both herbal and natural products. In 2011, the total estimated sales of herbal products were \$5.03 billion, with the top-selling supplements being cranberry, soy, saw palmetto, garlic, and echinacea.<sup>15</sup> A 2002 National Health Survey indicated that about 13% of elderly patients had used an herbal supplement during the preceding year.<sup>16</sup> The use of combined herbal and conventional therapy raises safety concerns because 51% of patients failed to inform their health care provider about their herbal therapy.<sup>11</sup> These safety concerns include the potential for herbal supplement-drug interactions. Lexi-Comp's Lexi-Interact database (Hudson, Ohio, Lexi-Comp, Inc., 2013) lists several hundred herb-drug interactions, with garlic, St. John's wort, the various ginseng products, and *Ginkgo biloba* leading the way. Therefore, individuals who take prescription or nonprescription medications should consult with a pharmacist or other health care provider before self-medicating with herbal supplements.

## Influences on Self-Medication

### Costs

Patients often seek self-care and nonprescription medications to avoid the costs associated with a primary care provider visit. Pharmacists can help these individuals by triaging to determine the appropriateness of self-care (see [Chapter 2](#)). Although nonprescription products can reduce overall costs, federal legislation eliminated one of the benefits. Nonprescription medications purchased over the counter can no longer be paid for by flexible spending accounts and health savings accounts. However, the Affordable Care Act of 2010 included a provision allowing reimbursement for nonprescription medications if they are prescribed. Various private health insurance plans and Medicare and state Medicaid programs are continually making decisions regarding payment/reimbursement for nonprescription products. For accurate and up-to-date answers regarding the tax status of nonprescription medication purchases, individuals should consult with their tax advisor for additional information. Many people have medical and prescription insurances with higher copays and deductibles; therefore, the patient's copay for a physician office visit may be comparable to or even higher than the cost of nonprescription treatment. This lower cost may result in even more self-care and nonprescription medication use in the future.

### Aging Population

The results of the 2010 census found the number of people 65 years old or older has increased 15.1% since 2000, compared with a total population increase of 9.7%.<sup>17</sup> The average life expectancy for Americans has increased, with individuals reaching age 65 years expected to live an additional 18.6 years. The percentage of older Americans is increasing sharply as the baby boom generation approaches the age of 65. By 2030, 72.1 million people in the United States will be 65 years or older, up from 39.6 million in 2009. The fastest-growing segment of the elderly is individuals older than 85 years. These patients will have a bigger impact on the future of the U.S. health care system because they tend to be in poorer health and require more services than patients between the ages of 65 and 85 years require.<sup>18</sup>

In a major 2005-2006 study of older adults, researchers found that 81% used at least one prescription drug, 42% used at least one nonprescription drug, and 49% used a dietary supplement. Almost half (46%) of older adults using prescription drugs also used nonprescription medications, with 4% at risk for major drug-drug interactions.<sup>19</sup> One study in elderly nursing home patients showed that use of nonprescription medications (93.9%) was only slightly less than that of prescription medications (98.2%). This study noted that, on average, nursing home residents used 8.8 unique medications per month, one-third (2.8) of which were nonprescription medications.<sup>20</sup> The elderly population's increased use of nonprescription medications can be attributed to the following:

- Conditions for which nonprescription medications are used, such as arthritis pain, insomnia, and constipation, become more prevalent with advancing age.
- Nonprescription medications provide low-cost alternatives to more expensive primary care provider visits and prescription medications.
- Accessibility to pharmacists in the community setting makes nonprescription medications an acceptable alternative to scheduling visits with primary care providers.

Elderly patients who use nonprescription medications have heightened safety concerns because of the greater likelihood for multiple disease states and concurrent use of prescription medications. For example, one study documented the use of nonprescription medications and dietary supplements in 45 elderly patients (average age of 85 years) residing in assisted-living facilities.<sup>21</sup> The results showed that elderly residents used an average of 3.4 nonprescription products, with the most common being nutritional dietary supplements (32%), gastrointestinal products (17%), pain relievers (16.3%), and herbal products (14.4%). Potential safety concerns of drug duplication (70%) and drug-disease-food interactions (20.8%) were identified in more than one-half of these patients.

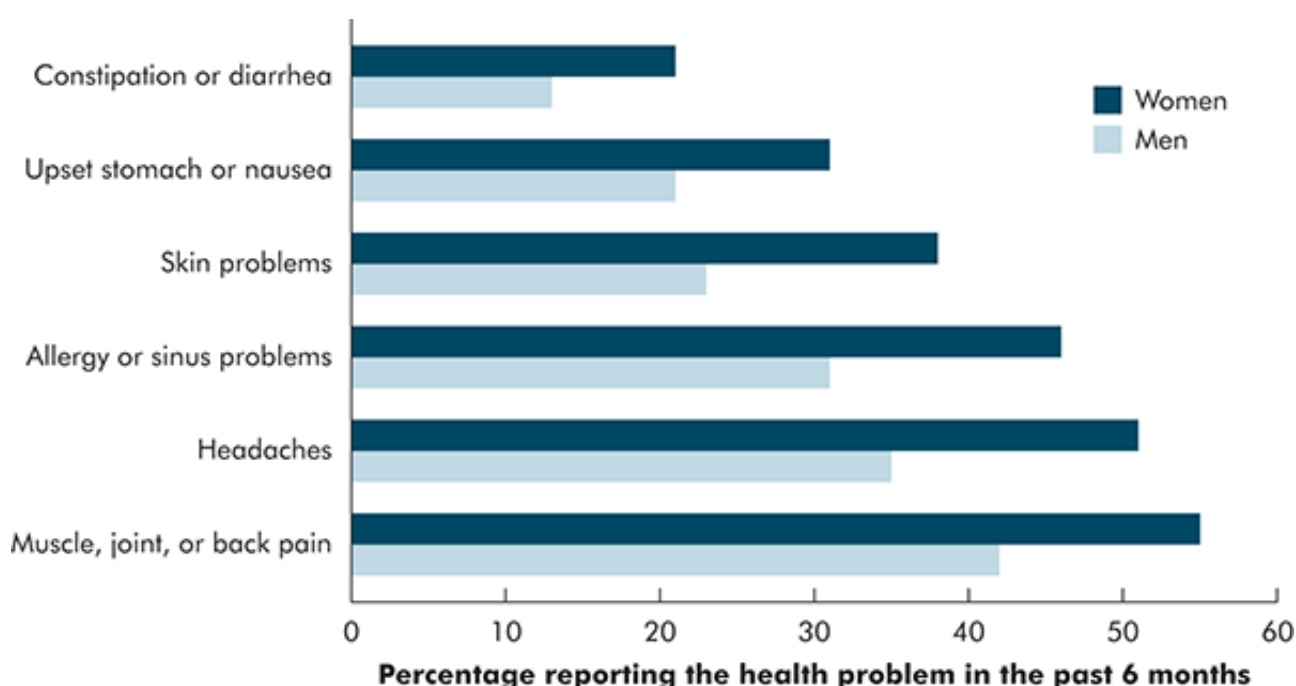

### Gender Differences

As is true worldwide, there are more women than men in the United States. The gender gap widens dramatically with age. For example, in 2009 the overall percentage of males (49%) and females (51%) was almost equal.<sup>17</sup> For ages 65-69, the female-to-male ratio is 114 women to 100 men; for ages 85 and older, the ratio is 216 women to 100 men.<sup>18</sup> The preponderance of elderly women has a considerable influence on self-medication. In the Self-Care in the New Millennium survey, women consistently reported that they had a variety of health problems in the past 6 months more frequently than did men.<sup>10</sup> [Figure 1-2](#) shows that, across the board, more women than men report having each

of the six ailments. Women were also more likely (82%) than men (71%) to report using nonprescription medications. This gender difference was also observed in dietary supplement use, which was reported by 30% of women but only 23% of men.<sup>10</sup> Therefore, the increasing population of older women should increase demand for nonprescription products in the future.

There are also gender-specific self-medication concerns, such as the use of nonprescription medications during pregnancy. The ability of pregnant women to self-medicate safely is limited because most products state, “if pregnant or breast-feeding, ask a health care professional before use.” Pharmacists are trained to assess whether a nonprescription medication is safe for use during pregnancy, yet women often make these decisions independently. Breast-feeding mothers are also faced with difficult choices when selecting nonprescription medications. As an example, all four primary nonprescription pain relievers (i.e., aspirin, acetaminophen, naproxen, and ibuprofen) have the potential to enter breast milk. Pharmacists can make the following recommendations to help avoid problems in women who are breast-feeding<sup>22</sup>:

- Advise using nonpharmacologic therapy, if possible.
- Advise taking medications immediately after nursing or before the infant's longest sleep period.
- Avoid recommending any medications that are extra strength, maximum strength, or long acting.
- Avoid recommending combination products.
- Counsel about potential side effects that could occur in the child.

Selected ailments self-treated by men and women. (Source: Reference 10.)

Determining the nonprescription status of an emergency contraception product (e.g., Plan B One-Step) is another example of an issue for which female patients will need direct access to the pharmacist. The pharmacist plays an important role in terms of ensuring timely access to the medication. A 2013 federal decision changed the status of Plan B One-Step, and it must now be readily available to all.

### Access to Nonprescription Drug Products for Self-Medication

The major benefits of nonprescription medications are accessibility and convenience. As mentioned earlier, these products are readily available at numerous locations, including pharmacies, supermarkets, and discount stores, thereby saving time for the consumer. The Consumer Healthcare Products Association released a white paper that provides a long list of benefits for the use of nonprescription products, including the following<sup>23</sup>:

- Numerous conditions can be treated effectively with these products, and products can be kept in the home to provide quick access. A number of national medical associations now provide guidelines for use. Households are being encouraged to have a stock of preparations for earwax removal; products for relieving sore throats, coughs, heartburn, diarrhea, skin rashes, allergies, and cold sores; and first-aid supplies. Pharmacists have an important role in advising individuals on which products to purchase and explaining the products' correct use.

- A variety of products and dosage forms allows patients to select the best choice to meet their needs.
- These products can be used to manage a condition or disease while waiting to see a health care provider. Cost is also a factor in determining whether to see a provider or attempt to treat at home.

The benefits of these products will occur only if they are used safely and effectively (the right product for the condition). Nonprescription drug labels include a significant amount of information that can assist the patient in product selection and use.

### Web-Based Drug Information and Internet Pharmacies

As people live longer, work longer, and take on a more active role in their health care, they need to become better informed about self-care options and how to safely self-medicate. Web-based health care-related information is easily and rapidly accessed in the privacy and comfort of one's home. According to a 2011 Pew Internet and American Life Project report, 80% of American Internet users, or 59% of U.S. adults, have searched for online health information.<sup>24</sup> Individuals who were most likely to search for health information online were women, non-Hispanic whites, adults younger than 65 years, and those with higher levels of education as well as higher income. Popular search topics were a specific disease/medical problem (66%), certain medical treatments/procedures (56%), exercise and fitness (27%), and various questions regarding drugs (24%) often combined with specific medical problems.

Dependence on the Internet for self-care information can be problematic. No single organization is accountable for the quality or accuracy of health-related information available on Web sites. The sheer number and diversity of Internet sources increases the likelihood that patients may unknowingly view biased or outdated information. Relatively new sources of information include social media sites such as Facebook, Twitter, YouTube, and My Space.

Sixty-two percent of the responders to the Pew report accessed those sites.<sup>24</sup> Because many sites contain inadequate, outdated, or incomplete information, it is not safe to simply "surf" and self-medicate. For example, one study that evaluated the suitability of written supplemental materials available on the Internet for nonprescription medications determined that most manufacturer-sponsored Web sites intended for consumers had information that scored poorly in the areas of reading level and use of uncommon words.<sup>25</sup> A number of valid Internet sources are available to provide information on nonprescription drugs, including the National Institutes of Health ([www.nlm.nih.gov/medlineplus](http://www.nlm.nih.gov/medlineplus)) and sites such as the Cleveland Clinic ([www.clevelandclinicmeded.com](http://www.clevelandclinicmeded.com)), WebMD ([www.webmd.com](http://www.webmd.com)), and Mayo Clinic ([www.mayoclinic.com](http://www.mayoclinic.com)).

Purchasing drugs online has become an issue in terms of safety, legality, quality, and effectiveness. In response to public safety concerns, the National Association of Boards of Pharmacy (NABP) evaluates the credentials of online pharmacies (also known as e-pharmacies) through the Verified Internet Pharmacy Practice Sites (VIPPS) program.<sup>26</sup> The VIPPS program is voluntary, and an e-pharmacy must agree to strict conditions, including NABP inspections, to be certified under its auspices. Use of the VIPPS logo on Web pages confers credibility to each e-pharmacy that meets the NABP standards. As of April 2013, 32 VIPPS-approved online pharmacies are in the United States.<sup>27</sup> Although prescription medications are available at all of the sites, some sites also sell nonprescription medications, nutritional dietary supplements, herbal products, and medical devices, in addition to providing "on-site" medical/pharmaceutical information.

### Rx-to-OTC Switch

An *Rx-to-OTC* switch is defined as over-the-counter (OTC) marketing of a drug product that was once a prescription (Rx) drug for the same indication with the same strength, dose, duration of use, dosage form, and route of administration.<sup>28</sup> Pharmaceutical companies can benefit financially by requesting that FDA switch from prescription to nonprescription status a medication that is about to potentially lose market share because of patent expiration and subsequent generic drug competition. The much-longer period of sales generated as a nonprescription medication can offset the decreased revenue associated with the agent being a prescription medication in competition with generic entities. However, FDA has the final word in reclassifying a drug from prescription to nonprescription status. FDA considers a medication for Rx-to-OTC switch if the following types of questions can be answered affirmatively:

- Can the patient adequately self-diagnose the clinical abnormality?
- Can the clinically abnormal condition be successfully self-treated?
- Is the self-treatment product safe and effective for consumer use under conditions of actual use?

Since 1976, more than 106 ingredients, indications, or dosage strengths have been switched from prescription to nonprescription status, resulting in more than 700 nonprescription products on the market.<sup>29</sup> These products include single-ingredient and combination agents. [Table 1-2](#) shows examples of pharmaceuticals switched from prescription to nonprescription status between 2007 and 2013.<sup>30</sup> Consumers benefit from Rx-to-OTC switches because they broaden access to important medications. In addition, the nonprescription versions are usually cost-effective for

consumers and third-party insurers. Examples of the cost benefits of Rx-to-OTC switches include the following:

- In one scenario, a female patient saves money by using a nonprescription vaginal antifungal product for a yeast infection. A nonprescription drug can be obtained for less than \$20; however, a physician's visit and prescription-only vaginal antifungal drug can cost almost \$100. Savings can be even greater when indirect costs (e.g., travel and lost time from work) are considered.
- A survey found that consumers save up to \$750 million a year as a result of using nonprescription cough/cold medications that once were available only by prescription. The same study demonstrated that physician visits for the common cold dropped by 110,000 a year between 1976 and 1989.<sup>29</sup>

The pharmacist is ideally situated to advise patients on appropriate choices of switched medications. In 1996, an entirely new nonprescription drug category called "smoking cessation aids" was created when Nicorette chewing gum, NicoDerm CQ transdermal patch, and Nicotrol transdermal patch were switched from prescription to nonprescription status. A 10-year review of the effect of nonprescription nicotine replacement therapy (NRT) concluded that "Studies over the decade of OTC nicotine replacement therapy (NRT) availability demonstrate that OTC availability increased access and utilization of treatment, while also demonstrating that the projected adverse effects of OTC switch have not materialized: OTC NRT is being used safely and effectively, without substantial misuse or abuse."<sup>31</sup> NRT is an example of a nonprescription product category that is perfectly positioned for pharmacist interaction with potential purchasers.

### Behind-the-Counter Medications

FDA continues to explore whether to expand the use of a third drug class, which would not require a prescription but would be kept behind the pharmacy counter and require a pharmacist to dispense it. Behind-the-counter (BTC) medications are also sometimes referred to as "pharmacist only" or "Schedule 3" medications. This class of medications could provide patients greater access to medications that require safeguards for their use. Pharmacists could ensure appropriate drug selection while screening for potential overlap and drug-disease or drug-drug interactions. Other countries such as Canada and the United Kingdom already have a BTC category of drugs (the statins, specifically simvastatin, used to lower cholesterol).

Recently, FDA has begun to explore expanding the definition of a new group of drugs that may otherwise require a prescription but might be available as nonprescription items. New criteria for use would include special conditions such as talking with a pharmacist, undergoing additional diagnostic testing, and, possibly, requiring the original prescription but not requiring the physician's agreement regarding renewals.

One current example of a BTC medication in the United States is pseudoephedrine (PSE). Nonprescription PSE has some therapeutic value, but it also has the potential for abuse. Because it is used to manufacture methamphetamine illicitly, PSE has become a major public health concern. PSE-containing products were moved behind the counter on the recommendation of the Drug Enforcement Administration to combat shoplifting and the sale of bulk quantities, which are needed to manufacture methamphetamine. Federal and state regulations require record keeping by the pharmacist. Purchasers must provide the pharmacy staff with photographic identification and a signature (in a logbook or via electronic documentation) when purchasing PSE-containing products. Quantities of PSE-containing products available for single purchase are limited as are quantities available for purchase over a certain period of time.

**TABLE 1-2 Examples of Prescription-to-Nonprescription Switches, 2007-2013**

<i>Year of Approval</i>	<i>Ingredient</i>	<i>Brand Name</i>	<i>Use</i>
2007	Cetirizine	Zyrtec	Allergy symptoms
2007	Cetirizine, pseudoephedrine	Zyrtec-D	Allergy symptoms
2007	Orlistat	Alli	Weight-loss aid
2009	Lansoprazole	Prevacid 24 HR	Acid reducer, heartburn
2009	Levonorgestrel	Plan B One-Step	Contraception
2009	Omeprazole, sodium bicarbonate	Zegerid OTC	Acid reducer, heartburn
2010	Ibuprofen, phenylephrine	Advil Congestion Relief	Pain relief, nasal congestion

2011	Fexofenadine	Allegra	Allergy symptoms
2011	Fexofenadine, pseudoephedrine	Allegra D 12-Hour, Allegra D 24-Hour	Allergy symptoms
2013	Oxybutynin	Oxytrol for women	Overactive bladder

Source: Reference 30.

Another example of making a nonprescription medication BTC is Plan B One-Step, an emergency contraceptive. In this instance, FDA wanted to ensure that Plan B One-Step was available without a prescription to all ages of females, so the agency classified it as BTC.

Despite the potential advantages, several strong lobbying groups oppose the expansion of BTC medications. Manufacturers of nonprescription medications oppose the creation of BTC medications because the restriction would reduce the number of retail outlets for their products and thereby reduce sales. Some grocery stores and other mass retailers without pharmacies that have traditionally sold nonprescription medications would be unable to sell BTC medications. A 2009 Government Accounting Office report, "Nonprescription Drug Considerations Regarding a Behind-the-Counter Drug Class," states that three factors need to be considered: (1) the ability of the pharmacist to provide the necessary counseling, (2) an appropriate infrastructure in place in pharmacies to protect consumer privacy, and (3) cost issues.<sup>32</sup> The BTC discussion will continue and changes may or may not occur.

### Self-Medication and the Safe Use of Nonprescription Drug Products

Informed, appropriate, and responsible use of nonprescription medications is crucial for effective self-medication. Casual or inappropriate use of nonprescription medications can lead to serious adverse effects (e.g., liver toxicity with prolonged intake of high doses of acetaminophen), drug-drug interactions (e.g., warfarin and naproxen), and indirect effects (e.g., from delay in seeking appropriate medical attention).

In 2007, FDA issued an initial warning for consumers to avoid treating children younger than 2 years with nonprescription cough and cold products because of an increased risk of overdose that requires emergency medical treatment. FDA cited studies estimating that during a 2-year period, 1519 children younger than 2 years were admitted to emergency departments for evaluation after known or possible exposure to cough/cold products. A large percentage of these incidents were related to dosing and use of the drug that differed from labeling instructions. In response to the warning, the manufacturers changed labels to state not to use the products in children under the age of 4 years and to ask a physician for dosing in children ages 4-6 years. Pharmacists can take a prominent role in ensuring the safe use of cough/cold medications in children by counseling parents to (1) carefully determine their child's dose according to weight, not age; (2) avoid mistakenly duplicating ingredients if giving multi-ingredient products (e.g., adding a dose of Tylenol after administering a cough/cold medication that contains acetaminophen); and (3) use the provided dosing device correctly to measure the amount needed.

A major challenge exists because of the numerous combination products that are available. Consumers may not be aware that they are using a single-entity product (i.e., acetaminophen) and also a combination product containing the same ingredient. The use of multiple combination products may contribute to duplicate therapies. The reality of drug-food interactions or drug-drug interactions (between different nonprescription products or between a nonprescription product and a prescription product) can lead to serious problems.

Pharmacists can combat misuse of nonprescription medications through the following measures:

- Be actively involved in helping patients with their self-care opportunities (see [Chapter 2](#) for a discussion of patient assessment processes).
- Ensure that patients are able to read and understand product labeling, and provide supplemental educational materials where appropriate.
- Help patients avoid drug interactions.
- Warn patients about potential allergic reactions and side effects.
- Discuss appropriate drug storage and handling.

### Nonprescription Drug Labeling

The Omnibus Budget Reconciliation Act of 1990 mandates that pharmacists "offer to counsel" on the prescription medications they dispense. However, nonprescription medications are exempt from this provision, so it is typically the consumer's responsibility to seek information from the pharmacist when he or she has a question. In the absence of this consultation, the consumer is on his or her own to understand what is written on the product label and to ensure proper use.

To assist consumers in understanding product labels, FDA mandated the use of a standard label format for nonprescription medications. The standard product label for nonprescription medications, titled "Drug Facts," has

specific sections detailing active ingredients, uses, warnings, when to use the product, directions, and inactive ingredients (see [Chapter 4](#)). The label is designed to be easy to read, with all relevant information about taking the drug appearing in the same sequence on all package labels. This consistency enables patients to find information in a familiar spot on the label regardless of the use for the product (e.g., pain, cough/cold, or diarrhea). Initiated in 2002, the Drug Facts label has been on all nonprescription medications since May 15, 2005. Other products such as herbs and dietary supplements do not use the Drug Facts label format.

NCPIE commissioned a survey to determine whether the Drug Facts label has helped to promote the message that nonprescription medications must be taken with care.<sup>33</sup> Results of this survey of a little more than 1000 adult Americans included the following:

- As for reading the label: 44% looked for the active ingredient; 20% read about possible side effects; and 8% read nothing on the label.
- As for following the dosing recommendations: 48% of respondents confided that, if they needed to increase product effectiveness, they would take more than the recommended dose by either taking the next dose sooner than directed (35%), taking more than the recommended amount at a single time (32%), or taking the medication more times during the day than recommended (18%).
- Providers cited nonprescription medications being used incorrectly in the following ways: combining of nonprescription and prescription medications (51%), chronic use of a nonprescription medication (44%), use of a nonprescription drug for a prescription indication (32%), and use of more than one nonprescription product with the same active ingredient (27%).

The likelihood of inappropriate nonprescription drug use resulting from misreading of product labels increases when patients have limited reading skills or language barriers. The National Assessment of Adult Literacy found that a majority (53%) of adults were at an intermediate level of health literacy, 12% were proficient, and the remaining 35% were either at a basic or below basic level.<sup>34</sup> In another survey, 40%-70% of parents made errors when giving nonprescription medications to their children.<sup>35</sup> Effects of health illiteracy are particularly profound for adults ages 65 or older. Such a low level of literacy could be expected to adversely affect health care in patients using nonprescription medications. Other factors that can impair the ability to read nonprescription drug labeling include the size of type and critical information being covered by price or antitheft tags.<sup>36,37</sup> The U.S. Department of Health and Human Services is now undertaking a national action plan to improve literacy. This plan is designed to restructure the methods of creating and disseminating health information.<sup>34</sup> Despite literacy concerns, studies have concluded that nonprescription medications are being used safely. For example, appropriate use of nonprescription medications to treat upper gastrointestinal symptoms has been documented.<sup>38</sup>

### Nonprescription Drug Product Reformulation

FDA sometimes initiates reformulation of nonprescription drug products because of safety or efficacy concerns. At times, this reformulation is also known as brand name extension. For example, Kaopectate is a brand-name antidiarrheal product that has been on the market for many years and has strong name recognition. The name *Kaopectate* was originally derived from its active ingredients, kaolin and pectin. However, in 1992 it was reformulated with attapulgite because FDA banned the use of pectin in nonprescription products because of insufficient data regarding its safety and efficacy. The product was reformulated again in 2003 to contain bismuth subsalicylate because all attapulgite-containing medications were discontinued. Despite all these reformulations, the product maintained its original brand name, Kaopectate.

Confusion and misuse can occur when a nonprescription drug product is reformulated to contain different active ingredient(s) but does not change its brand name. Although reformulated products may be labeled as being “new and improved,” the packaging may not indicate that the active ingredient is entirely different. Again using Kaopectate as an example, before its reformulation in 2003, the product could be used in children and had pediatric dosing instructions on the label. However, in 2004, FDA ruled that antidiarrheals containing bismuth subsalicylate could be labeled for use by only adults and children ages 12 years and older. Therefore, the most recent version of the Kaopectate label does not include pediatric dosing information. As a result of all these formulation changes, there was a time in 2004 when patients had the option of purchasing up to three different types of Kaopectate: one containing attapulgite, one with bismuth subsalicylate and pediatric dosing information, and one with bismuth subsalicylate and no pediatric dosing information. In addition, patients with aspirin or salicylate allergies who may have previously taken the old formulation of Kaopectate could not take the new version because it contained bismuth subsalicylate. The Kaopectate example shows that a potentially serious adverse reaction can occur in patients who do not carefully recheck the label of a “new and improved” product that they have used safely in the past.

Another example of a brand-name extension is the Pepto-Bismol products. Pepto-Bismol is a very recognizable name, yet it is used for myriad products that contain different active ingredients such as bismuth subsalicylate (adult liquid and chewable tablets) and calcium carbonate (kid’s chewable tablets). Each of these products is an example of

a product line extension in which the manufacturer uses a well-known brand name for many nonprescription medications that have different ingredients and indications. This example is additional evidence and support for encouraging patients to read labels carefully and often.

It is also important to note that drug manufacturers can reformulate products for their own reasons. Changes to PSE-containing products are an example of a drug manufacturer-driven product reformulation. When the government restricted the sale of PSE-containing products to BTC status, many large pharmaceutical companies rushed to reformulate their brand-name products to contain a different decongestant, phenylephrine, which is not restricted. In most cases, the brand names of these products did not change. This therapeutic switch was not related to safety or efficacy concerns; rather, manufacturers feared that BTC restrictions would decrease sales. In fact, before the reformulation, phenylephrine was not widely used because of its limited effectiveness. Health care providers need to remain current with product reformulations and help patients understand how these changes affect self-care.

### Drug Interactions

The risk for drug interactions increases as patients use more nonprescription medications. Diet and lifestyle can also have considerable effects on a medication's ability to work in the body. Certain foods, beverages (e.g., grapefruit juice), alcohol, caffeine, herbal supplements, and even cigarette smoking can interact with medications. These interactions may increase or decrease the effectiveness of certain medications, or they may cause dangerous side effects or other therapeutic problems. For example, one study concluded that older adults were unaware of the adverse risks associated with concurrent use of nonprescription pain medications, alcohol, high blood pressure medications, and regular caffeine use; the study also concluded that health care providers need to increase their educational efforts.<sup>39</sup> The increasing use of herbal supplements creates the potential for interactions between nonprescription and prescription medications. A survey conducted in a rural community found that 91% of the individuals using one or more herbs/natural products were also using at least one prescription or nonprescription medication and that 21% of those individuals were using a combination of products with a possibility of an interaction.<sup>40</sup> The public is being made aware of potential problems through articles in magazines, newspapers, and online information. However, to avoid drug interactions, patients should consult pharmacists before selecting herbal products, nutritional dietary supplements, or nonprescription medications. [Table 1-3](#) lists some commonly used nonprescription medications and their interactions with food, alcohol, certain medical conditions, and other nonprescription medications.

### Allergies to Active or Inactive Ingredients

Although the likelihood is low, any medication can cause an allergic reaction. For example, allergic reactions have occurred in patients taking common nonprescription pain relievers, such as aspirin, ibuprofen, and naproxen. Patients should always be counseled about the signs and symptoms of an allergic reaction (e.g., itching, hives, and trouble breathing) and instructed to seek medical care immediately. Both active and inactive ingredients can cause allergic reactions and side effects. Inactive ingredients in nonprescription medications (e.g., binders, disintegrants, fillers, and preservatives) can cause reactions in a few individuals. Therefore, for safety reasons, FDA requires that inactive ingredients also be listed on the label. [Table 1-4](#) lists some of the common inactive ingredients used in drug formulations and their known adverse effects.

**TABLE 1-3 Potential Interactions with Selected Nonprescription Drugs**

<i>Drug-Drug Interactions</i>		
<i>OTC Drug</i>	<i>Drug</i>	<i>Potential Adverse Effect</i>
Aluminum-containing antacids	Ascorbic acid	Increases aluminum absorption and excretion, primarily in patients with renal dysfunction
Aluminum-containing antacids	Bisacodyl	Decreases effect of bisacodyl
Aspirin	Products containing aluminum, calcium, or magnesium	Decreases blood aspirin concentration by increasing aspirin elimination
Iron (ferrous sulfate)	Products containing aluminum, calcium, or magnesium	Decreases iron absorption
Mineral oil	Docusate	Increases mineral oil absorption
Psyllium	Digoxin	Decreases digoxin absorption

Psyllium	Lithium	Decreases lithium absorption
<b>Drug-Food/Beverage Interaction</b>		
<b>OTC Drug</b>	<b>Food/Beverage</b>	<b>Potential Adverse Effect</b>
Aspirin	Garlic	Increases risk of bleeding
<b>Drug-Disease Interactions</b>		
<b>OTC Drug</b>	<b>Condition</b>	<b>Mechanism</b>
Aspirin	Hyperuricemia/gout	Decreases renal excretion of uric acid (with smaller aspirin doses)
Aspirin, naproxen, ibuprofen	Gastrointestinal disease	Alters gastric mucosal barrier
Doxylamine succinate, phenylephrine HCl	Glaucoma, increased intraocular pressure	Obstructs aqueous outflow
Pheniramine maleate/naphazoline HCl, pseudoephedrine, nicotine	Hypertension	Increases vascular resistance
<b>Drug-Alcohol Interactions</b>		
<b>OTC Drug</b>	<b>Potential Adverse Effect</b>	<b>Mechanism</b>
Aspirin	Increased gastrointestinal blood loss	Increases gastrointestinal mucosal damage
Diphenhydramine HCl	Increased sedation	Depresses central nervous system
Insulin	Increased hypoglycemia	Decreases hepatic gluconeogenesis
Ketoconazole (topical)	Vomiting, tachycardia	Causes disulfiram-like reaction
Yohimbine	Increased blood pressure	Increases norepinephrine level

Key: HCl = Hydrochloric acid; OTC = over-the-counter.

#### Handling and Storage of Nonprescription Medications

Appropriate product handling, from the time it leaves the manufacturing facility to when it gets into a patient's home, is critical to ensure consistent potency. Patients reasonably assume that because nonprescription drug products are under the aegis of FDA, they are pure and have their stated potency. Although this is almost always the case, recalls of nonprescription medications because of impurity, contamination, or other issues can occur. Patients should be aware of some clues that should arouse suspicion about a nonprescription product, including abnormal odors, color changes, texture differences, and abnormal shape of a solid dosage form. Patients should avoid taking any drug product they suspect is bad and call their pharmacist for guidance. Pharmacists should also remove any recalled drug product from their shelves and post notices that inform patients of the recall and tell them what action they should take.

**TABLE 1-4 Adverse Effects of Some Inactive Ingredients Used in Drug Preparations**

<b>Inactive Ingredient</b>	<b>Use</b>	<b>Where Found</b>	<b>Adverse Reactions</b>
Aspartame	Sweetener	Liquid sucrose-free preparations	Headaches, caution in patients with PKU
Benzalkonium	Preservative	Antiasthmatic	Airway constriction, contact dermatitis, contact lens

chloride		drugs, nasal decongestants	discoloration, allergic reactions
Benzyl alcohol	Preservative	Liquid preparations	Neonatal deaths, severe respiratory and metabolic complications, erythema, pruritus, eye irritation
Lactose	Filler	Capsules and tablets	Diarrhea, dehydration, cramping
Propylene glycol	Solubilizer	Liquid preparations	Respiratory problems, irregular heartbeat, low blood pressure, seizures, skin rashes, metabolic acidosis, hyperglycemia
Saccharin	Sweetener	Liquid preparations	Possible cross-sensitivity with sulfonamides, dermatologic reactions, pruritus, nausea, vomiting, diarrhea, alterations in taste, gastrointestinal irritation
Sulfites	Antioxidant	Antiasthmatic drugs; anti-inflammatory drugs	Wheezing, breathing difficulties, nausea, vomiting, diarrhea, abdominal pain, hypotension, seizures, tachycardia, dermatologic reactions
Yellow tartrazine	Coloring agent	Solid/liquid preparations	Allergic reaction similar to that of aspirin; minimal dermatologic and gastrointestinal effects

Key: PKU = Phenylketonuria.

Source: Micromedex 2.0. Englewood, CO: Thomson Reuters; 2010.

Before any product is used, especially one that was purchased quite some time ago, patients should check the expiration date that appears on the product label. Health care providers should be aware of conflicting information about the real meaning of a drug product expiration date. Pharmacists should help patients understand that after the expiration date, the product is no longer under the manufacturer's warranty and may no longer work.

Drugs must be stored properly to maintain their potency. Prescription and nonprescription medications are often mistakenly stored in bathroom cabinets, usually above the sink. Humidity and heat from the shower and sink are easily trapped in the cabinet, accelerating the degradation of the medications, even if they are in a prescription vial or bottle. Patients need to be aware that all medications should be stored away from high humidity in a cool, dark place. Furthermore, all medications should be stored in places to ensure they are kept out of a child's reach. This precaution is especially important for the many nonprescription medications that are not packaged in child-resistant containers. Examples of this type of packaging include blister packs, lozenges, topical creams or ointments, spray canisters, and bulk powder containers (e.g., laxatives).

Table 1-5 lists some nonprescription medications and health care products that are generally kept on hand to treat minor ailments or injuries; storage recommendations are also listed. Patients should be encouraged to check product expiration dates and purge medication cabinets at least once every 6 months.

**TABLE 1-5 Recommended Storage Places of Selected Nonprescription Health Care Products**

<b><i>Closet/Kitchen Cabinet or Shelf</i></b>	<b><i>Bathroom Medicine Cabinet</i></b>
Analgesics (relieve pain)	Adhesive bandages
Antacids (relieve upset stomach)	Adhesive tape
Antibiotic ointments (reduce risk of infection)	Alcohol wipes
Antihistamines (relieve allergy symptoms)	Calibrated measuring spoon
Antipyretics (reduce fever; adult and child formulations)	Dental floss
Antiseptics (help prevent infection)	Disinfectant
Decongestants (relieve stuffy nose and cold)	Gauze pads
Hydrocortisone (relieves itching and inflammation)	Thermometer

## Pharmacists' Role in Nonprescription Drug Therapy

The public's ability to discern critical information about the condition being treated and the clinical risk-benefit of a nonprescription drug is highly variable. Many individuals are confused by the array of product choices; line extensions; and overstated, vague, or misleading marketing messages. Generally, package labeling is limited in the breadth and depth of the message it communicates; it can never address the informational needs of all patients. Therefore, the pharmacist-patient interaction is vital for ensuring the best possible outcome from nonprescription drug therapy. In 2007, *U.S. Pharmacist* published survey results concerning chain and independent pharmacists and their roles in counseling on nonprescription medications.<sup>41</sup> More than 90% of the pharmacists stated that they had an active role in counseling patients on nonprescription medications, with more than 40% recommending 6-10 products per day. **Table 1-6** shows how pharmacists ranked the importance of various counseling topics. Pharmacists clearly feel they should help each patient select the most appropriate drug for his or her condition and counsel on how to avoid drug interactions.

A study in two community pharmacies found that consumers widely accepted a pharmacist intervention in their nonprescription therapy.<sup>42</sup> Of the consumers who completed a follow-up phone call from a pharmacist and claimed adherence to the previous advice, 83% experienced "great relief" and 75% stated the follow-up was very helpful. However, only 45% would be willing to pay for a pharmacist's advice.

The underlying goal of pharmacists' counseling is to ensure that the patient receives accurate, practical information written at the consumer level and that the patient understands it in the context of the ailment being treated. Validation of the patient's understanding is also critically important. The pharmacist should always encourage the patient to ask questions and learn more. During the initial encounter with a patient who is seeking assistance with nonprescription medications, the pharmacist should do the following:

- Assess, by interview and observation, the patient's physical complaint/symptoms and medical condition (**Chapter 2**).
- Differentiate self-treatable conditions from those requiring referral to a primary care provider or emergency department.
- Advise and counsel the patient on the proper course of action (i.e., no drug treatment, self-treatment with nonprescription medications, or referral to another health care provider or emergency department).
- Advise the patient on the outcome of the selected course of action.
- Assure the patient that the desired therapeutic outcome can be achieved if the selected/recommended nonprescription medications are taken as directed on the label and/or as directed by the primary care provider or pharmacist.
- Reinforce the concept that the pharmacist and primary care provider are qualified to perform a follow-up assessment of the treatment.
- If self-care with a nonprescription medication is in the best interest of the patient, pharmacists can help in the following ways:
  - Assess patient risk factors (e.g., contraindications, warnings, precautions, comorbidities, age, and organ function).
  - Assist in product selection.
  - Counsel the patient about proper drug use (e.g., dosage, administration technique, monitoring parameters, and duration of self-therapy).
  - Maintain an accurate patient drug profile that includes prescription, nonprescription, nutritional and dietary supplement, and herbal products.
  - Assess the potential of nonprescription medications to mask symptoms of a more serious condition.
  - Educate the patient on when to seek medical attention if the recommended nonprescription medication is ineffective or if symptoms worsen.

**TABLE 1-6 Pharmacist Ranking of Nonprescription Drug Counseling Topics**

<b>Survey Question: "Which of the following counseling topics are most important when discussing OTC-related products with patients?"</b>	<b>Average Rank (1 = highest importance; 5 = lowest importance)</b>
Selection of right product	1.5
Rx-to-OTC drug interactions	2.5
Side effects/adverse reactions	3.0
Directions/instructions	3.0

Cost	4.4
------	-----

Key: OTC = Over-the-counter; Rx = prescription.

### Key Points for Self-Care and Nonprescription Pharmacotherapy

- Self-care will play an increasingly important role in health care, and self-medication represents a significant element in the self-care process.
- Nonprescription medications are used by millions of Americans each year because they offer safe and effective relief for a variety of common health care ailments.
- Health care providers and FDA agree that nonprescription medications, although safe and effective, have some risks that are associated with patients not reading and closely following the label instructions when taking the medications.
- Patients, manufacturers, governmental agencies, and particularly pharmacists should become even more intent on recognizing that each group fulfills essential functions in ensuring the safe, appropriate, effective, and economical use of nonprescription medications.

## Handbook of Nonprescription Drugs > Chapter 2. Patient Assessment and Consultation

### Patient Assessment and Consultation: Introduction

Self-care, self-diagnosis, and self-medication are important components of the health care system in the United States. Instead of seeking the advice of a health care provider, many people self-diagnose and treat their symptoms using a vast array of self-care options, ranging from nonprescription medications, herbal products, and home remedies to yoga, meditation, and spiritual healing. Survey data show that about 80% of Americans who have conditions that can be treated with nonprescription medications would purchase a specific nonprescription drug if advised by their pharmacist.<sup>1</sup> Nonprescription medications allow individuals to manage their medical problems rapidly, economically, and conveniently. In addition, they may prevent unnecessary visits to a primary care provider or specialist. Patients often believe medications that move from prescription to nonprescription status are more effective than older nonprescription medications, and one study showed that 9 of 10 Americans believe that nonprescription medications are a key part of their family health care.<sup>2</sup> The demand for and shift toward self-medication are further described and documented in [Chapter 1](#).

The appropriate use of a nonprescription product, as with any medication, requires attention to the intended use, effectiveness, safety, and convenience of administration. Although warnings are required on the labels of these products, labeling alone may be insufficient. The patient may need assistance in selecting and properly using a nonprescription medication. Inappropriate use and misuse of nonprescription medications can increase the risk of drug misadventures,<sup>3</sup> resulting in increased health care costs and more serious illness. Further, because 23% of all drug therapy problems in the general population involve one or more nonprescription drug products,<sup>4</sup> health care providers must assume a crucial role in helping patients to use self-treatment options safely and effectively.

*Editor's Note:* This chapter is based on the 17th edition chapter of the same title, written by Lawrence M. Brown and Brian J. Isetts.

### Self-Care Problem Solving Processes

Interacting with a patient regarding self-treatment is a primary care activity that carries a great professional responsibility. Patients with self-care needs present differently from those who have already received a treatment decision from a health care provider. To determine which recommendation is most appropriate for a patient, the health care provider must complete the following problem-solving steps ([Figure 2-1](#) provides more detail):

- Collect and assess patient-specific information relative to each health problem.
- Create and implement a care plan to resolve each health problem.
- Evaluate the results of the care plan and make adjustments when the outcome is less than optimal.<sup>4</sup>

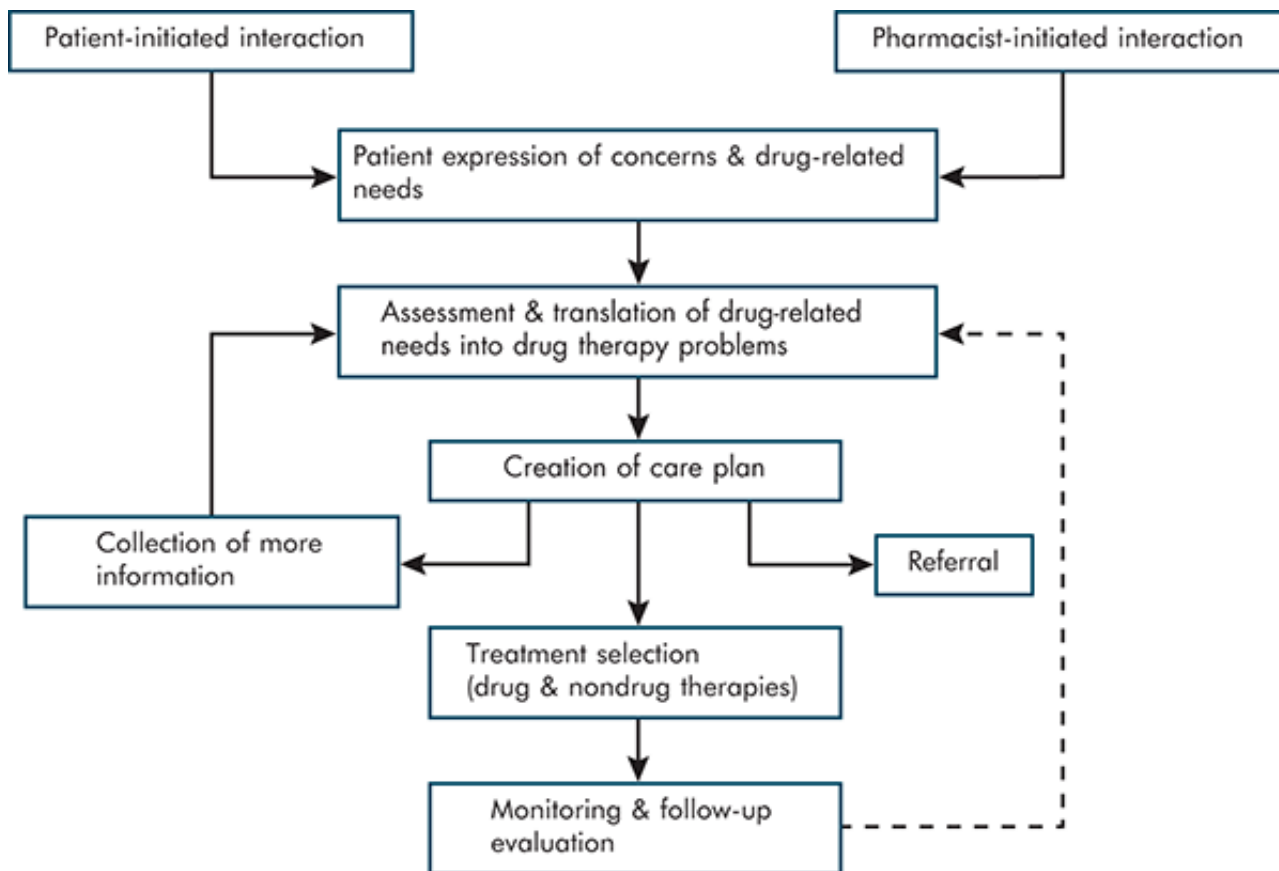

Health care providers must use systematic, comprehensive, and efficient cognitive processes to ensure that their patients realize optimal therapeutic outcomes. A variety of approaches to ensure optimal results is documented in the literature, and selected examples are outlined in [Table 2-1](#). Although the approaches differ in terms of level of specificity and terminology, they are all designed to address the previous problem-solving steps. In addition, a technique described as LEARN can be used in conjunction with any self-care problem-solving model to ensure that patient-specific cultural characteristics are taken into account during therapeutic decision making. Details are described in [Chapter 3](#).

This chapter describes two self-care problem-solving approaches. The comprehensive method is useful for students who are novice problem solvers, whereas the abbreviated approach is more suited to health care providers who are experienced problem solvers. The primary difference between these approaches relates to their levels of structure and specificity.

Educational research asserts that novice problem solvers, such as students, require explicit instruction with ample opportunities for practice and feedback. As students become more proficient problem solvers, they require less structure and can eventually adapt to problem-solving methods that are little more than brief prompts to the initiation of complex problem-solving steps.<sup>5</sup> In contrast, experienced problem solvers have created cognitive structures that enable them to complete the steps in solving problems with few prompts and in a much more timely fashion. They view explicit approaches as cumbersome and unworkable for use in their busy practices.<sup>5</sup>

### Comprehensive Problem-Solving Model

Copyright © American Pharmacists Association  
 All rights reserved. Any use is subject to the Terms of Use.

Patient-pharmacist consultation process.

The comprehensive problem-solving model is based on the guided-design instructional format that models the steps of decision making. The detailed processes facilitate student development of a framework for organizing and applying acquired information to the solving of novel problems.<sup>6</sup> The basic steps used in the comprehensive problem-solving model are as follows:

1. Gather information.
2. Perform assessment and triage.
3. Prepare and implement a plan.
4. Educate the patient.
5. Evaluate patient outcomes.

A structured approach for teaching students to counsel self-care patients. *Am J Pharm Educ.* 2007;71(1):8. Accessed at <http://www.ncbi.nlm.nih.gov/pmc/articles/PMC1847542/>, May 17, 2013.

### Step 1: Gather Information

When a patient presents to a health care provider and is in need of self-care advice, the provider must collect information about the patient that is pertinent to solving the patient's problem. This information falls into two general categories: (1) information about the symptoms that prompted the patient to seek assistance and (2) information about the patient's background characteristics.

It may be argued that it is unnecessary to collect all the patient's background characteristics to solve every patient problem. However, it should be remembered that novice problem solvers do not yet have the expertise to selectively elicit the information most pertinent to a specific situation. Therefore, this model provides prompts to ask about all of the listed characteristics to avoid overlooking information that is critical to the solution of the problem.

### Step 2: Assessment and Triage

The second step involves the assessment of information gathered in step 1 to identify the patient's problem, its severity, and its most probable cause. Clear articulation of the problem is critical (1) to assist with differentiation among conditions with similar symptoms and (2) to determine the goals of self-treatment. Comparing the patient's symptoms to those of a particular condition will help to differentiate and determine the most likely primary problem. For example, it is inadequate to conclude simply that a patient's problem is a common cold. In this instance, the therapeutic goal—to relieve the cold—is too vague to be useful because there are many symptoms that may or may not be associated with a common cold. Further, this goal offers little in the way of guidance relative to the type of nonprescription product that may be indicated. On the other hand, if the patient's problem is nasal congestion secondary to a common cold, the goal would be to relieve the congestion. This goal is much more focused and allows evaluation of a more limited set of potential therapeutic options.

Step 1 also involves assessment of patient data to identify exclusions for self-treatment. It may not be appropriate for an individual to self-treat for several reasons, including:

1. The symptoms require medical referral (e.g., eye pain).
2. The patient is not an appropriate candidate for self-care (e.g., a woman with diabetes who develops a vaginal candidal infection).
3. The symptoms are too severe or long lasting for self-treatment.
4. Effective nonprescription therapy is not available.
5. Nonprescription dosages or duration of treatment is inadequate to treat the condition.

Finally, the first step involves formulating a list of all possible solutions to the patient's problem. At this point, nothing should be ruled in or out. Four general options are available to health care providers who are advising patients about self-care: (1) recommend self-care with drug, nondrug, and/or alternative/complementary therapies; (2) refer the patient to another health care provider for treatment; (3) recommend self-care until another health care provider can be consulted; or (4) take no action. In the context of self-treatment, all potential product categories, dosage forms, and nondrug products and measures should be included in the list. Similarly, all potential sources of primary care (e.g., urgent care clinic, physician, physician assistant, nurse practitioner, dentist, or emergency department) should be considered.

Critics of this approach have sometimes indicated that including no action as an option is unconscionable or not in the best interest of patients. In fact, taking no action may be preferred in some situations. For example, consider a situation involving a patient with a limited income who suffers from an asymptomatic, common wart that is in a location where it is neither noticeable nor likely to be spread easily to others. Because most common warts resolve spontaneously without treatment and the patient has limited income to pay for a nonprescription product, taking no action may indeed be the best solution in this instance. Furthermore, it is important to remember that, at this point in the decision-making process, all ideas are listed and none are prejudged. This approach is taken because the comprehensive problem-solving model is targeted at novice problem solvers who have little experience in identifying alternative therapeutic options. Therefore, the model prompts those with less experience in patient assessment to formulate a list of all alternatives to prevent them from prematurely ruling out appropriate options.

### Step 3: Prepare and Implement a Plan

In step 3, each of the plausible solutions is evaluated to determine whether and to what extent each achieves the intended goal(s) and also is concordant with the patient's preferences in terms of therapeutic goals, cost, and overall approach, including personal philosophy and health beliefs for self-care. Next, the optimal therapeutic alternative is identified on the basis of patient-specific and therapy-specific variables. Patient-specific variables include age, gender, medication history, medical conditions, allergies, social habits (alcohol, tobacco use), patient preferences, family/home dynamics, and economic status. Therapy-specific variables include dosage forms, ingredients, side effects, adverse effects, potential interactions, relative effectiveness, flavor, and price. Step 3 also involves communication of the therapeutic plan to the patient. The plan should include an explanation of the condition, the treatment recommendation(s), and the rationale for the treatment recommendation(s).

#### Step 4: Educate the Patient

Patient education is designed to provide a clear and concise description of the treatment and its administration, any side effects and precautions, expected outcome and time to achieve it, and guidelines for appropriate use, as well as the appropriate health care provider to contact if a problem occurs or if the expected outcome is not achieved. Where applicable, the plan should also include nondrug measures, lifestyle changes, and additional information resources. Including family members in this process may be appropriate to ensure the best chance for a positive outcome. The health care provider should ensure that the patient understands the plan by having the patient repeat it and by correcting any misunderstandings. Finally, after answering any remaining questions, the provider should document the interaction in the patient's profile and encourage the patient to call or return if the symptoms fail to resolve.

#### Step 5: Evaluate Patient Outcomes

In some instances, patients do not realize the full intended benefit from their health care provider's recommendations. If further treatment is needed, the patient and health care provider can come together to begin the problem-solving cycle anew. For example, a patient who does not achieve the desired outcome with the proper use of a particular nonprescription product may realize the goal with another product or referral. It may be prudent to obtain the patient's telephone number so the health care provider can contact the patient to evaluate outcomes. Cases 2-1 and 2-2 illustrate the application of this model to self-care problem solving.

#### Abbreviated Problem-Solving Model

The abbreviated problem-solving model is better known as the QuEST/SCHOLAR method. It was first presented by Leibowitz and Ginsburg at the inaugural 2002 Self-Care Institute of the American Pharmacists Association. This method employs simple acronyms to prompt health care providers to complete key steps in the self-care problem-solving process. Although no published studies have compared QuEST/SCHOLAR with other problem-solving models, the easy-to-remember acronyms may expedite completion of the problem-solving process relative to more structured models that contain no such prompts.

Each letter in the acronym QuEST represents an ordered step in the problem-solving process as follows<sup>7</sup>:

- **Q**uickly and accurately assess the patient.
- **E**stablish that a patient is an appropriate self-care candidate (using the SCHOLAR-MAC questioning process described here).
- **S**uggest appropriate self-care strategies.
- **T**alk with the patient.

Similarly, each letter in SCHOLAR represents information that the health care provider should elicit from each patient or caregiver, and includes:

- **S**ymptoms: What are the patient's symptoms?
- **C**haracteristics: What are the symptoms like?
- **H**istory: What has been done so far?
- **O**nset: When did the symptoms begin?
- **L**ocation: Where are the symptoms occurring?
- **A**ggravating factors: What makes the symptoms worse?
- **R**emitting factors: What makes the symptoms better?

Because nothing in the SCHOLAR line of questioning is specific to an individual's medical history, the MAC acronym was added to QuEST/SCHOLAR and is intended to prompt users to collect the following additional key patient information:

- **M**edications: prescription and nonprescription as well as alternative and complimentary therapies
- **A**llergies: to medications and other substances

- **Conditions:** coexisting health conditions

Cases 2-3 and 2-4 illustrate the application of this model to self-care problem solving.

### Case 2-1

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of difficulty sleeping. He describes difficulty falling asleep about 2-3 nights a week and has early awakening with inability to fall back to sleep 5-7 days a week. "I just don't sleep very well anymore, and I wonder if there's something I can take that will help." Symptoms started approximately 1 month ago.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	He sometimes, but not always, has "better sleep" if he sleeps upright in a recliner chair instead of the bed.
c. description of the patient's efforts to relieve the symptoms	He tried melatonin 3 mg each evening last week for 3-4 nights with no relief.
d. patient's identity	James Markum
e. age, sex, height, and weight	81 years old, male, 5 ft 9 in. tall, 170 lb
f. patient's occupation	Retired railroad worker
g. patient's dietary habits	Normal balanced diet; three cups of caffeinated coffee daily; no alcohol
h. patient's sleep habits	Averages 5-6 hours per night. Naps one to two times per day in morning and/or afternoon.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Gastroesophageal reflux disease: omeprazole 20 mg daily; hypertension: hydrochlorothiazide 25 mg daily, lisinopril 20 mg daily; depression: sertraline 100 mg daily; Alzheimer's dementia: donepezil 5 mg daily
j. allergies	NKA
k. history of other adverse reactions to medications	None
l. other (describe) _____	None
<b>Assessment and Triage</b>	

2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Insomnia, possibly secondary to current medical conditions
3. Identify exclusions for self-treatment.	≥65 years old, chronic insomnia (>3 weeks), sleep disturbances possibly secondary to medical disorders
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer patient to his primary care provider. (2) Recommend self-care with lifestyle modifications for good sleep hygiene and diphenhydramine. (3) Recommend self-care until patient can see his primary care provider. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Patient should consult his primary care provider.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"I recommend you see your primary care provider for treatment of your sleep problems."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"This is the best option for you since you have had the sleep problems for several weeks and your situation may be related to your current medical conditions. Also, the over-the-counter medications we typically use to treat sleep problems are not the best option for you. You may require prescription medications or adjustments of your current medications by your primary care provider."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"Are there any drugs I can take to help until I get an appointment with my physician?"
Answer the patient's or caregiver's questions.	"No. You tried the melatonin and it didn't work. There are no other over-the-counter medications that are safe and effective for your sleep problems. I recommend seeing your physician as soon as possible. If you are unable to see your physician immediately, you can try to improve sleep by avoiding or reducing caffeine, avoiding daytime naps, and participating in something relaxing prior to bedtime, such as reading."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact the patient in 1-2 days to ensure that he sought medical care for

insomnia.

Key: NKA = No known allergies.

**Case 2-2**

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of a burning sensation in her stomach and throat that is often accompanied by feeling of fullness and "acid in my throat." The burning occurs after a heavy meal no more than once weekly. Symptoms last 2-4 hours after a meal and began about 1 month ago.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Symptoms occur after eating lunch out with coworkers or after potlucks at work and last 2-4 hours after the meal.
c. description of the patient's efforts to relieve the symptoms	Peppermint candy did not help symptoms. She tried Tums (calcium carbonate 500 mg) once without full symptomatic relief.
d. patient's identity	Jill Golden
e. age, sex, height, and weight	43 years old, female, 5 ft 4 in., 175 lb
f. patient's occupation	Office assistant
g. patient's dietary habits	Normal balanced diet; 4 or 5 cups of caffeinated coffee daily; 3 or 4 alcoholic beverages once per week
h. patient's sleep habits	Averages 7-9 hours per night
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	No concurrent medical conditions; multivitamin daily
j. allergies	NKA
k. history of other adverse reactions to medications	None
l. other (describe) _____	Weight gain of 10 pounds in the past 3 months
<b>Assessment and Triage</b>	

2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Infrequent postprandial burning sensation is consistent with uncomplicated heartburn. Patient denies pregnancy.
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer patient to her primary care provider. (2) Recommend self-care with lifestyle modifications and nonprescription acid-reducing medication. (3) Recommend self-care until patient can see her primary care provider. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	A nonprescription acid-reducing medication along with lifestyle modifications should be effective.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"There are a number of things you can do on your own to decrease your symptoms. In addition, I recommend that you use the acid-reducer famotidine 20 mg for additional relief."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Referral to a primary care provider may not be necessary if adequate relief is achieved from the recommended medication. Because the heartburn is predictable with large meals, primarily after lunch, using the famotidine on an as-needed basis should be sufficient."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. appropriate dose and frequency of administration	"Swallow one tablet at any time from <b>10-60 minutes before</b> eating food or drinking beverages that cause heartburn."
b. maximum number of days the therapy should be employed	"You can use this for up to 14 days in a row, if needed. If you think you need it for a longer period of time, call your primary care provider for further evaluation. From what you said, I can't imagine you'll need this more than once a week, if that."
c. product administration procedures	"Be sure to take this with a full glass of water."
d. expected time to onset of relief	"You should feel better a few hours after you take this. Often the relief happens sooner."
e. degree of relief that can be reasonably expected	"You should expect at least some relief; often patients get complete relief with a dose."

f. most common side effects	"Some of the more common side effects are headache, diarrhea, dizziness and constipation, but these don't happen too often and are rarely serious."
g. side effects that warrant medical intervention should they occur	"If you experience any unusual bleeding or bruising, be sure to call your primary care provider and stop using this medicine."
h. patient options in the event that condition worsens or persists	"If this situation worsens please consult a primary care provider."
i. product storage requirements	"Store this medicine in a cool dry place out of the reach of children."
j. specific nondrug measures	"Other things that can help you include eating smaller, more frequent meals and avoiding or reducing consumption of foods and drinks that trigger symptoms."
Solicit follow-up questions from the patient or caregiver.	"May I take the medication after I start the meal if I have forgotten to take it prior?"
Answer the patient's or caregiver's questions.	"Yes, but the medication may not be as effective in prevention of heartburn symptoms because of the delayed onset of action."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	To evaluate efficacy of the treatment, advise the patient to call the pharmacy after using the as-needed medication for heartburn prevention.

Key: NKA = No known allergies.

### Case 2-3

A mother of a 3-month-old boy calls the pharmacy requesting advice for her son who has had several watery stools since yesterday.

<b>Information to Obtain from the Patient</b>	<b>What the Parent Told You</b>
<i>Quickly and accurately assess the patient:</i>	
Ask about the current problem (SCHOLAR).	
<b>Symptoms</b> What are the main and associated symptoms?	"My son has had watery diarrhea since yesterday."
<b>Characteristics</b> What is the situation like? Is it changing?	"The stool is very thin and has no consistency at all. He's breast-fed, and he has stopped eating the last few hours. He seems more tired and has not had a wet diaper for several hours."
<b>History</b> What has been done so far?	"I haven't given him anything to stop the diarrhea."

<b>Onset</b> When did it start?	"About 24 hours ago."
<b>Location</b> Where is the problem?	"Just diarrhea. No vomiting."
<b>Aggravating factors</b> What makes it worse?	"Nothing."
<b>Remitting factors</b> What makes it better?	"Nothing."
<b>Ask about other Medications, Allergies, and Conditions (MAC):</b> Within reason, get as much detail as possible to assist in the decision-making process.	<ul style="list-style-type: none"> <li>• "My son takes D-Vi-Sol Vitamin D drops daily."</li> <li>• "He's not allergic to anything that I know of."</li> <li>• "He is otherwise very healthy. This is the first time he has been sick."</li> </ul>
<b>The "E.S.T." pieces of QuEST: Establish, Select, and Talk</b>	<b>Your assessment, recommendation, and counseling</b>
<b>Establish</b> that the patient is an appropriate self-care candidate: <ul style="list-style-type: none"> <li>• Any severe symptoms?</li> <li>• Any symptoms that persist or return repeatedly?</li> <li>• Is the patient self-treating to avoid medical care?</li> </ul>	The child's symptoms are severe given that he is under 6 months old with diarrhea and signs of moderate-severe dehydration. He is not a candidate for self-care.
<b>Suggest</b> appropriate self-care strategies.	"Ma'am, there are no appropriate self-care strategies for your son because he is so young. I strongly suggest you call your son's pediatrician as soon as possible to decide what to do. Your son may need rehydration that could be done only in an emergency department.
<b>Talk</b> with the patient about: <ul style="list-style-type: none"> <li>• Medication action, administration, and adverse effects</li> <li>• What to expect from the treatment</li> <li>• Appropriate follow-up</li> </ul>	Key Counseling Points: "Because your child is so young and has diarrhea, you should seek medical attention immediately to ensure that he gets adequately hydrated to prevent complications."

#### Case 2-4

A 35-year-old female is a regular patient of yours. She was walking into your pharmacy from her car to pick up a prescription and was stung by a bee. She wants to know what she should do to stop the burning.

<b>Information to Obtain from the Patient</b>	<b>What the Patient Told You</b>
<i>Quickly and accurately assess the patient:</i>	
Ask about the current problem (SCHOLAR).	
<b>Symptoms</b> What are the main and	"Pain from a bee sting on my right hand."

associated symptoms?	
<b>Characteristics</b> What is the situation like? Is it changing?	"Burning, itching, and redness."
<b>History</b> What has been done so far?	"Nothing."
<b>Onset</b> When did it start?	"Five minutes ago as I was walking from my car to the pharmacy."
<b>Location</b> Where is the problem?	"Palm of my right hand."
<b>Aggravating factors</b> What makes it worse?	"When I touch the bee sting area."
<b>Remitting factors</b> What makes it better?	"Nothing has been tried yet."
<b>Ask about other Medications, Allergies, and Conditions (MAC):</b> Within reason, get as much detail as possible to assist in the decision-making process.	<ul style="list-style-type: none"> <li>• "I take levothyroxine 50 mcg every day."</li> <li>• "I'm not allergic to any medications."</li> <li>• "This is the first time I've ever had a bee sting."</li> </ul>
<b>The "E.S.T." pieces of QuEST: Establish, Select, and Talk</b>	<b>Your assessment, recommendation, and counseling</b>
<b>Establish</b> that the patient is an appropriate self-care candidate: <ul style="list-style-type: none"> <li>• Any severe symptoms?</li> <li>• Any symptoms that persist or return repeatedly?</li> <li>• Is the patient self-treating to avoid medical care?</li> </ul>	<ul style="list-style-type: none"> <li>• Symptoms are mild and localized to the right hand. Because she is experiencing her first bee sting, the risk of hypersensitivity is low.</li> <li>• She is not exhibiting any signs of an anaphylactic reaction, such as hives, swelling, dizziness, weakness, or difficulty breathing.</li> </ul>
<b>Suggest</b> appropriate self-care strategies.	<ul style="list-style-type: none"> <li>• Nondrug: Remove the stinger by scraping with a credit card immediately; then apply an ice pack or cold compress.</li> <li>• Medication: Apply local anesthetic such as benzocaine 20% aerosol spray to affected area 3-4 times daily for up to 7 days to reduce itching and burning.</li> </ul>
<b>Talk</b> with the patient about: <ul style="list-style-type: none"> <li>• Medication action, administration, and adverse effects</li> <li>• What to expect from the treatment</li> <li>• Appropriate follow-up</li> </ul>	<p>Key Counseling Points:</p> <ul style="list-style-type: none"> <li>• "I think you can do a few things to help this situation. Benzocaine is a topical anesthetic that will help relieve itching and irritation associated with the bee sting. Spray the affected area 3-4 times daily for up to 7 days. If the site becomes more irritated or redness increases, stop using the spray."</li> <li>• "The benzocaine should provide immediate relief. The symptoms should resolve over time and should not last longer than 1 week."</li> <li>• "If you experience any hives, excessive swelling, dizziness, vomiting, or difficulty breathing, seek medical attention immediately. If the condition worsens or is not resolved by 1 week, seek medical attention."</li> <li>• "Keep the area clean by washing regularly with soap and water; do this before each application of benzocaine."</li> </ul>

### High-Risk and Special Patient Groups

Providing appropriate self-care recommendations is especially important for vulnerable populations. Certain groups of patients—infants and children, older persons ( $\geq 65$  years of age), and pregnant and breast-feeding women—may experience a higher incidence of drug therapy problems. Because these problems can have dire consequences, high-risk patients require special attention. Awareness of the physiologic state, possible pathologic conditions, and social context of high-risk patients is necessary to properly assess their medical conditions and recommend appropriate treatment.

In many respects, infants, children, and persons of advanced age require surprisingly similar considerations. They all have a need for drug dosages that differ from those for other age groups because of the following features:

- They have altered pharmacokinetic parameters.
- Their ability to cope with illness or adverse drug events is decreased because of physiologic changes associated with either child development or normal aging.
- Their patterns of judgment are impaired because of either immaturity or altered sensory function.
- They experience drug effects and potential adverse reactions that are unique to their age groups.
- They have a need for special consideration with medication administration.

Yet, because each of these patient groups is heterogeneous, it is important to consider these features individually for each patient.

### Special Considerations in Infants and Children

A study of the prevalence of nonprescription medication use in 3-year-old children found that 53.7% had been given a nonprescription medication within the preceding 3 months. The most commonly used medications were acetaminophen and cough or cold products. Analysis of vitamin supplement use found that 54.4% of 3-year-olds in the United States were given vitamin and mineral supplements within the preceding 3 months.<sup>8</sup> Providing self-care recommendations for pediatric patients is challenging because of differences in physiology and pharmacokinetics, lack of clinical data, insufficient drug labeling, and problems associated with drug dosing and administration.<sup>9</sup> For most products, the Food and Drug Administration (FDA) recommends against self-medication in children younger than 2 years and against the use of cough and cold products in children younger than 4 years.<sup>10</sup> Some package labeling provides dosage guidelines by weight rather than by age group. Pharmacists can provide recommendations regarding medications that are FDA approved for children (e.g., acetaminophen products), but they should recommend referral to a primary care provider for medical conditions or medications that extend beyond the FDA-approved labeling for nonprescription products.

### Physiologic and Pharmacokinetic Differences

Pediatric patients are at risk for drug therapy problems because their body and organ functions are in a continuous state of development. Not only do the pharmacokinetic properties of medications differ between children and adults, these properties also can undergo rapid change as children grow and mature.<sup>11</sup> Furthermore, illness in children is potentially more serious than in adults, given that the physiologic state of children is less tolerant of changes. For example, fever, vomiting, and diarrhea represent greater potential risks because children are more susceptible to the effects of fluid loss. Therefore, the pharmacist should consider referral to another health care provider sooner for children with certain conditions than for an adult with the same condition.

### Potential Drug Therapy Problems

The health care provider should be sensitive to the potential for drug therapy problems among children. In some illnesses such as diarrhea (see [Chapter 16](#)), nondrug therapy is often more appropriate than therapy with nonprescription antidiarrheals. In some situations, specific medications are contraindicated; for example, aspirin should not be administered to young children with certain viral illnesses (especially influenza and varicella) because of its association with Reye's syndrome (see [Chapter 5](#)). For younger children, solid dosage forms are inappropriate and the health care provider will need to guide parents to liquid or chewable formulations.

#### **Inaccurate Dosing**

Labeling for nonprescription medications generally uses age-based guidelines to determine dosages; however, many products do not provide dosage information for children younger than 6 years. Applying label instructions designed for dosing children older than 6 years to a younger child can result in excessive dosing and potential toxicity for the younger child. Inaccurate dosing by parents can result from determining an incorrect dose from the label instructions, by measuring an incorrect amount, or both. A study of 200 children, 10 years of age and younger, who had been given a dose of acetaminophen or ibuprofen in the preceding 24 hours, found that 51% of them had been given an incorrect dose by their caregiver.<sup>12</sup> Pharmacists must help parents interpret labels and better educate them about accurate dosing.

#### **Improper Administration/Dosage Forms**

Selecting the proper medication and dosage is not beneficial unless the medication is actually administered correctly. Proper administration of medications to pediatric patients requires that health care providers and caregivers have an appreciation of available dosage forms, delivery methodologies, routes of administration, palatability, and how to use measuring devices.

A young child can swallow liquid formulations more easily than other dosage forms, and the dose can be titrated to the patient's weight/age; therefore, liquids are often used in pediatric populations. Because elixirs and syrups can have high alcohol and sugar content, respectively, these liquid formulations may be less desirable than suspensions and solutions. A suspension also may mask the disagreeable taste of a medication. Refrigeration also may improve the flavor of liquid formulations.

Problems with drug administration can result in the child receiving the wrong dose. In a mock dosing scenario in which caregivers had the choice of using teaspoons, tablespoons, syringes, droppers, measuring cups, and measuring tubes, only 67% of the caregivers accurately measured the dose they intended to administer.<sup>12</sup> The volume delivered by household teaspoons ranges from 2.5 to 7.8 mL and may also vary greatly when the same spoon is used by different individuals. The American Academy of Pediatrics Committee on Drugs highly recommends the use of appropriate devices for liquid administration, such as a medication cup, cylindrical dosing spoon, oral dropper, or oral syringe. Ease of administration and accuracy should be considered when choosing a dosing device. Plastic medication cups are fairly accurate for volumes of exact multiples of 5 mL (5 mL, 10 mL, 15 mL, etc.). An oral syringe is preferable to the other oral dosing devices for higher viscosity liquids because the syringe completely expels the total measured dose. Potent liquid medications should be administered with an oral syringe to ensure that the correct dose is given. The health care provider should demonstrate to caregivers how to read and use all these devices.

In response to the problem of inaccurate measurement of doses, FDA released in May 2011 guidelines for liquid nonprescription drug products that include any type of dispensing device, such as a dropper, cup, syringe, or spoon.<sup>13,14</sup> These products include liquid analgesics, liquid cough and cold products, and lactase replacement drops. The following recommendations are the key points of the guidance:

- A dosing device should be included with all oral liquid nonprescription products.
- The device should be calibrated to the dose recommended in the product directions.
- The device should be used only with the product in which it is packaged.
- The markings should remain visible even when the liquid is in the device.

In May 2011, the Consumer Healthcare Products Association also announced that its member companies would voluntarily convert nonprescription single-ingredient liquid pediatric acetaminophen medications to just one concentration (160 mg/5 mL) for use in all children younger than 12 years. Most concentrated infant drops (80 mg/0.8 mL; 80 mg/1 mL) were being phased out starting mid-2011. Infant products will include flow restrictors and will be packaged with oral syringes for more accurate dosing. Products for children ages 2 to younger than 12 years will still be packaged with dosing cups. Because both concentrations will be available during the transition period, parents and caregivers should carefully read and follow product labeling, and health care providers should pay special attention to this issue during the education step.<sup>15</sup>

A child older than 4 years can usually swallow tablets or capsules. Tablets that are neither sustained-release nor enteric-coated formulations may be crushed. Most capsules may be opened and the contents sprinkled on small amounts of food (e.g., applesauce, jelly, or pudding) to improve palatability. If the child does not eat the full portion, underdosing can occur. If multiple medications are necessary, the child may be more cooperative if allowed to choose what flavored drink to use and which medication to take first. [Table 2-2](#) presents selected guidelines for administering oral medications to pediatric patients.

**TABLE 2-2 Selected Administration Guidelines for Oral Medications**

Infants
<ul style="list-style-type: none"> <li>• Use a calibrated dropper or oral syringe.</li> <li>• If a medicine dropper is used, the medication should be squirted into the side of the cheek and not straight back into the throat so that the infant does not choke.</li> <li>• Do not place the child's medication in the formula because the baby might not like the taste of the formula and might refuse to take this formula in the future.</li> <li>• Support the infant's head while holding the infant in the lap.</li> <li>• Give small amounts of medication at a time to prevent choking.</li> <li>• If desired, crush non-enteric-coated or non-sustained-release tablets into a powder and sprinkle them on small amounts of food.</li> <li>• Provide physical comfort while administering medications to help calm the infant.</li> </ul>
Toddlers

- Allow the toddler to choose a position in which to take the medication.
- If necessary, disguise the taste of the medication with a small volume of flavored drink or small amounts of food. A rinse with a flavored drink or water will help remove an unpleasant aftertaste.
- If the medication is not palatable, ask the pharmacist whether the pharmacy offers a flavoring service and can add flavoring to the child's medication. Refrigeration also may help.
- Make sure that the medication is not referred to as candy.
- Use simple commands in the toddler's jargon to obtain cooperation.
- Allow the toddler to choose which medication (if multiple) to take first.
- Provide verbal and tactile responses to promote cooperative taking of medication.
- Allow the toddler to become familiar with the oral dosing device.

### Preschool Children

- If possible, place a tablet or capsule near the back of the tongue; then provide water or a flavored liquid to aid the swallowing of the medication.
- If the child's teeth are loose, do not use chewable tablets.
- Use a follow-up rinse with a flavored drink to help minimize any unpleasant medication aftertaste.
- Allow the child to help make decisions about dosage formulation, place of administration, which medication to take first, and type of flavored drink to use.

### Adverse Drug Effects

Adverse reactions are another potential drug therapy problem in children. Adverse drug events in children may differ from those in adults. Antihistamines and central nervous system (CNS) depressants may cause excitation in children. In contrast, sympathomimetics such as pseudoephedrine may cause drowsiness in children. In the United States, drug-induced acute liver failure is most commonly caused by acetaminophen, and about 18% of these cases were a result of accidental overdose. In addition, administration of acetaminophen at doses above the recommended daily dose over a period of 2-4 days can result in hepatotoxicity in children.<sup>16</sup>

### Nonadherence

Nonadherence may occur when children refuse to take medication, when caregivers give up before the child receives the entire dose, or when caregivers just forget to give a dose. Adherence may be improved by recommending a sweetly flavored product because children may be more willing to take a medication if they like the flavor, consistency, or texture.<sup>17</sup> However, it is important to stress to caregivers to keep all medications out of the reach of children, especially those that taste good and could be mistaken as "candy" by the child. Nonadherence also can occur when caregivers do not understand instructions or do not pass them on to day care providers, teachers, or school nurses. A 2003 study that surveyed 82 child day care centers found that 52% of centers reported forgetting to give a dose of medication to a child in their care during the preceding year, and 49% reported that the child's medication was not available.<sup>18</sup>

### Assessment and Consultation

Assessment and consultation for pediatric patients usually involve the parents or caregivers but may involve the child directly. A 2003 article by Sleath and coworkers<sup>19</sup> lists six overall steps for communicating with children and improving their medication use process (Table 2-3). One should remember that it is important to include the child and parent or caregiver during the patient counseling process, and that the child's and parents' or caregivers' concerns or fears about the medication should be considered and addressed.

#### TABLE 2-3 Six Steps for Improving Medication Use in Children

##### Pharmacists should use a patient-centered style that focuses on the following steps:

1. Educating both the child and parents about the medication.
2. Investigating any concerns or fears that the child or parents may have about the medication.
3. Asking the child and parents about priorities for improved quality of life.
4. Following up with the child and parents to learn whether they consider the child's treatment effective.
5. Offering to follow up with the pediatrician to improve the child's therapy (if needed).
6. Encouraging the child or parents to ask questions about the medication.

### Special Considerations in Persons of Advanced Age

Social, economic, physiologic, and age-related health factors place persons of advanced age at high risk for medical problems and predispose them to consume large numbers of nonprescription medications. This population as a group consumes more medications than any other age segment of our society. Individuals ages 65 years or older

take on average 1.8 nonprescription medications daily, and factors that affect this number include geographic area, race/ethnicity, and gender.<sup>20</sup> Nonprescription drug use in this population is highest in residents of the Midwestern United States, Caucasians, and women. Analgesics, laxatives, and nutritional supplements are the most common nonprescription medications used by persons of advanced age. A study in 86 women who were 65 years of age or older reported an average use of 3.8 nonprescription medications per person and, in the 45% of women who used herbal products, an average number of 2.5 herbal products.<sup>21</sup>

The response to drug therapy by older patients is more scattered and unpredictable than that of other populations. Pharmacokinetic, pharmacodynamic, and various nonpharmacologic factors predispose older patients to potential problems with nonprescription medications. Preexisting medical conditions in older persons may affect the use of some nonprescription medications. For example, antihistamines should be avoided in patients with emphysema, bronchitis, glaucoma, and urinary retention from prostatic hypertrophy. Although nasal and oral decongestants can be used without adverse effect in many older persons, caution may be necessary in some patients with heart disease, hypertension, thyroid disease, and diabetes because of potential adverse effects of sympathomimetics on heart rate, blood pressure, and blood glucose.

The American Geriatrics Association's 2012 Beers criteria is a valuable source of information about safe prescription and nonprescription medication use by older patients. The evidence-based criteria identify drugs that pose risks in the elderly population, and this update included more nonprescription medications than in previous versions.<sup>22</sup>

### Physiologic and Pharmacokinetic Differences

Persons of advanced age often have impaired vision (e.g., difficulty reading small print and differentiating colors of similar contrast) and hearing loss. Health care providers should be aware of patient behaviors that indicate visual or hearing loss and should consider these impairments when communicating with older patients. Additional instructions for nonprescription medications may need to be provided in larger, high-contrast, dark print. Asking the patient to repeat counseling instructions can ensure that the directions were heard correctly and understood.

Subtle changes in mental status, such as confusion, may be anticipated in older patients, especially those who are anxious about their state of health. Older patients with cognitive impairments may have difficulty comprehending directions. Patients may not remember the names of all their medications or may not be able to remember instructions. Because of memory lapses, some older patients may require special drug delivery systems (e.g., transdermal patches or sustained-release preparations) to help them adhere to their dosage regimen. Older patients with cognitive impairments are less likely to read and interpret labels correctly,<sup>23</sup> which further emphasizes their need for special dosage form considerations.

Misbeliefs about the health problems can cause elderly patients to underreport their symptoms.<sup>23</sup> For example, they may attribute treatable symptoms to simply growing older. In addition, older patients are often reluctant to share health information with others. Accurate perception and reporting of symptoms are vital to the successful selection and use of any medication. Therefore, health care providers must take special care to establish rapport and carefully question older patients to recommend appropriate care.

The aging process and many chronic diseases can alter a patient's nutritional status. Older patients who are most at risk for undernourishment or malnutrition are homebound patients and nursing home residents. Limited income, poverty, multiple chronic diseases, mental status changes, multiple drug therapy, or a combination of these factors may cause malnutrition in older patients. The patient's nutritional status and weight are important because these factors can alter pharmacokinetics and pharmacodynamics. For example, a recent study demonstrated that malnourishment in elderly patients with diabetes is associated with a higher incidence of hypoglycemia independent of the use of insulin and sulphonylureas.<sup>24</sup>

Aging alters the absorption, distribution, metabolism, and elimination of certain medications, increasing the susceptibility of older patients to drug therapy problems. Pharmacokinetic changes, which are well described in the literature, are caused not only by advancing age but also by the effects of disease states and often by multiple drug use. For example, there has been concern that prolonged use of proton pump inhibitors will lead to vitamin B<sub>12</sub> deficiency. This is because vitamin B<sub>12</sub> requires stomach acid for absorption. There is no evidence that long-term omeprazole use by young, healthy adults leads to vitamin B<sub>12</sub> deficiency. In contrast, older patients are at risk because stomach acid and vitamin B<sub>12</sub> absorption normally decrease with age.<sup>25</sup>

Older persons appear to have a greater sensitivity to some medications, particularly anticholinergic medications, which may relate in part to alterations in cholinergic transmission. Nonprescription medications with anticholinergic effects (e.g., certain antihistamines) may worsen preexisting medical conditions and symptoms such as congestive heart failure, diabetes mellitus, glaucoma, constipation, angina, urinary dysfunction, sleep disturbance, and dementia.<sup>26</sup> The risk of accidents, such as falls, also may increase as a result of sedation or pupillary dilation induced by anticholinergic medications and the inability to accommodate the effect.

Both subjective and objective evidence indicates that older patients have an enhanced CNS sensitivity to

medications, especially CNS depressants such as sedatives.<sup>22</sup> Increased brain sensitivity and other changes (e.g., decreased coordination, prolongation of reaction time, and impairment of short-term memory) manifest as increased frequency of confusion, urinary incontinence, and number of falls, especially among older women. Co-administered medications may exaggerate all these changes, particularly if they are taken in the usual adult dose or if multiple medications are used.

Control of bowel and bladder function lessens with advancing age. A further decrease in bowel efficiency is likely with laxative use. Anticholinergic and CNS medications may reduce neurologic control. Antihistamines have sedative properties that may reduce bladder control in older persons.<sup>27</sup> Adverse effects of nonprescription medications often increase when these medications are added to an existing medication regimen through interactions with other therapies and health conditions.

NSAIDs are widely used, especially by patients with chronic pain, osteoarthritis, and rheumatoid arthritis. The incidence of NSAID-related toxicity is greater for older patients because of their frequent use of NSAIDs and the increased prevalence of comorbid conditions and concomitant drug therapies. These patients may be especially susceptible to NSAID-associated peptic ulcer disease as well as congestive heart failure.

## Other Potential Drug Therapy Problems

### Duplicate Therapy

Older patients may receive unnecessary drug therapy when medications are added to their regimen without an assessment to determine whether an existing medication can be stopped. For example, patients may be taking a prescription proton pump inhibitor such as Nexium and be unaware that their newly purchased nonprescription stomach medicine, Prilosec OTC, is in the same drug class. Duplicate therapy also may occur if patients are seeing multiple health care providers for various medical problems or using multiple pharmacies. Use of a single pharmacy can significantly lower the risk of inappropriate drug combinations. Nonprescription medications commonly involved in drug interactions in older persons include aspirin, other NSAIDs, antacids, cimetidine, and antihistamines.<sup>28</sup>

Certain illnesses or medications may contraindicate the use of other medications. Many older patients have conditions such as coronary artery disease, renal dysfunction, and congestive heart failure, which can be aggravated by concurrent therapy for other acute problems. In addition it is important to consider whether an older patient is requesting a nonprescription medication to treat an adverse reaction from another medication. This assessment is best performed by a pharmacist.

### Inaccurate Dosing/Dosage Forms

Normal doses of certain medications such as analgesics and sedating antihistamines may be too high for older patients because they have diminished hepatic and renal function. These situations may necessitate either lowering the dose or increasing the dosing interval. Furthermore, because of physical limitations, older patients may experience difficulty with some dosage forms (e.g., swallowing large calcium or vitamin tablets). Arthritis or tremors may make it difficult for older patients to open and close containers. Child-resistant containers may be especially difficult for older patients to open if they have deficits in manual dexterity. A pharmacist should direct older patients to products without child-resistant containers but also warn them of the potential poisoning hazard for unintended users, such as visiting grandchildren or other young individuals in the household.

### Nonadherence

The prevalence of nonadherence with medications is high in the older population and is often the result of their inadequate understanding of their medication regimen. Poor adherence may result from difficulty swallowing or other administration procedures. It also may result from an inability to afford the medication because of a limited or fixed income. Older patients may lack an adequate social support network to provide assistance in managing a complex group of illnesses. Health care providers may need to involve caregivers in administering certain types of medications (e.g., suppositories and eye drops) to patients to help ensure adherence.

### Special Considerations in Pregnant Patients

Drug therapy during pregnancy may be necessary to treat medical conditions or to manage common complaints of pregnancy, such as vomiting or constipation. Because most medications cross the placenta to some extent, a mother who ingests a medication is likely to expose her fetus. Therefore, the desire to ease the mother's discomfort must be balanced with concern for the developing fetus.

A 2001 study<sup>29</sup> found that 13% of pregnant women from an academic setting birthing center used dietary supplements. Of these women, 25% reported using supplements to relieve nausea and vomiting, and 25% reported stopping the use of these products because of concern for their fetus. The authors concluded that, although the use of dietary supplements was low among these women, the lack of safety data for the products is of concern. In another study,<sup>30</sup> women attending an antenatal clinic reported using an average of 2.3-2.6 nonprescription medications in the three pregnancy trimesters, which was slightly higher than nonprescription drug use in the 3 months before pregnancy. The most frequently consumed medications were analgesics, vitamin and mineral supplements, and gastrointestinal preparations. In addition, approximately 10% of pregnant women used herbal products.

## Potential Drug Therapy Problems

Pregnant women should never presume that a nonprescription medication is safe to use during pregnancy. They should first consult with a health care provider to determine whether a medication is teratogenic (i.e., causes abnormal embryonic development). Nausea and vomiting during pregnancy can cause another medication-related problem: difficulty in taking oral dosage forms of medications. There are ways to address this problem as well, but it requires the involvement of a health care provider to work with the patient to explore options and solutions.

### **Teratogenic Effects**

Several factors are important in determining whether a medication taken by a pregnant woman will adversely affect the fetus. Two such factors are the stage of pregnancy and the ability of the medication to pass from maternal to fetal circulation through the placenta. The first trimester, when organogenesis occurs, is the period of greatest risk for inducing major anatomic malformations. However, exposure at other periods of gestation may be no less important because the exact critical period depends on the specific medication in question. Patients should work closely with their health care provider to evaluate the risks and benefits of each situation.

Drug therapy problems are also important considerations for pregnant patients. Although dosage guidelines for some prescription medications (e.g., phenytoin) differ for pregnant patients, no information on dosage adjustments exists for nonprescription medications. Unnecessary drug therapy should be avoided. Nondrug therapy (e.g., use of a humidifier or vaporizer for relief of nasal congestion secondary to a common cold) is often more appropriate than drug therapy for pregnant women. Use of cigarettes and ingestion of alcohol should be avoided because they have been associated with increased risk to the fetus.<sup>31</sup> Consumption of moderate doses of caffeine appears to be safe.<sup>32</sup> In pregnant patients, the primary concern is drug safety. All nonprescription medications have a Drug Facts label, which is arranged the same way on all nonprescription medications. One section of the Drug Facts label is for pregnant women. With nonprescription medications, the label usually tells a pregnant woman to speak with a health care provider before using the medicine. Some nonprescription medications are known to cause certain problems in pregnancy. The labels for these medications give pregnant women facts about why and when they should not use the medications. For example, aspirin can cause fetal and maternal hemorrhage if taken during the third trimester.

Thus, the labeling on aspirin products warns against this practice.<sup>33</sup>

### **Nonadherence**

Nausea and vomiting associated with pregnancy are probably the leading causes of nonadherence in pregnant women because they prevent consumption of most oral medications on a consistent basis. Health care providers can recommend eating small meals, frequent snacks, and crackers to alleviate or minimize nausea and vomiting. The patient should avoid foods, smells, or situations that cause vomiting. If necessary, the use of an effervescent glucose or buffered carbohydrate solution or ginger may be effective.<sup>34</sup> If ginger ale is used, it should be verified that the product actually includes ginger. Only if these measures are ineffective should an antihistamine or antiemetic be considered. Consultation with a primary care provider may be indicated at this point. It is very important for providers to be cognizant of potential adherence issues during pregnancy and to take a proactive role in helping to prevent them.

### **Management of the Pregnant Patient**

The health care provider can assist the self-treating pregnant woman in deciding which drug or nondrug treatments she should consider and when self-treatment may be harmful to her or her unborn child. When the health care provider has more than one medication option, the preferred medication will be the one that has the best efficacy and safety profiles. Ascertaining the trimester of pregnancy is important because it is a factor in determining whether some nonprescription medications can be used safely. Health care providers should discourage pregnant women from self-medicating with nonprescription medications without receiving counseling from a primary care provider or pharmacist. The assessment and management of the pregnant patient requires observation of the following principles:

1. The health care provider must be alert to the possibility of pregnancy in any woman of childbearing age who has certain key symptoms of early pregnancy, such as nausea, vomiting, and frequent urination. Any woman who fits this profile should be warned not to take a medication that might be of questionable safety until her pregnancy status is confirmed.
2. The health care provider should generally advise the pregnant patient to avoid using medications at any stage of pregnancy unless the patient's primary care provider deems the use essential. In addition, because the safety and effectiveness of homeopathic and herbal remedies in pregnancy have not been established, their use should be discouraged.
3. The health care provider should advise the pregnant patient to increase her reliance on nondrug modalities as treatment alternatives (see the section Nonadherence).
4. The health care provider should refer the patient to a primary care provider for certain problems that carry increased risk of poor outcomes in pregnancy (e.g., high blood pressure, vaginal bleeding, urinary tract infections, severe nausea and vomiting, rapid weight gain, and edema).

### Special Considerations in the Nursing Mother

A mother's drug use while breast-feeding can have an adverse effect on the infant. The concentration of a medication in the mother's milk depends on a number of factors, including the medication's concentration in the mother's blood; the medication's molecular weight, lipid solubility, degree of ionization, and degree of binding to plasma and milk protein; and the extent of the medication's active secretion into the milk. Other important considerations include the relationship between the time of taking a medication and the time of breast-feeding, as well as the medication's potential for causing toxicity in infants. In addition, some medications such as decongestants may decrease milk supply.<sup>32</sup>

When advising a nursing mother on self-care, the health care provider should first decide whether a medication is really necessary. Then, if a medication is indicated, the safest one (e.g., acetaminophen instead of aspirin) is recommended, and the mother is advised to take the medication just after breast-feeding or just before the infant's lengthy sleep periods to minimize infant exposure during subsequent nursing periods.<sup>35,36</sup> It is preferable to select a medication that has been in use for a long time and that has shown no apparent harm to nursing infants. If appropriate, topical or local therapy may be preferred to oral, systemic therapy. In general, advise against medications that are extra strength, maximum strength, or long acting, or products that contain a variety of active ingredients.<sup>36</sup>

When taken in therapeutic doses, most medications are not present in breast milk in sufficient concentrations to cause significant harm to the infant.<sup>32</sup> However, several medications are contraindicated for use while breast-feeding, and others should be used with caution by nursing mothers. The amount of caffeine in caffeine-containing beverages is not harmful, but higher doses (i.e., >1 gram daily) have been reported to cause irritability and poor sleep patterns in infants.<sup>34</sup> Many nonprescription medications have no data on their transfer into breast milk and their possible clinical effects.

Nonprescription medications that are usually considered compatible with breast-feeding include the following<sup>32,37</sup>:

- *Analgesics*: acetaminophen, ibuprofen, and naproxen
- *Antacids*
- *Antidiarrheals*: loperamide
- *Antihistamines*: brompheniramine, chlorpheniramine, diphenhydramine, and triprolidine
- *Antisecretory agents*: famotidine and ranitidine
- *Cough preparations*: dextromethorphan
- *Cromolyn sodium*
- *Decongestants*: pseudoephedrine
- *Fluoride*
- *Laxatives*: bran type, bulk-forming type, docusate, glycerin suppositories, magnesium hydroxide, and senna
- *Vitamins*

### CAM Use in Special Populations

Special consideration should be given to the risk-benefit assessment of complementary and alternative medicine (CAM) use in children, older persons, and pregnant and nursing women because the level of use is high in these populations. Herbal use in a study population of children ages 3 weeks to 18 years was 45% during the year before they were surveyed.<sup>38</sup> In the adult population, use of herbal products is estimated to be about 57%; only 33% of the patients told their health care provider about their use of herbal products.<sup>39</sup>

During a typical patient medication interview, the emphasis is usually on prescription and nonprescription medications. Although patients may not even consider herbal and home remedies to be therapeutic agents, their use also may cause drug therapy problems. Therefore, specific questions need to be asked to assess the current use of such remedies. Patients have a tendency to view herbal products as safe for use because they are natural products and not drugs. In the previously mentioned study of herbal use, "77% of patients or caregivers did not believe or were uncertain if herbal products had any side effects and only 27% could name a potential side effect. Sixty-six percent were unsure or thought that herbal products did not interact with other medications."<sup>38</sup>

It is imperative that a specific assessment of herbal use be completed. In this context, the health care provider should ask about herbal use but also include examples. One might say, "Okay, now I am going to ask you about any herbal or natural products you may be taking. This would be things like St. John's wort, echinacea, ginseng, ginkgo, cod liver oil, or even home remedies that you might use." Phrased this way, the question leaves little doubt as to the type of products to which the health care provider is referring. Furthermore, it takes patients off the defensive, while still expressing the health care provider's need to know about the use of such products.

### Key Points for Patient Assessment and Consultation

The use of nonprescription medications represents an important component of the health care system. Under ideal

conditions, consumers can diagnose their own symptoms, select a nonprescription product, and monitor their own therapeutic response. If properly used, nonprescription medications can relieve patients' minor physical complaints and permit primary care providers to concentrate on more serious illnesses. If used improperly, however, nonprescription products can create a multitude of drug therapy problems. The key points discussed in this chapter include the following:

- Twenty-three percent of all drug therapy problems experienced by patients are either caused or resolved by nonprescription medications.
- Health care providers should use systematic cognitive processes to effectively address patients' self-care needs.
- The consistent and systematic patient care process helps providers be complete and concise when assuming responsibility for a patient's self-care needs.
- There are special drug-related needs associated with high-risk groups, such as infants and children, older persons, and pregnant and breast-feeding women.

To be of greatest service to patients, health care providers must continually expand their therapeutic knowledge and work to improve their interpersonal communication skills. As providers strive to fulfill their responsibilities and continue to expand their patient care services, people will learn of the services and seek their assistance whenever they are in doubt about self-treatment. The result will be better informed patients who will use the expertise of their health care providers to experience better outcomes with their self-care interventions.

## Handbook of Nonprescription Drugs > Chapter 3. Developing Cultural Competency for Self-Care

### Developing Cultural Competency for Self-Care: Introduction

Culture influences beliefs about the health care system and may impact patients' decisions regarding self-care. This chapter explores cultural competency in health care to help guide health care providers in promoting self-care and in counseling patients from diverse backgrounds and cultures. If cultural issues are not considered during the patient interview, the health care provider may be less able to assess and/or counsel a patient effectively.

Providers may be able to formulate a more appropriate self-care plan for a given health issue if they understand the patient's cultural point-of-view and incorporate the patient's health care beliefs into the plan. In this chapter, major demographic shifts in the composition of the U.S. population are outlined to illustrate the relevance of diversity in health and the overall delivery of health care. Emphasis is placed on defining and listing important cultural terms and theoretical frameworks for cross-cultural care so that providers are able to better understand the cultural context in which patients may make self-care decisions related to overall health. General characteristics found in major racial and ethnic groups in the United States are discussed, as well as differences in cultural approaches to seeking care, particularly self-care. Attention is given to cultural assessment techniques and communication strategies to assist health care providers in communicating effectively with patients of diverse cultures and in developing a more culturally competent treatment plan.

The terms *Western*, *American*, and *conventional medicine* often are used synonymously to mean therapies regulated by the Food and Drug Administration (FDA), including prescription and nonprescription products. The terms *complementary*, *alternative*, and *traditional* are referred to as complementary and alternative medicine (CAM). In general, CAM encompasses a broad array of health practices from all over the world. Examples include magnet therapy, acupuncture, herbs, mind and body techniques, homeopathy, and massage therapy. The concept of CAM is introduced in this chapter to encourage health care providers to consider the use of these modalities among diverse patient populations. (See Chapters 50 through 52 for an in-depth discussion of CAM.)

### Rationale for Cultural Competency in Self-Care

#### Demographic Changes in the U.S. Population

For statistical purposes, the U.S. Census Bureau classifies five races: (1) Black or African American, (2) Asian, (3) Native Hawaiian and other Pacific Islander, (4) American Indian and Alaska Native, and (5) White.<sup>1</sup> Individuals who identify as Hispanic (considered to be an ethnicity by the U.S. Census Bureau) may be of any race(s); race and Hispanic origin are considered separate categories. For example, individuals may classify themselves as non-Hispanic White, Hispanic White, non-Hispanic Black, or Hispanic Black.

The heterogeneity of the classification options should be recognized. For example, the groups included under Asian (e.g., Vietnamese, Filipino, and Indian) and Pacific Islander (e.g., Fijian and Samoan) exhibit great variability. This is also true for the Hispanic classification, which includes four diverse groups: Mexican Americans, Puerto Ricans, Cubans, and others (e.g., Central Americans, South Americans, and Spaniards). People in the United States increasingly identify themselves as belonging to two or more racial groups, making the issue of race and ethnic background complex.<sup>1,2</sup>

The reported number of racial and ethnic minorities has resulted in a shift in the composition of the U.S. population (Table 3-1).<sup>1-4</sup> In 2010, there were nearly 39.8 million foreign-born inhabitants, with Latin America as the leading region of origin.<sup>1</sup> In perspective, one of every three U.S. residents identifies with a race or ethnicity that is not White. The largest racial and ethnic minority group is Hispanic followed by Black or African American and Asian. Other changes in health care delivery include aging of the baby boomer generation and people 65 years and older, comprising 13% of the population.<sup>1,2</sup> Although people in all U.S. geographical areas are aging, those in certain regions are becoming younger, which may partially be attributed to the lower median childbearing age in some minority and foreign immigrant groups. Current trends in migration patterns have created unevenly distributed racial and ethnic diversity across the United States. Therefore, transformation and diversity in ethnic consumer markets will be more pronounced in certain regions. The U.S. population is also diverse according to sex, physical disabilities, religious preference, and sexual orientation. The religious landscape of the United States indicates that about 78% of the population is Christian, 16% is not affiliated with any religion, and about 5% is aligned with non-Christian faiths.<sup>5</sup> These demographic changes have penetrated most areas in the United States that previously were considered homogeneous in culture, making the importance of cultural competence a national issue. Providers in every practice setting are likely to interact with patients from diverse cultures and backgrounds.

**TABLE 3-1 Changes in Racial, Ethnic, Social, and Economic Characteristics in the United States (2000, 2010)**

<i>Characteristic<sup>a</sup></i>	<i>Percentage of Total Population</i>	
	<i>2000</i>	<i>2010 &amp; Estimates</i>
Total population <sup>b</sup>	100.0	100.0
	(281.4 million)	(308.7 million)
White	75.1	72.4
Hispanic	12.5	16.3
Black or African American	12.3	12.6
Asian	3.6	4.8
American Indian and Alaska Native	0.9	0.9
Native Hawaiian and Pacific Islander	0.1	0.2
<b>Other Demographic Markers<sup>c</sup></b>		
Population 65 years and older	12.4	13.0
Education below 12th grade	19.6	14.6
Born outside of the United States	11.1	12.8
Language other than English spoken at home	17.9	20.3
Families (poverty level)	9.2	10.5

<sup>a</sup> Total adds up to greater than 100% because of some cross-classification in Census data.

<sup>b</sup> Total is based on race “alone or in combination with one or more other races.”

<sup>c</sup> The median age of the population is 35.3 years for 2000 and 37.2 years for 2010 and estimates.

**TABLE 3-2 Health Disparities among Racial and Ethnic Groups in the United States**

<i>Disparity Focus</i>	<i>Examples</i>
Infant mortality	Higher death rates exist in African American (2.5 times), American Indian, and Puerto Rican infants compared with white infants.
Heart disease and stroke	Heart disease and stroke rates of death are 29% and 40% higher, respectively, among African American adults than whites.
Diabetes	American Indians and Alaskan Natives are 2.6 times as likely to have diabetes as non-Hispanic whites.
HIV/AIDS	African Americans and Hispanic Americans represent 66% of adults with AIDS.
Immunizations	Hispanic and African American adults ages 65 years and older are less likely than whites of the same age to receive influenza and pneumococcal vaccination.
Hepatitis	In 2000, about 50% of people with Hepatitis B in the United States identify as Asian Americans and Pacific Islanders.

Key: AIDS = Acquired immunodeficiency syndrome; HIV = human immunodeficiency syndrome.

Source: Reference 7.

## Health Disparities

Although the health of some racial and ethnic groups has improved, health disparities persist.<sup>6</sup> In many cases, health disparities cannot be explained solely on the basis of information about the biologic and genetic characteristics of racial and ethnic groups. Health disparities often result from “complex interactions among genetic variations, environmental factors, socioeconomic factors, and specific health beliefs and behaviors.”<sup>6</sup>

Individuals from some minority groups do not equally experience long life spans, good health, and access to health services. Low rates of cancer screening and treatment among racial and ethnic minority groups are attributed to cultural and linguistic barriers, as well as limited access to health services. Heart disease and stroke are the leading causes of death for all U.S. racial and ethnic groups (Table 3-2).<sup>7</sup>

Factors linked to health disparities include race, socioeconomic status, health practices, psychosocial stressors, lack of resources, environmental exposures, discrimination, and access to health care.<sup>6</sup> These factors will continue to influence future patterns of disease, disability, and health care utilization unless they are addressed. For instance, Hispanics and American Indians under 65 years of age are more likely to be uninsured than those in other racial and ethnic groups. Persons living in poverty are more likely to be in fair or poor health and to have disabling conditions.<sup>8</sup>

In an effort to create a healthier society and develop strategies to decrease the gap in health care, the U.S. government has guided public health policy over three decades through the Healthy People initiative.<sup>9</sup> By setting health care priorities and measurable health objectives, Healthy People 2020 provides a foundation for the health care agenda for the next decade. The overarching goals address how the United States can strive for health equity and improved health across the population, promote behaviors and environments that are healthy, and help achieve a higher quality of life.<sup>9</sup>

Several specific objectives within Healthy People 2020 are linked to self-care such as self-monitoring blood glucose in diabetes, taking measures to prevent sunburn, and quitting smoking. This initiative is a road map to better health and can be used by different people, states, communities, professional organizations, and groups to improve overall health.

## Health Care Provider Competencies and Workforce Issues

One of the factors identified by government agencies and health care groups as a cause of health disparities is the lack of awareness of cultural issues and health disparities among health care providers. This problem may be attributed to limited formal education on cultural issues among health profession schools. To ensure effective delivery of culturally and linguistically appropriate care in cross-cultural settings, providers should understand basic cultural issues related to health and illness, health disparities among different groups, and communication strategies for culturally diverse patients.<sup>10</sup> Although cultural competency and diversity education are required as part of accreditation in health professional training, lack of workforce diversity still exists in health care.

The current racial and ethnic composition of health care professionals in the United States does not reflect the general population. For example, only 4.4% and 6.6% of Doctor of Pharmacy graduates in 2011 were Hispanic and African American, respectively.<sup>11</sup> Health care providers who share the same racial and/or ethnic minority and socioeconomic backgrounds with their patients are more likely than providers from different backgrounds to

- Provide cultural and/or linguistic concordance (e.g., when patients can consult providers from their primary racial, ethnic, and/or language background)
- Improve trust and comfort for follow-up and partnership
- Provide advocacy and leadership for policies and programs aimed at improvements for vulnerable populations

This shared identity may improve access to care, quality of provider-patient communication, and outcomes.<sup>12</sup>

These issues highlight the need for providers of all races to understand the influences of culture in health care and for health sciences curricula to incorporate content on cultural competency.<sup>13</sup> The Health Resources and Services Administration (HRSA) also provides information on the rationale and resources for cultural competence in diverse health professional programs such as dentistry, medicine, and nursing.<sup>12,14</sup>

In 2000, the Office of Minority Health developed the National Standards for Culturally and Linguistically Appropriate Services (CLAS) in Health Care.<sup>15</sup> These standards, which were updated in 2013, are based on an in-depth review of the literature, regulations, laws, and standards currently used by federal and state agencies. The new 15 standards are divided into four main sections that address: (1) the principal standard; (2) governance, leadership, and workforce; (3) communication and language assistance; and (4) engagement, continuous improvement, and accountability.

One intended purpose of the national standards is to provide criteria that credentialing and accreditation agencies can use to ensure the level and quality of culturally appropriate care that providers and institutions deliver and to accredit many health organizations. Some of these agencies include the Joint Commission,<sup>16</sup> the National Committee for Quality Assurance, professional organizations such as the American Medical Association and American Nurses Association, and quality review organizations such as peer review organizations.

### Research in Minorities, Pharmacogenomics, and Drug Response

Historically, culturally diverse populations have been underrepresented in clinical research trials. This problem has been addressed in part by the National Institutes of Health (NIH) Revitalization Act of 1993, amended in October 2001. This act requires ethnic minorities and women to be included in clinical studies funded by the NIH.<sup>17</sup> In addition, the NIH has a National Institute on Minority Health and Health Disparities to help address research among racial and ethnic groups.

Although research exists on the potential pharmacokinetic and pharmacodynamic differences among varied racial and ethnic groups, more information is needed. In addition, little data exist on differences in response to nonprescription drugs among individuals from diverse racial and cultural groups.

The field of pharmacogenomics uses genome-wide approaches to study the inherited basis of differences between persons in the response to drugs.<sup>18</sup> Although unique opportunities exist to target drug choices and dosages based on a person's genes, there are challenges in understanding the relationship of the social environment, behaviors, diet, and access to genomic testing among various races and ethnicities. Prospects exist to enhance therapies, but more data are needed to clarify the clinical implications of pharmacogenomics for diverse patient populations.

### Definitions

#### Culture

What is culture? Cultural identity is developed on the basis of characteristics such as ethnicity, sex, age, race, country of origin, language, sexual orientation, and religious and spiritual beliefs. One definition of *culture* is an "integrated pattern of human behavior that includes thoughts, communications, languages, practices, beliefs, values, customs, courtesies, rituals, manners of interacting and roles, relationships and expected behaviors of a racial, ethnic, religious or social group."<sup>19</sup> Culture can influence all aspects of human behavior. Of particular importance is the role of culture in help seeking and health maintenance behaviors, and the way these health beliefs and practices are passed from generation to generation.

Another definition of *culture* is the sum of socially inherited characteristics of a human group. This definition includes assumptions learned from family and society about the nature of the physical, social, and supernatural world, as well as the goals of life and the permissible means that one can take to achieve them.<sup>20</sup> Culture, as a learned set of values, beliefs, and meanings, guides patient decisions, attitudes, and actions.

Unique individuals with slightly different characteristics or beliefs may belong to the same cultural group. Individual differences must be considered when working with patients from specific ethnic or cultural groups. There is a great risk in stereotyping and assuming that a person within a group will always behave in the same manner. Stereotyping may be viewed as an assumption about behaviors or characteristics exhibited by a group of people.<sup>21</sup>

Generalizations may be based on documented or self-described behaviors or characteristics found in groups of people or cultures and may be used as a starting point for understanding cultures. For example, a stereotype would be that all racial and ethnic minorities use CAM. A generalization would be that high CAM use is documented in many racial and ethnic minorities. During each consultation, the patient should be treated as an individual with unique beliefs and values. However, having a general idea of behaviors and characteristics of groups of people can help providers be aware of potential health beliefs and behaviors. Providers should still avoid stereotyping and be cautious if making generalizations about groups of people.

#### Acculturation

Variations in behaviors among members of a group become more important when people belonging to a specific cultural group migrate to and live in places that have a different, but dominant, culture. In this case, the effect of acculturation or assimilation can be observed. *Acculturation* is a process by which members of a specific cultural group adopt the beliefs and behaviors of a dominant group, but they may still value and practice their own traditional beliefs and behaviors when in the presence of their own group members.<sup>20</sup>

One model of acculturation creates four identities based on the degree that individuals retain a home culture and adapt to a (new) host culture.<sup>22</sup> Individuals who are able to function well in both their home and host culture and/or language have been able to *integrate* both cultures. These persons are often able to navigate back and forth between cultures. Persons who adopt the new host culture but let go of their original home culture *assimilate*. They function well in the host culture but may have little knowledge or understanding of the cultural heritage or language of

their forebearers. Some individuals may live between cultures and feel *separated* because they do not fit into either the new host culture or the home culture. Older individuals who have moved to a new country but hold onto their home culture and/or language and never fully adopt the new host culture or language may feel *marginalized*. In the acculturation process, people who are influenced by the host culture may behave differently from the norms found in their home culture.

Although acculturation is often directed at a minority group adopting habits and language patterns of the dominant group, the outcomes of acculturation can be reciprocal. The dominant group may also adopt patterns typical of the minority group. Adopting ethnic slang words, enjoying ethnic foods and dances, and dressing in a manner that represents different cultures are examples of reciprocal acculturation practices. When individuals lose or modify their cultural identity to acquire a new identity that differs from their original cultural group (*assimilation*), these behaviors and adaptations may cause internal conflicts among members of the cultural group. For example, conflicts can arise when younger members of a cultural group (e.g., second- or third-generation immigrants) do not follow traditions of the older generation and start to exhibit behaviors and beliefs more consistent with the host culture. In some instances, the children of immigrants may not speak their parents' native language.

Culture and acculturation can influence an individual's beliefs and attitudes toward health, illness, and treatment, which will influence the person's decisions regarding health and self-care issues. When providers do not understand a patient's culture, the effective delivery of patient-centered care and, consequently, the achievement of optimal health outcomes may be impeded. Incongruent beliefs and expectations between the provider and the patient may lead to misunderstandings, confusion, and, ultimately, undesirable therapeutic outcomes.

### Cultural Competence

*Cultural competence* has been defined as a set of congruent behaviors and attitudes among professionals that enables them to work effectively in cross-cultural situations.<sup>23</sup> Cultural competence is a continuous process undertaken to ensure that care is delivered in an effective manner among diverse populations of patients and providers while avoiding cultural assumptions.

Several cultural competency models have been used by providers and educators to better understand stages and processes of cultural competency. Common models (Table 3-3) describe cultural competency as a process versus an achievement and were developed by Terry Cross,<sup>24</sup> Larry Purnell,<sup>25</sup> and Josepha Campinha-Bacote.<sup>26</sup> The Cultural Competence Continuum (Cross) explores six stages of cultural competency from cultural destructiveness to cultural proficiency. As providers and educators gain more experience and develop their skills and knowledge they may move toward cultural proficiency.<sup>24</sup>

The Purnell model, which is based in several disciplinary theories (e.g., organizational, family development, religion, and political science), describes the inter-relationship of several cultural domains such as heritage, family roles, workforce issues, and high-risk behaviors (Figure 3-1).<sup>25</sup> In this model, the providers go through a zigzag process from "unconscious incompetence," where they may not realize that they lack knowledge and skills to work in diverse cultures, toward "unconscious competence," where they have a positive attitude and a more developed foundation of knowledge and skills to adapt care in an efficient manner.

Cultural awareness, cultural knowledge, cultural skills, and cultural encounters are the primary constructs in the cultural competence process developed by Campinha-Bacote.<sup>26</sup> These constructs are interdependent, and at the core, where they intersect, is "The Process of Cultural Competence." Overlapping these constructs is cultural desire—a concept that providers are caring and *want* to gain knowledge and skills to navigate across cultures. In this model, providers would also accept an attitude of *cultural humility*, recognizing that they will be in a state of learning about cultures throughout their lives. Health care providers can use these models as a framework for working with diverse cultures and developing cultural competency.

### Barriers to Self-Care Management

Differences in language, health literacy, and culture pose barriers that health care providers may encounter every day in their practice. In some cases, small differences in the interpretation of language, gesture, or eye contact may lead to misunderstandings between people of different cultures and their health care providers. The provider's lack of cultural competency may impede the delivery of appropriate care.

#### Fear and Mistrust of Health Care Providers

Mistrust of providers may create barriers to self-care management, including reduced preventive and follow-up care. Patients may feel that providers did not consider their concerns; therefore, their expectations were not met. The disparities for racial and ethnic minorities, as historically found in African Americans, American Indians, and other groups, have been associated with discriminatory treatment and systemic racism. Many negative institutionalized health care policies and social aspects of provider-patient relationships remain as barriers to effective care. Racism is insidious, cumulative, and chronic; its effects can be felt in health care organizations, providers, and patients.

Ongoing mistrust and perceptions by patients can adversely affect patient satisfaction and health outcomes.<sup>27</sup>

**TABLE 3-3 Cultural Competency Models and Applied Examples for Self-Care**

<b>Model</b>	<b>Attributes</b>	<b>Applied Examples in Self-Care</b>
Cultural Competence Continuum (Terry Cross)	<p><i>Cultural Destructiveness</i> (Beginning of the continuum and the most negative stage.)</p> <ul style="list-style-type: none"> <li>• Attitudes and policies support bigotry, racism, discrimination, and exploitation harmful to cultures and patients.</li> <li>• Behavior is intentional or unintentional.</li> </ul> <p>In the Tuskegee study, the U.S. Public Health Service withheld syphilis treatment from African American men.</p>	A health care provider judges a patient who is using CAM and assumes patient is not well educated or informed.
	<p><i>Cultural Incapacity</i></p> <ul style="list-style-type: none"> <li>• Organizations or providers do not have any programs or services to respond to needs of patients from other cultures.</li> <li>• Ethnocentrism (dominant culture makes assumptions about other cultures) often exists.</li> </ul>	A pharmacy may not carry candles requested by several patients. This common, inexpensive noninvasive adjunct self-care therapy (prayer and candles) is perceived to not be important.
	<p><i>Cultural Blindness</i></p> <ul style="list-style-type: none"> <li>• Organizations or individuals try to remain unbiased.</li> <li>• Assumption exists that culture or race makes no difference; treat everyone “equally.”</li> <li>• Organizations have programs, but do not tailor them to address cultural needs of different groups.</li> </ul>	Bandage is “flesh” colored and would be camouflaged on anyone, regardless of skin tone.
	<p><i>Cultural Precompetence</i> (Toward positive end of continuum)</p> <ul style="list-style-type: none"> <li>• Health care organizations or individuals recognize that cultural differences exist.</li> <li>• Organizations may reach out to cultures by hiring diverse workforce, interpreters, or translators for written materials.</li> <li>• Organizations limit their efforts to several initiatives and may become frustrated with lack of progress.</li> </ul>	Providers might be quick to point to an herbal product line available in their pharmacy targeted for a specific cultural group and assume that this action suffices to care for different cultures.
	<p><i>Cultural Competence</i></p> <ul style="list-style-type: none"> <li>• Ongoing acceptance and respect exist for differences among cultural groups.</li> <li>• Providers and organizations continually increase their cultural competence knowledge and skills.</li> <li>• Implement models to deliver culturally appropriate care—true commitment to improve outcomes of patients from diverse cultures.</li> <li>• Providers strive to assess personal cultural biases and beliefs.</li> <li>• Concerted efforts are made to meet and work with people of diverse backgrounds in the community.</li> <li>• Ongoing assessments occur to improve care for different cultures.</li> </ul>	Organizations may be committed to training their personnel to better understand the self-care needs of patients from different cultural groups.
	<p><i>Cultural Proficiency</i> (Highest level in the continuum)</p> <ul style="list-style-type: none"> <li>• Organizations and providers have a true commitment to culturally competent practices. They engage in research, evaluate new approaches to</li> </ul>	Organizations and providers may work with community members to identify commonly used self-care and herbal products. They provide ongoing training for staff and students on community health beliefs and

	care, publish and disseminate findings, advocate for improvements, and conduct trainings. • Organizations and providers continually work to achieve cultural proficiency. They value the positive effect and transformation of understanding and engaging different cultures.	values.
Purnell model	<i>Unconsciously Incompetent</i> Providers do not realize what they do not know about other cultures or the influence of culture across person, family, and community.	A provider encourages influenza vaccine for an individual without recognizing that the family home is multigenerational and everyone could be vaccinated.
	<i>Consciously Incompetent</i> Providers recognize that they have challenges working with persons from diverse backgrounds.	A provider realizes that different values about contraception may exist in a Nigerian culture and takes time to research information about the beliefs.
	<i>Consciously Competent</i> Providers are aware of their effort to work effectively within or across different cultures.	A provider trains the entire staff on a new refugee population resettled in the community and invites key cultural leaders to help role-play and address potential cultural beliefs and practices.
	<i>Unconsciously Competent</i> Providers are more easily able to navigate within a different culture or across new cultures; their approach may seem effortless.	A provider has worked with Mexican American patients with diabetes over time and understands different cultural barriers to self-management.
Campinha-Bacote model	<i>Cultural Awareness</i> Providers explore their own culture and profession through a process of understanding personal biases and assumptions about different cultures.	Providers acknowledge cultural differences in home remedies and self-care treatments such as chicken soup and hot tea with lemon to alleviate cold symptoms.
	<i>Cultural Knowledge</i> Process involves gaining more information about diverse cultures, values, beliefs, and practices.	Providers learn about common herbs and alternative therapies used in the Vietnamese-American Buddhist population living in the neighborhood surrounding the pharmacy or clinic.
	<i>Cultural Skill</i> Providers can collect, assess, evaluate, and adapt cultural information from diverse patients to improve care.	Providers recognize that when supplying information about religion and culture in the social history, a woman who identifies as Islamic may prefer to have a female provider to discuss medication for a yeast infection.
	<i>Cultural Encounters</i> Providers actually have the opportunity to interact with one or more patients and families of diverse cultures to enrich their awareness, knowledge, and skills.	Providers are able to see multiple patients who are Hispanic each day and over time understand the importance of family in making decisions about diet and diabetes management.
	<i>Cultural Desire</i> Providers are sincerely motivated to grow in their capacity and skill to navigate across cultures.	In addition to working with patients from the large Catholic parish nearby, the Hindu provider volunteers at the parish community and outreach events.

Key: CAM = Complementary and alternative medicine.

Source: References 24-26.

The NIH mandates for inclusion of racial and ethnic minorities have succeeded in encouraging accountability in research design, institutional review board approval, and federal research funding.<sup>27</sup> However, recruitment and retention of minority groups in research studies remains inadequate. This lack of participation has also been linked to

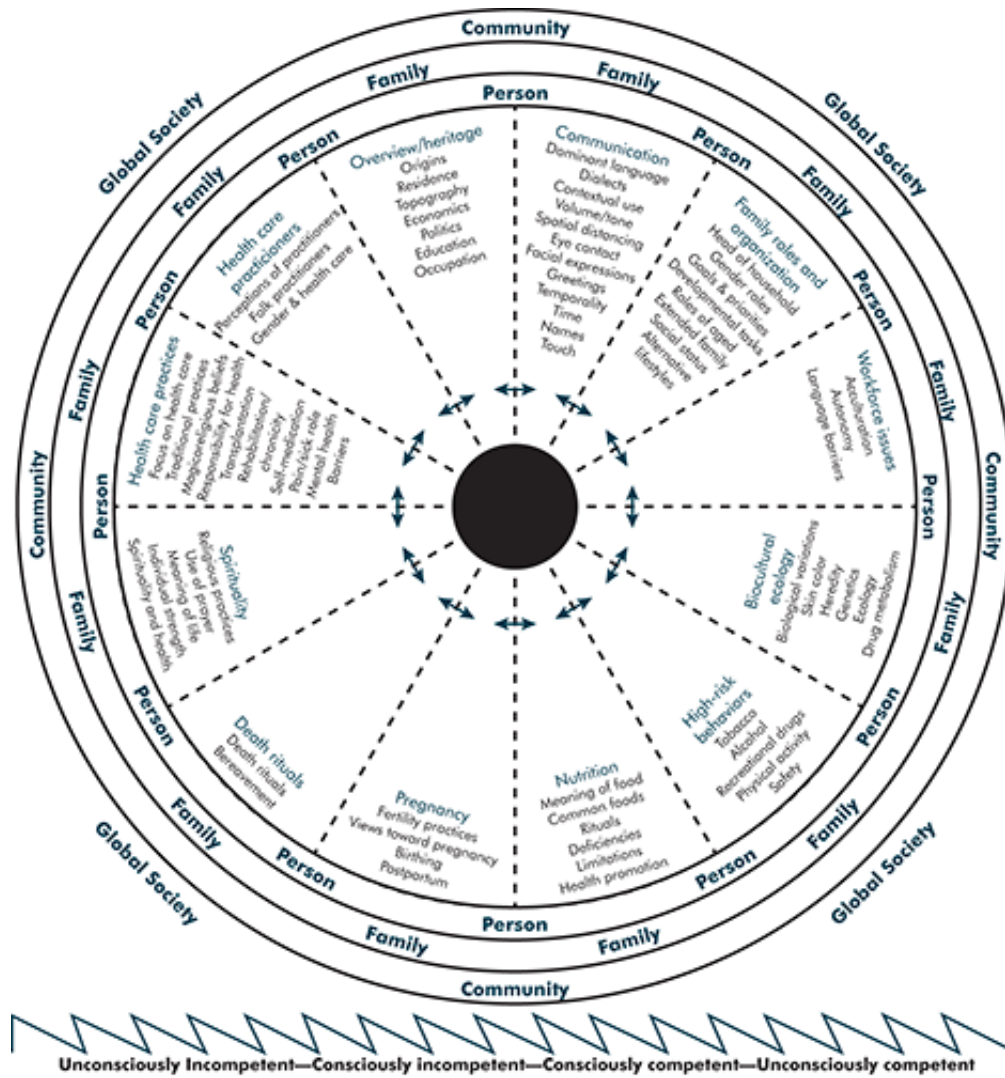

barriers in the optimal use of health care facilities, willingness to seek care, and follow-up on treatment recommendations.

Persons from racial and ethnic minority groups may also differ in their perceptions about research and research participation. For example, in many African American and other communities, mistrust of research exists as a result of the Tuskegee study conducted by the U.S. Public Health Service (USPHS) for 40 years between 1932 and 1972.<sup>28</sup> In the study, African American men, with ( $n = 399$ ) and without ( $n = 201$ ) syphilis, were enrolled, without informed consent, for “free” medical examinations and meals while researchers monitored the effects of the disease. Even when penicillin was discovered as a treatment for syphilis, subjects were not informed of the treatment option nor were they offered the antibiotic. Because of the unethical decisions of that study, many African Americans who are not recent immigrants are unwilling to participate in clinical trials and other aspects of the medical system. Fear persists that unfair treatment and further abuses will occur.<sup>27-28</sup>

American Indians have also survived a past that includes government policies and wars that resulted in damaging a people and culture. Some American Indians have sustained cultural traditions through family and clan relationships, kinships with homelands, religious ceremonies, and ancient rituals.<sup>27</sup>

The long history of American Indians and African Americans with public health services has led these populations to often mistrust providers and health systems. This patient perception may exist on the basis of multiple aspects:

- Feelings of prejudice against them
- Fear that their best interests are not considered and that they are treated differently from other patients
- Apprehension that their concerns and problems are not heard
- Concern that their traditional medical practices and beliefs will not be affirmed and will be called primitive
- Lack of confidence in the health care providers' skills because of the quality of the historical resources provided by the USPHS or through the Indian Health Services.<sup>29</sup>

**Variant cultural characteristics:** age, generation, nationality, race, color, gender, religion, educational status, socioeconomic status, occupation, military status, political beliefs, urban versus rural residence, enclave identity, marital status, parental status, physical characteristics, sexual orientation, gender issues, and reason for migration (sojourner, immigrant, undocumented status)

**Unconsciously incompetent:** not being aware that one is lacking knowledge about another culture

**Consciously incompetent:** being aware that one is lacking knowledge about another culture

**Consciously competent:** learning about the client's culture, verifying generalizations about the client's culture, and providing culturally specific interventions

**Unconsciously competent:** automatically providing culturally congruent care to clients of diverse cultures

Purnell Model for Cultural Competence. (Source: Reprinted with permission from reference 25.)

Other minorities such as Hispanics or Asian Americans may also have perceptions of mistrust, but the mistrust is often derived from sources in their history outside the United States. Many immigrants have experienced political oppression or government policies that fostered suspicion or unfair practices. Fears may be centered on deportation if they entered the country undocumented, or skepticism may be present because of experiences and language barriers.

Reducing mistrust of the health care system requires repeated positive encounters over time. Some key practices that health care providers can adopt to foster trusting relationships include one-on-one outreach and frequent involvement of the provider with the targeted community. Volunteering and partnering with community leaders such as clergy or other spiritual leaders can help form networks and establish program approval at the earliest stage of the health care-planning process.<sup>29</sup>

Training of community health workers can be an effective strategy for garnering trust in the community, especially when time and resources are limited. Community liaisons can help diffuse health messages, integrate culturally and linguistically diverse prevention programs, provide information about new health technologies, and conduct screenings in the language and the context that the group understands. Health care providers should embrace cultural competency training to gain knowledge and skills to better tailor patients' self-care plans and deliver culturally appropriate health messages.

Language Barriers

Many patients who cannot speak or read English have difficulty in communicating with their health care providers or reading instructions on prescription and nonprescription labels. Limited English proficiency creates a significant barrier to seeking self-care or the advice of a health care provider such as the pharmacist. Because of language barriers, patients may rely on television advertisements on channels in their language of origin or on the recommendations of family members or relatives.

In many cultures, patients may express their symptoms in a different manner than what is typically encountered in a Western medical system. For example, patients from different cultural groups may express pain differently from patients raised in a Western culture. In some Asian heritage cultures, patients may not request analgesics even when they are in extreme pain, which may lead to undertreatment.

### Literacy and Health Literacy

Studies have documented a relationship between poor reading skills and poor health.<sup>30</sup> People who cannot read often hide their illiteracy because of shame, embarrassment, low self-esteem, and fear. As a result, many health care providers often overlook this potential source of misinformation concerning nonprescription products and nonadherence to prescription drugs.

To detect literacy problems, the provider should be sensitive to cues that indicate the patient has difficulty reading. For example, patients may say they “forgot their glasses” when asked to read. People who read poorly may never join a group education class. Instead, such patients may prefer one-on-one consultations with their health care providers.

Health literacy, or “the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions,” is also an important skill to self-management and decision making about nonprescription products.<sup>30</sup> A person may have high reading literacy but not functional health literacy (i.e., be able to make good decisions about their health).

In different cultures, styles of communication and belief systems can affect health literacy.<sup>30</sup> Health illiteracy is more common in minority groups and may be linked to general literacy levels and/or language. For example, some immigrants may have completed only a third or fourth grade education because of prolonged military conflicts and poverty in their home country. Overall low health literacy makes it difficult for providers to rely on nonprescription labels, drug information pamphlets, or prescription labels produced by the pharmacy computer systems. Through verbal communication with the patient, an interpreter, or an adult family member, providers must ensure that the patient understands the instructions and/or prescription label directions.

The prerequisite requirements of the FDA Durham-Humphrey (1951) and Kefauver-Harris (1962) amendments, used in evaluating New Drug Applications for proposed nonprescription drugs, demonstrate the need for improved health literacy. The criteria for nonprescription drug approval include evidence that (1) patients can recognize and diagnose themselves for the condition specified in the proposed indication, (2) patients can read the product label and extract the key information necessary to use the drug properly, (3) the drug is effective when used as recommended, and (4) the drug is safe when used as instructed. The consumer must be able to read and understand the information on the label to know the proper dosage, recognize warnings and contraindications, and determine whether contraindications apply.

FDA labeling requirements implemented in 2002 were intended to allow patients to read and understand nonprescription drug labels more easily. The standard product label for nonprescription drugs, titled “Drug Facts,” has specific sections for active ingredients, uses, warnings, when to use the product, directions, and inactive ingredients (see [Chapters 1 and 4](#)). Manufacturers are required to use large print, simple language, and an easy-to-read format on the labels to help patients with product selection and dosage instruction. In addition to these requirements, providers should be alert to the educational needs of all patients, particularly those with poor reading skills.

To ensure that patients understand aspects of their condition and their responsibility for self-care, providers may improve clinical outcomes by integrating the following tips. First, the provider should never take for granted that the patient can comprehend fully all instructions whether written or spoken. Providers should be aware of the potential for shame and treat the patient with respect. Patient education specialists suggest using the teach-back method to ensure the clarity of the message. This method involves using phrases such as “Tell me in your own word how you are going to take this medicine.” Gaps in the patient’s interpretation will provide additional opportunities to explain the process again or to correct gaps using different methods to deliver the message. Counseling should be followed with materials such as pictures or demonstration products.<sup>31</sup>

### Sociocultural Framework for Self-Care Practices

Self-care behaviors have been defined as “the range of health and illness behaviors undertaken by individuals on behalf of their own health.”<sup>32</sup> However, these behaviors have not been well described among various racial and ethnic minorities. Factors that influence self-care behaviors can include understanding the cultural context of health

and attitudes toward taking responsibility for one's own health and illness.<sup>33,34</sup> Further, religious beliefs, family and social contacts, cultural expectations, educational training, and personal experiences affect self-care behaviors.

These interpretations are within the foundations of an ethnomedical model of care.<sup>35</sup>

According to Kleinman,<sup>35</sup> the patient's understanding of a disease is based on a consensus of beliefs, information, and expectations pertaining to the illness that are shared with a social network. This understanding helps a patient interpret healing and sickness. Normative beliefs are generated by social interaction and personal experiences, which may differ completely from evidence-based medicine and the use of technology to diagnose and treat patients (biomedical model).<sup>35</sup> For example, some cultures may view hypertension as caused by "bad nerves" or "high excitement" and may not understand that the disease is the chronic elevation of arterial blood pressure.

Providers who do not consider a patient's beliefs and expectations may encounter resistance to their professional advice. Expecting a patient to respond to the provider's advice solely on the basis of biomedical principles may evoke considerable frustration for the patient and the provider. Each patient may have different social support needs and concerns related to making decisions about self-care behaviors and medication use. Providers should remember the significance of "groupness" in minority populations' self-care behaviors. One classic example involves patients who are neither able nor willing to modify their dietary intake of certain foods (e.g., high fat, salty, and/or low fiber) so as not to impose these restrictions on the whole family. These patients are willing to sacrifice their own health to avoid inconveniencing their family.

Normative beliefs based on the group's experiences may also assist the individual in making the decision whether to seek care from the health system or to use CAM.<sup>36</sup> Self-care practices of many cultural groups involve use of home remedies, herbs, or other treatments that are passed from generation to generation. Communicating within the framework of the patient's culture helps break down barriers, while also facilitating trust and understanding between the patient and health care provider. Through this knowledge, the provider can lead a patient successfully away from harmful practices and provide safe, culturally appropriate alternatives. Subsequently, the provider can develop interventions, even biomedical ones, within the context of the patient's belief system. If the folk practices are not harmful or are even beneficial to the patient, the provider may be able to accept them as part of a monitored treatment plan.

For example, a patient who is being monitored and treated through Western medicine might also use a folk or traditional healer. Some common healing methods include prayers, massage, and aromatherapy. Because these practices may be harmless and potentially additive to Western medicine, the provider may accept and even encourage their use. Providers should maintain open and consistent communication with the patient, traditional healer, and other health care providers regarding new information on CAM.

Patients and/or their family members are responsible for the day-to-day management of their illness. Consequently, better methods are needed to determine the patient's health-seeking behaviors, informational needs, preferences, and expectations about treatment management approaches. Providers are encouraged to develop a framework for understanding how patients interpret their illness experiences. This framework, according to Kleinman,<sup>35</sup> goes beyond discrete medical episodes of "controlling the biological malfunctioning of disease" to include the psychosocial dynamics of family-based care, healer-client transactions, spiritualism, shamanic cures, and other important holistic approaches based on the patient's world view as mentioned earlier. Using this approach reduces the adverse effect of miscommunication, misinformed decisions, and harmful health behaviors.

### General Description of Beliefs by Different Population Groups

Some common themes have emerged in the literature related to chronic illness and self-care behaviors in the social context of older adults from African American, American Indian, Asian American, and Hispanic backgrounds.<sup>33</sup> These self-care behaviors may be found more often among racial and ethnic groups whose identities are rooted in their home culture and who may have less identity with Western culture and values. The following concepts highlight how self-care practices may be connected to various cultural ideals or beliefs:

1. *Concepts of independence and interdependence.* In Western medicine, independence, self-determination, and autonomy may be linked to increased self-care. Among African Americans, particularly women, values of self-reliance and independence are consistent with self-care. Among older American Indians and Hispanics, family needs may supersede the importance of individual health. Messages of self-care in these populations may need to focus on helping the overall family structure. Among older Asian Americans, a mixed phenomenon may occur because of a higher emphasis on self-discipline consistent with self-care, but family needs may be valued over those of an individual.
2. *Acceptance of intergenerational households.* European American households are less likely than those of other racial and ethnic groups to have older family members living in a household. When households have several generations living together, different dynamics of social and family support for self-care may exist. The literature is unclear whether this influence is positive or negative.
3. *Gender roles within the family structure.* Across cultures, the woman is often given the role of the "health

manager” in the family, even if the household is patriarchal. When family units are intact, wives may have a greater role in influencing self-care practices of the family. When an older married man is widowed, for example, he may have a decreased ability for self-care practices, which may be noted especially among African American and Hispanic men.

4. *Family traditions related to CAM use.* In general, older adults and immigrants from African, American Indian, Asian, and Hispanic cultures more often use CAM as part of self-care compared with whites. Older Asian Americans may use more CAM because of the tendency for friends to provide health-related help.
5. *Role of friends.* Friends, godparents, and “fictive kin” (very close friendships that are family-like) can be relied on for support as much as family. For example, in some African American communities, women will rely strongly on each other to help provide child care. Hispanics, American Indians, and Asian Americans also have strong extended friendships that are closely connected to the family.
6. *Religious and spiritual beliefs of cultures.* The role of God and spiritual healing may influence how persons from a cultural group use and/or accept self-care practices. In some American Indian cultures, physical health is not as important as spiritual or emotional health. In some African American communities, churches have a central role that is sometimes of a familial nature.

Differences in health beliefs and behaviors, as well as the interplay of biological and societal influences, are documented in the literature.<sup>20,36,37</sup> Table 3-4 lists some of the characteristics found to be shared among people in major racial and ethnic minority groups in the United States. Not every member of an ethnic or cultural group will conform to these attitudes and beliefs. This chapter uses these examples to help sensitize providers to aspects of health behavior they may encounter; however, each patient should be evaluated individually. Awareness of this diversity may help providers deliver more effective care with increased cultural competence.

Religious beliefs are also important in patients’ acceptance of the diagnosis and treatment. A set of beliefs, attitudes, and expectations of illness and treatment based on religion may cause friction with the health care system and the health care team. For example, a person whose religious background is Jewish or Islamic may have restrictions on the use of certain nonprescription products. Omega-3 fatty acids and other animal-based or gelatin-containing products may or may not ascribe to strict religious guidelines (kosher or halal) regarding consumption of animal-based products.<sup>38,39</sup>

Individuals from different cultures may choose to treat illnesses by using different rituals and religious items that are outside the realm of Western medicine. For example, patients who identify as Hispanic may use home remedies or other artifacts recommended by spiritual healers, sometimes called *curanderos*. These healers may use a combination of herbal remedies and religious rituals. When providers are nonjudgmental, they can better understand how and when the patient plans to use drug therapy or another alternative treatment. Knowing this information can help providers determine what treatments the patient used previously or is going to use or whether major interactions exist between the nonprescription product and the patient’s alternative treatment.

### Use of Nonprescription Medications by Culturally Diverse Patients

Limited data are available on the use of nonprescription products among patients of diverse cultural groups or among patients with diverse sexual or religious preferences. For many cultural groups, especially those without prescription drug coverage, nonprescription products represent the most frequently used treatments prior to consulting a provider.<sup>40</sup> Because of financial constraints, fear of the health care system, lack of health care access, and cultural beliefs, some immigrants may use the pharmacist as the first source of care. In many countries, the pharmacist plays a significant role in assessing symptoms and triaging the patient to appropriate medical care. Because of the limited access to health care in many countries, pharmacists have served as primary care providers. Many patients from other countries might seek this same level of pharmacist involvement in their care while in the United States. For example, evidence is consistent about a link between health-seeking behaviors and antibiotic use among patients accustomed to over-the-counter access found in some pharmacies in Mexico.<sup>20</sup> Patients’ expectations may include that the pharmacist will provide them with antibiotics as nonprescription products. Failure to do so may negatively influence the patients’ expectations of the pharmacist. Understanding these beliefs can help providers communicate to the patient the rationale for the therapeutic recommendations.

**TABLE 3-4 Examples of Cultural Behaviors That May Be Observed among Selected Racial and Ethnic Groups<sup>a</sup>**

<i>Group</i>	<i>General Characteristics</i>
African American (not recent immigrant)	<ul style="list-style-type: none"> <li>• Recognize importance of family</li> <li>• May use home remedies and folk medicine</li> <li>• May distrust the health care system because of previous experiences with system</li> <li>• Recognize importance of religion in achieving cure</li> </ul>
American Indian	<ul style="list-style-type: none"> <li>• May use sweat lodges as a method of cure</li> </ul>

	<ul style="list-style-type: none"> <li>• May use herbal medicine and natural roots</li> <li>• May use prayer for cure of illnesses</li> <li>• May believe that health is a harmony with “Mother Earth”</li> <li>• May use healer (medicine man)</li> </ul>
Asian heritage	<ul style="list-style-type: none"> <li>• Recognize importance of family</li> <li>• May believe that balance between forces may define health (<i>yin</i> and <i>yang</i>)</li> <li>• May believe that illnesses may be caused by an imbalance of cold and hot forces</li> <li>• May use alternative medicine</li> <li>• May use Chinese herbal products</li> <li>• May distrust Western medicine</li> </ul>
Hispanic heritage	<ul style="list-style-type: none"> <li>• Recognize importance of family (family members may be deeply involved in the care of the patient)</li> <li>• May use <i>curanderos/curanderas</i> (traditional healers)</li> <li>• May use home remedies—mostly teas or herbal remedies</li> <li>• May use religious medals for good luck</li> <li>• May believe that health is a matter of luck</li> <li>• May have an attitude toward recovery that is pessimistic (fatalism)</li> <li>• May believe that illnesses are classified as hot and cold with treatment chosen depending on the classification of the disease</li> </ul>

<sup>a</sup> The described behaviors have been observed in these racial and ethnic groups and are meant solely as a guide and not as stereotypes.

### Suboptimal Responses to Nonprescription Drug Therapy

The improper use of nonprescription products places vulnerable populations at an increased risk for adverse drug reactions, drug-drug interactions, and toxicities from long-term exposure. Therefore, the misuse and abuse of drugs that are available for self-treatment may outweigh the benefit-risk ratio in some patients. Increased use of nonprescription products by minority groups may create another self-care challenge.

Self-care is important for patients with chronic illnesses. The need for quick relief may prompt more frequent use of nonprescription medicines, thus raising the risk of overmedication and a tendency for people to self-medicate for conditions. Lowered tolerance for discomfort can also lead people to rely on drug therapy, especially nonprescription pain relievers, instead of seeking long-term behaviorally oriented prevention strategies. Another example is the use of vitamins, laxatives, and antacids to counteract poor eating habits. Poor self-management practices can mask more serious symptoms and complicate the diagnosis of serious diseases.

Low-income patients are often vulnerable to the harmful effects of overuse of nonprescription products for several reasons. First, patients who are chronically ill and have inadequate health insurance may restrict use of prescription drugs when their costs increase.<sup>41</sup> Many uninsured patients use nonprescription products as alternatives to prescription drugs simply because of cost.<sup>42</sup> These same patients may seek medical care only for the most urgent symptoms, delaying routine visits to their primary care provider's office. Health care providers who counsel patients on the use of nonprescription products can help prevent delays in seeking medical care. Conditions such as hypertension and hyperlipidemia are often not recognized because of lack of symptoms.<sup>43</sup> Nonprescription products may be used by patients to treat minor symptoms associated with these conditions such as headache or chest discomfort. The key problem with a suboptimal response to a nonprescription medication is that a more serious condition may not be diagnosed until the patient experiences a complication.

### Communication with Culturally Diverse Groups

#### Data Gathering

When interacting with patients from different cultures, providers should use specific communication skills aimed at identifying the patient's cultural beliefs. These communication skills include (1) an openness to alternative viewpoints and approaches; (2) a clear understanding of one's own prejudices and biases (self-awareness); (3) engagement to identify the patient's beliefs, expectations, and barriers to treatment; (4) an understanding of how the patient's beliefs and attitudes may influence the treatment plan; and (5) an ability to negotiate treatment that is acceptable to the patient and the provider. Trust is essential to gaining awareness of the issues involved in the interaction, and

appropriate language is crucial to effective communication.<sup>15</sup>

Diverse techniques have been suggested to improve communication and care in cross-cultural settings. One classic model has been described for individual and institutional cross-cultural development.<sup>44</sup> This technique, described by the acronym “LEARN,” may be used in clinical encounters. The primary steps (Table 3-5) in LEARN are as follows:

- **L**isten with sympathy and understanding to the patient’s perception of the problem.
- **E**xplain your perceptions of the problem.
- **A**cknowledge and discuss the differences and similarities.
- **R**ecommend treatment.
- **N**egotiate a treatment plan that is mutually agreed upon.

Within “L” of LEARN, providers can apply the 4C’s of the patient understanding of illness that have been adapted from Kleinman’s Patient Explanatory Model.<sup>21</sup> With the 4C’s, providers elicit the following from the patient (and/or family):

1. What do you *call* the problem? (perception)
2. What do you think *caused* the problem? (beliefs regarding source of illness)
3. How do you *cope* with the problem? (use of CAM or other treatments)
4. What *concerns* do you have about the problem or treatment? (understanding of fears; may also address adherence)

**TABLE 3-5 Examples of Ways to Use LEARN**

<p><b>L</b>isten with sympathy to patient’s perception. A woman from Somalia is reluctant to give her mother medication for pain. When asked, she explains that she would prefer to help her mother’s pain through massage.<sup>a</sup></p>	<p><b>E</b>xplain your perceptions of the problem. A pharmacist encounters a patient from Iraq who has received U.S. refugee assistance. The patient has upper respiratory sneezing and coughing and requests an antibiotic because of antibiotics’ wider availability in pharmacies in Iraq without a prescription. The pharmacist tries to explain (1) the differences in pharmacy practice in the two countries, and (2) health care providers’ concern that overprescribed antibiotics are not working because of resistance. The pharmacist recommends appropriate nonprescription symptomatic therapy. Further, she suggests that the patient see a primary care provider and helps the patient find a provider.<sup>b</sup></p>	<p><b>A</b>cknowledge, <b>R</b>ecommend, and <b>N</b>egotiate: A patient from Cambodia complains that her 7-year-old child has had a “fever” for several days. In the pharmacy, the pharmacist has read that the word for “fever” in Cambodian may not necessarily mean an elevated temperature. Rather, the term may refer only to not feeling well. The pharmacist clarifies with the mother that the child actually has had a common cold and no elevated temperature.<sup>c</sup> Together they find an appropriate over-the-counter therapy to treat the symptoms. The mother agrees with the plan.</p>

**TABLE 3-6 Recommended Actions to Develop Effective Cross-Cultural Communication**

- Acknowledge that diversity exists.
- Understand that culture is part of what makes individuals unique.
- Respect people or cultures that may be unfamiliar or different from one’s own.
- Conduct a self-assessment to identify one’s own cultural beliefs and biases.
- Recognize differences in the way people define and value health and illness.
- Be patient, flexible, and willing to modify health care delivery to meet patients’ cultural needs.
- Allow for differences among members of the same cultural group. (Do not expect all individuals from a cultural group to behave identically at all times.)

- Appreciate the richness of culture.
- Embrace diversity.
- Understand that cultural beliefs and values are difficult to change and, in many instances, are learned from birth.

Table 3-6 provides guidelines to help the provider communicate better with culturally diverse patients. In many instances, the communication barrier may include the patient's inability to speak the provider's language. Several Web sites provide tips for providers to work with health care interpreters and with patients who have limited English proficiency (Table 3-7).

An interpreter provides a means of addressing a language barrier, but this approach has limitations. Problems may arise when family members are used as interpreters because the patient and family members may be put in an uncomfortable position. This situation becomes more critical when a younger family member, sometimes a child, is asked to interpret for older family members, such as parents or grandparents, in a clinical encounter. Putting a child in a position of responsibility is not acceptable and can lead to family conflicts by altering the hierarchy within the family. It also places an undue burden on the child, so this situation should be avoided.

Using family members or untrained personnel to interpret may lead to receiving or transmitting inaccurate information. The health care provider may fail to detect relevant and critical information, or the interpreter and/or patient may misinterpret the information. These problems can be avoided when the health care provider uses personnel who are trained in medical language interpretation and are familiar with the providers.

To assist with communication, the Agency for Healthcare Research and Quality has a Web site exploring health literacy issues in a pharmacy setting.<sup>45,46</sup> Educational materials should be at a sixth grade reading level or below and a variety of media used to convey a health message.<sup>46</sup>

#### Assessment of Cultural Issues on Patient Adherence

Providers can better assess the role that culture may play in a patient's acceptance of the diagnosis and treatment of an illness if they learn about cultural health beliefs and values, gain insight into the patient's understanding of the

disease state (e.g., Patient Explanatory Model), and improve cross-cultural communication skills. For example, patients from some Latin American cultures may have the perception that injectable dosage forms are more effective than oral tablets. This belief is probably based on the practice of primary care providers in some Latin American countries using injectable drugs with repository drug delivery formulations to provide more sustained drug delivery. These injectable drugs may be available for purchase and administration without a prescription from a pharmacy in those countries and can be a form of self-care. This technique is sometimes used because of the geographic distances many patients must travel to receive care and helps achieve a more predictable duration of treatment. Furthermore, this form of drug delivery ensures adherence with treatment. Because a cure is often achieved with this repository of products such as antibiotics, the patient may associate the effectiveness of care with this method of drug administration. Because injectable dosage forms are not routinely used in outpatient settings in the United States, Hispanic patients may leave a health care facility with a prescription for an oral product believing that the treatment is not going to be effective. This lack of confidence in the therapy may affect adherence and the achievement of a cure. If providers are aware of this cultural belief and assess the patient's preferences or beliefs for a variety of treatments, they can modify the treatment or educate the patient about the benefits of oral dosage forms. Although this approach seems simplistic, time and individual assessment of the patient's beliefs and preferences are required.

### Decision Making and Nonprescription Products

Patient autonomy concerning health care extends to taking part in the decision making for the need for treatment; monitoring of treatment progress; and use of nonprescription medications, home monitoring devices, and diagnostic kits at intervals during the treatment process. Because rates of chronic conditions<sup>9</sup> are higher among minority populations, drugs, including nonprescription products, may be more widely used.

### Development of a Self-Care Plan

Self-care activities include a range of individual health behaviors such as health maintenance, use of preventive services, symptom evaluation, self-treatment, interaction with health care providers, and seeking of advice through lay and alternative care networks.<sup>47</sup> In general, providers should encourage their patients' and their families' participation in self-care behaviors to promote patient empowerment. Unfortunately, some health care providers do not encourage self-care behaviors because they are not aware of appropriately targeted techniques, strategies, and support systems that patients can use.

When assisting patients in their self-care behaviors and self-medication, providers can help initiate dialogue with the patient for informed decision making. Providers can also participate in health screening programs to identify health risks in the community and lead health awareness campaigns.<sup>48</sup>

The self-care plan should include the cultural differences and beliefs identified by the patient. These beliefs, as well as the role of the family in the patient's care, will help dictate the most appropriate recommendation. The provider must then use this information to develop self-care recommendations and patient education strategies.

Communication with other health care providers about the patient's cultural beliefs and preferences is essential. A collaborative approach helps ensure that all providers are aware of the patient's preferences. For example, when developing a plan of care for the treatment of a self-limiting illness that requires nonprescription drug therapy, the provider can synthesize other providers' knowledge and skills by expanding on "Negotiating a Treatment Plan" from the LEARN model. When negotiating a plan, providers can evaluate the following:

- Communication styles and needs (e.g., interpreter, family support)
- Patient beliefs, perceptions (4C's and Patient Explanatory Model), and relevant restrictions related to religion or culture
- Prior treatments (prescription, nonprescription, and CAM) and acceptance of these therapies
- Use of tools to help patients understand and apply a recommendation (e.g., medication calendar, pictograms, and dosing reminders)
- Appropriate follow-up support (e.g., adverse event, worsening of condition, or need to see provider)

### Ensuring Cultural Competence in Health Care

#### Organizational Commitment

Even the most culturally competent providers will find it difficult to optimize care for patients without having organizational commitment and support. Both providers and health system leaders should have a commitment to change, hold a real conviction of the significance of the task, and conduct in-depth self-assessments of the beliefs and attitudes of the personnel and the institution.

Organizations can conduct self-assessments of the level of cultural competence in the institution and the care being provided. The Georgetown University National Center for Cultural Competence (NCCC) developed a survey aimed at assessing the level of cultural competence in institutions and of the health care provider.

Ongoing organizational support for cultural competency training within the workforce provides a path for continuous improvement. In 2013, five states had legislative requirements to provide cultural competency training to part or all of their health care workforce.<sup>49</sup>

To develop targeted health service programs that are culturally competent, the provider may follow the recommendations and guidelines from NCCC, which include planning guides, policy briefs, monographs, and multimedia products. The resource materials are designed to assist meeting and conference planners in infusing principles, content, and themes related to cultural and linguistic competence into their service delivery systems (Table 3-7).

Cases 3-1 and 3-2 illustrate aspects of culturally competent care in the area of self-care. These cases are examples of issues that may be observed in community practice.

### Key Points for Multicultural Aspects of Self-Care

- Cultural issues affect patients' attitudes and behaviors toward health and illness, as well as their acceptance and adherence to treatment plans.
- Major shifts in the demographics of the U.S. population are affecting the delivery of care to patients.
- Racial and ethnic minority populations have experienced a range of health disparities compared with their white counterparts. A disproportionately high number of minority patients continue to experience increased rates of complications with chronic diseases compared with other populations.
- The inability of health care providers to deliver culturally competent care can affect the health outcomes of diverse populations.
- Health care providers should evaluate their biases and prejudices and acquire knowledge and skills to effectively care for patients from diverse cultures. Delivering culturally competent care should be a goal of every health care provider, particularly in the area of self-care.
- Self-care lends itself very well to the practice of culturally competent care. Many racial and ethnic minority groups seek nonprescription products, as well as CAM therapies, as their main source of care.

### Case 3-1

<b><i>Cultural Competence in Self-Care (Referral)</i></b>
<b><i>Patient Complaint and History</i></b>
Mr. Jackson is a 54-year-old African American man. He and his wife request information about over-the-counter products for constipation. Mr. Jackson looks uncomfortable and indicates that he has experienced constipation over the past month or two. For the past 2 weeks, he has increased water and fiber intake in his diet through fresh fruit, oatmeal, and whole grains. Mr. Jackson's last bowel movement was 2 days ago, but he states that he didn't think he really emptied his bowels. Mr. Jackson's wife says that he seems to be weaker in the past couple days. When you offer different laxatives and probiotics, both Mr. Jackson and his wife don't really seem interested.
Upon further discussion, the couple acknowledges that they have heard information in the news about the importance of detoxifying the bowels periodically because toxins can build up and lead to constipation (cause). Mr. Jackson has tried to increase his water and fiber intake by eating more fresh fruits and whole grains (cope). Further, they reveal that 2 days ago he had a colon cleansing using oral herbs and laxative preparations. Since that day, he has felt a little weak and nauseated. He has also noted some blood in the rectal area.
<b>Clinical and Cultural Considerations</b>
Although not endorsed by the Food and Drug Administration or the medical community, colon cleansings have been promoted to detoxify the body, with some marketing specifically targeted African American populations. Cleansings may be available via oral, enema, or more invasive colonic irrigation routes. Because Mr. Jackson was experiencing constipation, he and his wife may have decided to explore this perceived "natural" remedy. They may also be confused between a colon preparation for medical colonoscopy versus a detoxification in the lay and natural health communities. These cleansings can cause nausea and weakness, may deplete natural flora from the colon, cause electrolyte imbalances, and increase risks for infection and dehydration, leading to more serious complications. Because Mr. Jackson has experienced weakness and noted blood in the stool, he should be referred to a primary care provider for evaluation.
According to the National Cancer Institute, colorectal cancer incidence (62.1% in African Americans versus 51.6% across all racial and ethnic groups) and mortality rates (26.7% in African Americans versus 19.4% across all racial and ethnic groups) are higher among African Americans compared with all racial and ethnic groups combined. Mr. Jackson, as a 54-year-old, has been eligible for colorectal screenings since the age of 50, and some expert panels within the American Society of Gastroenterologists recommend screening starting at age 45 for African Americans.

By receiving a referral to a provider, Mr. Jackson can be evaluated for any potential negative effects of the natural colon cleansing, for constipation, and for colonoscopy screening. His wife may be eligible for screening as well.

### Case 3-2

<b>Cultural Competence in Self-Care</b>
<b>Patient Complaint and History</b>
Mrs. Morales comes into the pharmacy today complaining of increased urination and thirst. She has a history of type 2 diabetes and hypertension and was started on insulin yesterday.
<b>Clinical and Cultural Considerations</b>
<p>Mrs. Morales has been started on insulin, but after your interview you discovered that the patient is not planning to fill the prescription. She has come to the pharmacy to get your advice on which over-the-counter medications can help control her diabetes. In your approach to the patient you should reflect a level of acknowledgment of her desire to seek treatment for her diabetes and her symptoms and demonstrate a level of <i>respeto</i> (respect) and <i>confianza</i> (trust). It is important to rule out acute symptoms of infection or other causes of hyperglycemia. It is also important to acknowledge and identify the reasons that the patient is unwilling to fill her insulin prescription and to try to help the patient understand the need to treat her symptoms and diabetes. In this case, the patient states that in her culture, insulin use is associated with “end stage” diabetes and foot amputations. She explains that everyone in her family who started using insulin ultimately had an amputation and that she is unwilling to use insulin and end up with an amputation. It is important to explain to the patient that diabetes is a progressive disease and, in many cases the patient may require insulin to prevent further deterioration and complications. This approach may require that you dispel the “myth” or “belief” that may have deep-rooted cultural implications. In this case, the identification of peers (ideally of the same cultural group) who are using insulin will prove to be an important clinical tool. It will also be important to seek the support of the patient’s family to reinforce the need to dispel the myth. In addition, the patient could benefit from receiving educational material about diabetes, as well as insulin and its benefits. Developing a culturally sensitive approach to manage the patient’s diabetes is critical. Collaboration with the patient’s primary care provider and sharing of information are essential.</p>

## Handbook of Nonprescription Drugs > Chapter 4. Legal and Regulatory Issues in Self-Care Pharmacy Practice

### Legal and Regulatory Issues in Self-Care Pharmacy Practice: Introduction

This chapter analyzes the federal laws and regulations that govern the manufacturing, distribution, labeling, and marketing of the products that patients commonly use for self-care. Theories of civil liability, negligence, and breach of warranty are also discussed. Nonprescription drugs are regulated differently than prescription drugs and other consumer health care products, such as dietary supplements and homeopathic medicines. It is important that health care providers have a basic understanding of these regulations so they can respond to their patients' questions and concerns about the self-care products they use.

### Regulation of Nonprescription Drugs

The first major federal legislation enacted in the United States to regulate drugs was the Pure Food and Drugs Act of 1906.<sup>1</sup> Under this act, drugs were required to meet only the standards of strength, quality, and purity claimed by the manufacturers. "Unsafe" and "nonefficacious" drug products were not actually prohibited by the statute. Federal law did not mandate drug safety until passage of the 1938 Federal Food, Drug, and Cosmetic Act (FDC Act).<sup>2</sup> In 1951, the Durham-Humphrey amendment to the FDC Act established two classes of drugs: prescription-only and nonprescription (also referred to as over-the-counter, or OTC).<sup>3</sup> Before that time, manufacturers were free to determine whether to market their drug products as prescription or nonprescription items. Under the Durham-Humphrey amendment, only drugs that could be used safely without medical supervision and had labeling that included adequate directions for use could be marketed without a prescription.

The next major change in federal law occurred in 1962, when the FDC Act was again amended through passage of the Kefauver-Harris Act.<sup>4</sup> This amendment required that all new drugs be shown to be effective as well as safe for their intended uses. As a result of this amendment, the Food and Drug Administration (FDA) undertook a review of the effectiveness of 4500 new drug products, including 512 nonprescription drugs that had been approved only for safety since 1938.

In 1972, FDA initiated a massive scientific review of the 700 active ingredients in 300,000 nonprescription drug formulations to ensure that they were safe and effective and also bore fully informative labeling. This review process, which is still under way, is often referred to as the "OTC Drug Review."<sup>5</sup> FDA is also responsible for the labeling of nonprescription drugs and reclassifying (i.e., switching) drugs from prescription to nonprescription status. Consequently, nonprescription drugs that are on the market today fall into one of the three following categories:

- Approved through the drug approval process and either (1) reclassified from prescription to nonprescription status or (2) approved directly as a nonprescription drug.
- Marketed in accordance with the OTC monograph for that ingredient (see the online section titled OTC Monograph Process).<sup>6</sup>
- On the market pending a determination under the OTC Drug Review monograph process of the drug's disposition.

### Drug Approval Process

The FDC Act of 1938, as amended in 1962, requires that all new drugs introduced for marketing be cleared in advance through a New Drug Application (NDA) that proves the drug safe and effective for human use. Products marketed before 1938 were exempted from the NDA requirement under a grandfather clause. However, FDA's Office of Nonprescription Products has evaluated, or is in the process of evaluating, all nonprescription drugs for safety, effectiveness, and labeling, regardless of the date of marketing entry.<sup>6</sup>

A new chemical entity never before marketed in the United States is classified as a new drug and, in most cases, would be approved initially for prescription use only. An NDA for a nonprescription drug product can also be approved directly (without reclassification), as occurred with ibuprofen 200 mg (a dose that was never available by prescription). When a new drug is used for many years by many patients (referred to in the FDC Act as "used for a material time and material extent"), it may be considered generally recognized as safe and effective and qualify for marketing as a nonprescription drug. In addition, certain data regarding the safety, efficacy, and use of the product in a foreign country can be used to determine whether a drug can be marketed as a nonprescription product in the United States.<sup>7</sup>

Some drugs are available in the same strength as prescription-only and nonprescription products, but they are marketed for different uses. For example, nonprescription meclizine is available for motion sickness, which is easy to self-diagnose. It is also available as a prescription drug for the management of vertigo, which should be diagnosed and treated by a primary care provider.

### New Drug Application

An NDA is the vehicle through which persons or entities, referred to in the regulations as "sponsors," apply to FDA to seek approval of a new pharmaceutical for sale and marketing in the United States. The data gathered during the animal studies and human clinical trials of an Investigational New Drug (IND) become part of the NDA. The goals of the NDA are to provide FDA with enough information to determine, among other things, whether (1) the drug is safe and effective for its proposed use(s); (2) the benefits of the drug outweigh the risks; and (3) the methods and controls used in manufacturing the drug are adequate to preserve the drug's identity, strength, quality, and purity.<sup>8</sup> During this process a determination is also made as to whether the drug product is a candidate for nonprescription status.

The approved NDA is manufacturer specific and allows only the sponsor to market the product. Any other manufacturer interested in marketing a similar product would first need to seek FDA approval through its own NDA. If a second manufacturer seeks to manufacture a prescription drug product that is essentially a copy of a previously-FDA-approved product, a full NDA is not necessary; an Abbreviated NDA (ANDA) may be submitted instead, eliminating the need for duplicative testing. The second manufacturer, and any subsequent manufacturer, must demonstrate that its product is bioequivalent to the original product.

All NDAs must contain, among other things, complete labeling information; the final printed labeling is usually the last step before approval (see the section "Drug Facts" Labeling for Nonprescription Drugs in this chapter).

### OTC Monograph Process

An OTC monograph is developed for therapeutic classes of ingredients that are generally recognized as safe and effective (also referred to as "GRASE"). A manufacturer desiring to market a product that contains an ingredient covered under an OTC monograph need not seek FDA's prior approval. In this case, marketing is not exclusive; any manufacturer may market a similar product without specific approval.

Under the monograph approach, all data and information supporting safety and efficacy of the ingredient and its nonprescription status are publicly available. The FDA Office of Nonprescription Products has established the monographs through a complex administrative process called "rulemaking," which allows the general public, manufacturers, and other interested parties to comment on proposed rules. Each individual rulemaking has resulted in an extensive administrative record. [Figure 4-1](#) illustrates the process by which the OTC drug monographs are reviewed.

Under a final OTC monograph, the manufacturer has considerable flexibility in labeling. All the required monograph labeling (requirements vary for each therapeutic class) must be included; for example, antacids must include terms such as *heartburn*, *acid indigestion*, and *sour stomach*. In addition, certain language not included in the monograph may be used in specific places on the label without prior approval. For example, *hospital-tested* or *pleasant-tasting antacid* are terms considered outside the scope of the monograph but are permissible in antacid labeling. However, even though these permissible terms are not preapproved, they are subject to the general labeling provision of the FDC Act and may not be false or misleading. Monographs primarily address active ingredient(s) in the product, and in most cases final formulations are not subject to monograph specifications. Manufacturers are free to include any inactive ingredients that serve a pharmaceutical purpose, provided those ingredients are safe and do not interfere with either product effectiveness or any required final product testing. With regard to final product testing, although FDA prior approval of a product covered under an OTC monograph is not required, the monograph itself may require additional testing of the product prior to marketing. This is true even though the product contains GRASE ingredients; for example, antacids must pass an acid-neutralizing test. Laws and regulations require the manufacturer, packer, or distributor whose name appears on the label of a nonprescription medication to report certain adverse events associated with the drug.<sup>9,10</sup> FDA's MedWatch program, a safety information and adverse event reporting system for medical products, including nonprescription drugs, is addressed later in this chapter, under Adverse Event Reporting.<sup>11</sup>

## Labeling and Packaging Issues

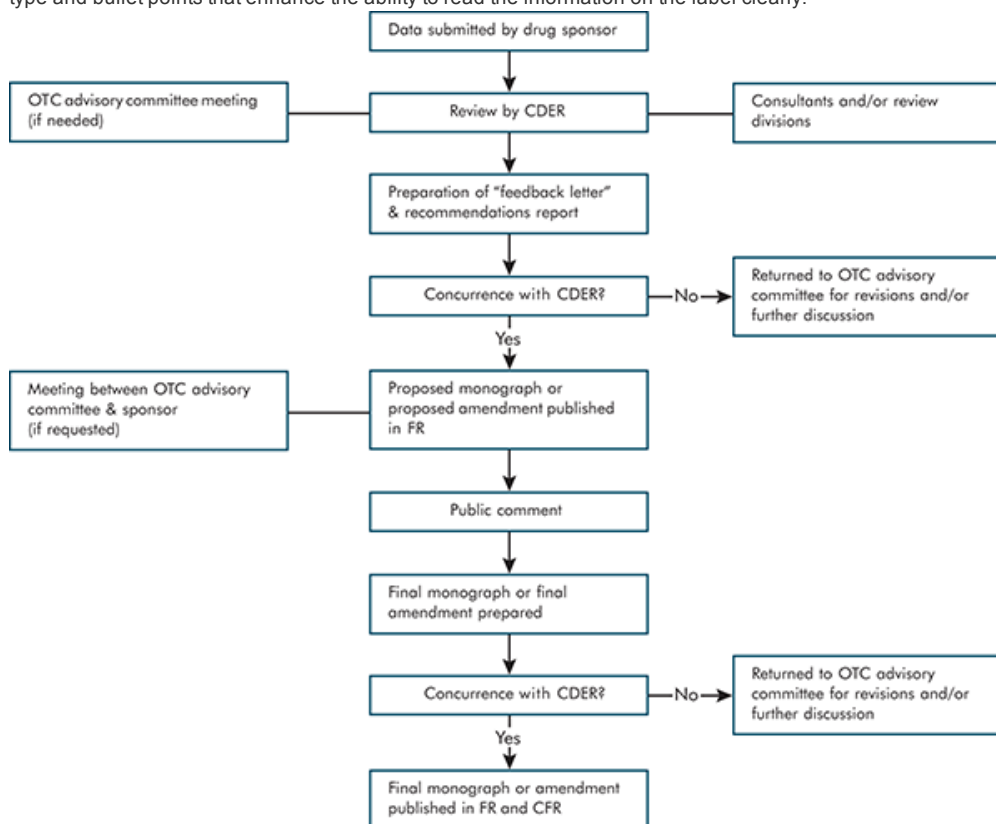

### "Drug Facts" Labeling for Nonprescription Drugs

It is essential that the labeling of nonprescription drug products clearly communicates to the consumer the important information on how to use the product safely and effectively. For many years, FDA and consumers have been concerned about the adequacy of labeling for nonprescription drugs.<sup>12</sup> This concern is heightened because an increasing number of prescription drugs are being reclassified from prescription to nonprescription status. Many of these reclassified drugs require the patient to perform more sophisticated self-diagnostic and self-monitoring evaluations. Therefore, a greater number of sophisticated messages must be communicated through the nonprescription label to provide adequate directions and safety information. Recognizing these concerns, FDA has changed nonprescription drug labeling requirements. FDA regulations now require a standardized content and format for the labels on all nonprescription drugs on the market.<sup>13</sup> Nonprescription drug labels have an area on the package designated as the "Drug Facts" box (Figure 4-2), which contains the information required by FDA to be on the label.<sup>14</sup> A nonprescription product that lacks this labeling feature may be considered misbranded and subject to the same enforcement approach that FDA can take with other misbranded drugs, including issuance of a warning letter, product seizures, and injunctions.

The nonprescription labeling regulations are intended to improve the consumer's ability to read and understand information about the product's benefits and risks and its directions for use. The Drug Facts labeling also helps consumers select the right product to meet their needs. The format enables them to determine readily and easily whether a product contains ingredients they need, do not need, or should not take. It also allows consumers to compare similar products to determine the appropriate ingredients for their symptoms or personal health situation.

The Drug Facts labeling format, with standardized headings and subheadings, also uses terms that are familiar to consumers (e.g., *uses* instead of *indications*). Lay terms are also used instead of medical terminology (e.g., *lung* instead of *pulmonary*).

The population of persons 65 years of age or older is increasing. Older people are significant users of nonprescription products, and they may have greater difficulty reading product labels because of decreasing visual functioning. The labeling requirements set a minimal type size for labels, ranging from 6 point Helvetica type for text to 14 point for certain headings. An easy-to-read font style is also required, as are other graphic features such as bold type and bullet points that enhance the ability to read the information on the label clearly.

OTC drug monograph review process, showing how CDER determines the safety and effectiveness of OTC drug products. Key: CDER, Center for Drug Evaluation and Research; *CFR*, Code of Federal Regulations; *FR*, Federal Register; OTC, over-the-counter. (Source: Adapted from U.S. Food and Drug Administration, Center for Drug Evaluation and Research. *The CDER Handbook*. Rockville, MD: Department of Health and Human Services, U.S. Food and Drug Administration, Center for Drug Evaluation and Research; 1998. Accessed at <http://www.fda.gov/downloads/AboutFDA/CentersOffices/CDER/UCM198415.pdf>, August 15, 2011.)

Health care providers, particularly pharmacists, should be familiar with the Drug Facts format. It is an essential counseling tool for nonprescription drugs. This format allows pharmacists to readily find information on the label and point it out to the patient. Figures 4-3 and 4-4 show examples of product labels

<b>Drug Facts</b>	
<b>Active ingredient (in each tablet)</b>	<b>Purpose</b>
Chlorpheniramine maleate 2 mg.....	Antihistamine
<b>Uses</b> temporarily relieves these symptoms due to hay fever or other upper respiratory allergies: ■ sneezing ■ runny nose ■ itchy, watery eyes ■ itchy throat	
<b>Warnings</b>	
<b>Ask a doctor before use if you have</b>	
■ glaucoma ■ a breathing problem such as emphysema or chronic bronchitis	
■ trouble urinating due to an enlarged prostate gland	
<b>Ask a doctor or pharmacist before use if you are taking tranquilizers or sedatives</b>	
<b>When using this product</b>	
■ you may get drowsy ■ avoid alcoholic drinks	
■ alcohol, sedatives, and tranquilizers may increase drowsiness	
■ be careful when driving a motor vehicle or operating machinery	
■ excitability may occur, especially in children	
<b>If pregnant or breast-feeding, ask a health professional before use.</b>	
<b>Keep out of reach of children.</b> In case of overdose, get medical help or contact a Poison Control Center right away.	
<b>Directions</b>	
adults and children 12 years and over	take 2 tablets every 4 to 6 hours; not more than 12 tablets in 24 hours
children 6 years to under 12 years	take 1 tablet every 4 to 6 hours; not more than 6 tablets in 24 hours
children under 6 years	ask a doctor

#### Tamper-Evident Packaging

In the wake of several high-profile tampering incidents involving nonprescription drug products, such as Tylenol in the 1980s, FDA instituted several packaging, labeling, and manufacturing requirements to protect consumers. Historically, the term "tamper-resistant" described methods used to prevent tampering. The focus has shifted to "tamper-evident" to heighten consumer awareness of any evidence of tampering, rather than attempt to make products difficult to breach or tamper-proof.

With few exceptions (dermatologic, dentifrice, insulin, and lozenge products), nonprescription drug products must have one or more barriers to entry that, if breached or missing from the package, provide consumers with evidence that tampering may have occurred.<sup>16</sup> Packages must contain unique designs or other characteristics that typically cannot be duplicated. In addition, to alert the consumer to the specific tamper-evident features, the retail package must contain a statement that identifies the feature. The statement must be prominently placed on the package in a way that it will be unaffected if the tamper-evident feature is missing or breached. For example, the statement on a bottle with a shrink band might say "For your protection, this bottle has an imprinted seal around the neck."

Patients should be educated to check for the tamper-evident features on every nonprescription drug product they purchase and, if the features are missing or look suspicious, to return the product as soon as possible to the pharmacy or store where it was purchased.

#### Drug Reclassification: Prescription-to-Nonprescription (OTC) Switch

Traditionally, a prescription-to-nonprescription (OTC) switch occurs in one of three ways:

- The drug is switched through the nonprescription drug review process.
- The manufacturer requests the switch by submitting a supplemental application to its approved NDA.
- The manufacturer or other party petitions FDA.

Through the nonprescription drug review process, panels of nongovernment experts are reviewing the prescription drug products that were on the market before 1962 to determine whether some are appropriate for nonprescription marketing. This ongoing process has produced more than 40 reclassifications from prescription-only to nonprescription status since the 1970s. See [Table 4-1](#).<sup>17</sup>

Another common way that a prescription drug is switched to nonprescription status is for the manufacturer to submit data to FDA, in the form of a supplemental NDA, demonstrating that the drug is appropriate for self-administration. Typically, these applications include studies showing that the product's labeling can be read, understood, and followed by a consumer without the guidance of a health care provider.<sup>18</sup> FDA reviews this information, along with any information known about the drug from its prescription use history. All of this information is usually presented to FDA's Nonprescription Drugs Advisory Committee, which comprises nongovernment experts. This committee serves as a forum for the exchange of ideas and recommends to FDA whether the drug in question should be switched to nonprescription status. The FDA is not bound by the committee's recommendation, but the agency usually follows the committee's advice.

**TABLE 4-1 Selected List of Reclassified Drugs**

<i>Ingredient</i>	<i>Indication(s)</i>	<i>Ingredient</i>	<i>Indication(s)</i>
-------------------	----------------------	-------------------	----------------------

Acidulated phosphate fluoride	Dental rinse	Loperamide HCl	Antidiarrheal
Brompheniramine maleate	Antihistamine	Miconazole nitrate	Antifungal
Butoconazole nitrate	Antifungal	Minoxidil	Baldness
Cetirizine	Antihistamine	Naproxen	Analgesic
Chlorpheniramine maleate	Antihistamine	Nicotine	Smoking cessation
Cimetidine	Heartburn	Nicotine polacrilex	Smoking cessation
Clemastine fumarate	Antihistamine	Omeprazole	Heartburn (proton pump inhibitor)
Clotrimazole	Antifungal	Omeprazole and sodium bicarbonate	Heartburn
Cromolyn sodium	Allergy prevention/treatment	Orlistat	Weight-loss aid
Dexbrompheniramine maleate	Antihistamine	Oxybutynin	Overactive bladder
Diphenhydramine HCl	Antihistamine	Oxymetazoline HCl	Decongestant
Docosanol	Cold sore/fever blister	Phenylephrine HCl	Decongestant
Doxylamine succinate	Sleep aid	Polyethylene glycol 3350	Laxative
Dyclonine HCl	Oral anesthetic	Pseudoephedrine HCl	Decongestant
Famotidine	Heartburn	Pyrantel pamoate	Pinworm treatment
Fexofenadine hydrochloride (NDA)	Antihistamine	Ranitidine	Heartburn
Guaifenesin	Expectorant	Sodium fluoride	Dental rinse
Hydrocortisone	Antipruritic, anti-inflammatory	Stannous fluoride	Dental rinse or gel
Ibuprofen	Analgesic	Terbinafine HCl	Antifungal
Ketoconazole	Antifungal (shampoo only)	Tolnaftate	Antifungal
Ketotifen	Antihistamine	Triclosan	Antigingivitis
Lansoprazole	Heartburn, reflux	Triprolidine HCl	Antihistamine
Levonorgestrel	Contraception	Xylometazoline HCl	Decongestant
Loratadine	Nonsedating antihistamine		

Overall, more than 700 nonprescription drug products on the market today use ingredients or dosages once available only by prescription.<sup>19</sup> The categories of drug products that have seen the most activity in this area are analgesics, H<sub>1</sub> and H<sub>2</sub> histamine-receptor antagonists, antifungal medications, smoking cessation agents, and topical medications used to treat minor skin conditions. Drug products in these categories are good candidates for prescription-to-nonprescription reclassification because they are used to treat self-limiting conditions that are easily identified by laypersons, with or without the assistance of a health care provider.

A company, usually the manufacturer, can also petition FDA to switch a drug or class of drugs to nonprescription status. In recent years, however, FDA has received petitions that originated not from the drug's manufacturer, but from third party payers.<sup>20</sup> These third party payers, citing FDA's statutory authority under Section 503(b) of the FDC Act to remove the prescription requirement for a drug when doing so will not create a threat to public health, have petitioned FDA to switch certain drugs from prescription to nonprescription status.

It is easy to understand why third party payers, employers, and state and federal health care programs have taken a strong interest in increasing the number of prescription-to-OTC switches. The availability of nonprescription drug products for self-treatment may save consumers millions of dollars in health care costs by reducing the number of physician visits, preventing unnecessary sick days from work, and decreasing costs associated with the advancement of disease states that could have been limited by treatment with a nonprescription product. Medicare Part D is another area in which patients may benefit by purchasing a nonprescription rather than a prescription medication to slow progression to the coverage gap. That said, out-of-pocket expenditures may increase for many consumers if employers, insurers, and other third party payers no longer cover the cost of the medications as the result of a prescription-to-OTC switch. Nevertheless, it will be important for health care providers to stress to their patients the importance of continuing needed drug therapy, even if the cost of the medication is no longer covered by insurance.

Exact standards or switch criteria are very difficult to set because many factors must be carefully considered. The information that must be gathered from the expert opinions of advisors and consultants regarding a drug's classification as nonprescription includes, but is not limited to, the following:

- Is the condition self-diagnosable?
- Is the condition self-treatable?
- Does the product possess misuse and/or abuse potential?
- Is the product habit forming?
- Do methods of use preclude nonprescription availability?
- Do the benefits of availability outweigh the risks?
- Can adequate directions for use be written?

Further scientific scrutiny typically addresses the following questions:

- Does the reclassification candidate have an adequate margin of safety?
- Has the reclassification candidate been used for a sufficiently long time (e.g., 3-5 years) on the prescription market to yield a full characterization of its safety profile?
- Has a vigorous risk analysis been performed? If so, what are the results?
- Has the efficacy literature been reviewed in a way that supports the expected use and labeling of the reclassification candidate?
- Have potential drug interactions for the reclassification candidate been characterized?

FDA has explored the benefits and regulatory and legislative issues related to behind-the-counter availability of drugs in the United States.<sup>21</sup> Products in this class would be available without a prescription, but they would be stored behind the pharmacy counter and sold only by a pharmacist. Such a class of drugs may address concerns surrounding the desire for increased availability of certain drug products, while also ensuring oversight of a health care provider, particularly a pharmacist, to ensure that these medications are used appropriately.

A de facto third class of drugs has been created and currently exists, however. For example, under federal law and the laws of most states, the sale of certain Schedule V controlled substances, such as codeine-based cough and cold products, is permitted without a prescription, but only from a pharmacist. Pseudoephedrine is also an example of a behind-the-counter product that is sold without a prescription but with pharmacist oversight. In addition, many states have passed laws permitting pharmacists to furnish prescription medications to patients without a prescription in certain circumstances, often through a standing order, protocol, or collaborative practice arrangement with a physician. Products furnished under this model retain prescription-only status, but their availability directly from the pharmacist without a visit to the physician improves patient access to needed medications. Evidence that consumers have benefited and pharmacists have successfully managed risks in these areas could be used as support for a broader, federally sanctioned third class of drugs.

In 2012, FDA took a step toward the creation of this third class of drugs when it proposed a new paradigm under which the agency would approve certain prescription drugs for OTC use under conditions of safe use. Because the undertreatment of many common diseases or conditions is recognized as a public health problem, making certain medications more accessible as nonprescription drugs in health care settings such as pharmacies may improve patient outcomes. The required conditions of safe use would be drug-product specific and, according to FDA, might include using innovative technologies in addition to requiring pharmacist intervention. Medications discussed as potential candidates for OTC approval include those used for treatment of hyperlipidemia, hypertension, migraine headaches, asthma, and allergic reactions.<sup>22</sup>

Activity in the area of prescription-to-OTC switches seems certain to increase in the coming years. Health care providers can reasonably expect that more prescription drugs will be subjected to review, as payers, the pharmaceutical industry, and FDA continue to grapple with the difficult task of balancing economic pressures with safety concerns. As more drugs are switched to nonprescription status, health care providers will be called on to play a greater role in assessing the need for treatment and monitoring the use of these drugs.

### Case Study—Levonorgestrel Rx-to-OTC Switch

In July 2013, a prescription (Rx)-to-OTC switch occurred, not as the result of pressure from a third party payer, but as the result of litigation in federal court over the issue of whether levonorgestrel-based emergency contraceptives should be sold without a prescription and without point-of-sale or age restrictions. The product's manufacturer originally petitioned FDA in 2003 to market its levonorgestrel-based emergency contraceptives for use without a prescription for women 15 years of age and older.<sup>23</sup> A Citizen's Petition seeking to remove all age restrictions followed. FDA finally granted this petition when, after several amendments, further research, and much litigation, the United States District Court for the Eastern District of New York issued a landmark opinion that granted the OTC sale of levonorgestrel-based emergency contraceptives to all women and girls, regardless of age.<sup>24</sup> As a result of the decision, FDA agreed to allow certain levonorgestrel-based products to be distributed over the counter to women and girls of all ages.<sup>25</sup> This represents one of the most substantial changes from prescription to nonprescription status over the past decade.

### Regulation of Methamphetamine Precursors

Over the past several years, state and federal regulators have increased the regulation of nonprescription products that contain pseudoephedrine and other methamphetamine precursors. These laws were enacted to combat the growing problem of illicit methamphetamine laboratories, operated by "garage chemists" who use pseudoephedrine as the precursor in the manufacturing process. Although the federal government has passed laws that directly regulate retail sales of products containing pseudoephedrine, many states have passed more stringent laws, and it is important that retail sellers be familiar with both state and federal regulations.

Under federal law, the Comprehensive Methamphetamine Control Act of 1996 and the Combat Methamphetamine Epidemic Act of 2005 regulate the sale of products containing pseudoephedrine by limiting the quantities that can be purchased at retail and by imposing certain record-keeping and reporting requirements on sellers, including pharmacies.<sup>26</sup> Key requirements concerning the sale of pseudoephedrine-containing products under the federal laws include the following requirements:

- These products must be kept behind the counter or in a locked cabinet.
- Individuals may not purchase more than 3.6 grams of pseudoephedrine in 1 day and not more than 9 grams in any 30-day period or, if purchased from a mail-order pharmacy or a "mobile vendor," no more than 7.5 grams in any 30-day period.
- Purchasers must present a state or federal government-issued photo identification card at the time of purchase.
- Sellers must maintain either a written or an electronic logbook as follows:
  - All pseudoephedrine transactions for a period of not less than 2 years from the date of purchase are recorded.
  - Specific information, including the name and address of the purchaser, the name of the product, the quantity purchased, and the date and time of the transaction, must be included.
  - Products packaged for individual sale that contain less than 60 mg of pseudoephedrine are exempt from the logbook requirements but still must be kept behind the counter.
- The person selling the pseudoephedrine must confirm that the information provided by the purchaser matches that provided on the identification card.
- The purchaser must provide a signature verifying that the information provided is correct.

The Combat Methamphetamine Enhancement Act of 2010<sup>27</sup> requires retail sellers of methamphetamine precursors, except pharmacies that are DEA registrants, to submit to the U.S. Attorney General a self-certification, stating that the seller understands each of the requirements under the federal methamphetamine precursor laws. The Attorney General will develop and make available on the Drug Enforcement Administration (DEA) Web site a list of all self-certified retailers or persons and will require that all distributors of methamphetamine precursors sell those products only to retailers or persons registered with the DEA or included on the self-certification list.

In addition to federal law, nearly every state has enacted its own laws to regulate the sale of methamphetamine precursors.<sup>28</sup> The regulatory approach varies from state to state, and many state laws are more stringent than federal law. Retailers and other persons are required to comply with the most stringent law; therefore, it is essential that they be familiar with the methamphetamine precursor laws in their states.

### Marketing Issues

#### Product Line Extensions

Product line extensions are becoming more commonplace in the nonprescription drug market. Product line extensions include new strengths, formulations, combinations of ingredients, and even a totally different therapeutic entity of a brand-name product that was originally marketed as a single-ingredient product at a specific dose to treat a specific symptom. In developing product line extensions, manufacturers hope to capitalize on the loyalty created by consumer recognition and trust of a brand name.

Product line extensions can create consumer confusion and inappropriate drug selection and use.<sup>29</sup> Health care providers must be familiar with the

range of products within a brand name to recommend them safely and correctly and to counsel patients on these products. Particular care must be taken with respect to the active ingredients because these often differ within a product line. Some product line extensions carry the original brand name on the label and retain the active ingredient of the original product, but strengths may vary. Some manufacturers with many product line extensions continue to use the original brand name on the label, but the product line extensions contain none of the active ingredients of the original products and have a suffix attached to the brand name for differentiation (e.g., PM, EX, DM, AF, Cold and Flu, Non-Drowsy, Extra, Allergy-Sinus-Headache, Advanced Formula, PH, Day/Night, and Plus).

#### Nonprescription Drug Advertising

FDA handles most matters involving the labeling, as opposed to the advertisement, of nonprescription drugs, whereas the Federal Trade Commission (FTC) is responsible for matters involving claims made in advertisements for nonprescription drug products.<sup>30</sup> In the 1970s, the Federal Trade Commission Act (FTC Act) was amended to prohibit advertisers from using language to describe the therapeutic benefits of a nonprescription drug product that differs from language approved by FDA for use in the product labeling.

The FTC Act requires that advertising be truthful and forthright. Depending on the claim, advertisers may be required to back up their representations with competent and reliable scientific evidence, including tests, studies, or other objective data.

In 1973, the National Association of Broadcasters and the Consumer Healthcare Products Association developed a code of guidelines for manufacturers to follow in creating television advertisements for nonprescription drugs.<sup>31</sup> The guidelines, which are updated periodically, set standards for truthfulness and honesty and suggest that an advertisement should, among other things, do the following:

- Comply with all relevant applicable laws and regulations.
- Urge the consumer to read and follow label directions.
- Contain no claims of product effectiveness that are unsupported by clinical or other scientific evidence, responsible medical opinion, or experience through use.
- Present no information in a manner that suggests the product prevents or cures a serious condition that must be treated by a licensed health care provider.
- Emphasize the uses, results, and advantages of the particular product.
- Reference no physicians, hospitals, or nurses, unless such representations can be supported by independent evidence.
- Present no negative or unfair reflections about competing nonprescription drug products, unless those reflections can be supported scientifically and presented in a manner that consumers can perceive differences in the uses.

Consumers should be analytical when listening to or reading marketing messages, particularly because some can be subjective, superficial, vague, or potentially misleading. Health care providers, particularly the pharmacist and the primary care provider, are well positioned to assist patients in separating fact from ambiguity with regard to nonprescription drug use and to serve the public interest as an objective, informed source of nonprescription drug information.

#### Vitamins, Minerals, Botanical Medicines, and Other Dietary Supplements

Dietary supplements are regulated under the federal Dietary Supplement Health and Education Act of 1994 (DSHEA). This act became law in recognition that many consumers believe dietary supplements have health benefits. The law represents a balance between consumer access to dietary supplements and the authority of FDA to withdraw dangerous products and address false and misleading claims. FDA's authority to regulate dietary supplements is significantly less than that for prescription and nonprescription products. A thorough discussion of dietary supplements, including regulatory issues, clinical issues, and patient assessment issues, can be found in [Chapter 50](#).

#### Homeopathy

Homeopathic drugs are recognized as drugs under the FDC Act, which defines the term *drug* as "articles recognized in the official United States Pharmacopoeia, official Homeopathic Pharmacopoeia of the United States ('HPUS'), or official National Formulary, (i) or any supplement to any of them."<sup>32</sup> Furthermore, the act provides that whenever a drug is recognized in both the *United States Pharmacopoeia* and the *HPUS*, it is subject to the requirements of the *United States Pharmacopoeia*, unless it is labeled and offered for sale as a homeopathic drug, in which case it is subject to the provisions of the *HPUS*. A discussion of homeopathic products can be found in [Chapter 52](#).

#### Drug-Cosmetic Products

Some nonprescription drug products are also considered cosmetic products.<sup>33</sup> The claim(s) made for the product determine whether it is a drug, a cosmetic, or a drug-cosmetic. Labeling and marketing requirements differ depending on how a product is classified. Often this distinction is not apparent to consumers, so they may wonder why a product they consider to be a cosmetic contains Drug Facts labeling. If a product has a drug-intended use and a cosmetic-intended use, it is considered a drug-cosmetic. For example, a nonmedicated shampoo is a cosmetic because its intended use is to clean the hair, which is a cosmetic claim. An antidandruff shampoo is a drug because its intended use is to treat dandruff, which is considered a drug claim. Therefore, an antidandruff shampoo that claims to clean the hair and treat dandruff would be a drug-cosmetic and bear OTC Drug Facts labeling. Other drug-cosmetic products include toothpastes that contain fluoride, deodorants that are also antiperspirants, moisturizers, and some cosmetics that are marketed with sun-protection claims.

#### Identifying and Removing Potentially Dangerous Products from the Market

##### Adverse Event Reporting

Pharmacists play a critical role in helping FDA, consumers, and the pharmaceutical industry manage the risks associated with regulated products. To fulfill this responsibility, pharmacists and other health care providers must understand FDA's adverse event reporting system.

The FDA MedWatch program is a voluntary adverse event reporting system that allows health care providers and consumers to report serious adverse drug reactions directly to the agency.<sup>34</sup> FDA analyzes trends and correlations between drug use and adverse reports from information submitted to MedWatch. There is no cost to either the provider or the consumer for filing a report. Although the program is voluntary, it is ineffective unless properly used. Providers should take their role in patient safety seriously and, as part of that responsibility, make sure that serious adverse drug reactions suspected to be associated with drugs are reported to FDA. Official reporting forms are available from FDA by calling 1-800-FDA-1088. Reports can also be submitted online by accessing the MedWatch Web site ([www.fda.gov/medwatch/index.html](http://www.fda.gov/medwatch/index.html)). FDA safety alerts and product recall information are also accessible at this site.

It is important to understand that submitting a report to FDA does not constitute a legal claim, nor does it in any way constitute an acknowledgment that there has even been an adverse drug reaction associated with use of the product. The identities of the providers and the patients are confidential. Providers are encouraged to report all suspected adverse reactions and to ensure effective review of the reports. FDA asks that providers describe the reaction, the exposure to the regulated product, the time between exposure and reaction, and the underlying disease.

## Product Recalls

When a product regulated by FDA is identified as a potential risk to the public, removal of the product from the market may be necessary. Products may pose a risk for a variety of reasons, including adulteration, misbranding, or discovery of an unacceptable risk of adverse effects through postmarket surveillance.

FDA has two methods available to force the removal of a product from the market. First, if the drug is misbranded or adulterated or is an unapproved new drug, the FDC Act allows FDA to seize the product and order that it be held pending a review by the court.<sup>35</sup> Second, FDA can also seek a court injunction, preventing further distribution or sale of the product. Both of these remedies are potentially expensive and time consuming and, more important, do not address the issue of retrieving drugs that have already been purchased.

A third avenue that FDA may pursue is to request that the manufacturer recall the product from the market. FDA has no statutory authority to order a recall, but when potentially serious health risks are associated with the use of a drug product, manufacturers typically are willing to institute a recall. If a recall is instituted, FDA does have the authority to prescribe the procedures to which the recall must conform. This cooperation between FDA and its regulated industries has proven over the years to be the quickest and most reliable method for removing potentially dangerous products from the market. This method has been successful because it is in the interest of both FDA and the industry to remove unsafe and defective products from consumer hands as soon as possible. FDA guidelines governing product recalls make clear that FDA expects manufacturers to take full responsibility for product recalls, including follow-up checks to ensure that recalls are successful. Under the guidelines, manufacturers are expected to notify FDA when recalls are started, make reports to FDA on their progress, and undertake recalls when asked to do so.<sup>36</sup>

The guidelines categorize all recalls into one of three classes according to the level of hazard associated with the product at issue:

- *Class I* recalls are for dangerous or defective products that predictably could cause serious health problems or death.
- *Class II* recalls are for products that might cause a temporary health problem or pose only a slight threat of a serious nature.
- *Class III* recalls are for products that are unlikely to cause any adverse health reaction but violate FDA labeling or manufacturing regulations.

The manufacturer is responsible for notifying sellers of the recall. The sellers, including pharmacists, are responsible for contacting customers, if necessary. A pharmacist is also responsible for knowing what drugs or other regulated products have been recalled. Failing to remove a recalled product from the shelf and subsequently providing the product to a consumer may violate the FDC Act and also expose the pharmacist to civil liability if someone is injured by use of the product.

FDA issues general information about new recalls that it is monitoring through FDA Enforcement Reports, a weekly publication available on FDA's Web site ([www.fda.gov/Safety/Recalls/EnforcementReports/default.htm](http://www.fda.gov/Safety/Recalls/EnforcementReports/default.htm)).

## Patient Protection and Affordable Care Act

The most recent federal legislation to affect the health care industry, including nonprescription drug products, is the Affordable Care Act (ACA).<sup>37</sup> The ACA was signed into law on March 23, 2010, with most provisions effective January 2014. Section 9003, however, became effective January 1, 2011. This section affects the regulation and purchase of nonprescription drug products by further revising the definition of medical expenses. According to Section 9003, any nonprescription drug products purchased without a prescription may no longer be paid for or reimbursed under health flexible spending arrangements (FSAs), health reimbursement arrangements (HRAs), health savings accounts (HSAs), or Archer Medical Savings Accounts (Archer MSAs). The exception to this is insulin, which will remain reimbursable through FSAs, HRAs, HSAs, and Archer MSAs. Therefore, the only way an individual may pay or be reimbursed for nonprescription drug products through such account is by obtaining a prescription for such drug products. This restriction does not apply to items that are not drug products, such as devices, supplies, and other similar medical-related items.

## Nonprescription Drug Products and Civil Liability

Nonprescription drug products are, by nature, deemed to be safe and effective for use by the general public for self-care, without the oversight of a health care provider. However, no drug, whether prescription or nonprescription, is completely safe. As with any product, injuries can result from the use of a nonprescription product. For example, a patient can have an allergic reaction to an ingredient in a nonprescription product, can become injured as a result of an interaction between a nonprescription product and another drug, or suffer injury resulting from a side effect associated with the use of the drug. The fact that these types of injuries can and do occur, however, does not mean that the drugs causing the problem are inherently dangerous or unsafe, or that they should not be available without a prescription.

Whether a health care provider can be held liable for money damages for recommending or selling a nonprescription drug product that causes an injury is an issue that is decided under state law, and the legislation varies from state to state. A complete analysis of the nuances of the various theories of liability is beyond the scope of this chapter. There are, however, some general principles that health care providers may find useful to understand and guard against potential civil liability.

It is important to note that regardless of what a court may decide in any given case, the primary obligation of a health care provider is to provide health care. This obligation may include recommending or selling appropriate nonprescription drug products for patient self-care. A health care provider who refuses to recommend or sell a product for fear of incurring civil liability is not providing health care and is doing a disservice to himself or herself, the profession, and the patient.

### Theories of Civil Liability

The body of law concerning civil liability is guided by the general principle that, in a civilized society, people are responsible for their actions. If one's actions cause an injury to another person, the law may require that the injured person be compensated. In the U.S. justice system, an injured person who seeks compensation for the injuries that he or she has sustained as a result of another's actions has the right to bring a civil lawsuit against the person who caused the injury. Typically, the injured party (the plaintiff) will ask the court to award money damages to be paid by the party causing the injury (the defendant). For example, a plaintiff who sustains an injury after taking a nonprescription medication recommended by a pharmacist can file a lawsuit against the pharmacist, seeking monetary compensation for the injuries. The plaintiff may seek compensation for the past, present, and future medical bills that he or she has incurred or will incur as a result of the injury; any income lost from missing work; the pain and suffering endured; and any permanent injury or damage.

The mere fact that an injury occurred does not, however, entitle the plaintiff to damages. The plaintiff has the burden of proving that he or she has satisfied each of the elements required to be proved under the theory of liability alleged in the complaint. The theories of liability that can be alleged against a health care provider in connection with an injury caused by a nonprescription drug product include negligence, breach of warranty, and strict product liability.

### Negligence

The sole fact that an injury has occurred does not mean that a party can be found liable for negligence. Similarly, even if a health care provider makes a mistake, that action alone does not necessarily entitle the injured party to compensation. To prevail in a case alleging negligence of a health care provider, the plaintiff must prove four elements: (1) the defendant owed the plaintiff a duty of care; (2) the defendant by his or her conduct breached that duty; (3) the breach caused the plaintiff's injury; and (4) in fact, the plaintiff sustained some cognizable injury or damage. If the plaintiff cannot prove all of these elements, there can be no liability.

The first element, duty, is decided by the court. The relevant inquiry is whether the health care provider failed to exercise the degree of care that a reasonable and prudent person would have used under similar circumstances. Courts will examine the relationship between the parties; the foreseeability that the defendant's actions, or failure to act, could cause an injury; and the gravity of harm that resulted from the act or failure to act. After the court defines the duty, the jury will decide whether the duty has been breached by the health care provider.

In a historical case that addressed liability for injuries resulting from a pharmacist's recommendation of a nonprescription drug product, the court defined the duty as requiring the pharmacist to exercise a high degree of care in advising the purchaser of the injurious effects of the recommended nonprescription product.<sup>38</sup> In that case, the patient presented the pharmacist with a prescription for a product to treat poison ivy. The pharmacist advised the patient to use a nonprescription product instead of the product prescribed by the physician. A reaction between the nonprescription ointment and a residue present on the patient's skin caused the skin to turn black. The court stated:

In the discharge of their functions, druggists, apothecaries, and other persons dealing in drugs, poisons, and medicines, are required, not only to be skillful, but also exceedingly cautious and prudent, in view of the terrific consequences which may attend the least inattention on their part. The highest degree of care known among practical men must be used by them to prevent injury from the use of their compounds, and they are held to a special degree of responsibility corresponding with their superior knowledge and are generally held liable for the slightest negligence.

The court sustained a jury verdict awarding money damages to the plaintiff, finding that the recommendation of the nonprescription drug product and the recommendation that the plaintiff continue to use the product even after she began to notice that her skin was turning black constituted a breach of the standard of care owed to the patient.

Although each state's law differs and the ruling in any case is dependent on the facts presented, courts likely will hold pharmacists and other health care providers to a high standard of care in connection with the recommendation of nonprescription drug products. For example, a reasonable pharmacist likely would not recommend that a patient discontinue all antidepressant medications and take St. John's wort to treat clinical depression. Nor would a reasonable health care provider recommend that a patient take aspirin if it is known that the patient is also on warfarin therapy. The health care provider must act reasonably and make recommendations that are in the patient's best interest. If, despite the exercise of due care, an injury results, a provider likely would not be held liable for negligence.

Even if a duty and a breach were found, the provider would not be liable for injuries that were not caused by the negligent conduct. If, for example, the evidence in the poison ivy case described above showed that the patient's skin turned black not because of any reaction between the product recommended by the pharmacist but because of some inherent condition the patient suffered from, which coincidentally manifested itself at the same time that the patient began using the nonprescription ointment, the pharmacist would not be held liable. Again, the plaintiff must prove all four elements—duty, breach, causation, and injury—to prevail.

#### Breach of Warranty

Liability for breach of warranty is based on the theory that the defendant violated either an express or implied agreement concerning the quality of the product in connection with its sale. Express warranties arise out of specific statements made by the seller, whereas implied warranties are created by and imposed by law. Keep in mind that warranty liability can arise only if the health care provider sold the product that fails to perform. Therefore, a recommendation by a provider that the patient buy a certain cough and cold preparation that causes injury will not result in warranty liability if the provider merely recommended but did not sell the product.

The Uniform Commercial Code (UCC), which has been adopted by nearly every state, defines an express warranty as "an affirmation of fact or promise made to the buyer that relates to the goods and becomes a basis of the bargain."<sup>39,40</sup> In one of the few published cases addressing the breach of an express warranty made by a pharmacist in connection with the sale of a drug product, the court found the representation that the product sold "was the same as what the plaintiff's prescription called for" created an express warranty, and when the product sold was in fact different—and caused an injury—the pharmacist was held liable.<sup>40</sup> As an example, the pharmacist in the poison ivy case advised the plaintiff that the blackened skin that resulted after the first use of the nonprescription product would clear up with continued use of the ointment. Instead, it worsened. On those facts, the plaintiff likely could have stated a claim for breach of express warranty.

Express warranties should not be confused with "sales talk," or puffery, which are statements made to induce a sale that do not specifically relate to the ability of the product. For example, a statement such as "this is the best ointment you will ever buy" would likely be viewed as sales talk, not an express warranty.

Implied warranties are created by law. Two implied warranties included in the UCC should most concern health care providers who sell goods: (1) the implied warranty of fitness for a particular purpose and (2) the implied warranty of merchantability. When a seller recommends a particular product to meet the buyer's specific needs, it is implied that the product recommended is fit for that purpose. Therefore, for example, if a health care provider recommends and sells a product to treat a specific condition, and it turns out that the product should not have been used for that purpose, the plaintiff could claim the provider breached the warranty of fitness for a particular purpose.

The implied warranty of merchantability states that the product sold is fit for all general purposes for which the product typically is sold. Included within this warranty is the understanding that the products sold and their containers meet certain minimum quality standards. If a pharmacist sells a product that is outdated, contaminated, or subpotent, he or she has breached the implied warranty of merchantability.

Warranty claims often are brought against not only the immediate seller of the product but also the product's manufacturer. However, if the condition that has rendered the product unfit for ordinary purposes was caused by the manufacturer, and not the seller, the seller is not necessarily relieved of responsibility. State laws vary in this area, with some states having laws that limit the liability of the seller in those circumstances. In general, to avoid warranty liability, the provider must be mindful of the source and origin of the products it sells.

#### Strict Product Liability

Unlike a negligence or warranty theory, strict liability is imposed when a product causes an injury to the user, even if the seller was not negligent and made no express or implied representations regarding the product. Although this type of case is typically brought against the manufacturer, it remains a viable theory of recovery against retail sellers of products in many states. The theory is based on the idea that a seller of a product that has profited from the sale should also be required to compensate victims who are injured by the product, even if the seller was not in any way negligent in causing the injury. The mere sale of a product that is found to be defective, even if the defect is unknown or even unknowable to the seller, can form the basis for imposing strict liability.

When the product involved is a prescription drug product, courts have almost universally held that pharmacists cannot be held strictly liable for injuries caused by products they dispense. However, when a pharmacist acts as a retailer and sells goods that cause injuries, the theory may remain viable. Again, many states have laws that will automatically pass liability up the chain, past the retailer to the manufacturer.

Again, the most important rule that a pharmacist or any health care provider can follow to avoid civil liability is simply to practice health care as it should be practiced. Caring for the patient and acting in the patient's best interest to improve the patient's health and well-being should be the primary concern of all health care providers. More often than not, adherence to that general principle will provide a defense if a patient claims that the provider's conduct in connection with the recommendation or sale of a product caused an injury.

#### Key Points for Legal and Regulatory Issues in Self-Care Pharmacy Practice

- Although nonprescription drug products are readily available, they are subject to regulatory and legal requirements to ensure their safety and efficacy.

- The Drug Facts labeling panel is a useful consumer counseling tool for health care providers.
- Dietary supplements and homeopathic products are not subject to all the regulations that govern prescription and nonprescription drugs.
- Health care providers play a critical role in helping FDA, consumers, and industry manage risks associated with nonprescription drug products and should voluntarily report adverse events to FDA's MedWatch program or the manufacturer.
- With increasing frequency, FDA is approving product switches from prescription to nonprescription status. Health care providers play a crucial role in educating their patients as to the safe and proper use of recently switched products.
- Although liability risks may be associated with the sale of a nonprescription drug product, health care providers must remember that their primary role is to provide health care and that the best way to protect themselves is to act reasonably and in the best interest of their patient when recommending a nonprescription product.

## Handbook of Nonprescription Drugs > Chapter 5. Headache

### Headache: Introduction

Worldwide, 47% of the population suffers from headache at any given time, and 66% will suffer from headache at some point in their lives. Migraine headache is more severe and debilitating compared with tension-type headache. However, the overall disease burden to society is similar between the two headache types because 38% of the population suffers from tension-type headache and 10% from migraine.<sup>1</sup>

Many headache sufferers self-treat with nonprescription remedies rather than seek medical attention. As much as two-thirds of nonprescription analgesic use may be for headache.<sup>2</sup> One study<sup>2</sup> found that 24% of patients chronically overused medication and only 14.5% had ever been advised to limit their intake of acute headache treatments. Clearly, an opportunity to improve medication use exists among patients self-treating for various pain syndromes. Headaches are generally classified as primary or secondary. Primary headaches (approximately 90% of headaches) are not associated with an underlying illness. Examples include episodic and chronic tension-type headaches, migraine headache with and without aura, cluster headaches, and medication-overuse headaches. Secondary headaches are symptoms of an underlying condition, such as head trauma, stroke, substance abuse or withdrawal, bacterial and viral diseases, and disorders of craniofacial structures.

This chapter focuses on the most common headaches that are amenable to self-treatment: tension-type, diagnosed migraine, and sinus headaches. Nonprescription analgesics are useful in treating headache, either as monotherapy or as adjuncts to nonpharmacologic or prescription therapy.

Tension-type headaches, also called stress headaches, can be episodic or chronic. Chronic headaches occur 15 or more days per month for at least 3 months.<sup>1</sup> The prevalence of tension-type headache is greatest in the age range 40–49 years, occurs in a ratio of 5:4 of women to men, and increases with higher levels of education.<sup>3</sup>

The prevalence of migraine headache in the United States is about 18% for women and 6% for men. Onset usually begins in the first three decades of life, with greatest prevalence at around age 40. Among children, boys and girls are affected equally, but attacks usually greatly decrease in boys after puberty.<sup>4</sup> Migraine without aura (i.e., neurologic symptoms that precede the head pain) occurs almost twice as frequently as migraine with aura, and many individuals may have both types of headaches. Up to 70% of patients with migraine have family histories of migraine, suggesting that this disease is influenced by heredity.

The economic impact of migraine headache is substantial. Direct costs for medical services have been estimated at \$1 billion in the United States. A greater burden comes from lost productivity and wages, with migraine costing \$13 billion for American employers. Migraine headaches affect health-related quality of life in a manner similar to that of depression.<sup>4</sup>

Headache is a frequently reported symptom in patients with acute sinusitis. These patients also experience other sinus symptoms such as toothache in the upper teeth, facial pain, nasal stuffiness, and nasal discharge. The prevalence of sinus headache is low, and up to 90% of patients who believe they have sinus headache may actually be experiencing migraine headache.<sup>5</sup>

### Pathophysiology of Headache

*Tension-type headaches* often manifest in response to stress, anxiety, depression, emotional conflicts, and other stimuli. The episodic tension-type headache subtype is thought to have a peripheral pain source, whereas the chronic tension-type headache has a central mechanism. A genetic component appears to influence the presence or absence of tension type headache. Furthermore, it is likely that tension-type and migraine headache share pathophysiologic features, making them more similar than distinct.<sup>6</sup> *Migraine headaches* probably arise from a complex interaction of neuronal and vascular factors. Stress, fatigue, irregular sleep patterns, fasting or a missed meal, vasoactive substances in food, caffeine, alcohol, changes in female hormones, changes in barometric pressure and altitude, lights, odor, neck pain, exercise, and sexual activity may trigger migraine.<sup>7</sup> Medications (e.g., reserpine, nitrates, oral contraceptives, and postmenopausal hormones) can also trigger migraine. Although their role in migraine headache is still debated, personality features of migraine sufferers include perfectionism, rigidity, and compulsiveness. Menstrual migraines appear at the menstrual stage of the ovarian cycle and occur in less than 10% of women. For some women, these migraine headaches occur at specific times before, after, or during the menstrual cycle.

Most investigation into the pathophysiology of headache has centered on migraine headache. The best evidence suggests that migraine occurs through dysfunction of the trigeminovascular system. Neuronal depolarization that

spreads slowly across the cerebral cortex is observed during the aura phase. Magnesium deficiency may contribute to this state. During the headache phase, stimulation (by an axon reflex) of trigeminal sensory fibers in the large cerebral and dural vessels causes neuropeptide release with concomitant neurogenic inflammation, vasodilation, and activation of platelets and mast cells. Menstrual migraine pathophysiology occurs through estrogen withdrawal followed by serotonin withdrawal. Decreased serotonin is associated with increased calcitonin gene-related peptide and substance P from trigeminal nerves, which lead to vasodilation of vessels and sensitivity of the trigeminal nerves. Estrogen may also influence nitric oxide, magnesium, or prostaglandins, which may contribute to the menstrual migraine.<sup>8,9</sup> *Sinus headache* occurs when infection or blockage of the paranasal sinuses causes inflammation or distension of the sensitive sinus walls (see [Chapter 11](#)). Pathophysiologic mechanisms at work during migraine headache can produce prominent sinus congestion.

*Medication-overuse headache* results from a rebound effect after the withdrawal of an analgesic. This type of headache differs from a headache related to a medication side effect. Some patients who suffer from migraine or tension headaches receive some relief from nonprescription medication, and over time may increase their use of the nonprescription treatment, which can lead to medication-overuse headaches. These headaches are usually associated with frequent use (more than twice weekly) for 3 months or longer and occur within hours of stopping the agent; re-administration of the agent provides relief.<sup>10</sup> Agents associated with medication-overuse headaches are acetaminophen, some nonsteroidal anti-inflammatory drugs (NSAIDs), aspirin, caffeine, triptans, opioids, butalbital, and ergotamine formulations.<sup>10</sup> Symptomatology shifts from the baseline headache type to a nearly continuous headache, particularly noticeable on awakening.

### Clinical Presentation of Headache

Headaches can be differentiated by their signs and symptoms; the major defining characteristics are listed in [Table 5-1](#). The severity of pain associated with tension-type headaches is highly variable. Some headaches are so mild they do not require treatment, whereas others are sufficiently severe to be disabling. Shivering or cold temperatures may increase pain from tension-type headaches. Chronic tension-type headaches occurring at least 15 days per month for at least 6 months may be a manifestation of psychological conflict, depression, or anxiety. These headaches may be associated with sleep disturbances, shortness of breath, constipation, weight loss, fatigue, decreased sexual drive, palpitations, and menstrual changes.

Migraine headaches are classified as migraine with or without aura. Aura manifests as a series of neurologic symptoms: shimmering or flashing areas, blind spots, visual and auditory hallucinations, muscle weakness that is usually one sided, and difficulty speaking (rarely). These symptoms may last up to 30 minutes, and the throbbing headache pain that follows may last from several hours to 2 days. Migraines without aura begin immediately with throbbing headache pain. Both forms of migraine often are associated with nausea, vomiting, photophobia, phonophobia, sinus symptoms, tinnitus, light-headedness, vertigo, and irritability, and are aggravated by routine physical activity. Premonitory (prodrome) symptoms in migraine can be neuropsychiatric (e.g., anxiety, irritability, yawning, unhappiness, and insomnia), sensory (e.g., phonophobia, photophobia, focusing difficulties, and speech difficulties), digestive (e.g., food craving, nausea, vomiting, diarrhea, and constipation), and general (e.g., asthenia, tiredness, fluid retention, and urinary frequency).<sup>11</sup>

Sinus headache is usually localized to facial areas over the sinuses and is difficult to differentiate from migraine without aura. The pain quality of a sinus headache is typically a dull and pressure-like sensation. Stooping or blowing the nose often intensifies the pain of sinus headache, but the headache is not accompanied by nausea, vomiting, or visual disturbances. Persistent sinus pain and/or discharge suggests possible infection and requires referral for medical evaluation.

### Treatment of Headache

#### Treatment Goals

The goals of treating headache are (1) to alleviate acute pain, (2) to restore normal functioning, (3) to prevent relapse, and (4) to minimize side effects. For chronic headache, an additional goal is to reduce the frequency of headaches.

#### General Treatment Approach

Most patients with episodic headaches respond adequately to self-treatment with nonpharmacologic interventions, nonprescription medications, or both. However, some patients with episodic headaches and most with chronic headaches are candidates for prescription treatments. Throughout this chapter, the abbreviation *NSAID* will be used to denote the class of nonsalicylate nonsteroidal anti-inflammatory drugs (e.g., ibuprofen and naproxen).

#### **TABLE 5-1 Characteristics of Tension-Type, Migraine, and Sinus Headaches**

			<i>Sinus Headache</i>
--	--	--	-----------------------

	<b><i>Tension-Type Headache</i></b>	<b><i>Migraine Headache</i></b>	
Location	Bilateral Over the top of the head, extending to base of skull	Usually unilateral	Face, forehead, or periorbital area
Nature	Varies from diffuse ache to tight, pressing, constricting pain	Throbbing; may be preceded by an aura	Pressure behind eyes or face; dull, bilateral pain; worse in the morning
Onset	Gradual	Sudden	Simultaneous with sinus symptoms, including purulent nasal discharge
Duration	Minutes to days	Hours to 2 days	Days (resolves with sinus symptoms)
Non-headache symptoms	Scalp tenderness	Nausea	Nasal congestion

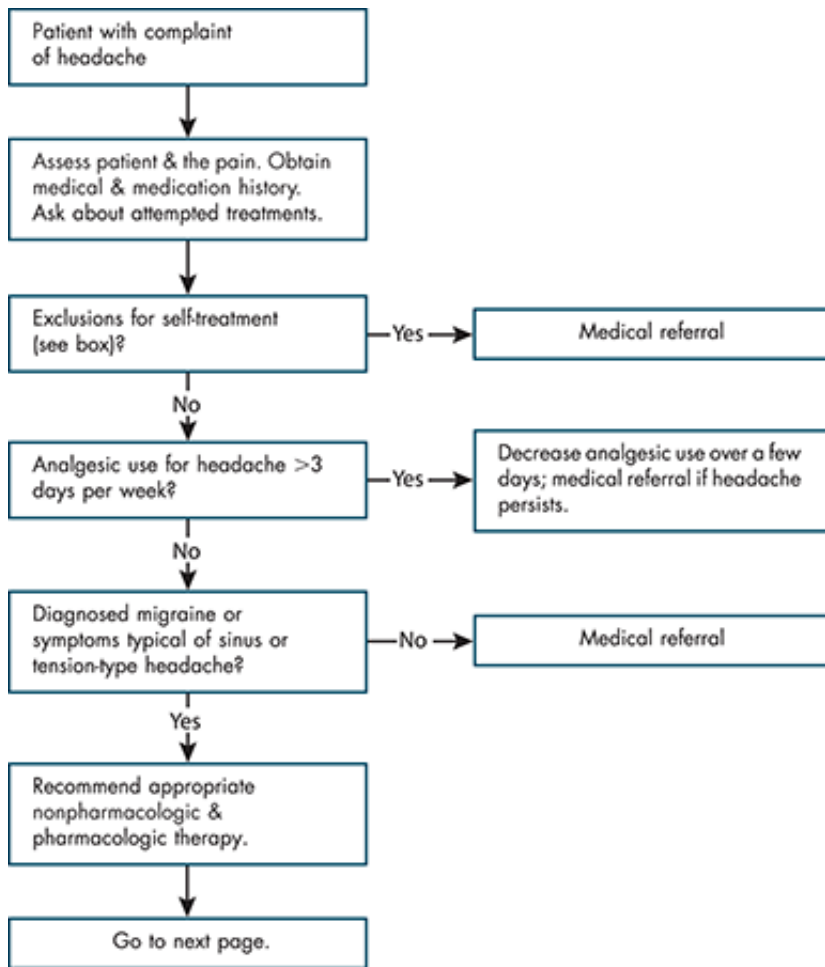

Episodic tension-type headaches often respond well to nonprescription analgesics, including acetaminophen, NSAIDs, and salicylates, especially when taken at onset of the headache. If nonprescription analgesics are used to treat chronic headache, frequency of use should be limited to less than 3 days per week to prevent medication-overuse headache. When medication-overuse headache is suspected, the use of offending agent(s) should be tapered and subsequently eliminated. Most often, tapering of an agent should be done with medical supervision because use of prescription therapies may be needed to combat the increased headaches that temporarily ensue during the days to weeks of the withdrawal period.<sup>10</sup> In addition to nonprescription or prescription medication, chronic tension-type headaches may benefit from physical therapy and relaxation exercises. [Figure 5-1](#) outlines the self-treatment of headaches and lists exclusions for self-treatment.

A medical diagnosis of migraine headache is required before self-treatment can be recommended. Taking an NSAID or salicylate at the onset of symptoms can abort mild or moderate migraine headache. Once a migraine has evolved, analgesics are less effective. Patients with migraines who can predict the occurrence of the headache (e.g., during menstruation) should take an analgesic (usually an NSAID) before occurrence of the event known to trigger the headache, as well as throughout the duration of the event. For patients with coexisting tension and migraine headaches, treatment of the initiating headache type can abort the mixed headache.

Sinus headaches respond well to decongestants (e.g., pseudoephedrine or phenylephrine), which are useful for sinus drainage (see [Chapter 11](#)). Concomitant use of decongestants and nonprescription analgesics can relieve sinus headache pain.

### Nonpharmacologic Therapy

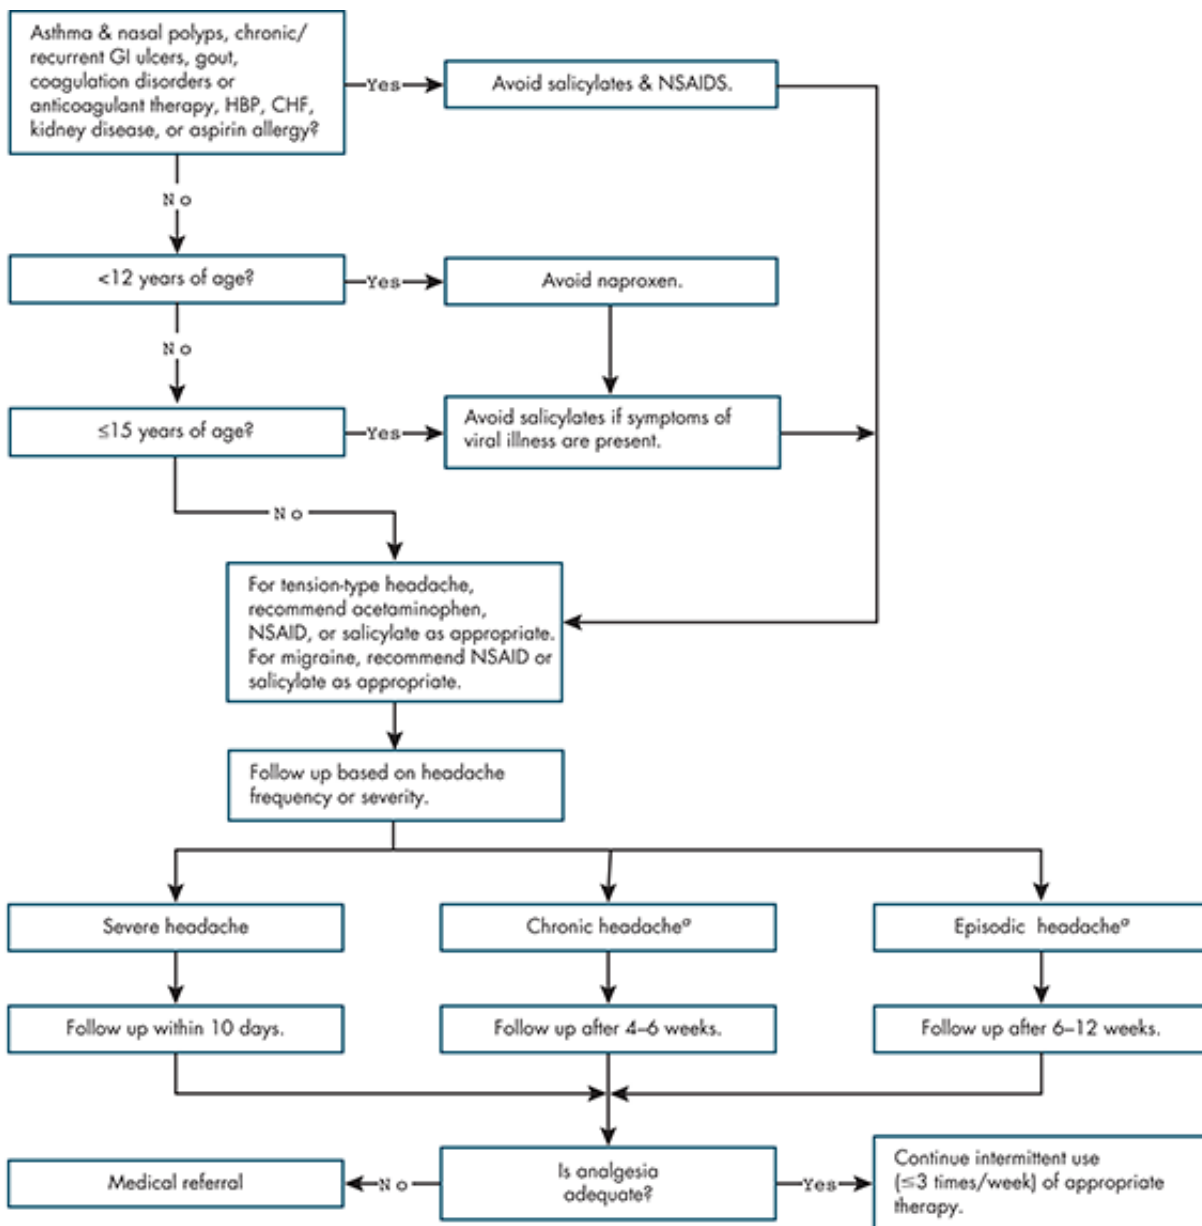

Chronic tension-type headaches may respond to relaxation exercises and physical therapy that emphasizes stretching and strengthening of head and neck muscles. General treatment measures for migraine include maintaining regular sleeping, eating, and exercise schedules, stress management, biofeedback, and cognitive therapy.<sup>7</sup> Some patients benefit from applying ice or cold packs combined with pressure to the forehead or temple areas to reduce pain associated with acute migraine attacks.

### Exclusions for Self-Treatment

- Severe head pain
- Headaches that persist for 10 days with or without treatment
- Last trimester of pregnancy
- <8 years of age
- High fever or signs of serious infection
- History of liver disease or consumption of  $\geq 3$  alcoholic drinks per day
- Headache associated with underlying pathology (secondary headache), except for minor sinus headache
- Symptoms consistent with migraine, but no formal diagnosis of migraine headache

All rights reserved. Any use is subject to the Terms of Use.

<sup>o</sup> Once a diagnosis of chronic tension-type or episodic headache is established, self-care can resume. Avoid using analgesics more often than 3 days per week. Seek medical attention if there is a change in the headache, or if medications are needed for 10 or more consecutive days.

Copyright © American Pharmacists Association  
All rights reserved. Any use is subject to the Terms of Use.

Self-care of headache. Key: CHF = Congestive heart failure; GI = gastrointestinal; HBP = high blood pressure; NSAID = nonsteroidal anti-inflammatory drug; OTC = over-the-counter.

Nutritional strategies are intended to prevent migraine and are based on (1) dietary restriction of foods that contain triggers, (2) avoidance of hunger and low blood glucose (a trigger of migraine), and (3) magnesium supplementation. Advocates of nutritional therapy recommend avoiding known food allergies and foods with vasoactive substances, such as nitrites; tyramine (found in red wine and aged cheese); phenylalanine (found in the artificial sweetener aspartame); monosodium glutamate (often found in Asian food); caffeine; and theobromines (found in chocolate).

### Pharmacologic Therapy

Available nonprescription analgesics for management of headache include acetaminophen, NSAIDs (ibuprofen and naproxen), and salicylates (aspirin and magnesium salicylate). Selection of an analgesic should be based on a careful review of a patient's medical and medication histories. Medical management of nausea accompanying migraine headache also may be indicated to improve symptomatic relief and facilitate medication delivery by the oral route.

### Acetaminophen

Acetaminophen is an effective analgesic and antipyretic. Acetaminophen produces analgesia through central inhibition of prostaglandin synthesis.

Acetaminophen is rapidly absorbed from the gastrointestinal (GI) tract and extensively metabolized in the liver to

inactive glucuronic and sulfuric acid conjugates. Acetaminophen is also metabolized by the cytochrome P450 enzyme system to a hepatotoxic intermediate metabolite that is detoxified by glutathione. When given by suppository, rectal bioavailability of acetaminophen is approximately 50%-60% of that achieved with oral administration. Onset of analgesic activity of acetaminophen is about 30 minutes after oral administration. Duration of activity is about 4 hours and is increased to 6-8 hours with an extended-release formulation.

FDA-approved uses for nonprescription acetaminophen include reducing fever and relieving mild-moderate pain. It is effective in relieving mild-moderate pain of nonvisceral origin (i.e., pain that is not organ related). Randomized, double-blind studies have documented the effectiveness of acetaminophen 1000 mg compared to placebo in patients with migraine and tension-type headache.<sup>12</sup>

Recommended children and adult dosages of acetaminophen are provided in [Tables 5-2](#) and [5-3](#). [Table 5-2](#) provides more stringent nonprescription acetaminophen dosing for children younger than 12 years old. [Table 5-4](#) lists selected trade-name products. Acetaminophen is available for administration in various oral and rectal dosage forms.

Recent changes implemented to decrease pediatric dosing errors with liquid acetaminophen formulations include having only one concentration (160 mg/5 mL) available for all children younger than 12 years.<sup>13</sup> Acetaminophen oral capsules contain tasteless granules that can be emptied onto a spoon containing a small amount of cold beverage (hot beverages result in a bitter taste) or soft food. Capsule contents should not be added to a cup of liquid because large numbers of granules may adhere to the cup.

Acetaminophen is potentially hepatotoxic in doses exceeding 4 g/day, especially with chronic use. Patients should be cautioned against exceeding the dose limit. More conservative dosing (i.e.,  $\leq 2$  g/day) or avoidance may be warranted in patients at increased risk for acetaminophen-induced hepatotoxicity, including those with diagnosed liver disease, concurrent use of other potentially hepatotoxic drugs, poor nutritional intake, or ingestion of three or more alcoholic drinks per day.<sup>14</sup> One alcoholic drink is defined as 12 ounces of beer, 5 ounces of wine, or 1.5 ounces 80-proof liquor.

In 2011, FDA mandated placement of a boxed warning on acetaminophen products indicating that more than 4 g/day may cause severe liver damage. At that time, FDA *recommended* reduction of acetaminophen maximum daily dosage of 3900-4000 mg to 3000-3250 mg in efforts to reduce the risk of accidental overdose. The manufacturer of Tylenol responded to the agency's suggestion and volunteered to reduce their maximum daily dosage for Regular Strength Tylenol to 3250 mg (10 tablets) and Extra Strength Tylenol to 3000 mg (6 tablets). However, most generic manufacturers continued to follow the mandated maximum daily dosage of 4 g/day. Several acetaminophen 650 mg products (tablets and suppositories) are available with labeling that includes a maximum daily dosage of 3900 mg (6 doses).<sup>15</sup> In January 2014, FDA urged health care professionals to no longer prescribe or dispense prescription products containing more than 325 mg acetaminophen per dosage unit. The agency also stated that it intended, in the near future, "to institute proceedings to withdraw approval of prescription combination drug products containing >325 mg of acetaminophen per dosage unit that remain on the market."<sup>16</sup>

Acetaminophen poisoning is a major reason for contacting poison control centers and the leading cause of acute liver failure in the United States.<sup>17</sup> Hepatotoxicity from acetaminophen is probably dose related and is uncommon at recommended doses.<sup>18</sup> Unintended chronic overdose comprises about half of the cases of acetaminophen-induced acute liver failure. Contributing factors include repeated dosing in excess of package labeling, use of more than one product containing acetaminophen, and alcohol ingestion.<sup>19</sup>

**TABLE 5-2 FDA-Approved Dosages for Nonprescription Analgesics in Children Younger than 12 Years<sup>a</sup>**

		<i>Ibuprofen (mg) Dose by Body Weight (mg/kg)</i>	<i>Acetaminophen (mg)</i>	<i>Aspirin (mg)</i>
<b>Age (years)</b>	<b>Weight (lb)</b>	<b>5-10 mg/kg</b>	<b>10-15 mg/kg</b>	<b>10-15 mg/kg</b>
<2	<24	Ask a doctor <sup>a</sup>	Ask a doctor <sup>a</sup>	Ask a doctor <sup>a</sup>
2-3	24-35	100	160	160
4-5	36-47	150	240	240
6-8	48-59	200	320	320
9-10	60-71	250	400	400
11	72-95	300	480	480

<sup>a</sup> OTC labeling limits use to children over age 3. For patients seeking dosing advice for younger children, weight-based dosing is recommended.

**TABLE 5-3 Recommended Dosages of Nonprescription Analgesics for Adults and Children 12 Years and Older**

<b>Agent</b>	<b>Dosage Forms</b>	<b>Usual Adult Dosage (maximum daily dosage)</b>
Acetaminophen <sup>a,b</sup>	Immediate-release, extended-release, effervescent, disintegrating, rapid-release, and chewable tablets; capsules; liquid drops; elixir; suspension; suppositories	325-1000 mg every 4-6 hours (suggested 3250 mg <sup>a</sup> )
Ibuprofen	Immediate-release and chewable tablets; capsules; suspension; liquid drops	200-400 mg every 4-6 hours (1200 mg)
Naproxen sodium	Tablets	220 mg every 8-12 hours (660 mg) Over age 65 years: 220 mg every 12 hours (440 mg)
Aspirin	Immediate-release, buffered, enteric-coated, film-coated, effervescent, and chewable tablets; suppositories	650-1000 mg every 4-6 hours (4000 mg)
Magnesium salicylate	Tablets	650 mg every 4 hours or 1000 mg every 6 hours (4000 mg)

<sup>a</sup> The manufacturer's voluntary dosing reductions in 2011 resulted in the following dosage Extra Strength Tylenol: 2 tablets (500 mg each) every 6 hours with a maximum daily dosage of 3000 mg (6 tablets). The maximum daily dosage for Regular Strength Tylenol was reduced to 3250 mg. However, a maximum daily dosage of 4000 mg is allowed for acetaminophen labeling.<sup>15</sup>

<sup>b</sup> In January 2014, FDA urged health care professionals to no longer prescribe or dispense prescription products containing >325 mg acetaminophen per dosage unit. The agency also stated that it intended, in the near future, "to institute proceedings to withdraw approval of prescription combination drug products containing >325 mg of acetaminophen per dosage unit that remain on the market."<sup>16</sup>

Early symptoms of acetaminophen intoxication can include nausea, vomiting, drowsiness, confusion, and abdominal pain, but these symptoms may be absent, belying the potential severity of the exposure. Serious clinical manifestations of hepatotoxicity begin 2-4 days after acute ingestion of acetaminophen and include increased plasma aspartate aminotransferase (AST) and alanine aminotransferase (ALT); increased plasma bilirubin with jaundice; prolonged prothrombin time; and obtundation. In the majority of cases, hepatic damage is reversible over a period of weeks or months, but more severe cases may require liver transplant or result in fatal hepatic necrosis.

**TABLE 5-4 Selected Single-Entity Nonprescription Acetaminophen Products**

<b>Trade Name</b>	<b>Acetaminophen Content</b>
<b>Pediatric Formulations</b>	
Children's Tylenol Meltaway Tablets	80 mg
FeverAll Infants' Suppositories	80 mg
FeverAll Children's Suppositories	120 mg
FeverAll Junior Strength Suppositories	325 mg
Jr Tylenol Meltaway Tablets	160 mg
Children's Tylenol Oral Suspension	160 mg/5 mL
Infants' Tylenol Oral Suspension	160 mg/5 mL
<b>Adult Formulations</b>	

Tylenol Arthritis Pain Extended Release Caplets	650 mg
Tylenol 8 hour Extended Release Caplets	650 mg
Tylenol Extra Strength Caplets	500 mg
Tylenol Rapid Blast Liquid	500 mg/15 mL
Tylenol Regular Strength Tablets	325 mg

Because of the potential seriousness of acetaminophen overdose, all cases should be referred to a poison control center or emergency department. Supportive care is provided along with activated charcoal to reduce acetaminophen absorption in patients who present within 1 hour after ingestion. When acetaminophen serum levels, related to time since ingestion, exceed those known to cause hepatic injury, prompt administration of acetylcysteine is warranted to supplement glutathione, which is essential for deactivation of a toxic intermediate metabolite of acetaminophen. Acetylcysteine's effectiveness decreases if it is administered more than 8 hours after acute ingestion. For patients with chronic ingestions of greater than 4 g/day, administration of acetylcysteine is indicated until liver toxicity is ruled out by assessment of liver function tests.

Asymptomatic elevations in serum ALT have been reported in otherwise healthy individuals taking acetaminophen 4 g/day. In a prospective study, 39% of patients experienced ALT elevations greater than three times the upper limit of normal. These elevations generally appeared in the first week of use, with some resolution despite continued dosing.

The clinical significance of this observation is uncertain.<sup>20</sup>

Patients with glucose-6-phosphate dehydrogenase deficiency, a hereditary disease that causes premature breakdown of red blood cells, should use caution when taking acetaminophen. Patients with hypersensitivity to acetaminophen are contraindicated for future use.

Rare but serious cutaneous adverse reactions (SCAR) have been found to be associated with use of acetaminophen as well as other analgesics including NSAIDs. Skin reactions may occur in either new or ongoing users of the drug and have the potential to progress into life-threatening rash such as Stevens-Johnson syndrome and toxic epidermal necrolysis. Although these events are very rare, it is important to be aware of the possibility and refer patients for further evaluation.<sup>21</sup>

Clinically important drug interactions of acetaminophen are listed in [Table 5-5](#). For patients taking warfarin, acetaminophen is considered the analgesic of choice; however, it has been associated with increases in international normalized ratio (INR). Regular acetaminophen use should be discouraged in patients on warfarin. Patients who require higher scheduled doses (e.g., those with osteoarthritis) should have their INR monitored and warfarin adjusted as acetaminophen doses are titrated.

**TABLE 5-5 Clinically Important Drug-Drug Interactions with Nonprescription Analgesic Agents**

<i>Analgesic/Antipyretic</i>	<i>Drug</i>	<i>Potential Interaction</i>	<i>Management/Preventive Measures</i>
Acetaminophen	Alcohol	Increased risk of hepatotoxicity	Avoid concurrent use if possible; minimize alcohol intake when using acetaminophen.
Acetaminophen	Warfarin	Increased risk of bleeding (elevations in INR)	Limit acetaminophen to occasional use; monitor INR for several weeks when acetaminophen 2-4 grams daily is added or discontinued in patients on warfarin.
Aspirin	Valproic acid	Displacement from protein-binding sites and inhibition of valproic acid metabolism	Avoid concurrent use; use naproxen instead of aspirin (no interaction).
Aspirin	NSAIDs, including COX-2 inhibitors	Increased risk of gastroduodenal ulcers and bleeding	Avoid concurrent use if possible; consider use of gastroprotective agents (e.g., PPIs).
Ibuprofen	Aspirin	Decreased antiplatelet effect of aspirin	Aspirin should be taken at least 30 minutes before or 8 hours after ibuprofen. Use acetaminophen (or other analgesic) instead of ibuprofen.
Ibuprofen	Phenytoin	Displacement from	Monitor free phenytoin levels; adjust

		protein-binding sites	dose as indicated.
NSAIDs (several)	Bisphosphonates	Increased risk of GI or esophageal ulceration	Use caution with concomitant use.
NSAIDs (several)	Digoxin	Renal clearance of digoxin inhibited	Monitor digoxin levels; adjust dose as indicated.
Salicylates and NSAIDs (several)	Antihypertensive agents, beta-blockers, ACE inhibitors, vasodilators, diuretics	Antihypertensive effect inhibited; possible hyperkalemia with potassium-sparing diuretics and ACE inhibitors	Monitor blood pressure, cardiac function, and potassium levels.
Salicylates and NSAIDs	Anticoagulants	Increased risk of bleeding, especially GI	Avoid concurrent use, if possible; risk is lowest with salsalate and choline magnesium trisalicylate.
Salicylates and NSAIDs	Alcohol	Increased risk of GI bleeding	Avoid concurrent use, if possible; minimize alcohol intake when using salicylates and NSAIDs.
Salicylates and NSAIDs (several)	Methotrexate	Decreased methotrexate clearance	Avoid salicylates and NSAIDs with high-dose methotrexate therapy; monitor levels with concurrent treatment.
Salicylates (moderate-high doses)	Sulfonylureas	Increased risk of hypoglycemia	Avoid concurrent use, if possible; monitor blood glucose levels when changing salicylate dose.

Key: ACE = Angiotensin-converting enzyme; COX = cyclooxygenase; GI = gastrointestinal; INR = international normalized ratio; NSAID = nonsteroidal anti-inflammatory drug; PPI = protein pump inhibitor.

### Nonsteroidal Anti-Inflammatory Drugs

NSAIDs relieve pain through central and peripheral inhibition of cyclooxygenase (COX) and subsequent inhibition of prostaglandin synthesis.

All nonprescription NSAIDs are rapidly absorbed from the GI tract with consistently high bioavailability. They are extensively metabolized, mainly by glucuronidation, to inactive compounds in the liver. Elimination occurs primarily through the kidneys. Onset of activity for naproxen sodium and standard ibuprofen is about 30 minutes. Ibuprofen sodium dehydrate is absorbed more rapidly and has a slightly shorter onset of action than that of standard ibuprofen. Duration of activity for naproxen sodium is up to 12 hours and 6-8 hours for ibuprofen. FDA-approved uses for nonprescription NSAIDs include reducing fever and relieving minor pain associated with headache, the common cold, toothache, muscle ache, backache, arthritis, and menstrual cramps. NSAIDs have analgesic, antipyretic, and anti-inflammatory activity, and they are useful in managing mild-moderate pain of nonvisceral origin. Naproxen sodium and ibuprofen became available for nonprescription use in 1994 and 1984, respectively, and both are propionic acid derivatives. Although FDA approved ketoprofen for nonprescription use, no commercially available nonprescription analgesics currently contain this agent.

Recommended children and adult dosages of nonprescription NSAIDs are provided in [Tables 5-2](#) and [5-3](#). [Table 5-6](#) lists selected trade-name products. Unfortunately, liquid formulations of ibuprofen have the same pediatric dosing errors mentioned earlier for acetaminophen, but no changes have been implemented to mitigate the dosing errors for ibuprofen. A dose-effect relationship has been demonstrated for ibuprofen analgesia in the range of 100-400 mg. NSAID overdoses usually produce minimal symptoms of toxicity and are rarely fatal. In a prospective study of 329 cases of ibuprofen overdose, 43% of ibuprofen-overdose patients were asymptomatic. Among patients with symptoms, GI and central nervous system (CNS) symptoms were most common (in 42% and 30% of patients, respectively) and included nausea, vomiting, abdominal pain, lethargy, stupor, coma, nystagmus, dizziness, and light-headedness. Hypotension, bradycardia, tachycardia, dyspnea, and painful breathing were also reported.<sup>22</sup>

**TABLE 5-6 Selected Single-Entity Nonprescription Nonsteroidal Anti-Inflammatory Drugs**

<i>Trade Name</i>	<i>Primary Ingredients</i>

<b>Pediatric Formulations of Ibuprofen Products</b>	
Children's Advil Suspension	Ibuprofen 100 mg/5 mL
Children's Motrin Suspension	Ibuprofen 100 mg/5 mL
Infants' Motrin Concentrated Drops	Ibuprofen 50 mg/1.25 mL
Junior Strength Motrin Chewable Tablets	Ibuprofen 100 mg
<b>Adult Formulations of Ibuprofen Products</b>	
Advil Migraine Solubilized Capsules	Ibuprofen 200 mg
Advil Tablets/Caplets/Gel Caplets/Film-Coated Tablets <sup>a</sup>	Ibuprofen 200 mg
Motrin IB Tablets/Caplets	Ibuprofen 200 mg
<b>Naproxen Products</b>	
Aleve Tablets/Caplets/Liquid Gels/Gel Caps	Naproxen sodium 220 mg
Midol Extended Relief Caplets	Naproxen sodium 220 mg

<sup>a</sup> Provided as 256 mg of ibuprofen sodium.

The most frequent adverse effects of NSAIDs involve the GI tract and include dyspepsia, heartburn, nausea, anorexia, and epigastric pain, even among children using pediatric formulations. NSAIDs may be taken with food, milk, or antacids if upset stomach occurs. Tablets should be taken with a full glass of water, suspensions should be shaken thoroughly, and enteric-coated or sustained-release preparations should be neither crushed nor chewed. Other adverse effects include dizziness, fatigue, headache, and nervousness. Rashes or itching, photosensitivity, and fluid retention or edema may occur in some patients; however, at normal doses, these effects are usually rare. GI ulceration, perforation, and bleeding are uncommon but serious complications of NSAID use. Risk factors include age older than 60 years, prior ulcer disease for GI bleeding, concurrent use of anticoagulants (including aspirin), higher dose or longer duration of treatment, and moderate use of alcohol. Package labeling for NSAIDs includes warnings about stomach bleeding with adult doses (see the box A Word about NSAIDs and Stomach Bleeding).<sup>23</sup>

#### A Word About NSAIDs and Stomach Bleeding

In 2010, FDA approved a label warning concerning stomach bleeding for nonprescription products that contain NSAIDs in adult doses:

**Stomach bleeding warning:** This product contains an NSAID, which may cause severe stomach bleeding. The chance is higher if you:

- Are age 60 or older.
- Have had stomach ulcers or bleeding problems.
- Take a blood thinning (anticoagulant) or steroid drug.
- Take other drugs containing prescription or nonprescription NSAIDs (aspirin, ibuprofen, naproxen, or others).
- Have 3 or more alcoholic drinks every day while using this product.
- Take more or for a longer time than directed.

Ask a doctor before use if the stomach bleeding warning applies to you:

- You have a history of stomach problems, such as heartburn.
- You have high blood pressure, heart disease, liver cirrhosis, or kidney disease.
- You are taking a diuretic.

Stop use and ask a doctor if:

- You experience any of the following signs of stomach bleeding:
  - Feel faint.
  - Vomit blood.
  - Have bloody or black stools.<sup>34</sup>
  - Have stomach pain that does not get better.

NSAIDs are associated with increased risk for myocardial infarction, heart failure, hypertension, and stroke. The mechanism by which the risk is conferred is not clear, but it may be related to increased thromboxane A<sub>2</sub> activity and

suppressed vascular prostacyclin synthesis, resulting in vasoconstriction and platelet aggregation. According to results from a meta-analysis of randomized trials, the cardiovascular risk of nonselective NSAIDs appears to depend on dose and duration. In addition, the risk differs between individual nonselective NSAIDs. For instance, ibuprofen has been associated with a significant increase in cardiovascular risk, whereas naproxen has not; thus, naproxen is considered the preferred, safer option.<sup>24</sup>

The American Heart Association recommends that patients with or at high risk for cardiovascular disease (e.g., hyperlipidemia, hypertension, diabetes, or other macrovascular disease) avoid NSAIDs. Low-risk patients should exercise caution in using NSAIDs by taking the minimum dose for the shortest duration needed to control symptoms. Clinical evidence has shown that the use of NSAIDs in patients who have a past history of myocardial infarction will increase their risk of future cardiovascular events indefinitely.<sup>25</sup>

Clinically important drug-drug interactions of NSAIDs are listed in [Table 5-5](#). Ibuprofen increases bleeding time by reversibly inhibiting platelet aggregation. Patients taking aspirin for cardiovascular prophylaxis should take it at least 1 hour before or 8 hours after ibuprofen to avoid a pharmacodynamic interaction that inhibits the antiplatelet effect of aspirin. In doses of 1200-2400 mg/day, ibuprofen does not appear to affect the INR in patients taking warfarin. However, ibuprofen should not be recommended for self-treatment in patients who are concurrently taking anticoagulants because its antiplatelet activity could increase GI bleeding.

Patients who ingest three or more alcoholic drinks per day should be cautioned about the increased risk of adverse GI events, including stomach bleeding. They also should be referred to their primary care provider for monitoring of their NSAID use.

NSAIDs may decrease renal blood flow and glomerular filtration rate as a result of inhibition of renal prostaglandin synthesis. Consequently, increased blood urea nitrogen and serum creatinine values can occur, often with concomitant sodium and water retention. Advanced age, hypertension, diabetes, atherosclerotic cardiovascular disease, and use of diuretics appear to increase the risk of renal toxicity with ibuprofen use. Therefore, patients with a history of impaired renal function, congestive heart failure, or diseases that compromise renal hemodynamics should not self-medicate with NSAIDs.

## Salicylates

Salicylates inhibit prostaglandin synthesis from arachidonic acid by inhibiting both isoforms of the COX enzyme (COX-1 and COX-2). The resulting decrease in prostaglandins reduces the sensitivity of pain receptors to the initiation of pain impulses at sites of inflammation and trauma. Although some evidence suggests that aspirin also produces analgesia through a central mechanism, its site of action is primarily peripheral.

Salicylates are absorbed by passive diffusion of the nonionized drug in the stomach and small intestine. Factors affecting absorption include dosage form, gastric pH, gastric-emptying time, dissolution rate, and the presence of antacids or food. Absorption from immediate-release aspirin products is complete. Rectal absorption of a salicylate suppository is slow and unreliable, as well as proportional to rectal retention time.

Once absorbed, aspirin is hydrolyzed in the plasma to salicylic acid in 1-2 hours. Salicylic acid is widely distributed to all tissues and fluids in the body, including the CNS, breast milk, and fetal tissue. Protein binding is concentration dependent. At concentrations lower than 100 mg/mL, approximately 90% of salicylic acid is bound to albumin, whereas at concentrations greater than 400 mg/mL, approximately 75% is bound. Salicylic acid is largely eliminated through the kidney. Urine pH determines the amount of unchanged drug that is eliminated, with urinary concentrations increasing substantially in more alkaline urine (pH ~8).

Dosage form alterations include enteric coating, buffering, and sustained release. These formulations were developed to change the rate of absorption and/or reduce the potential for GI toxicity. Enteric-coated aspirin is absorbed only from the small intestine; its absorption is markedly slowed by food, which is attributed to prolonged gastric-emptying time. Hypochlorhydria from acid-suppressing agents (especially proton pump inhibitors) may result in dissolution of enteric-coated products in the stomach, negating any potential benefit on local gastric toxicity. For patients requiring rapid pain relief, enteric-coated aspirin is inappropriate because of the delay in absorption and the time to analgesic effect.

Buffered aspirin products are available in both tablet and effervescent forms. Although buffered products are absorbed more rapidly than are nonbuffered products, time to onset of effect is not improved appreciably. Common buffers include aluminum hydroxide; magnesium carbonate, hydroxide, or oxide; calcium carbonate; and sodium bicarbonate (in effervescent formulations). Some effervescent aspirin solutions contain large amounts of sodium and must be avoided by patients who require restricted sodium intake (e.g., patients with hypertension, heart failure, or renal failure). Sustained-release aspirin is formulated to prolong duration of action by slowing dissolution and absorption. Magnesium salicylate is available as a tablet or capsule. Sodium salicylate is approved for nonprescription use, but it is not currently available in a commercial product.

FDA-approved uses for salicylates include treatment of symptoms for osteoarthritis, rheumatoid arthritis, and other rheumatologic diseases, as well as temporary relief of minor aches and pains associated with backache or muscle aches. Salicylates also are effective in treating mild-moderate pain from musculoskeletal conditions and fever.

Because of its inhibitory effects on platelet function, aspirin is also indicated for prevention of thromboembolic events

(e.g., myocardial infarction and stroke) in high-risk patients.

Recommended children and adult dosages of nonprescription salicylates are provided in [Tables 5-2](#) and [5-3](#). [Table 5-7](#) provides selected salicylate products. Aspirin dosages ranging from 4-6 g/day are usually needed to produce anti-inflammatory effects. The maximum analgesic dosage for self-medication with aspirin is 4 g/day; therefore, anti-inflammatory activity often will not occur unless the drug is used at the high end of the acceptable dosage range.

**TABLE 5-7 Selected Adult Formulations of Nonprescription Single-Entity Salicylate Products**

<i>Trade Name</i>	<i>Primary Ingredients</i>
Bayer Low-Dose Aspirin Tablets	Aspirin 81 mg
St. Joseph 81 mg Chewable Aspirin	Aspirin 81 mg
Ecotrin Regular Strength Safety Enteric-Coated Tablets	Aspirin 325 mg
Genuine Bayer Aspirin Tablets	Aspirin 325 mg
Bayer Plus Extra Strength	Aspirin 500 mg
Extra Strength Doan's Caplets	Magnesium salicylate 580 mg
Percogesic Maximum Strength Backache Relief Coated Caplets	Magnesium salicylate tetrahydrate 580 mg

Mild salicylate intoxication (salicylism) occurs with chronic toxic blood levels, generally achieved in adults who take 90-100 mg/kg/day of a salicylate for at least 2 days. Conditions that predispose patients to salicylate toxicity include (1) marked renal or hepatic impairment (e.g., uremia, cirrhosis, or hepatitis); (2) metabolic disorders (e.g., hypoxia or hypothyroidism); (3) unstable disease (e.g., cardiac arrhythmias, intractable epilepsy, or poorly controlled diabetes); (4) status asthmaticus; and (5) multiple comorbidities. Symptoms include headache, dizziness, tinnitus, difficulty hearing, dimness of vision, mental confusion, lassitude, drowsiness, sweating, thirst, hyperventilation, nausea, vomiting, and occasional diarrhea. These symptoms can all be reversed by lowering the plasma concentration to a therapeutic range. Tinnitus, typically one of the early signs of toxicity, should not be used as a sole indicator of salicylate toxicity.

Acute salicylate intoxication is categorized as mild (ingestion of <150 mg/kg), moderate (ingestion of 150-300 mg/kg), or severe (ingestion of >300 mg/kg). Symptoms depend on the concentration and include lethargy, nausea, vomiting, dehydration, tinnitus, hemorrhage, tachypnea and pulmonary edema, convulsions, and coma. Acid-base disturbances are prominent and range from respiratory alkalosis to metabolic acidosis. Initially, salicylate affects the respiratory center in the medulla, producing hyperventilation and respiratory alkalosis. In severely intoxicated adults and in most salicylate-poisoned children younger than 5 years, respiratory alkalosis progresses rapidly to metabolic acidosis. Children are more prone than are adults to develop high fever in salicylate poisoning. Hypoglycemia resulting from increased glucose utilization may be especially serious in children. Bleeding may occur from the GI tract or mucosal surfaces, and petechiae are a prominent feature at autopsy.

Emergency management of acute salicylate intoxication is directed toward preventing absorption of salicylate from the GI tract and providing supportive care. Activated charcoal should be used at home only if recommended by poison control center or emergency department personnel. In an emergency department setting, gastrointestinal decontamination with gastric lavage or activated charcoal may be undertaken. Enhancing renal elimination can be accomplished through alkalinization of the urine. Dosing recommendations for the use of activated charcoal are included in [Chapter 20](#).

Aspirin is known to commonly cause dyspepsia, which may be minimized by taking it with food. In addition, aspirin is associated with gastritis and ulceration of the upper GI tract. It produces GI mucosal damage by penetrating the protective mucous and bicarbonate layers of the gastric mucosa and permitting back diffusion of acid, thereby causing cellular and vascular erosion. Two distinct mechanisms cause this problem: (1) a local irritant effect resulting from the medication contacting the gastric mucosa and (2) a systemic effect from prostaglandin inhibition. Lack of upper abdominal pain or discomfort is not a reliable indicator for the absence of gastrointestinal damage associated with use of aspirin or other NSAIDs.<sup>26</sup>

The use of aspirin has been shown to increase the risk for serious upper GI events two- to fourfold.<sup>26</sup> It is recommended that the lowest effective dose be used for cardioprotection (usually 81 mg) and that the use of proton pump inhibitors may be indicated for gastric protection.<sup>26</sup> Patients with risk factors for upper GI bleeding should avoid self-treatment with aspirin. These risk factors include (1) history of uncomplicated or bleeding peptic ulcer; (2) age older than 60 years; (3) concomitant use of aspirin or other NSAIDs, anticoagulants, antiplatelet agents, bisphosphonates, selective serotonin reuptake inhibitors, or systemic corticosteroids; (4) infection with *Helicobacter pylori*; (5) rheumatoid arthritis; (6) NSAID-related dyspepsia; and (7) concomitant use of alcohol.<sup>27</sup>

Various aspirin formulations may have different rates of GI side effects. Enteric coating may decrease local gastric

irritation. However, with regard to the risk of major GI ulceration and bleeding, no difference has been identified among plain, enteric-coated, and buffered products.

Serious aspirin intolerance is uncommon and consists of two types: cutaneous (urticaria and angioedema) or respiratory (bronchospasm, laryngospasm, and rhinorrhea). The mechanism is not immunologically mediated. Risk factors for serious aspirin intolerance include chronic urticaria (for the cutaneous type) and asthma with nasal polyps (for the respiratory type). Ten percent of people diagnosed with asthma have aspirin sensitivity.<sup>28</sup> Severity of the intolerance is variable, ranging from minor to severe. Patients with aspirin intolerance generally are advised to avoid aspirin and other NSAIDs. However, the nonacetylated salicylates (magnesium salicylate) are considered safe, and acetaminophen will not cause cross-sensitivity.<sup>28</sup>

Nonprescription salicylates interact with several other important drugs and drug classes. Clinically important drug interactions of salicylates are listed in [Table 5-5](#). When monitoring therapy in patients who are taking high-dose salicylates, health care providers should review current drug interaction references for newly identified interactions. Aspirin ingestion may produce positive results on fecal occult blood testing; therefore, its use should be discontinued for at least 3 days before testing. Similarly, aspirin should be discontinued 2-7 days before surgery and should not be used to relieve pain after tonsillectomy, dental extraction, or other surgical procedures, except under the close supervision of a health care provider. Aspirin can potentiate bleeding from capillary sites such as those found in the GI tract, tonsillar beds, and tooth sockets.

Because of the effect on hemostasis, aspirin is contraindicated in patients with hypoprothrombinemia, vitamin K deficiency, hemophilia, history of any bleeding disorder, or history of peptic ulcer disease. Patients with compromised renal function have the potential for decreased renal excretion of magnesium, allowing accumulation of toxic levels when taking magnesium salicylate. The maximum 24-hour dose of magnesium salicylate contains 264 mg (11 mEq) of magnesium.

All salicylates should be avoided in patients with a history of gout or hyperuricemia because of dose-related effects on renal uric acid handling. Dosages of 1-2 g/day inhibit tubular uric acid secretion without affecting reabsorption and may increase plasma uric acid levels, which can precipitate or worsen a gout attack. Moderate dosages of 2-3 g/day have little effect on uric acid secretion. More than 5 g/day may decrease plasma uric acid by increasing its renal excretion, but because these salicylate doses are toxic, they should not be used in the clinical management of gout or hyperuricemia.

Reye's syndrome is an acute illness occurring almost exclusively in children 15 years of age or younger. The cause is unknown, but viral and toxic agents, especially salicylates, have been associated with the syndrome. Onset usually follows a viral infection with influenza (type A or B) or varicella zoster (chickenpox). Reye's syndrome is characterized by progressive neurologic damage, fatty liver with encephalopathy, and hypoglycemia. The mortality rate may be as high as 50%.

The American Academy of Pediatrics, FDA, the Centers for Disease Control and Prevention, and the Surgeon General have issued warnings that aspirin and other salicylates (including bismuth subsalicylate and nonaspirin salicylates) should be avoided in children and teenagers who have influenza or chickenpox. The following contraindication is listed on labels of nonprescription aspirin and aspirin-containing products:

Aspirin should not be used in children and teenagers for viral infections, with or without fever, because of the risk of Reye's syndrome with concomitant use of aspirin in certain viral illnesses.

Although a simple viral upper respiratory infection (e.g., a common cold) is not a contraindication to aspirin use, it can be difficult to differentiate symptoms of this type of infection from those of influenza and chickenpox. Many health care providers, therefore, recommend a conservative approach of avoiding aspirin whenever symptoms resembling those of influenza are present. The use of aspirin as a pediatric antipyretic has all but ceased in the United States, as have reports of Reye's syndrome.

FDA requires a warning label regarding alcohol use on all nonprescription analgesic/antipyretic products for adult use. Concurrent use of aspirin with alcohol increases the risk of adverse GI events, including stomach bleeding. Patients who consume three or more alcoholic drinks daily should be counseled about the risks and referred to their primary care provider before using aspirin.

## Combination Products

Many nonprescription analgesics are available in combination products ([Table 5-8](#)).

Caffeine is used as an adjunct to analgesics for tension-type and migraine headaches. It also may have its own analgesic properties and is known to cause withdrawal headache when taken regularly. Combination dosage forms containing a decongestant and either acetaminophen or an NSAID are also available. These combinations appear logical for use in sinus headaches or other indications for which both analgesia and decongestion are needed.

**TABLE 5-8 Selected Nonprescription Combination Analgesic Products**

<i>Trade Name</i>	<i>Primary Ingredients</i>
<b>Acetaminophen-Containing Products</b>	

Excedrin Tension Headache	Acetaminophen 500 mg; caffeine 65 mg
Excedrin PM	Acetaminophen 500 mg; 38 mg
Excedrin Sinus	Acetaminophen 325 mg; phenylephrine 5 mg
Goody's PM Powder	Acetaminophen 500 mg; diphenhydramine 38 mg
Percogesic Original Strength	Acetaminophen 325 mg; diphenhydramine 12.5 mg
Percogesic Extra Strength	Acetaminophen 500 mg; diphenhydramine 12.5 mg
Sudafed PE Pressure + Pain	Acetaminophen 325 mg; phenylephrine 5 mg
Tylenol PM	Acetaminophen 500 mg; diphenhydramine 25 mg
Tylenol Sinus Congestion and Pain	Acetaminophen 325 mg; phenylephrine 5 mg
<b>NSAID-Containing Products</b>	
Advil Cold & Sinus	Ibuprofen 200 mg; pseudoephedrine 30 mg
Advil Congestion Relief	Ibuprofen 200 mg; phenylephrine 10 mg
Aleve-D Sinus & Headache	Naproxen sodium 220 mg; pseudoephedrine 120 mg
Motrin PM	Naproxen sodium 200 mg; diphenhydramine 38 mg
Sudafed 12h Pressure + Pain	Naproxen sodium 220 mg; pseudoephedrine 120 mg
<b>Aspirin-Containing Products</b>	
Anacin Maximum Strength	Aspirin 500 mg; caffeine 32 mg
Anacin Regular Strength	Aspirin 400 mg; caffeine 32 mg
Bayer Cafiaspirina	Aspirin 500 mg; caffeine 40 mg
Excedrin Extra Strength or Excedrin Migraine	Aspirin 250 mg; acetaminophen 250 mg; caffeine 65 mg
Goody's Cool Orange Powder	Aspirin 500 mg; acetaminophen 325 mg; caffeine 65 mg
Goody's Extra Strength Headache Powder	Aspirin 500 mg; acetaminophen 260 mg; caffeine 32.5 mg
Goody's Extra Strength or Goody's Migraine Relief caps	Aspirin 250 mg; acetaminophen 250 mg; caffeine 65 mg

Key: NSAID = Nonsteroidal anti-inflammatory.

Enhanced analgesia has been reported for various antihistamine/analgesic combinations, including orphenadrine/acetaminophen and phenyltoloxamine/acetaminophen. Although these combinations have demonstrated superior efficacy in acute pain, compared with acetaminophen alone, their use is limited by the sedating effects of the antihistamines.

### Pharmacotherapeutic Comparison

#### Aspirin versus Nonacetylated Salicylates

Although definitive clinical data are lacking, aspirin and nonacetylated salicylates are believed to be equal in anti-inflammatory potency; however, aspirin is thought to be a superior analgesic and antipyretic.

#### Aspirin versus Acetaminophen

Numerous controlled studies have demonstrated the equivalent analgesic efficacy of aspirin and acetaminophen on a milligram-for-milligram basis; however, statistical methods used to compare effectiveness between different studies show that acetaminophen may not be quite as effective in some types of pain.<sup>29</sup>

#### Aspirin versus NSAID

Ibuprofen has been shown to be at least as effective as aspirin in treating various types of pain, including dental extraction pain, dysmenorrhea, and episiotomy pain. Because aspirin must be dosed near the self-care maximum to achieve anti-inflammatory effects, NSAIDs may be preferred for self-treatment of inflammatory disorders such as rheumatoid arthritis or acute muscle injury.<sup>29</sup>

#### NSAID versus Acetaminophen

For episodic tension-type headache, acetaminophen 1000 mg appears to provide relief that is equivalent to naproxen 375 mg.<sup>30</sup> For moderate-severe dental or sore throat pain in children, single doses of acetaminophen 7-15 mg/kg produced pain relief similar to that of ibuprofen 4-10 mg/kg. Ibuprofen was a more effective antipyretic, and both drugs were well tolerated.<sup>31</sup> A review of evidence comparing ibuprofen with acetaminophen for headache treatment in children and adults found that only two trials had shown a modest advantage for ibuprofen, and the researchers concluded that the two agents should be considered equally effective.<sup>32</sup> Acetaminophen does not have anti-inflammatory properties, which may limit its effectiveness in some conditions, including dysmenorrhea.<sup>29</sup>

#### Naproxen versus Ibuprofen

Naproxen sodium 220 mg and ibuprofen 200 mg appear to have similar efficacy. The onset of activity also is similar between the two NSAIDs. Duration of action of naproxen is somewhat longer than that of ibuprofen, but the clinical significance of this difference is not clear. Nonetheless, some patients report better response to one NSAID than to another for reasons that are unclear.

### Product Selection Guidelines

#### Special Population Considerations

Age is an important consideration in the selection of an appropriate nonprescription medication for self-treatment of headache. Parents of children younger than 8 years should consult a pediatrician prior to giving their children nonprescription medications. Children 2 years and older may use acetaminophen or ibuprofen. Children 12 years and older may use naproxen. To decrease the risk of Reye's syndrome, parents should not use aspirin or aspirin-containing products in children ages 15 years or younger, unless directed to do so by a primary care provider. Older adults are at increased risk for many adverse effects of salicylates and NSAIDs. Comorbidities, impaired renal function, and use of other medications contribute to the increased risk. Older adults are more vulnerable to serious GI toxicity, hypertensive, and renal effects of salicylates and NSAIDs.<sup>33</sup> For this reason, acetaminophen is generally recognized as the treatment of choice for management of mild-moderate pain in older adults.

When aspirin's effect on hemostasis is a concern and peripheral anti-inflammatory activity is not needed, acetaminophen is an appropriate analgesic for self-medication. Alternatively, if a peripheral anti-inflammatory agent is indicated, prescription salicylate compounds (e.g., salsalate and choline magnesium trisalicylate) are reasonable alternatives.

Acetaminophen crosses the placenta but it is considered safe for use during pregnancy (FDA pregnancy category B). Acetaminophen appears in breast milk, producing a milk-to-maternal plasma ratio of 0.5:1.0. A 1-gram maternal dose has an estimated maximum infant dose that is 1.85% of the maternal dose. The only adverse effect reported in infants exposed to acetaminophen through breast milk is a rarely occurring maculopapular rash, which subsides upon drug discontinuation. Acetaminophen use is considered compatible with breast-feeding.

No evidence exists that NSAIDs are teratogenic in either humans or animals. However, use of these agents is contraindicated during the third trimester of pregnancy because all potent prostaglandin synthesis inhibitors can cause delayed parturition, prolonged labor, and increased postpartum bleeding. Ibuprofen and naproxen are pregnancy categories B and C, respectively, in the first trimester and pregnancy category D in the third trimester. These agents also can have adverse fetal cardiovascular effects (e.g., premature closure of the ductus arteriosus). Lactating women taking up to 2.4 grams of ibuprofen per day showed no measurable excretion of ibuprofen into breast milk; therefore, ibuprofen is considered compatible with breast-feeding. Naproxen also is considered compatible with breast-feeding.

Aspirin should be avoided during pregnancy, especially during the last trimester, and during breast-feeding. Aspirin is pregnancy category D during the last trimester; its ingestion during pregnancy may produce maternal adverse effects, such as anemia, antepartum or postpartum hemorrhage, and prolonged gestation and labor. Regular aspirin ingestion during pregnancy may increase the risk for complicated deliveries, including unplanned cesarean section, breech delivery, or forceps delivery. However, definitive data supporting this concern are lacking.

Aspirin readily crosses the placenta and can be found in higher concentrations in the neonate than in the mother. Salicylate elimination is slow in neonates because of the liver's immaturity and underdeveloped capacity to form glycine and glucuronic acid conjugates and because of reduced urinary excretion resulting from low glomerular filtration rates.

Fetal effects from in utero aspirin exposure include intrauterine growth retardation, congenital salicylate intoxication, decreased albumin-binding capacity, and increased perinatal mortality. In utero mortality results, in part, from antepartum hemorrhage or premature closure of the ductus arteriosus. In utero aspirin exposure within 1 week of delivery can produce neonatal hemorrhagic episodes and/or pruritic rash. Reported neonatal bleeding complications include petechiae, hematuria, cephalhematoma, subconjunctival hemorrhage, and bleeding after circumcision. An increased incidence of intracranial hemorrhage in premature or low-birth-weight infants associated with maternal aspirin use near the time of birth also has been reported.<sup>34</sup> An association between maternal aspirin ingestion, oral clefts, and congenital heart disease has been reported. However, the relationship between maternal aspirin ingestion and congenital malformation remains unresolved, and studies have failed to confirm a relationship between maternal ingestion of aspirin and increased risk for fetal malformation.

Aspirin and other salicylates are excreted into breast milk in low concentrations. After single-dose oral salicylate ingestion, peak milk levels occur at about 3 hours, producing a milk-to-maternal plasma ratio of 3:8. Although no adverse effects on platelet function in nursing infants exposed to aspirin via breast milk have been reported, these agents still must be considered a potential risk.<sup>34</sup>

Patients with renal impairment should exercise caution when using salicylates. Clinically important alterations in renal blood flow resulting in acute reduction in renal function can result from use of even short courses of salicylates. Renally impaired patients should be referred for medical evaluation for assistance in selecting an analgesic.

### Patient Factors

Nonprescription analgesics are available in a number of dosage forms. During patient assessment, health care providers should determine which dosage form will provide an optimum outcome for the patient. If rapid response is desired, then immediate-release oral dosage forms would be preferred over coated or extended-release forms. For patients experiencing migraine headache with severe nausea, rectal dosage forms may be preferred. Liquid dosage forms often are used in children or adult patients who have difficulty swallowing solid dosage forms.

Use of acetaminophen in the pediatric population is complicated by the various available strengths and formulations. Unintended over- or underdosing can occur when parents switch between infant drops (80 mg/0.8 mL) and elixir (160 mg/5 mL), incorrectly assuming that they are the same concentration.

Other issues with pediatric doses of acetaminophen were discussed at a joint meeting of the Nonprescription Drugs Advisory Committee and the Pediatric Advisory Committee; the committees recommended (1) a single concentration for solid-dose, single-ingredient acetaminophen products for children, (2) the addition of weight-based dosing for children ages 2-12, and (3) the addition of new label directions for children ages 6 months to 2 years that would include the indication for fever reduction.

In addition, rapidly growing infants quickly outgrow previous dose requirements. Therefore, recalculation of the pediatric dose according to present age and body weight is recommended at the time of each treatment course. Patients with significant alcohol ingestion (three or more drinks per day) should avoid self-treatment with nonprescription analgesics.

Patients who are intolerant to aspirin also may cross-react with other chemicals or drugs. Up to 15% of patients who are intolerant to aspirin may cross-react when exposed to tartrazine (Food Drug and Cosmetic Yellow Dye No. 5), which can be found in many drugs and foods. Among those with the respiratory type of aspirin sensitivity, the rate of cross-reaction between aspirin and acetaminophen, ibuprofen, and naproxen in documented aspirin-intolerant patients is 7%, 98%, and 100%, respectively.<sup>34</sup> High cross-reaction rates also are reported with some prescription NSAIDs. The proposed mechanism of cross-sensitivity between aspirin and NSAIDs involves shunting arachidonic metabolism down the lipoxygenase pathway (because of inhibition of the COX-1 enzyme pathway), resulting in accumulation of leukotrienes that can cause bronchospasm and anaphylaxis. Acetaminophen and nonacetylated salicylates are weak inhibitors of COX-1 at moderate doses. Therefore, patients with a history of aspirin intolerance should be advised to avoid all aspirin- and NSAID-containing products, and to use acetaminophen or a nonacetylated salicylate, with the caveat that acetaminophen does not offer anti-inflammatory properties.

### Patient Preferences

Consideration of dosing frequency in product selection may improve outcomes for individual patients. Naproxen can be taken 2-3 times daily and may improve patient adherence. Conversely, acetaminophen, ibuprofen, and salicylates may require dosing as frequently as every 4 hours. Because of the delayed absorption of sustained-release aspirin, this dosage form is not useful for rapid pain relief but may be useful as a bedtime medication.

### Complementary Therapies

Butterbur, feverfew, riboflavin, and coenzyme Q10 commonly are used for the prevention of migraine headaches and are discussed in depth in [Chapter 51](#). These natural products are generally ineffective for the treatment of headaches. Other unproven remedies include peppermint oil applied to the forehead and temples for treatment of tension headache, magnesium for treatment and prevention of migraine, and riboflavin for prevention of migraine

headache.

Acupuncture has been used to prevent migraine and tension-type headache. Evaluation of acupuncture is complicated by difficulties in blinding and differences in identifying acupuncture points. Overall, results have been variable, but several randomized, placebo-controlled trials found acupuncture effective in reducing frequency and severity of headache.<sup>35</sup>

### Assessment of Headache: A Case-Based Approach

Before self-treatment of headache can be recommended, the health care provider must assess the patient's headache as to type, severity, location, frequency, intensity over time, and age at onset. The next step is to obtain a medical and psychosocial history. All current medications should be inventoried, and all past and present headache treatments should be reviewed, with emphasis on determining which treatments, if any, were successful or preferred. Secondary headaches, other than minor sinus headache, are excluded from self-treatment. Headache associated with seizures, confusion, drowsiness, or cognitive impairment may be a sign of brain tumor, ischemic stroke, subdural hematoma, or subarachnoid hemorrhage. Headache accompanied by nausea, vomiting, fever, and stiff neck may indicate brain abscess or meningitis. Headache with night sweats, aching joints, fever, weight loss, and visual symptoms (e.g., blurring) in patients with rheumatoid arthritis may indicate cranial arteritis. Headache associated with localized facial pain, muscle tenderness, and limited motion of the jaw may indicate temporomandibular joint disorder.

Cases 5-1 and 5-2 illustrate assessment of a patient with headache.

### Patient Counseling for Headache

To optimize outcomes from therapy, the provider should instruct patients to take an appropriate dose of analgesic early in the course of the headache. The use of nonprescription analgesics to preempt or abort migraine headaches also should be explained to patients with migraines whose headaches are predictable. Patients who have headaches with some frequency should be encouraged to keep a log of their headaches to document triggers, frequency, intensity, duration of episodes, and response to treatment. This record also may be helpful in identifying factors that can improve headache prevention and treatment. Patients should be advised that continuing or escalating pain can be a sign of a more serious problem and that prompt medical attention is warranted. Appropriate drug and nondrug measures for treating headaches should be explained to the patient. Frequent use of nonprescription analgesics is not appropriate because of the risk for medication-overuse headache. Providers should convey the message that nonprescription analgesics are potent medications with accompanying potential adverse effects, interactions, and precautions/warnings. The box Patient Education for Headache lists specific information to provide patients.

### Case 5-1

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient states that a severe headache took place yesterday and incapacitated him for almost 8 hours. The pain eventually subsided, but nothing he could do would make it stop. This type of headache has happened several times in the past 2 months.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Bright light and loud sounds made the pain worse. Even slight movements of his head resulted in discomfort.
c. description of the patient's efforts to relieve the symptoms	He states that the only thing he could do was to lie down on his bed with the curtains drawn and the door shut. Acetaminophen has not been helping.

d. patient's identity	Dom Rugolo
e. age, sex, height, and weight	26 years old, male, 6 ft 1 in., 245 lb
f. patient's occupation	Produce manager at a grocery store
g. patient's dietary habits	He eats healthy some of the time but does like fruits and vegetables. He sometimes has difficulty eating regularly. He skips breakfast a lot because of his busy schedule and often eats frozen dinners because they are quick and easy.
h. patient's sleep habits	He has no problems sleeping. Because of the nature of his work, he has to be up at 5 am most days, but he tries to compensate for the early rising by going to bed at a decent hour.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	He has mild acne on his face that is currently being treated with tretinoin cream 0.025% applied topically daily.
j. allergies	Bactrim caused a bad rash a few years ago.
k. history of other adverse reactions to medications	None
l. other (describe) _____	He does not smoke but does drink infrequently with friends (1 or 2 beers every few weeks).
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s) (Table 5-1).	Mr. Rugolo might be having migraine headaches as indicated by intense pain that is exacerbated by bright lights, sounds, and head movement.
3. Identify exclusions for self-treatment (Figure 5-1).	Undiagnosed migraine is an exclusion for self-treatment.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical practitioner is required, and share this information with the patient or caregiver.	Options include: (1) Refer Mr. Rugolo to an appropriate health care provider. (2) Recommend self-care with a nonprescription analgesic. (3) Recommend self-care until Mr. Rugolo can see an appropriate health care provider. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Referral to a health care provider is appropriate for Mr. Rugolo. He may need a prescription-only therapy that is specific for migraines. Until a health care provider can be seen, the patient should take ibuprofen 200 mg every 4-6 hours. The dosage can be increased to 400 mg if necessary but is limited to 6 tablets per day. The patient should take the medication as soon

	as he feels the headache begin.
6. Describe the recommended therapeutic approach to the patient or caregiver.	“What you have been experiencing may be migraine headaches. It is recommended that you seek evaluation by your primary care provider to determine appropriate treatment. Take ibuprofen at the onset of headache until you can see your health care provider.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“Ibuprofen may be a good alternative to the acetaminophen you were taking because it is in a different class of medication and exerts its therapeutic action in a different manner. The most benefit will be seen if the ibuprofen is taken at the earliest sign of headache, rather than waiting for the pain to become severe.”
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	“Take ibuprofen 200 mg, 1 tablet every 4-6 hours. This dosage may be increased to 400 mg (2 tablets) every 4-6 hours if needed. Do not exceed 6 tablets in a 24-hour period.”
b. maximum number of days the therapy should be employed	“Use this medication only until you are able to see your health care provider. Self-care for a headache should not exceed 10 days. Also, limit treatment to 3 days per week.”
c. product administration procedures	“Start ibuprofen at the first sign of headache.”
d. expected time to onset of relief	“Relief should begin in 30-60 minutes.”
e. degree of relief that can be reasonably expected	“Complete resolution of your symptoms is unlikely. For this reason, you will need to see your health care provider.”
f. most common side effects	“Stomach upset. Taking ibuprofen with food may help prevent that.”
g. side effects that warrant medical intervention should they occur	“Ibuprofen should be stopped if there is severe stomach pain, bloody vomit, black stool, abnormal bruising or bleeding, or allergic reaction (swelling of the face or throat, difficulty breathing).”
h. patient options in the event that condition worsens or persists	“Follow up with the health care provider.”
i. product storage requirements	“Store ibuprofen in a closed container at room temperature away from moisture and children.”
j. Specific nondrug measures	“Keep track of events prior to the headaches to try and determine possible triggers.”

Solicit follow-up questions from the patient or caregiver.	“Are there effective treatments for these headaches that my doctor can give me? I don’t want to keep having my life disrupted by them.”
Answer the patient’s or caregiver’s questions.	“Multiple prescription medications for migraine headaches that have established safety and efficacy are available. Your health care provider will determine the appropriate course of treatment to help you minimize the effects that the headaches have on your life.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Call the patient in a few days to determine whether he is receiving further medical care.

**Case 5-2**

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient’s symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient states that she has had two mild headaches in the past few weeks. Both times the pain went from the top to the base of her head. The pain lasted only a few hours and went away by itself, but it was significant enough to prevent her from getting her work done for class. She wants to plan ahead for the next headache so she does not have to sacrifice study time.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient’s symptom(s)	The headaches have been happening before exams when her stress is at its peak.
c. description of the patient’s efforts to relieve the symptoms	She states that she stopped focusing on her work and relaxed until she fell asleep.
d. patient’s identity	Marta Schuler
e. age, sex, height, and weight	22 years old, female, 5 ft 8 in., 130 lb
f. patient’s occupation	Full-time student
g. patient’s dietary habits	She tries to eat healthy but is often on the run and skips breakfast frequently. For lunch she usually grabs a bagel and tea from the cafeteria. Dinner is usually a wrap or a salad, and she snacks on cashews throughout the day.
h. patient’s sleep habits	She tries to go to bed by midnight because she has class at 8 am. She sometimes stays up late studying, but that happens infrequently and usually does not disrupt her normal sleep pattern.
i. concurrent medical conditions,	She has mild asthma for which she has an emergency inhaler that she

prescription and nonprescription medications, and dietary supplements	has not needed in months.
j. allergies	None
k. history of other adverse reactions to medications	None
l. other (describe) _____	Ms. Schuler drinks socially on the weekend and says that she has a couple of drinks to unwind. She does not smoke.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s) (Table 5-1).	Ms. Schuler is having a tension headache that is most likely due to the stress of school.
3. Identify exclusions for self-treatment (Figure 5-1).	Ms. Schuler has no exclusions for self-treatment.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical practitioner is required, and share this information with the patient or caregiver.	Options include: (1) Refer Ms. Schuler to an appropriate health care provider. (2) Recommend self-care with a nonprescription analgesic. (3) Recommend self-care until Ms. Schuler can see an appropriate health care provider. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Ms. Schuler should use a nonprescription analgesic to help relieve her headache pain. Acetaminophen is an appropriate medication for short-term treatment for her symptoms.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"What you have been experiencing may be tension headaches. It is likely a result of the stress you are experiencing from school. Taking acetaminophen will help to relieve the symptoms."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"When taken as directed, acetaminophen can provide quick relief of headache symptoms and has a lower chance of gastrointestinal side effects compared with NSAIDs."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	"Take acetaminophen 500 mg, 1 tablet every 6 hours. This dosage may be increased to 2 tablets every 6 hours, if needed. Do not take more than

	6 tablets (3000 mg) in a 24-hour period. Note that many nonprescription and prescription products include acetaminophen, so avoid taking more than one product containing acetaminophen.”
b. maximum number of days the therapy should be employed	“Take the acetaminophen for no more than 10 days. Also, limit future treatment to 3 days per week.”
c. product administration procedures	“Start acetaminophen when you feel a headache starting. Take the medication with a full glass of water.”
d. expected time to onset of relief	“Relief should begin in 30-60 minutes.”
e. degree of relief that can be reasonably expected	“Complete resolution of your symptoms is possible.”
f. most common side effects	“Nausea and vomiting are the most common side effects.”
g. side effects that warrant medical intervention should they occur	“Acetaminophen should be stopped if you experience yellowing of the skin or eyes, bloody vomit, black stool, abnormal bruising or bleeding, or allergic reaction (hives, swelling of the face, difficulty breathing).”
h. patient options in the event that condition worsens or persists	“If acetaminophen does not relieve your headache, you also may try a nonsteroidal anti-inflammatory drug such as ibuprofen or naproxen. Otherwise, seek advice from your health care provider.”
i. product storage requirements	“Store acetaminophen in a closed container at room temperature away from moisture and children.”
j. Specific nondrug measures	“Managing your stress may help you avoid tension headaches. Relaxation exercises can help with stress management.”
Solicit follow-up questions from the patient or caregiver.	“Can I consume alcohol with this medication?”
Answer the patient’s or caregiver’s questions.	“Consuming alcohol while taking acetaminophen should be avoided. The combination can increase the risk of liver damage.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	To evaluate efficacy of the treatment, advise patient to call the pharmacy after using the recommended medication.

### Evaluation of Patient Outcomes for Headache

Appropriate follow-up will depend on headache frequency and severity, as well as patient factors. For patients with episodic headaches, a trial of 6-12 weeks may be needed to assess efficacy of treatment. For chronic headache, follow-up after 4-6 weeks should be adequate to assess treatment efficacy. For severe headaches, patients should be contacted within 10 days of initiation of self-treatment to assess efficacy and tolerability. In all cases, patients should seek medical attention if headaches persist longer than 10 days or worsen despite self-treatment.

One-quarter of migraine patients will benefit from preventive therapy but many do not receive it.<sup>36</sup> Patients with migraine headaches who are not adequately self-treated should be referred for a medical evaluation because effective prescription therapies are available to substantially limit pain and disability.

## Key Points for Headache

- Most tension-type, migraine, and sinus headaches are amenable to treatment with nonprescription medications.
- Patients with symptoms suggestive of secondary headaches (except for minor sinus headache) or undiagnosed migraine headaches should be referred for medical attention.
- Many patients with frequent headaches may experience improvement by identifying and modifying environmental, behavioral, nutritional, or other triggers for their headaches.
- The choice of nonprescription analgesic for an individual patient depends on patient preferences, presence of precautionary or contraindicating conditions, concomitant medications, cost, and other factors.
- Pharmacists have been identified as key sources of information on nonprescription analgesics to reduce risk for acetaminophen-induced hepatotoxicity and NSAID-induced GI bleeding, cardiovascular events, and nephrotoxicity.
- Use of nonprescription analgesics for headache should be limited to 3 days per week to prevent medication-overuse headache.

## Patient Education for Headache

The objectives of self-treatment are to (1) relieve headache pain, (2) prevent headaches when possible, and (3) prevent medication-overuse headaches by avoiding chronic use of nonprescription analgesics. Carefully following product instructions and the self-care measures listed here will help ensure the best results.

### Tension-Type Headaches

- Nonprescription pain relievers (analgesics) are usually effective in relieving tension-type headaches. However, consult your primary provider before using them for chronic tension-type headaches that occur more than 15 days per month for 6 months.
- If nonprescription pain relievers are used for chronic headaches, keep records of how often they are used, and share this information with your provider.

### Migraine Headache

- Avoid substances (food, caffeine, alcohol, and medications) or situations (stress, fatigue, oversleeping, fasting, and missing meals) that you know can trigger a migraine.
- Use the following nutritional strategies to prevent migraine:
  - Avoid foods or food additives known to trigger migraines, including red wine, aged cheese, aspartame, monosodium glutamate, coffee, tea, cola beverages, and chocolate.
  - Avoid foods to which you are allergic.
  - Eat regularly to avoid hunger and low blood sugar.
  - Consider taking magnesium supplements.
- If onset of migraines is predictable (e.g., headache occurs during menstruation), take aspirin, ibuprofen, or naproxen to prevent the headache. Start taking the analgesic 2 days before you expect the headache and continue regular use during the time the headache might start.
- Try to stop a migraine by taking aspirin, acetaminophen, or a nonsteroidal anti-inflammatory agent (NSAID) at the onset of headache pain.
- If desired, use an ice bag or cold pack applied with pressure to the forehead or temples to reduce the pain associated with acute migraine attacks.

### Sinus Headache

- Consider using a combination of a decongestant and a nonprescription analgesic to relieve the pain of sinus headache.

### Precautions for Nonprescription Analgesics

- If you are pregnant or breast-feeding, consult your primary care provider before taking any nonprescription medications.
- If you have a medical condition or are taking prescription medications, obtain medical advice before taking any of these medications. Nonprescription analgesics are known to interact with several medications.
- Do not take nonprescription analgesics longer than 10 days unless a medical provider has recommended prolonged use.
- Do not take these medications if you consume three or more alcoholic beverages daily.
- Do not exceed recommended dosages.
- Products containing aspartame and/or phenylalanine (usually chewable tablets) should not be given to individuals with phenylketonuria.

### **Salicylates (Aspirin and Magnesium Salicylate) and NSAIDs (Ibuprofen and Naproxen)**

- Do not take aspirin during the last 3 months of pregnancy unless a primary care provider is supervising such use. Unsupervised use of this medication could harm the unborn child or cause complications during delivery.
- Do not give aspirin or other salicylates to children 15 years of age or younger who are recovering from chickenpox or influenza. To avoid the risk of Reye's syndrome, a rare but potentially fatal condition, use acetaminophen for pain relief.
- Do not take aspirin or NSAIDs if you are allergic to aspirin or have asthma and nasal polyps. Take acetaminophen instead.
- Do not take aspirin or NSAIDs if you have stomach problems or ulcers, liver disease, kidney disease, or heart failure.
- Do not take NSAIDs if you have or are at high risk for heart disease or stroke unless the use is supervised by a health care provider.
- Do not take aspirin if you have gout, diabetes mellitus, or arthritis unless the use is supervised by a health care provider.
- Do not take salicylates or NSAIDs if you are taking anticoagulants.
- Do not take magnesium salicylate if you have kidney disease.
- Do not give naproxen to a child younger than 12 years.

#### **When to Seek Medical Attention**

- Stop taking salicylates or NSAIDs and seek medical attention if any of the following symptoms occur:
  - Headache, dizziness, ringing in the ears, difficulty in hearing, dimness of vision, mental confusion, lassitude, drowsiness, sweating, thirst, hyperventilation, nausea, vomiting, or occasional diarrhea. These symptoms indicate mild salicylate toxicity.
  - Dizziness, nausea and mild stomach pain, constipation, ringing in the ears, or swelling in the feet or legs. These symptoms are common side effects of salicylates and NSAIDs.
  - Rash or hives, or red, peeling skin; swelling in the face or around the eyes; wheezing or trouble breathing; bloody or cloudy urine; unexplained bruising and bleeding; or signs of stomach bleeding such as bloody or black tarry stools, severe stomach pain, or bloody vomit (see the box A Word about NSAIDs and Stomach Bleeding). These symptoms require immediate medical attention.

#### **Acetaminophen**

- To avoid possible damage to the liver, do not take more than 4 grams of acetaminophen a day from all nonprescription and prescription single-ingredient or combination products containing acetaminophen.
- Do not drink alcohol while taking this medication.
- Follow dosage instructions for acetaminophen carefully if you have glucose-6-phosphate dehydrogenase deficiency.

#### **When to Seek Medical Attention**

- Stop taking acetaminophen and seek medical attention if you develop nausea, vomiting, drowsiness, confusion, or abdominal pain.

## Handbook of Nonprescription Drugs > Chapter 6. Fever

### Fever: Introduction

Fever is a common reason for visits to pediatrician offices, with the National Ambulatory Medical Care Survey estimating that 6% of all ambulatory visits to pediatricians are related to fever.<sup>1</sup> Fever is also the leading cause of visits to the emergency room for children younger than 15 years.<sup>2</sup> In 2009, patients complaining primarily of fever made approximately 12.5 million medical office visits, with men making a slightly greater number of visits.<sup>3</sup> Children have more reported fevers compared with adults: the rate of reported fevers in children younger than 5 years is 10 in 100 persons versus the rate of 0.5 in 100 adults. Nonetheless, the rate of fever does not seem to differ significantly when distinguishing among gender, race, or geographic area of residence in the United States.<sup>4</sup>

Most fevers are self-limited and nonthreatening; however, fever can cause a great deal of discomfort and, in some cases, may indicate serious underlying pathology (e.g., acute infectious process) for which prompt medical evaluation is indicated. The principal reason for treating fever is to alleviate discomfort, but the underlying cause should be identified and treated appropriately. Fever must be distinguished from hyperthermia and hyperpyrexia. Fever is defined as a body temperature higher than the normal core temperature of 100°F (37.8°C). Fever is a regulated rise in body temperature maintained by the hypothalamus in response to a pyrogen. It is a sign of an increase in the body's thermoregulatory set point.

Hyperthermia, in contrast, represents a malfunctioning of the normal thermoregulatory process at the hypothalamic level caused by excessive heat exposure or production.<sup>5</sup> Because of their different mechanisms, treatment of fever versus hyperthermia also varies.

Hyperpyrexia is a body temperature greater than 106°F (41.1°C) that typically results in mental and physical consequences. Hyperpyrexia may result from either a fever or hyperthermia.

### Pathophysiology of Fever

Core body temperature is controlled by the hypothalamus and is regulated by a feedback system that involves information transmitted between the thermoregulatory center in the anterior hypothalamus and the thermosensitive neurons in the skin and central nervous system (CNS). Physiologic (e.g., sweating and vasodilation) and behavioral mechanisms regulate body temperature within the normal range. Although skin temperature may fluctuate greatly in response to environmental conditions, the core temperature is regulated within a narrow range.<sup>6</sup>

Normal thermoregulation prevents wide fluctuations in body temperature; the average temperature is usually maintained between 97.5°F and 98.9°F (36.4°C and 37.2°C), although the commonly accepted core body temperature is usually 98.6°F (37°C). Temperature maintained in this range is considered to be the "set point," or the point at which the physiologic or behavioral mechanisms are not activated.

Pyrogens are fever-producing substances that activate the body's host defenses, resulting in an increase in the set point. Pyrogens can be exogenous (e.g., microbes or toxins) or endogenous (e.g., immune cytokines). Exogenous pyrogens do not independently increase the hypothalamic temperature set point. They stimulate the release of endogenous pyrogens and thereby increase the core temperature. Endogenous pyrogens are products released in response to or from damaged tissue such as interleukins, interferons, and tumor necrosis factor.<sup>6-8</sup>

Prostaglandins of the E<sub>2</sub> series (PGE<sub>2</sub>) are produced in response to circulating pyrogens and elevate the thermoregulatory set point in the hypothalamus. Within hours, body temperature reaches the new set point, and fever occurs. During the period of upward temperature readjustment, the patient experiences chills caused by peripheral vasoconstriction and muscle rigidity to maintain homeostasis.<sup>6</sup>

An increase in body temperature may be idiopathic or can be caused by a variety of mechanisms, including an infectious process, pathologic processes, a response to certain drugs, or vigorous activity.

Most febrile episodes are caused by microbial infections (e.g., viruses, bacteria, fungi, yeasts, or protozoa). There is no basis for differentiating viral from bacterial infections according to the magnitude of the fever or the temperature reduction from antipyretic drug therapy. Fever is often less pronounced in elderly patients and neonates.

Consequently, infection may not be recognized easily in older patients if fever is the primary assessment criterion.<sup>9</sup> Noninfectious pathologic causes of increases in temperature include malignancies, tissue damage (e.g., myocardial infarction or surgery), antigen-antibody reactions, dehydration, heat stroke, CNS inflammation, and metabolic disorders such as hyperthyroidism or gout. Many of these processes actually may cause hyperthermia rather than fever because they interfere with the hypothalamic regulation of temperature.

Drug fever is simply defined as a febrile response to the administration of a medication. Its incidence is unknown in

an ambulatory setting, but the incidence among hospitalized patients is approximately 10% (Table 6-1). Drug-induced fevers usually range from 98.9°F (37.2°C) to as high as 109°F (42.8°C). Drug fever should be suspected in patients without an obvious source of fever. Drug fever often goes unrecognized because of inconsistent signs and symptoms, yet failure to discontinue the offending drug can result in substantial morbidity and mortality.<sup>10,11</sup>

**TABLE 6-1 Selected Medications That Induce Hyperthermia**

<i>Anti-Infectives</i>	<i>Antineoplastics</i>	<i>Cardiovascular</i>	<i>CNS Agents</i>	<i>Other Agents</i>
Aminoglycosides	Bleomycin	Epinephrine	Amphetamines	Allopurinol
Amphotericin B	Chlorambucil	Hydralazine	Barbiturates	Atropine
Cephalosporins	Cytarabine	Methyldopa	Benztropine	Azathioprine
Clindamycin	Daunorubicin	Nifedipine	Carbamazepine	Cimetidine
Chloramphenicol	Hydroxyurea	Procainamide	Haloperidol	Corticosteroids
Imipenem	l-Asparaginase	Quinidine	Lithium	Folate
Isoniazid	6-Mercaptopurine	Streptokinase	MAOIs	Inhaled anesthetics
Linezolid	Procarbazine		Nomifensine	Interferon
Macrolides	Streptozocin		Phenytoin	Iodides
Mebendazole			Phenothiazines	Metoclopramide
Nitrofurantoin			SNRIs	Propylthiouracil
Para-aminosalicylic acid			SSRIs	Prostaglandin E <sub>2</sub>
Penicillins			Sumatriptan	Salicylates
Rifampin			Trifluoperazine	Tolmetin
Streptomycin			Thioridazine	
Sulfonamides			TCA's	
Tetracyclines				
Vancomycin				

Key: CNS = Central nervous system; MAOIs = monoamine oxidase inhibitors; SNRIs = serotonin-norepinephrine reuptake inhibitors; SSRIs = selective serotonin reuptake inhibitors; TCAs = tricyclic antidepressants.

Source: References 5, 11, and Musselman ME, Saely S. Diagnosis and treatment of drug-induced hyperthermia. *Am J Health-Syst-Pharm.* 2013;70(1):34-42.

Drug fever may be differentiated from other causes by establishing a temporal relationship between the fever and the administration of a medication, as well as by observing a temperature elevation despite improvement of the underlying disorder.

The management of drug fever involves discontinuing the suspected medication whenever possible. If feasible, all medications should be temporarily discontinued. If the hyperthermia is drug-induced, the patient's temperature will generally decrease within 24 to 72 hours after the offending agent is withdrawn. After the patient's safety has been considered and the offending medication has been identified and discontinued, each medication may be restarted, one at a time, while monitoring for fever recurrence.<sup>11</sup>

### Clinical Presentation of Fever

Because the symptoms of fever are nonspecific and do not occur in all patients, the etiology of a fever is difficult to determine from the symptomatology. The most important sign of fever is an elevated temperature; therefore, accurate temperature measurement is paramount. Fever is a symptom of a larger underlying process, whether the process is an infection or abnormal metabolism or is drug induced. Once the symptom of fever is established, investigation into the underlying cause is important. Signs and symptoms that typically accompany fever and cause a great deal of

discomfort include headache, diaphoresis, generalized malaise, chills, tachycardia, arthralgia, myalgia, irritability, and anorexia. Most children will tolerate a fever well, so if they continue to be alert, play normally, and stay hydrated, the fever is not of great concern. However, high body temperature dulls intellectual function and causes disorientation and delirium, especially in individuals with preexisting dementia, cerebral arteriosclerosis, or alcoholism.

### Detection of Fever

Subjective assessment of fever typically involves feeling a part of the body, such as the forehead, for warmth. Although this method may identify an increase in skin temperature, it does not accurately detect a rise in core temperature. The most accurate method of detecting fever is to use a thermometer properly to measure body temperature. The patient's age and level of physical and emotional stress, the environmental temperature, the time of day, and the anatomical site at which the temperature is measured are important considerations, given that each factor can affect the results of temperature measurement.

Core temperature is estimated with various types of thermometers used at the rectal, axillary, oral, temporal, or tympanic sites. Rectal temperature has long been considered the gold standard measurement; however, its utility has been challenged.<sup>12</sup> Many patients prefer other methods of temperature measurement because of comfort and ease of use. Body temperature should be measured with the same thermometer at the same site over the course of an illness because the readings from different thermometers or sites may vary (Table 6-2). The discrepancy among the various sites of temperature measurement is normal and should not be ascribed to improper measurement technique. On average, a rectal temperature greater than 100.4°F (38.0°C), an oral temperature greater than 99.7°F (37.6°C), an axillary temperature greater than 99.3°F (37.4°C), a tympanic temperature greater than 100.0°F (37.8°C), or a temporal measurement greater than 100.1°F (37.8°C) is considered elevated.<sup>13</sup> The variation in temperatures at the different sites verifies a simple conception about temperature measurement among the public: add 1 degree to an oral temperature to get a rectal or tympanic measurement, and subtract 1 degree from an oral temperature for an axillary measurement. Normal body temperature may range 1.8°F-2.5°F (1°C-1.4°C) from these norms. Diurnal rhythms cause variances in body temperature during the day, with higher temperatures typically in the late afternoon to early evening. Because the Food and Drug Administration (FDA) regulates thermometers as medical devices, all approved types of thermometers are accurate and reliable, if used appropriately. Providers should not recommend mercury-in-glass thermometers for use at this point because of environmental concerns with mercury.<sup>14</sup>

**TABLE 6-2 Body Temperature Range Based on Site of Measurement**

<i>Site of Measurement</i>	<i>Normal Range<sup>a</sup></i>	<i>Fever<sup>a</sup></i>
Rectal	97.9°F-100.4°F (36.6°C-38°C)	≥100.4°F (38.0°C)
Oral	95.9°F-99.5°F (35.5°C-37.5°C)	≥99.5°F (37.5°C)
Axillary	94.5°F-99.3°F (34.7°C-37.4°C)	≥99.3°F (37.4°C)
Tympanic	96.3°F-100°F (35.7°C-37.8°C)	≥100°F (37.8°C)
Temporal	97.9°F-100.1°F (36.6°C-37.8°C)	≥100.7°F (38.1°C) for 0-2 months old ≥100.3°F (37.9°C) for 3-47 months old ≥100.1°F (37.8°C) for ≥4 years old

<sup>a</sup> Conversion formulas: Celsius = 5/9(°F - 32); Fahrenheit = (9/5 × °C) + 32.

Source: References 13 and 16.

Electronic probe thermometers are available for oral, rectal, and axillary temperature measurements. The probes have an electronic transducer that provides a temperature reading in about 10-60 seconds. The oral electronic probes are mostly available in either pen or pacifier shapes, although infant probes can be a different shape. The pacifier-shaped electronic thermometer is for oral use only and is useful in infants who are unable to hold probes under their tongues. The amount of time the pacifier needs to stay in the child's mouth varies depending on the manufacturer, but the time can range from 3 to 8 minutes.<sup>15,16</sup> The pen-shaped probe may be used in the oral, rectal,

or axillary area. Because of their electronic digital temperature displays, electronic thermometers provide quick readings, eliminate the possibility of glass breakage, and are easier to read compared with traditional glass thermometers. The use of disposable probe covers with electronic thermometers also reduces the need for disinfection after their use. Disinfection should still occur if the thermometer is being used for multiple patients. A thermometer that is used rectally should not be used subsequently for oral measurement.

Infrared thermometers are available for tympanic artery and temporal artery temperature measurements. These thermometers use infrared technology to detect heat from the arterial blood supply. They must be placed directly in the line of a blood supply, whether near the temporal artery or the tympanic membrane. Infrared thermometers measure body temperature in less than 5 seconds and are considered very accurate, if used appropriately. The major problem with infrared thermometers is that they are not always placed appropriately and consequently may give inaccurate readings. Infrared thermometers are relatively expensive and require batteries, but many families with young children prefer them because of their convenience and noninvasive nature. New technology also includes no-touch infrared thermometers, which offer the advantage of not having to wake a sleeping child to take a temperature.<sup>16,17</sup>

Color-change thermometers are easy to use, but they are not sufficiently accurate or reliable. The thermometer is an adhesive strip containing heat-sensitive material that changes color in response to different temperature gradients. The strip may be placed anywhere on the skin, but the forehead is used most often because the forehead shows less variation in temperature than other parts of the body. Although this method may detect changes in skin temperature, it does not reliably detect changes in core temperature.

Patient-related factors may preclude the use of a particular type of thermometer through a given route. Although there are a variety of routes of temperature measurement, rectal temperature measurement historically has been the standard because the site is not influenced by ambient temperatures, and it can be used in patients of varying ages.<sup>13</sup> Oral, tympanic, axillary, and temporal routes are all appropriate for temperature measurements if the proper procedure is followed.

**Table 6-3** describes the proper methods of taking rectal temperatures in children and adults. Rectal temperature measurement has a predictable rise in temperature and a high sensitivity and specificity compared with the body's core temperature. Although the rectal route is the closest estimate of the core temperature, its intrusive nature can be very frightening and possibly psychologically harmful to older children. In children younger than 3 months, however, rectal temperature is the preferred method of estimating fever and should be recommended if caregivers are confident they can safely use this route.<sup>16</sup> Risks associated with taking a rectal temperature include retention of the thermometer, rectal or intestinal perforation, and peritonitis. Rectal temperature measurement is also very time consuming, and the patient should never be left unattended while the rectal thermometer remains in place; a positional change may cause the thermometer to be expelled or broken. Rectal temperature measurement is relatively contraindicated in patients who are neutropenic, have had recent rectal surgery or injury, or have rectal pathology (e.g., obstructive hemorrhoids or diarrhea). In addition, rectal temperature measurement is slow to measure rapid changes in body temperature because of the large muscle mass and poor blood flow to the area.<sup>13,16,18</sup>

**TABLE 6-3 Guidelines for Rectal Temperature Measurements Using Electronic Thermometers**

1. Cover the tip of thermometer with a probe cover.
2. Turn on the thermometer and wait until it is ready for use.
3. Apply a water-soluble lubricant to tip of thermometer to allow for easy passage through the anal sphincter and to reduce risk of trauma.
4. For infants or young children, place child face down over your lap, separate the buttocks with the thumb and forefinger of one hand, and insert the thermometer gently in the direction of the child's umbilicus with the other hand. For infants, insert the thermometer to the length of the tip. For young children, insert it about 1 inch into the rectum.
5. For adults, have the patient lie on one side with the legs flexed to about a 45°H angle from the abdomen. Insert the tip 0.5-2 inches into the rectum by holding the thermometer 0.5-2 inches away from the tip and inserting it until the finger touches the anus. Have the patient take a deep breath during this process to facilitate proper positioning of the thermometer.

- |  |
|--|
| 6. Hold the thermometer in place until it beeps and a temperature is displayed.  |
| 7. Remove the thermometer.   |
| 8. Dispose of probe cover and clean thermometer with an antiseptic such as alcohol or a povidone/iodine solution by wiping away from the stem toward tip. Rinse with cool water. |
| 9. Wipe away any remaining lubricant from the anus.  |

**TABLE 6-4 Guidelines for Oral Temperature Measurements Using Electronic Thermometers**

<i>Digital Probe</i>
1. Wait 20-30 minutes after drinking or eating.
2. Place a clean disposable probe cover over tip.
3. Turn on the thermometer and wait until it is ready for use.
4. Place tip of thermometer under tongue.
5. Close mouth and breathe through nose.
6. Hold thermometer in place until it beeps and temperature has been recorded (usually after 5-30 seconds).
7. Record the displayed temperature.
8. Remove and dispose of probe cover.
<b>Digital Pacifier Thermometer</b>
1. Wait 30 minutes after drinking or eating.
2. Inspect the pacifier for any tears or cracks. Do not use if worn.
3. Press the button to turn on thermometer.
4. Place the pacifier in child's mouth.
5. Have the child hold pacifier in mouth without moving, if possible, for time specified on packaging of thermometer (2-6 minutes).
6. Record temperature when thermometer beeps.

Source: References 15 and 16.

Table 6-4 describes the proper methods of taking oral measurements with electronic thermometers.<sup>16</sup> Oral temperature should not be obtained when an individual is mouth breathing or hyperventilating; has recently had oral

surgery; is not fully alert; or is uncooperative, lethargic, or confused. Oral digital probe thermometers may not be appropriate for use in most children younger than 3 years. Children this young may find it difficult to maintain a tight seal around the thermometer and keep the thermometer under the tongue, in which case pacifier thermometers may be recommended. Pacifier thermometers provide reliable temperature readings compared with rectal measurements; however, in children younger than 3 months, pacifier thermometers are less accurate.<sup>19,20</sup> To ensure reliable measurement, the patient should neither smoke, engage in vigorous physical activity, nor drink hot or cold beverages for a minimum of 20 minutes before the temperature is measured.

**Table 6-5** describes the proper method of using tympanic thermometers, which varies slightly depending on the age of the patient.<sup>16</sup> Tympanic thermometers have digital readouts, and many can be set to provide either a rectal or an oral temperature equivalent. The tympanic membrane is close to the hypothalamus, and the blood supply to both anatomical areas is at the same temperature, providing an accurate reading of the core body temperature. The thermometer must be positioned in the ear canal properly to ensure that the measured infrared radiation is from the tympanic membrane and not from the ear canal or adjacent areas. In clinical trials, accuracy of tympanic thermometers has varied compared with rectal and oral routes.<sup>21,22</sup> Variations in temperature assessment have been attributed to cerumen impaction, inflammation in the ear canal (e.g., otitis media), age of patient (size of ear canal), and inappropriate technique.<sup>16</sup> Tympanic thermometers are not recommended in infants younger than 6 months; their ear canals are not developed fully, leading to inappropriate technique and inaccurate readings. Although not as reliable as the rectal method in children, if used correctly, tympanic thermometry has been found to be more accurate than axillary or oral thermometry in estimating core temperature.<sup>18</sup>

**TABLE 6-5 Guidelines for Tympanic Temperature Measurements**

1. Place a clean disposable lens cover over ear probe.
2. Turn on thermometer and wait until it is ready for use.
3. For children younger than 1 year, pull ear backward to straighten ear canal. Place ear probe into canal, and aim the tip of the probe toward patient's eye.
4. For patients older than 1 year, pull ear backward and up to straighten ear canal. Place the ear probe into canal, and aim the tip of probe toward patient's eye.
5. Press the button for temperature measurement (usually for only 1-5 seconds).
6. Read and record temperature.
7. Discard lens cover.

Source: Reference 16.

**TABLE 6-6 Guidelines for Temporal Artery Temperature Measurements**

1. Allow thermometer to acclimatize to the environment for about 30 minutes, if you moved the thermometer from a hot room to a cold room or vice versa.
2. Place probe on one side of forehead (near temporal area).
3. Depress button and hold while scanning for the temporal artery temperature.
4. Sweep thermometer across forehead to the hairline on the opposite side of the head. Ensure that probe remains in contact with skin at all times, and hold button down until finished scanning.
5. If there is sweat on the forehead, sweep the thermometer as normal, but nestle the thermometer on the neck

directly behind the ear lobe before releasing the button.

6. Lift thermometer, release the button, and document the recorded temperature.

Source: References 16 and 17.

Temporal touch thermometers are placed on the side of the forehead directly over the temporal artery and moved across the forehead (Table 6-6). The temporal artery is directly supplied by the hypothalamus and is near the surface of the skin at the side of the head, thereby allowing surface measurement with infrared technology to be possible. The thermometer is capable of providing a temperature reading in a few seconds. Its rapid, noninvasive nature makes it a preferable route of temperature measurement for individuals, and the temporal thermometer is significantly more sensitive than the tympanic thermometer for detecting fever.<sup>23</sup> However, in a recent study, the temporal temperature measurement still did not show superiority or greater reliability compared with the rectal method.<sup>21</sup> Temporal temperature measurement may differ from rectal temperature measurement by  $\pm 2.3^{\circ}\text{F}$  ( $1.3^{\circ}\text{C}$ ).<sup>20,21</sup> The presence of hair near the temporal area may confound the temperature reading, so hair must be pushed away before a reading is obtained.

No-touch infrared thermometers do not require contact with the patient for measurement. Temperature is measured by aiming the thermometer at the center of the forehead. Certain models may also allow for alternative sites such as the navel and neck, although these sites are less accurate.<sup>16</sup> Although no-touch infrared thermometers are convenient and less invasive, a study of children ages 1 month to 4 years treated in the emergency room found infrared thermometers to be less accurate and reliable than rectal measurement.<sup>24</sup>

Axillary temperature measurement is frequently used by caregivers and in ambulatory settings because it is relatively noninvasive. However, axillary measurement performed with digital thermometers (Table 6-7) is not as reliable for detecting fever compared with oral and rectal routes.<sup>25,26</sup> Reported large variations in temperatures taken by the axillary method are attributable to inappropriate placement of the thermometer, movement of arms during measurement leading to a poor seal around the thermometer, and measurements being taken for too short a period of time. Axillary temperature should not be taken directly after vigorous activity or bathing because both can affect body temperature temporarily without altering the thermoregulatory set point at the hypothalamus. If a fever is detected with the axillary method, a confirmation reading using another method is recommended.

**TABLE 6-7 Guidelines for Axillary Temperature Measurements Using Electronic Thermometer**

1. Place a clean disposable probe cover over tip.
2. Turn on thermometer and wait until it is ready for use.
3. Place tip of thermometer in armpit. Ensure that armpit is clean and dry. Thermometer must be touching skin, not clothes.
4. If taking a child's temperature, hold child close to secure the thermometer under armpit, if necessary.
5. Read and record temperature when thermometer beeps.

### Complications of Fever

The presence of fever is a cause of great concern, although in most cases fever may be self-limiting, and serious complications are rare. In one study, 73% of caregivers were "very concerned" about the potential complications of fever, and 88% were "very concerned" when a child's fever was not reduced by antipyretics. There is less concern about complications of fever now than 20 years ago; however, interviewed caregivers still list seizures (32%), brain damage (15%), and death (16%) as the main complications of fever.<sup>27</sup> Overall, the major risks of fever are rare but may include acute complications such as seizures, dehydration, and change in mental status.

Febrile seizure is defined as a seizure accompanied by fever in infants or children who do not have an intracranial infection, a metabolic disturbance, or a defined cause.<sup>28</sup> Febrile seizures occur in 2%-5% of all children from the

ages of 6 months to 5 years, with the peak occurrence in children ages 18-24 months. Risk factors for a first febrile seizure include day care attendance, developmental delay, a family history of febrile seizure, and a neonatal hospital stay of more than 30 days. The height of the fever and rate of increase also appear to be critical determinants in the precipitation of a first febrile seizure.<sup>29</sup> The most common seizures associated with fever are simple febrile seizures, which are characterized by nonfocal movements, generally of less than 15 minutes in duration, with only one occurrence in a 24-hour period. Significant neurologic sequelae (e.g., impaired intellectual development or epilepsy) are unlikely after a single pediatric febrile seizure. The risk of recurrence is increased in children who have had multiple febrile seizures, are younger than 1 year at the time of their first seizure, and have a family history of epilepsy. Antipyretics are generally recommended to make the child more comfortable, although they do not reduce the risk of recurrent febrile seizures.<sup>28,30,31</sup> Prophylaxis against simple febrile seizures with antiepileptic or antipyretic drugs is not recommended by the American Academy of Pediatrics.<sup>28</sup> Serious detrimental effects (e.g., dehydration, delirium, seizures, coma, or irreversible neurologic or muscle damage) occur more often in patients with hyperpyrexia (temperatures > 106°F [41.1°C]), which is usually associated with hyperthermia and not fever. Because of the homeostatic mechanisms of the hypothalamus, a febrile person with a core temperature exceeding 106°F (41.1°C) is rare. However, even lower body temperature elevations may be life threatening in patients with heart disease and pulmonary dysfunction. Increased risk of complications exists in infants and patients with brain tumors or hemorrhage, CNS infections, preexisting neurologic damage, and a decreased ability to dissipate heat attributed to lower tolerance of elevated body temperature. Elderly patients are at a higher risk for fever-related complications because of their decreased thirst perception and perspiration ability.<sup>6,32</sup>

## Treatment of Fever

Fever is a sign of an underlying process. Treatment should focus on the primary cause rather than on the temperature reading. No correlation exists between the magnitude and pattern of temperature elevation (i.e., persistent, intermittent, recurrent, or prolonged) and the principal etiology or severity of the disease. Therefore, trying to determine the cause of the fever on the sole basis of the temperature reading is difficult. The decision to treat fever is based on a patient-specific risk-benefit ratio and the desire to improve comfort.<sup>33</sup> Fever is not associated with many harmful effects unless the temperature exceeds 106°F (41.1°C); most fevers are of short duration and may actually have beneficial effects on host-defense mechanisms (e.g., antigen recognition, T-helper lymphocyte function, and leukocyte motility). Certain microbes are thermolabile, and their growth may be impaired by higher-than-normal temperatures. Therefore, overtreatment of fever for viral and bacterial infections may actually be detrimental.<sup>33</sup> Other arguments against treatment include the generally benign and self-limited course of fever, the delayed identification of the diagnosis, and the untoward effects of antipyretic medications.<sup>34</sup>

### Treatment Goals

The major goal of self-treatment is to alleviate the discomfort of fever rather than treating to a specific temperature.<sup>33,35</sup>

### General Treatment Approach

Treatment of fever using antipyretics (see [Chapter 5, Tables 5-2 and 5-3](#)) is most often indicated for patients with elevated temperatures who also have discomfort. Fever associated with discomfort may be treated with antipyretic agents as well as nonpharmacologic measures.

Self-care measures, including antipyretics, are appropriate initial therapy, unless a patient has exclusions for self-treatment ([Figure 6-1](#)). In addition, parents should be urged to call their child's pediatrician immediately or seek urgent medical care if their child has a history of seizure; refuses to stay hydrated; develops a rash; has a rectal temperature of 104°F (40.0°C) or higher or its equivalent; or is very sleepy, irritable, or difficult to wake. Children younger than 3 months should be referred for medical evaluation at rectal temperatures of 100.4°F (38.0°C) or higher. Children younger than 3 months have immature immune systems and are prone to more serious bacterial infections. In all cases, self-care measures should be started while medical evaluation is being sought.<sup>33,35,36</sup>

### Nonpharmacologic Therapy

Nonpharmacologic therapy consists mainly of adequate fluid intake to prevent dehydration. Sponging or baths have limited utility in the management of fever. Body sponging with tepid water may facilitate heat dissipation, given that only a small temperature gradient between the body and the sponging medium is necessary to achieve an effective antipyretic response. However, sponging is not routinely recommended for those with a temperature less than 104°F (40°C); sponging is usually uncomfortable and often induces shivering, which could further raise the temperature. Bathing with ice water or sponging with hydroalcoholic solutions (e.g., isopropyl or ethyl alcohol) is uncomfortable, dangerous, and not recommended. Alcohol poisoning can result from cutaneous absorption or inhalation of topically

applied alcohol solutions. Infants and children are at a higher risk of alcohol poisoning because of their smaller body mass. Unlike acetaminophen and nonsteroidal anti-inflammatory drugs (NSAIDs), sponging does not reduce the hypothalamic set point; therefore, sponging should follow oral antipyretic therapy by 1 hour to permit the appropriate reduction of the hypothalamic set point and a more sustained temperature-lowering response.<sup>37</sup>

Other nonpharmacologic interventions, regardless of the temperature, include wearing lightweight clothing, removing blankets, maintaining a comfortable room temperature of approximately 68°F (20°C), and drinking sufficient fluid to replenish insensible losses. Because a fever will cause a child to lose fluids more rapidly, sufficient fluid intake is recommended. Fluid intake in febrile children should be increased by at least 30-60 mL (1-2 ounces) of fluids per hour (e.g., sports drinks, fruit juice, water, balanced electrolyte replacement products, or ice pops) and by at least 60-120 mL (3-4 ounces) of fluids per hour in adults, unless fluids are contraindicated. Caution should be exercised in recommending fruit juice and sport drinks to patients with diarrhea; drinks with high sugar loads may worsen concurrent diarrhea.

### Pharmacologic Therapy

Antipyretics inhibit PGE<sub>2</sub> synthesis, which decreases the feedback between the thermoregulatory neurons and the hypothalamus, thereby reducing the hypothalamic set point during fever. All antipyretics decrease the production of PGE<sub>2</sub> by inhibiting the cyclooxygenase (COX) enzyme. NSAIDs and aspirin inhibit the COX enzyme in the periphery and CNS, whereas acetaminophen mainly inhibits the COX enzyme in the CNS.<sup>38</sup> Chapter 5 provides an in-depth discussion of the pharmacokinetics, dosing, adverse effect profile, interactions, contraindications, and precautions of nonprescription antipyretic agents.

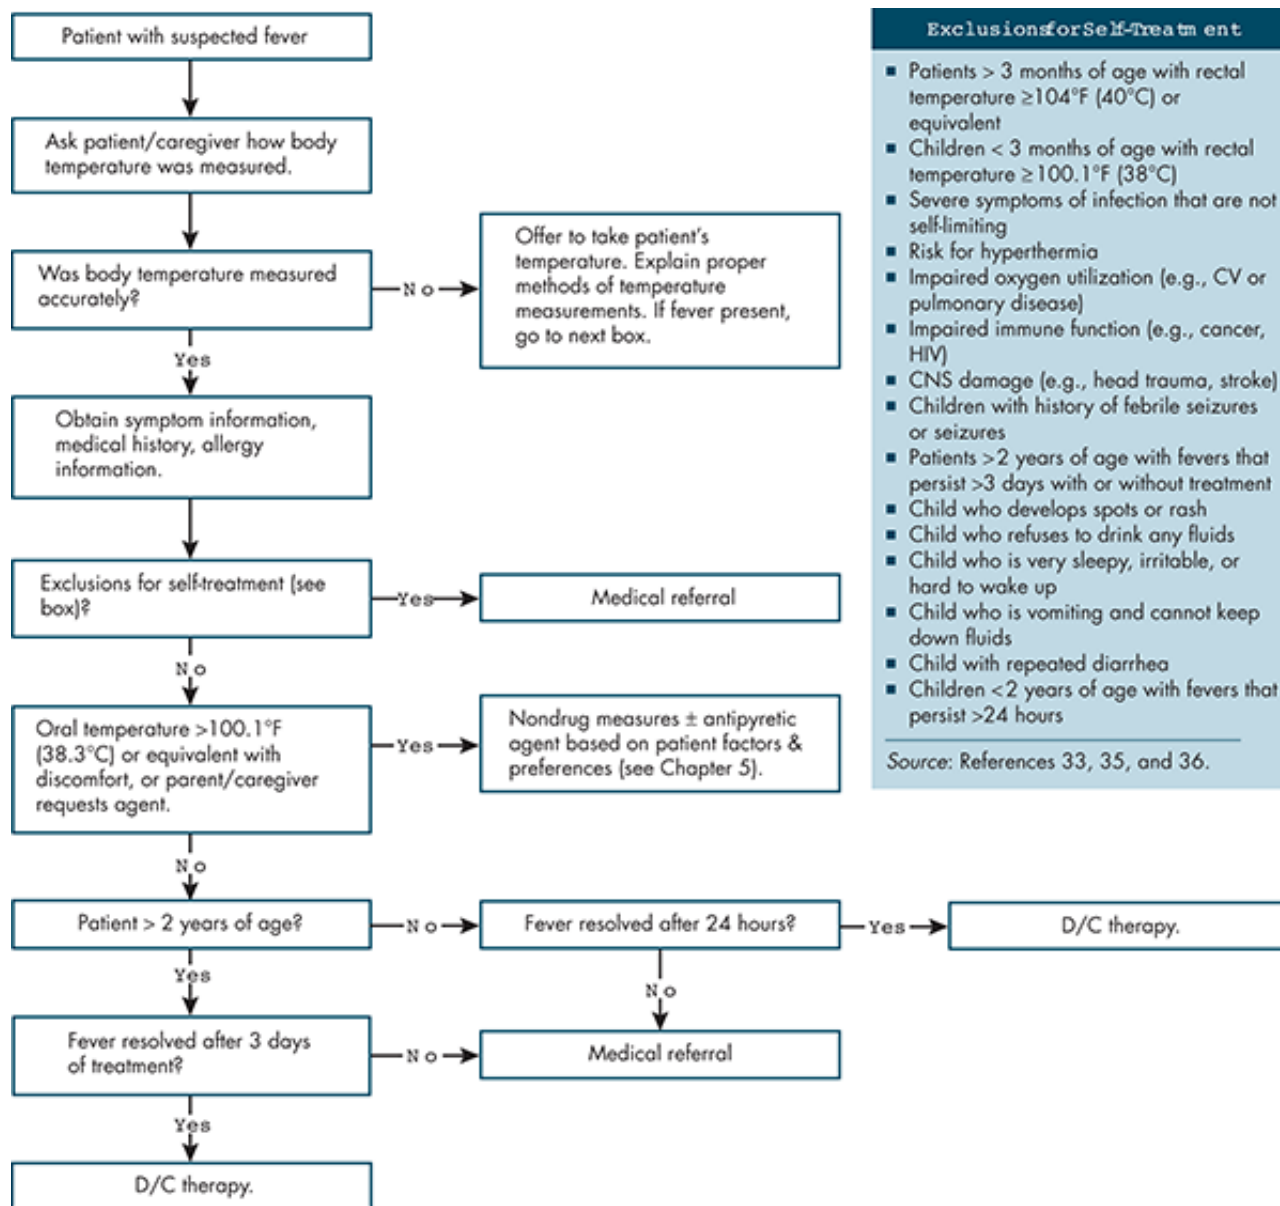

Acetaminophen typically reaches a maximum temperature reduction at 2 hours at the usual recommended dosing of 10-15 mg/kg every 4-6 hours, with a maximum of 5 doses per day (see Chapter 5, Tables 5-2 and 5-3).

Approximately 80% of children will experience a reduction in their fever with that dose.<sup>33</sup> Adult dosing ranges from 325-1000 mg every 4-6 hours up to a maximum of 4000 mg per day. Some providers have recommended loading doses of acetaminophen for the reduction of fever at 30 mg/kg per dose, after a small study found a faster (one-half hour) and more significant (0.9°F [0.5°C]) decrease compared with a traditional dose.<sup>39</sup> This practice is not recommended, however, because of the size and limitations of the study and the lack of any follow-up evidence for the practice.

Acetaminophen is also available as a rectal suppository. Although a suppository may be an advantage for caregivers who have problems giving their children oral medications, or for children who are vomiting or are having a febrile seizure, the suppository's absorption is erratic, and studies on its antipyretic activity are conflicting.<sup>40</sup>

Ibuprofen is the most common NSAID used as an antipyretic; it typically reaches a maximum temperature reduction at 2 hours at the recommended dosing of 5-10 mg/kg per dose every 6-8 hours, with a maximum of 4 doses per day (see Chapter 5, Tables 5-2 and 5-3). Note that ibuprofen is approved for the reduction of fever only in patients older than 6 months. Adult dosing ranges from 200 to 400 mg every 4-6 hours up to a maximum of 1200 mg per day.

Self-care of fever. Key: CNS = Central nervous system; D/C = discontinue; HIV = human immunodeficiency virus.

Although NSAIDs and acetaminophen are safe and effective when used at low doses for a short duration, they should not be used more than 3 days to treat fever without referral for further evaluation to determine the underlying cause. Common medication errors associated with over-the-counter antipyretics include overdosing or duplicating therapy attributed to using multiple products with similar ingredients, and inappropriate dosing for pediatric patients attributed to mathematical errors in calculating a weight-based dose. One study has shown that only 30% of parents were able to measure an accurate dose of acetaminophen, and another study demonstrated that 51% of the study's pediatric patients received an inaccurate dose of medication (62% for acetaminophen and 26% for ibuprofen).<sup>41</sup> Because of these alarming statistics, health care providers should provide an appropriate measuring device and/or demonstrate to patients and caregivers proper dosing and measurement of the medications. In addition, patients should be educated on the appropriate dosing interval and the avoidance of combining cold and cough products containing either acetaminophen or ibuprofen.

#### Pharmacotherapeutic Comparison

Both ibuprofen and acetaminophen are more effective than placebo in reducing fever, with both showing reductions of approximately 1-2 degrees within 30 minutes to 1 hour. Clinical trials comparing the antipyretic effects of ibuprofen to acetaminophen in recommended dosages have produced variable results, making conclusions on superiority of one agent difficult. A review of 14 clinical trials comparing ibuprofen and acetaminophen in febrile children did find that ibuprofen was slightly more effective than acetaminophen in reducing fever after a single dose; furthermore, ibuprofen was found to be more effective after 6 hours, thus showing a longer duration of action.<sup>42</sup> The same review found that multiple-dose studies failed to show any statistically significant clinical difference. The risk of serious

adverse effects did not differ between the medications. The authors concluded that the efficacy and safety between acetaminophen and ibuprofen are similar in recommended dosages, with slightly more benefit shown with ibuprofen in terms of onset and duration of action and fever reduction; however, more conclusive findings are needed. A meta-analysis looking at both children and adults also concluded that ibuprofen was more efficacious than acetaminophen in the reduction of fever in both adults and children and was equally as safe.<sup>43</sup> Although ibuprofen has been studied most frequently, other NSAIDs (e.g., naproxen and aspirin) may also be appropriate as antipyretics in adults. Alternating different antipyretics has become a widespread practice. A survey of 256 caregivers showed that 67% alternated acetaminophen and ibuprofen, and 81% of them stated that their health care provider or pediatrician advised them to do so. Although alternating the antipyretics was recommended, only 61% of caregivers received any type of written instructions on how to dose the medications, and the dosing intervals varied from 2 to 6 hours.<sup>41</sup> Despite those practices and clinical trials showing lower temperatures at 4 or more hours with combination therapy, the American Academy of Pediatrics at this time does not recommend alternation of antipyretics because of the risk of overdose, medication errors resulting from the complexity of the regimens, and increased side effects.<sup>33,41</sup> In addition, only one study actually showed less stress and time missed from daycare with alternating therapy.<sup>44</sup> Health care providers should continue to counsel patients and caregivers on the practical application of this practice if patients are instructed to alternate doses by their providers. For example, caregivers should be encouraged to write down the generic name, dose of the medication, and time of administration to minimize the likelihood of duplicate dosing and adverse effects. The use of antipyretics immediately after vaccine administration is a widespread practice meant to reduce anticipated discomfort and fever. Recently, two open-label, randomized trials found that administration of acetaminophen was effective in reducing febrile episodes, but it also significantly reduced the antibody response to several vaccines, although all levels were still considered protective. Even though the clinical significance of these antibody reductions is still unknown, prophylactic antipyretics either before or immediately after vaccine administration should be discouraged; however, symptomatic post-vaccination reactions may still be treated with antipyretics until additional data says otherwise.<sup>45</sup>

#### Product Selection Guidelines

Age is an important consideration in the selection of an antipyretic, particularly among neonates. Parents and caregivers of children younger than 3 months of age should seek medical evaluation at rectal temperatures or equivalent of 100.4°F (38.0°C) or higher. Children older than 3 months with a rectal temperature or equivalent of 104°F (40.0°C) or higher should also be referred. Ibuprofen should be used only in children older than 6 months; because of the risk of Reye's syndrome, children younger than 15 years of age should avoid using aspirin or aspirin-containing products as an antipyretic. A detailed description of additional criteria for the appropriate use of antipyretic agents is available in [Chapter 5](#).

The choice of an antipyretic depends on the patient. Both acetaminophen and ibuprofen are available in a variety of dosage forms for both children and adults, including tablets, chewable tablets, suspensions, and even suppositories. Selection of a dosage form can be left to patient preference. Consideration of palatability and the taste of the different ibuprofen and acetaminophen suspensions may improve outcomes and adherence of antipyretic regimens in children. A variety of flavors are available for both ibuprofen and acetaminophen liquids. The dosing frequency of ibuprofen at once every 6-8 hours versus acetaminophen at once every 4-6 hours may also improve adherence and be considered in product selection, especially in children who have difficulty taking medicine.

#### Complementary Therapies

Currently, insufficient evidence exists to recommend any dietary supplement or other complementary therapy for the treatment of fever.

#### Assessment of Fever: A Case-Based Approach

The first step in assessing a patient with a complaint of fever is to obtain an objective temperature measurement to determine whether fever is actually present. Subjective or inaccurate temperature measurement must be ruled out. If fever is present, assessment of its severity, the seriousness of the underlying cause, and other associated symptoms is indicated. Children who are capable of providing and understanding information should be included in any dialogue concerning their care.

Cases 6-1 and 6-2 are examples of the assessment of patients presenting with fever.

#### Patient Counseling for Fever

Although fever is a common symptom, it often is misunderstood and poorly treated. Studies suggest that fever is incorrectly considered a disease associated with detrimental consequences rather than a symptom, is frequently

treated inappropriately, and is evaluated improperly.<sup>46</sup> Many parents and caregivers have “fever phobia” that results in heightened anxiety and inappropriate treatment of fever.<sup>27</sup> Health care providers can improve patient outcomes by educating patients and caregivers about fever and by teaching patients self-assessment skills (e.g., the proper methods for measuring body temperature using the variety of thermometers available, as well as proper interpretation of the results). If patients are still using mercury-in-glass thermometers, they should be urged to dispose of them according to their local environmental standards. Health care providers should also explain the appropriate nonpharmacologic and pharmacologic treatments for fever and when to seek further medical care. Discussions of pharmacologic treatments should highlight methods for safe use of antipyretics and the avoidance of complementary therapies. The box Patient Education for Fever provides specific information to give the patient.

### Case 6-1

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient’s symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Nate Connor’s mother noticed his forehead felt warm when he woke up this morning for the start of the weekend. Normally a high-energy child, Nate wasn’t acting himself, which worried her. He also complained of having a slight headache and feeling uncomfortable.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient’s symptom(s)	Nate’s mom took his temperature with an oral thermometer, which was 102.4°F. She did not notice any other symptoms other than a slight stuffy nose.
c. description of the patient’s efforts to relieve the symptoms	She hadn’t tried anything to treat his fever up to this point.
d. patient’s identity	Nate Connor
e. patient’s age, sex, height, and weight	7 years old, male, 4 ft 2 in., 58 lb
f. patient’s occupation	Nate attends first grade
g. patient’s dietary habits	Normal diet
h. patient’s sleep habits	Normal sleep patterns
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	No medical conditions; Flintstones Multivitamin
j. allergies	NKDA
j. history of other adverse	None

reactions to medications	
k. other (describe) _____	Nate is not his usual high-energy self. His mother reported he is still playing and eating some, but not at his usual levels. You retake his temperature in the pharmacy using a temporal thermometer, and it reads 102.0°F.
<b>Assessment and Triage</b>	
2. Differentiate the patient's signs/symptoms and correctly identify the patient's primary problem(s).	Nate has a fever and his decreased activity level and headache indicate that he is in some discomfort. He most likely has a virus transmitted through contact with classmates at school. He has no other signs or symptoms of a bacterial infection.
3. Identify exclusions for self-treatment ( <a href="#">Figure 6-1</a> ).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the caregivers.	Options include: (1) Refer Nate for immediate medical attention. (2) Monitor his symptoms and fever and recommend nondrug measures only. (3) Recommend a medication alone or in combination with nondrug measures. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Nate has a fever and is in discomfort, most likely from a viral infection. He has no exclusions for self-care at this time ( <a href="#">Figure 6-1</a> ); therefore, treatment with either acetaminophen or ibuprofen is warranted. Drug therapy should be used in conjunction with nondrug measures. Nate prefers liquid medications, specifically cherry-flavored acetaminophen. He should not receive any aspirin-containing medications.
6. Describe the recommended therapeutic approach to the caregivers.	See <a href="#">Table 5-2</a> in <a href="#">Chapter 5</a> for recommended doses. If fever persists >72 hours with or without treatment, Nate should be seen by a health care provider.
7. Explain to the caregivers the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	Nate has a fever that is causing some discomfort, so minimizing the fever with an antipyretic medication, either acetaminophen or ibuprofen, should help. He currently does not need to see a health care provider, but you should contact one if his fever persists for >72 hours or if he complains of other symptoms, such as a stiff neck, severe headache or sore throat, severe ear pain, an unexplained rash, or he has repeated vomiting or diarrhea.
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the caregivers:	
a. appropriate dose and frequency of administration	"You can give Nate acetaminophen liquid (160 mg/5 mL). Give 2 teaspoonfuls or 10 mL (320 mg) every 4-6 hours. Do not exceed 5 doses per 24 hours."

b. maximum number of days the therapy should be employed	"Do not give Nate the medication for more than 3 days."
c. product administration procedures	"Measure liquid using appropriate dosing syringe or cup and have Nate swallow liquid."
d. expected time to onset of relief	"A reduction in fever is usually seen within ½-1 hour. Maximum reduction is usually seen within 2 hours."
e. degree of relief that can be reasonably expected	"A 1-2 degree reduction in temperature is expected, but complete resolution of symptoms may vary, depending on the underlying cause of the fever."
f. most common side effects	"Side effects are rare but gastrointestinal effects or rash is possible. Nate can take medication with food if gastrointestinal effects occur."
g. side effects that warrant medical intervention, should they occur	"Contact a health care provider if signs of an allergic reaction, such as a rash or trouble breathing, occur after a dose is given."
h. patient's options in the event that condition worsens or persists	"Contact a health care provider in 72 hours if the fever persists or if symptoms worsen."
i. product storage requirements	"Keep medication in a tightly secured container away from any extreme temperatures and out of reach of children."
j. specific nondrug measures	"Maintain room temperature at 68°F. Maintain adequate fluid intake and dress him in lightweight clothing."
Solicit follow-up questions from caregivers.	"Can I alternate ibuprofen with the acetaminophen for Nate?"
Answer caregivers' questions.	"You should not. The American Academy of Pediatrics does not recommend alternating ibuprofen and acetaminophen because of the increased risk of medication errors and side effects."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact Nate's mother in 1-2 days to see if his fever is improving.

Key: NKDA = No known drug allergies.

### Evaluation of Patient Outcomes for Fever

The primary monitoring parameters for febrile patients include temperature and discomfort. In one study, 32% of caregivers said they would check a febrile patient's temperature at least every hour.<sup>27</sup> Overaggressive monitoring may result from fever phobia. Because fever may actually be of benefit, the ultimate goal of antipyretic therapy is not to normalize temperature as much, but to improve overall comfort and well-being.<sup>33</sup> Associated symptoms (e.g., headache, diaphoresis, generalized malaise, chills, tachycardia, arthralgia, myalgia, irritability, and anorexia) should also be monitored daily. Although most patients demonstrate a reduction in temperature after each individual dose of an antipyretic, pharmacologic therapy for fever may take up to 1 day to result in a decrease in temperature. If symptoms are not improving or are worsening over the course of 3 days with self-treatment, regardless of a drop in

temperature, a health care provider should be consulted either by phone or appointment for further evaluation.<sup>36</sup> Timeliness of patient follow-up with medical care is important in determining the presence of a non-self-limiting underlying cause.

### Case 6-2

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	A mother calls the pharmacy claiming her newborn, Alison, is spiking a fever. Alison has not been eating as usual today. Alison's mother decided to take the baby's temperature rectally, and Alison had a temperature of 102.1°F.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The mother just noticed that Alison had a fever; the baby was fine the previous night when she went to bed.
c. description of the patient's efforts to relieve the symptoms	The mother has not tried anything at all at this point. She has not noticed any other symptoms, and she denies that the baby has any rash or coughing.
d. patient's identity	Alison Woods
e. patient's age, sex, height, and weight	10 weeks old, female, 13 lb
f. patient's occupation	None
g. patient's dietary habits	Breast milk every 3-4 hours
h. patient's sleep habits	Sleeps most of the day and night; awakes to eat every few hours.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	No significant medical conditions
j. allergies	NKDA
k. history of other adverse reactions to medications	No medications
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate the patient's signs and symptoms and correctly identify the patient's primary problem(s).	Alison has a fever that is concerning because of her age.

3. Identify exclusions for self-treatment (Figure 6-1).	Age < 3 months with a fever > 100.1°F
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the caregivers.	Options include: (1) Refer Alison to her pediatrician (2) Refer Alison to the emergency room for immediate medical attention. (3) Monitor her symptoms and fever and recommend nondrug measures only. (4) Recommend a medication alone or in combination with nondrug measures. (5) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Alison has an exclusion for self-care based on her age of 10 weeks and the temperature that was reported. Alison's mother should contact her pediatrician immediately to rule out any infectious etiology.
6. Describe the recommended therapeutic approach to the caregivers.	"No medication recommended at this time. Immediate medical referral."
7. Explain to the caregivers the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives	"Alison has a fever and is at high risk for an infection because of her immature immune system. Infants < 3 months also have yet to develop many of the signs that can be used to judge clinical appearance."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the caregivers:	
a. appropriate dose and frequency of administration	None recommended
b. patient's options in the event that condition worsens or persists	"If fever worsens or does not improve, you should take Alison to a hospital emergency department after speaking with the pediatrician."
c. specific nondrug measures	"Maintain room temperature at 68°F, and dress her in lightweight clothing"
Solicit follow-up questions from caregivers.	"I have ibuprofen (Advil) liquid at home. Is that OK to give her for now until I get to the pediatrician?"
Answer caregivers' questions.	"Ibuprofen is not recommended in children < 6 months of age. Please call your pediatrician immediately."
<b>Evaluation of Patient Outcome</b>	

9. Assess patient outcome.

Contact Alison's mother in 1-2 days to ensure that she sought medical care for Alison.

Key: NA = Not applicable; NKDA = no known drug allergies.

### Patient Education for Fever

The primary objectives of treating fever are to (1) relieve the discomfort of fever and (2) prevent complications associated with fever. For most patients, carefully following product instructions and the self-care measures listed here will help to ensure optimal therapeutic outcomes.

#### Temperature Measurement

- Do not rely on feeling the body to detect fever. Take a temperature reading with an appropriate thermometer.
- For children up to 3 months of age, the rectal method of temperature measurement is preferred ([Table 6-3](#)). Use of a tympanic thermometer is not recommended in children younger than 6 months because of the size and shape of the infant's ear canal.
- For children ages 6 months to 3 years, the rectal, oral, tympanic, or temporal method may be used if proper technique is followed ([Tables 6-3, 6-4, 6-5, and 6-6](#)).
- For individuals older than 3 years, the oral, tympanic, or temporal method is appropriate ([Tables 6-4, 6-5, and 6-6](#)).

#### Nondrug Measures

- Do not use isopropyl or ethyl alcohol for body sponging. Alcohol poisoning can result from skin absorption or inhalation of topically applied alcohol solutions.
- For all levels of fever, wear lightweight clothing, remove blankets, and maintain room temperature at 68°F.
- Unless advised otherwise, drink or provide sufficient fluids to replenish body fluid losses. For children, increase fluids by at least 1-2 ounces per hour; for adults, increase fluids by at least 2-4 ounces per hour. Sports drinks, fruit juice, a balanced electrolyte formulation, or water is acceptable.

#### Nonprescription Medications

- Nonprescription analgesics/antipyretics (see [Chapter 5, Tables 5-2 and 5-3](#)) help in alleviating discomfort associated with fever and reducing the temperature.
- Nonprescription analgesics/antipyretics typically take 30 minutes to 1 hour to begin to decrease temperature and discomfort.
- Monitor level of discomfort and body temperature using the same thermometer at the same body site two to three times per day during a febrile illness.
- Use single-entity nonprescription analgesics/antipyretics at low doses for up to 3 days for treatment of fever (see [Chapter 5, Tables 5-2 and 5-3](#) for dosages), unless you have exclusions for self-care ([Figure 6-1](#)).
- Avoid alternating antipyretics because of the complexity of the dosing regimens, increased risk of medication errors, and adverse effects.
- Dosing of either ibuprofen or acetaminophen in children should be based on body weight, not age.
- To avoid incorrect dosing, use a measuring device such as a syringe, dosing spoon, or medicine cup when administering liquid medication.
- If you are pregnant or have uncontrolled high blood pressure, congestive heart failure, renal failure, or an allergy to aspirin, avoid use of NSAIDs (ibuprofen and naproxen sodium) or aspirin-containing products.
- Avoid using aspirin and aspirin-containing products for fever in children younger than 15 years because of the possible risk of Reye's syndrome.

#### When to Seek Medical Attention

- Seek medical attention if fever or discomfort persists or worsens after 3 days of drug treatment.

#### Key Points for Fever

- Fever is self-limiting and rarely poses severe consequences unless the core temperature is greater than 106°F (41.1°C).
- The main treatment goal for fever is to eliminate the underlying cause as well as to alleviate the associated discomfort.
- Fever should be confirmed only by using a thermometer, which is an FDA-regulated medical device.
- Patients should be educated on the proper measurement techniques for the thermometry they utilize.
- Patients should be referred for further evaluation if their rectal temperature or its equivalent is greater than 104°F (40°C), they have a history of febrile seizures, they have comorbid conditions compromising their

health, or they are younger than 3 months with a temperature exceeding 100.4°F (38.0°C).

- Sponge baths using topical isopropyl or ethyl alcohol to reduce fever should be discouraged.
- Referral for further medical evaluation is appropriate to detect an underlying cause if 3 days of self-treatment are not successful in a patient older than 2 years of age and for more than 24 hours in a child younger than 2 years of age.
- Health care providers should counsel patients on the proper use of nonprescription antipyretic agents (including appropriate use of measuring devices) to limit medication errors and side effects. If a patient has been instructed to alternate antipyretic therapies by their health care provider, they should be counseled on the importance of recording the generic name of the drug given, the dose, and the time of administration to avoid any adverse effects.

**Handbook of Nonprescription Drugs > Chapter 7. Musculoskeletal Injuries and Disorders****Musculoskeletal Injuries and Disorders: Introduction**

Pain is one of the most common symptoms to prompt a visit to a health care provider. Because pain is a common symptom of disease or injury, patients often seek medical attention, although many seek to relieve the pain by self-treating with nonprescription analgesics. Much of the pain for which people attempt self-treatment arises from the musculoskeletal system. Musculoskeletal pain may be felt in the affected tissue itself or referred from another anatomic source (e.g., hip pain referred from its primary source in the low back).<sup>1</sup>

Musculoskeletal pain arises from the muscles, bones, joints, and connective tissue. The development of musculoskeletal pain can be acute, such as sport injuries (e.g., tendonitis, sprains, and strains), or it can stem from the exacerbation of a condition (e.g., osteoarthritis). Acute pain is typically defined as pain lasting less than 4 weeks. Pain lasting at least 3 months is considered chronic pain and may arise from degenerative joint disease, osteoarthritis, or chronic tendonitis (e.g., carpal tunnel).<sup>2</sup>

Use of nonprescription systemic and topical analgesics remains high, with more than \$3,893 million and \$516 million spent, respectively, per year in the United States on such remedies.<sup>3</sup> Ideally, a patient experiencing pain will ask a provider to assist in selecting a nonprescription product. Providers need to communicate effectively to understand the types of pain for which patients are seeking treatment to better understand the nature of their pain complaints. Providers must also be ready to offer reasonable recommendations for either treatment or further evaluation.

Musculoskeletal complaints result in a significant amount of lost work days, work limitations, loss of employment, and increased utilization of the health care system. These complaints are believed to be the greatest contributors to the economic burden of chronic pain, costing state and federal agencies \$100 billion annually. The total annual cost of persistent pain for adults in the United States, both noninstitutionalized and nonmilitary personnel, is estimated to be between \$560 and \$635 billion dollars.<sup>4,5</sup> More than 100 million adults in the United States battle chronic pain.<sup>5</sup>

**Pathophysiology of Musculoskeletal Injuries and Disorders**

The musculoskeletal system includes the muscles, tendons, ligaments, cartilage, and bones. Muscles are attached to bones by tendons, and ligaments connect bone to bone. Tendons and ligaments normally have limited ability to stretch and twist. Because of their tensile strength, tendons and ligaments rarely rupture unless subjected to intense forces, but they may become damaged when hyperextended or overused. Synovial bursae are fluid-filled sacs located between joint spaces to provide lubrication and cushioning. Cartilage functions as protective pads between bones in joints and in the vertebral column.<sup>6</sup>

Skeletal, or striated, muscle is composed of cells (myocytes) in which two constituents (actin and myosin) are primarily responsible for contraction. Muscle contraction also involves several electrolytes within the muscle tissue, including calcium and potassium. Pain receptors are located in skeletal muscle and the overlying fascia, and those receptors can be stimulated as a result of overuse or injury to the muscle or surrounding structures.<sup>1,6</sup>

Somatic pain occurs when pain impulses are transmitted from peripheral nociceptors to the central nervous system (CNS) by nerve fibers. Common sites of origin are muscles, fascia, and bones. Somatic pain is most commonly myofascial (e.g., muscle strain) or musculoskeletal (e.g., arthritis).<sup>1</sup> (See Chapter 5 for discussion of transduction, transmission, perception, and modulation of pain.)

Mechanoreceptors and chemoreceptors mediate muscle pain. These nerve endings are heterogeneous: only a single chemical can stimulate some endings, whereas a variety of chemical, mechanical, and thermal triggers can stimulate others.<sup>1,6</sup>

Erythema (redness), edema, and hyperalgesia (an exaggerated pain response to minor amounts of noxious stimuli<sup>5</sup>) at the affected site characterize the inflammatory response, which develops through participation of multiple mediators, including histamine, bradykinin, serotonin, leukotrienes, and prostaglandin E.<sup>1</sup> Muscle injuries can be categorized as delayed-onset muscle soreness (e.g., overexertion), myalgia, strains, tendonitis, bursitis, and sprains. Low back pain and osteoarthritis are common conditions associated with musculoskeletal complaints. *Overexertion* or *repeated unaccustomed eccentric muscle contraction* is associated with delayed-onset (8 hours or more) muscle soreness, which can last for days, usually peaking at 24–48 hours. This pain reflects muscle damage that was presumably initiated by force generated in the muscle fibers; the pain is thought to be induced by inflammation, acidosis, muscle spasms, and/or microlesions. Prolonged tonic contraction produced by exercise, tension, or poor posture and by body mechanics can also produce muscle pain. Overexertion is common in individuals who do not exercise regularly but then begin an exercise regimen at a level of high intensity.

*Myalgia*, or *muscle pain*, can result from systemic infections (e.g., influenza, coxsackievirus, measles, and other illnesses), chronic disorders (e.g., fibromyalgia and polymyalgia rheumatica), and medications (e.g., some cholesterol-lowering agents such as HMG-CoA reductase inhibitors). Abuse of alcohol may precipitate acute alcoholic myopathy. Bone and muscle pain related to a vitamin D deficiency (osteomalacia) may also occur.<sup>1</sup>

*Strains* are a result of an injury to a muscle or a tendon. A strain can be caused by an acute injury, or with prolonged overuse, a strain can become a chronic condition. The movements that cause a strain involve twisting or pulling. Tendons can become strained when their stretch capacity is exceeded (e.g., hyperextension injury of an arm or leg). The strain injury is caused by eccentric contraction of the muscle while the muscle is lengthening. A tear of the muscle or tendon can also occur.<sup>7</sup>

*Tendonitis* is the inflammation of a tendon, which results from acute injury or from chronic repetitive movements of a body part. An example of an overuse injury is carpal tunnel syndrome, a condition characterized by tingling or numbness of the first digits of the hand caused by repetitive use of the hands and wrists. Tendon sheaths become inflamed and constrict the median nerve as it passes through a narrow channel between the wrist bones.<sup>6</sup> Tendonitis can also commonly occur in the Achilles tendon, which connects the calf muscle to the heel.

Common terms that describe sports-related tendonitis from overuse include tennis or golfer's elbow, swimmer's shoulder, and jumper's knee. In sports-related overuse injuries, contributing factors for tendonitis can include increased age, poor technique, improper conditioning, exercise of prolonged intensity or duration, and poorly designed equipment for specific activities (e.g., poor cushioning of athletic shoes).

Finally, certain medications (e.g., fluoroquinolone antimicrobials) are associated with the development of tendonitis or tendon rupture and carry a boxed warning.<sup>8</sup>

*Bursitis* is a common cause of localized pain, tenderness, and swelling, which is worsened by any movement of the structure adjacent to the bursa, in the joint. Bursitis generally results from an acute injury to the joint or over-repetitive joint action. When pain is accompanied by the presence of a puncture site (possibly from intra-articular injection), an adjacent source of infection, or severe inflammation, an infectious cause should be suspected and ruled out before recommending self-treatment.

*Sprains* are the most common problem with ligaments. Sprains are graded by their characteristics, with grade I sprains resulting from excessive stretching, grade II sprains resulting from a partial tear, and grade III sprains involving a complete tear of the tissue. Grade II and III sprains typically result in moderate-severe pain, loss of function of the affected limb, and an inability to bear weight. Tears and ruptures are more common in ligaments than in tendons. Sprains commonly occur during physical activity. Approximately 628,000 sprains occur annually in the United States.<sup>7</sup>

*Low back pain* is the fifth most likely reason for a physician visit; the lifetime prevalence of developing low back pain approaches 80%.<sup>6,9</sup> The National Institute of Arthritis and Musculoskeletal and Skin Disease reports that 25% of people report at least 1 day of back pain in a 3-month period.<sup>10</sup>

Main risk factors for the development of low back pain include sedentary lifestyle (particularly one disrupted by bursts of activity), poor posture, improper shoes, excessive body weight, poor mattress and sleeping posture, and improper technique when lifting heavy objects. Most patients recover within a few days to a few weeks, even without treatment; if pain persists for more than 3 months, it is classified as chronic low back pain.<sup>2,11</sup> Other causes of low back pain include congenital anomalies, osteoarthritis, vertebral fractures and compressions, spinal tuberculosis, and referred pain from diseased kidneys, pancreas, liver, or prostate.<sup>1</sup>

*Osteoarthritis* is characterized by a gradual softening and destruction of the cartilage between bones. Cartilage and bone are destroyed in the joint spaces and regenerated, causing a rearrangement of the synovial architecture. Often referred to as "degenerative joint disease," osteoarthritis is caused by genetic, metabolic, and environmental factors. Heavy physical activity, repetitive movement, and lifting of heavy weights may aggravate this condition, whereas light-moderate activity does not and is generally helpful.<sup>12,13</sup> Approximately 27 million people in the United States have a diagnosis of osteoarthritis; by 2030, that number is expected to increase to 67 million.<sup>14</sup>

### Clinical Presentation of Musculoskeletal Injuries and Disorders

Table 7-1 lists many of the presenting signs and symptoms of musculoskeletal disorders and also differentiates other factors. Pain is a common symptom among all these disorders.

In addition to the pain induced by a sprain, patients have variable degrees of joint function. If a sprain patient has limited joint function, the injury is most likely a grade II or grade III sprain that requires proper workup to rule out a fracture or tear. If a joint is visibly deformed, it requires emergency assistance.

Patients with carpal tunnel syndrome often experience a diminished ability to feel heat or cold; a sense that their hands are swollen, even when they are not; a weakness in the hands; and a tendency to drop things. Symptoms persist during sleep and even when the hand is not being used, a characteristic that can be used to distinguish this disorder from others.

The pain of osteoarthritis does not correlate directly with the degree of joint damage. Pain is often referred, and

proximal muscles can be involved if a person with osteoarthritis guards the affected joint by changing his or her gait to reduce discomfort. The pain caused by chronic osteoarthritis often limits the patient's activities of daily living (ADLs) (e.g., inability to grip containers or walk more than a short distance).

Low back pain can also be neuropathic in nature, involving the sciatic nerve, causing sharp referred pain into one or both of the patient's legs. Low back pain can often limit a patient's ability to bend, move, sit, or walk.

Complications of untreated pain-inducing injuries include further tissue damage and (in advanced arthritis) bone and cartilage remodeling. Pain is associated with significant limitations, including a reduction in ADLs, disability, loss of work time, and physical impairments (e.g., insomnia). Be sure to look for warning signs and symptoms that preclude self-treatment of such disorders. (See exclusions for self-treatment in [Figure 7-1](#).)

### Treatment of Musculoskeletal Injuries and Disorders

Acute pain is the body's alarm system; it signals injury by trauma, disease, muscle spasms, or inflammation. Chronic pain, conversely, may or may not be indicative of injury and requires a primary care provider's assessment before treatment is initiated.

**TABLE 7-1 Comparison of Musculoskeletal Disorders**

<i>Myalgia</i>	<i>Tendonitis</i>	<i>Bursitis</i>	<i>Sprain</i>	<i>Strain</i>	<i>Osteoarthritis</i>
<b>Location</b>					
Muscles of the body	Tendon locations around joint areas	Inflammation of the bursae within joints; common locations include knee, shoulder, big toe	Stretching or tearing of a ligament within a joint	Hyperextension of a muscle or tendon	Weight-bearing joints, knees, hips, low back, hands
<b>Signs</b>					
Possible swelling (rare)	Warmth, swelling, erythema	Warmth, edema, erythema, and possible crepitus	Swelling, bruising	Swelling, bruising	Noninflammatory joints, narrowing of joint space, restructuring of bone and cartilage (resulting in joint deformities), possible joint swelling
<b>Symptoms</b>					
Dull, constant ache (sharp pain relatively rare); weakness and fatigue of muscles also common	Mild-severe pain generally occurring after use; loss of range of motion	Constant pain that worsens with movement or application of external pressure over the joint	Initial severe pain followed by pain, particularly with joint use; tenderness; reduction in joint stability and function	Initial severe pain with continued pain upon movement and at rest; muscle weakness; loss of some function	Dull joint pain relieved by rest; joint stiffness <20-30 minutes; localized symptoms to joint; crepitus
<b>Onset</b>					
Varies depending on cause (i.e., trauma = acute, but drug-induced = insidious)	Often gradual, but can develop suddenly	Acute with injury; recurs with precipitant use of joint	Acute with injury	Acute with injury	Insidious development over years
<b>Modifying Factors</b>					

Elimination of cause; use of stretching, rest, heat, topical analgesics, systemic analgesics	Elimination of cause; use of stretching, rest, ice, heat, topical analgesics, systemic analgesics	Joint rest; immobilization; topical analgesics; systemic analgesics	RICE; stretching; use of protective wraps (e.g., ankle tape, knee brace, cane); topical counterirritants; systemic analgesics	RICE; stretching; use of protective wraps; topical counterirritants; systemic analgesics	Continuous exercise (light-moderate activity); weight loss, analgesic medication; topical pain relievers
--	---	---	---	--	--

Key: RICE = rest, ice, compression, elevation ([Table 7-2](#)).

### Treatment Goals

Treatment of the patient with musculoskeletal complaints encompasses many different goals, including (1) decreasing the subjective intensity (severity) of pain; (2) decreasing the duration of pain, when possible; (3) restoring function of the affected area; (4) preventing re-injury and disability (i.e., improve ADLs); and (5) preventing acute pain from becoming chronic persistent pain.

### General Treatment Approach

Patients with musculoskeletal injuries present with common symptoms (especially pain and swelling of the affected area) and have similar self-treatment approaches. Nonpharmacologic therapy consisting of rest, ice, compression, and elevation (RICE) along with nonprescription oral analgesics and/or topical analgesics during the first 1-3 days following injury is helpful.<sup>7</sup> Before treatment can be recommended, however, the patient should be carefully screened to ensure appropriateness of self-treatment. The algorithm in [Figure 7-1](#) presents a stepwise approach to self-management of pain for patients who are not excluded for self-care.

Patients with acute low back pain are candidates for self-treatment. Management of acute back pain includes rest for 1-2 days and nonprescription oral or topical analgesics. Chronic low back pain requires medical evaluation before initiating therapy.<sup>15</sup>

Pain associated with osteoarthritis is approved for self-treatment after an initial medical diagnosis. The general treatment approach includes appropriate lifestyle changes (including physical activity and weight loss) and use of an analgesic, which may be a nonprescription medication.<sup>13</sup>

Self-care of musculoskeletal injuries and disorders. Key: ADR = Adverse drug reaction; FDA = Food and Drug Administration; OTC = over-the-counter; RICE = rest, ice, compression, elevation. (Source: Adapted from Self-care of self-limited pain. In: Albrant DH, ed. *The American Pharmaceutical Association Drug Treatment Protocols*. 2nd ed. Washington, DC: American Pharmaceutical Association; 2001:424-5.)

### Nonpharmacologic Therapy

Injury from playing sports or exercising can be prevented by warming up and stretching muscles before physical activity, ensuring proper hydration, and wearing appropriate footwear. Stretching must be done cautiously—without bouncing—to avoid muscle strain. For muscle cramps, stretching and massaging the affected area followed by immediate rest will loosen the muscle. For electrolyte depletion, oral supplementation of wasted electrolytes is appropriate, including fluids containing potassium, sodium, and magnesium (e.g., sports drinks or enhanced waters). RICE therapy promotes healing and helps reduce swelling and inflammation associated with muscle and joint injuries ([Table 7-2](#)). Ice should not be applied for more than 15-20 minutes because excessive icing causes considerable vasoconstriction and reduces vascular clearance of inflammatory mediators from the damaged area. Ice therapy can also be recommended for patients with osteoarthritis experiencing pain and/or swelling.<sup>13,16</sup> Both ice and heat, at temperatures outside the skin's threshold for tolerance, can be damaging and can result in blistering or burning; therefore, neither therapy should be applied directly to the skin.

#### TABLE 7-2 Guidelines for RICE Therapy

<ul style="list-style-type: none"> <li>• Rest the injured area and continue until pain is reduced (generally 1-2 days). Slings, splints, or crutches can be used, if necessary.</li> </ul>
<ul style="list-style-type: none"> <li>• As soon as possible, apply ice to the injured area in 15- to 20-minute increments, at least 3-4 times a day. Continue the ice-pack therapy until swelling subsides (usually 1-3 days, depending on the severity of injury).</li> </ul>
<ul style="list-style-type: none"> <li>• Apply compression to the injured area with an elastic support or an elasticized bandage as follows:</li> </ul>

- Choose the appropriate size bandage for the injured body part. If preferred, purchase a product specifically designed for the injured body part.
- If ice is also being applied to the injured area, soak the bandage in water to aid the transfer of cold.
- Wrap the injured area by overlapping the previous layer of bandage by about one-third to one-half its width.
- Wrap the point most distal from the injury (e.g., if the ankle is injured, begin wrapping just above the toes).
- Decrease the tightness of the bandage as you continue to wrap. If the bandage feels tight or uncomfortable, or if circulation is impaired, remove the compression bandage and rewrap it. Cold toes or swollen fingers indicate that the bandage is too tight.
- After using the bandage, wash it in lukewarm, soapy water; do not scrub it. Rinse the bandage thoroughly and allow to air dry on a flat surface.
- Roll up the bandage to prevent wrinkles, and store it in a cool, dry place. Do not iron the bandage to remove wrinkles.
• Elevate the injured area at or above the level of the heart 2-3 hours a day to decrease swelling and relieve pain.

Key: RICE = Rest, ice, compression, elevation.

Heat therapy is an alternative for patients who develop pain of a noninflammatory nature. It has been studied in the treatment of acute low back pain with favorable effects.<sup>9,15</sup> In addition, osteoarthritis guidelines recommend heat as adjunct nonpharmacological treatment for pain and stiffness.<sup>13,16</sup> Although its mechanism of action is not fully understood, heat may alleviate pain by increasing blood flow, reducing muscle spasm, and improving stiffness. Heat should be applied for 15-20 minutes, 3-4 times a day. Heat should not be applied to inflamed areas because it can intensify vasodilation and exacerbate vascular leakage.<sup>17</sup> Furthermore, heat should not be used with topical analgesics or over broken skin.

Heat should be applied to the affected area in the form of a warm wet compress, heating pad, or hot-water bottle. Ease of use favors newer, heat-generating adhesive and wrap products (e.g., ThermaCare, Precise, and various generic brands), which can be worn on the affected area up to 8 hours (some products can be used for 12 hours). The products come in various shapes, including back, hip, neck, knee, wrist and hand, shoulder, elbow, and lower abdomen. For nonadhesive products, the darker side of the heat cells should be placed toward the skin. The adhesive products should be applied on dry skin that is free of lotion. There are product exceptions to this that have unique directions (e.g., ThermaCare menstrual product, BodiHeat), such as placing the adhesive side on the undergarment or clothing.

Heating devices should not be used on areas of skin with decreased sensation, a practice that can lead to a skin burn. Specifically, ThermaCare heat-generating products should not be placed on the back of the knee or inside the bend of the arm.<sup>18</sup>

Although not generally associated with many side effects, at least two brands of heat-generating patches have been recalled for causing burns along with skin irritation.<sup>19,20</sup> Patients should be advised to remove the patch immediately if they have any pain or discomfort, itching, or burning. Heat wraps should be worn over a towel or layer of clothing in patients older than 55 years; heat wraps should not be used during sleep.

Limited scientific information is available regarding contrast therapy (alternating heat and ice) to aid in sports injury recovery. Anecdotally, some individuals report relief, but insufficient scientific evidence exists to recommend this therapy.<sup>21,22</sup>

Transcutaneous electrical nerve stimulation (TENS) therapy is used widely by various practitioners (e.g., physical therapists, physicians, and chiropractors) in the treatment of pain. FDA has approved TENS therapy for nonprescription use as a class II medical device for the relief of pain associated with sore, aching muscles; joint pain; or chronic intractable pain.<sup>23-25</sup> Pain relief is thought to come from two mechanisms: alteration of pain transmission and an increase in the production of natural endorphins. A TENS device is typically used for an interval of 15-30 minutes up to 3 times daily. The electrode pads can be placed on various areas of the body for pain relief (e.g., back,

legs, ankles, arms, and shoulders), but placement is product dependent. Because of safety concerns patients should avoid placing the electrodes on the throat, chest, or head or over the carotid arteries. The electrodes also should not be placed on open wounds, rashes, inflamed skin, cancerous lesions, or areas of skin with altered sensation, or over topical analgesics. Patients with internal or attached medical devices (e.g., pacemakers, defibrillators, electrocardiograms, and respirators); pregnant patients; and the pediatric population should not use nonprescription TENS devices.<sup>24,25</sup> The directions for proper and safe use of these devices are product specific, so the health care provider should review the directions with the patient.

Proper posture and the use of ergonomic controls (e.g., a chair with back support or an ergonomic keyboard) improve function and reduce pain. Heel lifts and better-fitting shoes are recommended for patients with Achilles tendonitis or low back pain. Approaches to chronic low back pain also include therapeutic interventions such as heat therapy, massage with traction, and, most important, mobilization with exercise or physical therapy. Chiropractic manipulation and acupuncture are also commonly used for the treatment of back pain.<sup>15</sup>

## Pharmacologic Therapy

### Systemic Analgesics

NSAIDs and acetaminophen are commonly used nonprescription analgesics; they are often employed in the initial treatment of musculoskeletal injuries. Systemic analgesic therapy should be limited to 10 days of self-care use,<sup>26</sup> and patients should seek appropriate medical care if the condition continues beyond this period or worsens during the course of treatment. (See Chapter 5 for dosages, safety, and properties of nonprescription systemic analgesics.) For the treatment of osteoarthritis of the hip and knee, acetaminophen (rather than NSAIDs) has been recommended historically by some organizations as first-line therapy, despite data suggesting that NSAIDs provide slightly improved pain relief.<sup>12,27</sup> This initial treatment recommendation is made on the basis of drug safety rather than efficacy. Chronic use of NSAIDs leads to more severe and prevalent side effects (e.g., nephropathy, gastrointestinal ulcerations and bleeding, and the potential for cardiac events). Recent recommendations published by the American College of Rheumatology (ACR), however, include both acetaminophen and NSAIDs among their initial therapy options. They recommend that if NSAIDs are used chronically for the management of osteoarthritis, a proton-pump inhibitor should be considered for gastrointestinal protection. See Chapter 13 for further information on risks of long-term use of proton-pump inhibitors. The ACR guidelines do express a strong recommendation to consider using topical NSAIDs rather than systemic NSAIDs in patients 75 years of age and older.<sup>13</sup>

### Topical Products

Topical analgesics may have local analgesic, anesthetic, antipruritic, and/or counterirritant effects. Nonprescription topical analgesics are approved specifically for the topical treatment of minor-moderate aches and pains of muscles and joints (e.g., simple backache, arthritis pain, strains, bruises, and sprains).<sup>28</sup> They are recommended as adjuncts to pharmacologic and nonpharmacologic therapy of musculoskeletal injuries and disorders.

#### Counterirritants

Topical counterirritants are applied to the skin to relieve pain.<sup>28,29</sup> Counterirritation is the paradoxical pain-relieving effect achieved by producing a less severe pain to counter a more intense one. The pain relief results more from nerve stimulation than depression.<sup>28,29</sup> When applied to the skin at pain sites, counterirritants produce a mild, local inflammatory reaction, which provides relief to the site underlying the skin surface being treated. These induced sensations distract from the deep-seated pain in muscles, joints, and tendons. Pain is only as intense as it is perceived to be, and the perception of other sensations caused by the counterirritant or its application (e.g., massage, warmth, or redness) causes the sufferer to disregard the sensation of pain.<sup>29</sup> On the basis of their topical effects, counterirritants are classified into four types (Table 7-3). Table 7-4 lists examples of commercially available products. All regulations and labeling for topical counterirritants are based on the detailed previous proposed rulemaking documents published in the *Federal Register* in 1979 and 1983.<sup>28,30</sup> FDA has recognized the ingredients in Table 7-3 as safe and effective (Category I) counterirritants for use in adults and in children ages 2 years and older.<sup>30</sup> Note that many topical nonprescription analgesic products have age limits older than 2 years.

Labels for most counterirritants indicate that the product is to be used for “the temporary relief of minor-moderate aches and sprains of muscles and joints.” In addition, the labeling recommended by most of FDA’s review panels includes claims for “simple backache, arthritis pain, strains, bruises, and sprains.”<sup>30</sup> In September 2012, FDA issued a Drug Safety Communication about serious burns associated with nonprescription topical counterirritants. Forty-three case reports of chemical burns were identified in FDA’s Adverse Event Reporting System (AERS) database and medical literature. Most of the second- and third-degree burn cases were associated with topical counterirritant products with higher concentrations of menthol as the single ingredient or with a combination product containing greater than 3% menthol and 10% methyl salicylate. In many of the case reports, the reactions occurred with only one

application, and the resulting injury occurred within 24 hours.<sup>31,32</sup> FDA recommendations for users of nonprescription topical analgesic products are presented in [Table 7-5](#). In the consumer version of the communication, FDA states that, although a feeling of warmth or coolness is normal with topical counterirritant use, patients should seek medical attention if burning pain or blistering occurs.<sup>32</sup>

[Table 7-3](#) provides dosing information for the various counterirritants.

The following sections describe the commonly used counterirritants currently available in the United States.

**Methyl Salicylate.** Methyl salicylate occurs naturally as wintergreen oil or sweet birch oil; gaultheria oil, teaberry oil, and mountain tea are other names for the compound. Methyl salicylate is usually combined with other ingredients (e.g., menthol and/or camphor).

**TABLE 7-3 Classification and Dosage Guidelines<sup>a</sup> for Nonprescription Counterirritant External Analgesics**

<b>Group</b>	<b>Ingredients</b>	<b>Concentration (%)</b>	<b>Mechanism of Action</b>	<b>Frequency and Duration of Use</b>
A	Allyl isothiocyanate Ammonia water Methyl salicylate Turpentine oil	0.5-5.0 1.0-2.5 10-60 6-50	Rubefacients (increase blood flow)	For all counterirritants: Apply no more than 3-4 times/day for up to 7 days
B	Camphor Menthol	3-11 1.25-16.0	Produce cooling sensation	As above in group A
C	Histamine dihydrochloride	0.025-0.1	Cause vasodilation	As above in group A
	Methyl nicotinate	0.25-1.0		
D	Capsicum Capsicum oleoresin	0.025-0.25 0.025-0.25	Incite irritation without rubefaction; are as potent as group A ingredients	For acute pain: As above in group A; For chronic pain: Apply 3-4 times/day for duration of pain (often long-term use with medical supervision)
	Capsaicin	0.025-0.25		

<sup>a</sup> Dosages approved for adults and for children 2 years and older.

**TABLE 7-4 Selected External Analgesic Products**

<b>Trade Name</b>	<b>Primary Ingredients</b>
<b>Menthol-Containing Products</b>	
Aspercreme Heat Pain Relieving Gel	Menthol 10%
Bengay Ultra Strength Pain Relieving Patch	Menthol 5%
Icy Hot No Mess Applicator	Menthol 16%
Mineral Ice	Menthol 2%
<b>Camphor-Containing Products</b>	
JointFlex Pain Relieving Cream	Camphor 3.1%
<b>Capsaicin-Containing Products</b>	
Capzasin Arthritis Pain Relief No-Mess Applicator	Capsaicin 0.15%
Capzasin-HP Arthritis Pain Relief Cream	Capsaicin 0.1%
Zostrix Hot and Cold Therapy	Capsaicin 0.025%

Zostrix-HP Arthritis Pain Relief Cream	Capsaicin 0.075%
<b>Histamine Dihydrochloride-Containing Products</b>	
Australian Dream Pain Relieving Arthritis Cream	Histamine dihydrochloride 0.025%
<b>Trolamine Salicylate-Containing Products</b>	
Aspercreme Cream/Lotion	Trolamine salicylate 10%
Sportscreme Deep Penetrating Pain Relieving Rub Cream	Trolamine salicylate 10%
<b>Combination Products</b>	
ActivOn Topical Analgesic Ultra Strength Arthritis	Histamine dihydrochloride 0.025%; menthol 4.127%
Arthritis Hot Cream	Methyl salicylate 15%; menthol 10%
Bengay Ultra Strength Pain Relieving Cream	Methyl salicylate 30%; menthol 10%; camphor 4%
Flexall Ultra Plus Relieving Gel	Menthol 16%; methyl salicylate 10%; camphor 3.1%
Icy Hot Cream Extra Strength/Precise Pain Relieving Cream	Methyl salicylate 30%; menthol 10%
Mentholatum Ointment	Camphor 9%; natural menthol 1.3%
Mentholatum Deep Heating Extra-Strength Pain Relieving Rub Cream	Methyl salicylate 30%; menthol 8%
Salonpas Pain Relief Patch	Methyl salicylate 10%; menthol 3%
Sloan's Liniment	Turpentine oil 47%; capsaicin 0.025% (from capsicum oleoresin)
Tiger Balm Arthritis Rub Cream	Camphor 11%; menthol 11%

**TABLE 7-5 FDA Recommendations for Application of Nonprescription Topical Analgesic Products**

• If pain, swelling, or blistering of the skin occurs after application of a topical analgesic, patients should immediately discontinue use of the product and seek medical attention.
• Do not bandage the area tightly where the product has been applied.
• Do not use any heat where the product has been applied.
• Do not apply to wounded, damaged, broken, or irritated skin.
• Do not allow these medications to come in contact with the eyes, or inside the nose, mouth, or genitals.

Source: References 31 and 32.

As a rubefacient, methyl salicylate causes vasodilation of cutaneous vasculature, thereby producing reactive hyperemia. This increase in blood pooling and/or flow is hypothesized to be accompanied by an increase in localized skin temperature, which in turn may exert a counterirritant effect. Because of its rubefacient action, methyl salicylate is responsible for the “hot” action in many topical counterirritant products.<sup>29</sup>

In addition to the mechanisms described previously, topically applied methyl salicylate products inhibit both central and peripheral prostaglandin synthesis. Studies on the rate and extent of percutaneous absorption of various commercially available methyl salicylate preparations show direct tissue penetration rather than redistribution by the systemic blood supply, indicating a localized effect of the topical product.<sup>29</sup>

Localized reactions (e.g., skin irritation or rash) and systemic reactions (e.g., salicylate toxicity) may occur with the use of methyl salicylate. Strong irritation may cause local reactions such as erythema, blistering, neurotoxicity, or thermal hyperalgesia. In addition, heat exposure and exercise after applying methyl salicylate have been shown to cause a threefold increase in systemic absorption of salicylate, which can lead to increases in adverse systemic reactions.<sup>33</sup> Table 7-5 reviews appropriate precautions to take when using topical analgesics. Because percutaneous absorption of salicylate can occur, methyl salicylate should be avoided in children and used with

caution in individuals who are sensitive to aspirin. Concomitant use of salicylate-containing topical analgesics and maintenance warfarin therapy has been implicated in prolonging prothrombin time.<sup>29</sup> Chapter 5 describes other potential drug interactions related to systemically absorbed salicylates. The report of the American Association of Poison Control Centers documents 10,000 encounters of methyl salicylate exposure in children ages 6 years and younger.<sup>34</sup> In children of that age, just a teaspoon of wintergreen oil can cause death.<sup>34</sup> Although an FDA survey found that oral ingestion of methyl salicylate in ointment form caused no deaths and that few cases manifested severe symptoms,<sup>28</sup> regulations require the use of child-resistant containers for liquid preparations containing concentrations greater than 5%.

**Camphor.** Although camphor occurs naturally and is obtained from the camphor tree, approximately three-fourths of the camphor used is prepared synthetically.

In concentrations of 0.1%–3.0%, camphor depresses cutaneous receptors and is used as a topical analgesic, anesthetic, and antipruritic. In concentrations exceeding 3%, particularly when combined with other counterirritant ingredients, camphor stimulates the nerve endings in the skin and induces relief of pain and discomfort by masking moderate-severe deeper visceral pain, with a milder pain arising from the skin at the level of innervation. When applied vigorously, it produces a rubefacient reaction.

Concentrations higher than those recommended are not more effective and can cause more serious adverse reactions if accidentally ingested.<sup>30</sup> The risk of toxicity relates to both the concentration of camphor in the ingested product and the extent of absorption of camphor into the body. CNS toxicity, expressed primarily as tonic-clonic seizures, is the major toxicity and begins to occur as early as 10 minutes following ingestion. High doses of camphor can cause nausea, vomiting, colic, headache, dizziness, delirium, convulsion, coma, and death.

Case reports of camphor toxicities in children continue.<sup>35,36</sup> In 2009, the American Academy of Pediatrics Committee on Drugs reaffirmed their statement on camphor, noting that although nonprescription camphor-containing preparations cannot exceed concentrations of 11%, camphor toxicity continues. The academy advised parents to be aware of this potential danger and recommended use of modalities that do not contain camphor.<sup>37</sup>

**Menthol.** Menthol is either prepared synthetically or extracted from peppermint oil (which contains a 30%–50% concentration of menthol). Menthol may be used safely in small quantities as a flavoring agent and has found wide acceptance in candy, chewing gum, cigarettes, cough drops, toothpaste, nasal sprays, and liqueurs. It is also used as a permeability enhancer to increase absorption of other topically administered medications.<sup>38</sup>

At concentrations less than 1%, menthol depresses cutaneous receptor response (i.e., acts as an anesthetic); at concentrations greater than 1.25%, menthol stimulates cutaneous receptor response (i.e., acts as a counterirritant). Recent studies have led to the identification of heat- and cold-sensitive receptors within sensory neurons called transient receptor potential (TRP) cation channels. Topically applied menthol activates the TRPM8 menthol receptor, triggering the sensation of cold.<sup>38</sup> The resultant cold sensation travels along pathways similar to the somatic pain sensations from the affected muscle or joint, which distracts from the sensation of pain. The initial feeling of coolness is soon followed by a sensation of warmth.

Menthol is contraindicated in patients with hypersensitivity or sensitization to the agent (e.g., urticaria, erythema, and other cutaneous lesions).<sup>38</sup> Treatment should be discontinued if the patient develops irritation, rash, burning, stinging, swelling, or infection.

**Methyl Nicotinate.** Although nicotinic acid is inactive topically, methyl nicotinate readily penetrates the cutaneous barrier. Vasodilation and elevation of skin temperature result from very low concentrations, with higher penetration rates seen with hydrophilic mediums (i.e., gels). One study showed that indomethacin, ibuprofen, and aspirin significantly depress the skin's vascular response to methyl nicotinate. Because these three drugs suppress prostaglandin biosynthesis, the vasodilator response to methyl nicotinate is mediated, at least in part, by prostaglandin biosynthesis.<sup>39</sup>

Generalized vascular dilation can occur when methyl nicotinate passes through the skin into the circulatory system. Therefore, persons who apply methyl nicotinate over large areas may experience a drop in blood pressure, a decrease in pulse rate, and syncope caused by generalized vascular dilation.<sup>27</sup>

**Capsicum Preparations.** Capsicum preparations (capsaicin, capsicum, and capsicum oleoresin) are derived from the fruit of various species of plants of the nightshade family. Capsicum contains about 1.5% of an irritating oleoresin, the major component of which is capsaicin (0.02%). Capsaicin is the major pungent ingredient of hot (chili) peppers. When applied to normal skin, capsaicin elicits a transient feeling of warmth through stimulation of the TRPV1 receptor. The mechanism of action is thought to be directly related to capsaicin's effects on the depletion of substance P. This substance is found in slow-conducting, unmyelinated type C neurons that innervate the dermis and epidermis. It is released in the skin in response to endogenous (e.g., stress) and exogenous (e.g., trauma or injury) factors. It appears that pruritic stimuli along with pain impulses are conveyed to central processing centers by type C fibers in the skin, for which capsaicin has selective activity. Local application of capsaicin to the peripheral axon appears to deplete substance P from sensory neurons. The depletion occurs both peripherally and centrally, presumably as the result of impulse initiation. When substance P is released, burning pain occurs but abates with

repeated applications. The diminishing sensation experienced with repeated applications can lead to adherence-related failures; health care providers should inform their patients about such effects and the importance of continuing therapy.<sup>40</sup>

Capsaicin has additional indications in comparison to other counterirritants. Capsaicin is used to reduce the pain—but not the inflammation—of rheumatoid arthritis and osteoarthritis; it is also used in a wide variety of other pain disorders (e.g., postherpetic neuralgia, psoriasis, and diabetic neuropathy).

The optimal dose of capsaicin varies among patients. The efficacy of capsaicin decreases (and local discomfort increases) when capsaicin is applied less often than directed because the drug's duration of action is 4-6 hours. Pain relief is usually noted within 14 days after therapy has begun, but relief will occasionally be delayed by as much as 4-6 weeks.

Once topical nonprescription capsaicin has begun to relieve pain, its use must continue regularly 3 or 4 times a day. If capsaicin treatment is stopped and the pain returns, treatment can be resumed. Capsaicin may produce a sensation of burning or stinging pain. However, as a result of tachyphylaxis, this local effect diminishes in intensity with repeated applications, typically within a few days but as long as 1-2 weeks.<sup>40-42</sup> To reduce the likelihood of capsaicin reaching topically sensitive areas (e.g., mucous membranes), patients should be instructed to use a glove for application and to wash their hands following use.<sup>40</sup> If the hands are the site of application, the patient should wait 30 minutes after application and then wash his or her hands. During use, capsaicin should not come in contact with the eyes or other sensitive areas of the body, as it will cause a burning sensation.<sup>40</sup> Capsaicin is available in a roll-on applicator or patch formulation, which may be preferred by some patients because of their ease of application. Patients using such formulations should still be instructed to wash their hands after handling the product. Use in patients with hypersensitivity to capsaicin is contraindicated. The agent should be discontinued temporarily if skin breaks down (i.e., skin is weeping and red; small ulcers are present), and the agent should not be applied to wounds or damaged skin.

In addition to skin reactions, capsaicin has also been associated with a cough, runny nose, or sneezing if particles are inhaled.<sup>40</sup> Overdose with use of capsaicin has not been reported, but more serious and intense side effects are reported with higher concentrations.<sup>43</sup>

Capsaicin is also available in a prescription patch formulation (Qutenza 8%) approved for the treatment of postherpetic neuralgia.<sup>43</sup>

### **Additional Counterirritants**

Allyl isothiocyanate, ammonia water, turpentine oil, and histamine dihydrochloride are also classified as Category I counterirritants by FDA, but few counterirritant preparations contain those ingredients. Most products that contain them also contain other topical analgesics, making any beneficial action or side effects of the products indistinguishable from other ingredients. In addition, very little evidence supports the efficacy of such compounds. Allyl isothiocyanate, ammonia water, and turpentine oil are rubefacients, so they should be expected to have effects similar to those of methyl salicylate. However, histamine dihydrochloride causes vasodilation, similar to the action of methyl nicotinate.

### **Pharmacotherapeutic Efficacy and Recommendations for Counterirritants**

Literature regarding the efficacy of counterirritants is conflicting; given their age, in some instances, current studies are lacking. However, Cochrane reviews evaluating the use of counterirritants in specific conditions and current guidelines for osteoarthritis provide some guidance on their use.

A 2009 Cochrane review reports that topical rubefacients (those specifically containing salicylates) are not supported by enough evidence to be recommended for use in acute or chronic pain. The authors noted that studies in assessing acute pain were limited; however, the studies included showed a 50% pain reduction in 1 in 3 patients treated after 1 week and a 50% pain reduction for 1 in 6 patients treated after 2 weeks. For chronic pain, however, the study concluded that topical rubefacients compare poorly with topical NSAIDs.<sup>44</sup>

After the Cochrane review, one study evaluated the use of a nonprescription combination methyl salicylate and menthol patch for the treatment of mild-moderate muscle strain; the results showed that pain relief was approximately 40% better in those using the 8-hour patch versus placebo.<sup>45</sup> These patches (Salonpas Pain Relief Patch and Salonpas Arthritis Pain Patch) are the only nonprescription analgesic patches to undergo FDA approval of a New Drug Application, which was granted in 2009.

Conflicting recommendations exist with capsaicin. An updated Cochrane Review in 2012 focused on reevaluating low concentration (<1%) capsaicin products for the treatment of chronic neuropathic pain. This review was conducted because the authors believed the 2009 conclusion might have been biased and ultimately may have overestimated capsaicin's efficacy. They utilized a stricter approach to the evaluation of evidence for inclusion in the updated review. The 2012 review states that there is insufficient evidence to make a conclusion about low-dose capsaicin in treating neuropathic pain but that it unlikely has any "meaningful effect."<sup>42</sup>

The National Institute for Health and Clinical Excellence guidelines for osteoarthritis do not support the use of rubefacients, with the exception of capsaicin.<sup>16,46</sup> The 2012 ACR guidelines for the management of osteoarthritis

conditionally recommend topical capsaicin as an initial option for the hand. The guidelines also conditionally recommend that capsaicin should not be used in the management of osteoarthritis of the knee. They do not make any recommendations regarding nonprescription topical analgesics in the management of osteoarthritis of the hip.<sup>13</sup>

## Other Topical Analgesics

### Trolamine Salicylate

Trolamine salicylate is a category III ingredient (insufficient data are available to establish safety and efficacy). Despite this designation, several nonprescription products contain trolamine salicylate as the primary ingredient (Table 7-4).

Trolamine salicylate, or triethanolamine salicylate, is not a counterirritant analgesic. It has been suggested that trolamine salicylate is absorbed through the skin and results in synovial fluid salicylate concentrations below those of oral aspirin. The recommended topical dosage of trolamine salicylate for adults and for children 2 years and older is a 10%-15% concentration applied to the affected area not more than 3 or 4 times a day. There are no recent studies published regarding the efficacy of topical trolamine salicylate.

Trolamine salicylate is still available over the counter and may be most useful to those patients who do not favor the localized irritation or the scent of Category I counterirritants. ACR guidelines conditionally recommend trolamine salicylate as an option for osteoarthritis of the hand.<sup>13</sup>

Trolamine salicylate has the same drug interactions and contraindications as other salicylates (see Chapter 5). During use, the agent should not contact the eyes or mucous membranes.

### Topical NSAIDs

Traditional topical NSAIDs are not currently available for nonprescription use in the United States, but they are available for prescription use (e.g., diclofenac). Their application on acute soft tissue strains and sprains, where the target tissue is situated closer to the skin surface, is reported to provide the benefits of oral NSAIDs with minimal systemic side effects. A 2010 Cochrane review recognizes the effectiveness of topical NSAIDs to treat acute musculoskeletal pain,<sup>47</sup> and a 2012 Cochrane review supports their use in the management of chronic pain from osteoarthritis.<sup>48</sup> Several guidelines recommend topical NSAIDs to be considered early in treatment for osteoarthritis.<sup>13,16,27</sup>

## Combination Products

General guidelines for nonprescription drug combination products state that Category I active ingredients from the same therapeutic category should not ordinarily be combined, unless the combination is deemed safer or more effective and has enhanced patient acceptance or quality of formulation.<sup>30</sup> Four separate chemical and/or pharmacologic groups of counterirritants provide four qualitatively different types of irritation. Many marketed preparations aim for at least two such effects when greater potency is desired, provided that each active ingredient is from a different group.

Combining counterirritants with skin protectants is irrational; the protectants oppose and may nullify counterirritant effects.

Preparation labels must list the active ingredients, including their concentrations, and must identify them by their officially recognized, established names. In addition, manufacturers voluntarily list ingredients on the label. Many manufacturers of combination products list only some of the active ingredients under the "active" heading, and they list many of the other pharmacologically viable products in the inactive ingredients section (e.g., BenGay Vanishing Scent Gel lists camphor and Aspercreme Heat Pain Relieving Gel lists capsaicin under inactive ingredients). Although the concentrations of inactive ingredients are not listed, they are generally below therapeutically determined amounts and are added for reasons other than pain-relieving effects. The manner of use and the frequency of applications should also be indicated.<sup>28</sup>

## Product Selection Guidelines

### Special Populations

No significant variability in response has been noted among patients of different ages or racial backgrounds. Variability related to the minimum age of patients does exist in product labeling. According to the tentative final monograph published in the *Federal Register* in 1983, use of external analgesics, as labeled within the confines of the statement, is to be avoided in children younger than 2 years.<sup>30</sup> However, most available products elect to label the minimum age as older than 12 years, and some products (particularly capsaicin products) list 18 years and older. Providers should follow labeling instructions for the products used. These products should be used cautiously, or avoided, in populations who cannot effectively communicate side effects they are experiencing after application of a topical analgesic. Of particular concern is use of such products in young children.

Musculoskeletal complaints are common in pregnancy, but complications may occur; therefore, patients should be

evaluated by their primary care provider.<sup>49</sup> Limited information is available regarding use of nonprescription topical analgesics in pregnancy. Capsaicin, in the prescription patch formulation, is pregnancy category B. One source lists the nonprescription formulation as category C, but limited data are available to determine a pregnancy classification.<sup>50</sup> Camphor, menthol, methyl salicylate, trolamine salicylate, and methyl nicotinate are not categorized. Topical camphor is suggested to be compatible during pregnancy based on a determination of limited data that it is low risk.<sup>51</sup> Definitive recommendations are not available because of the limited—or in some cases, complete lack of—data that are available on topical use in pregnancy. Consideration should be given to the systemic absorption of topical salicylates, particularly in the third trimester. Information regarding salicylates in pregnancy can be found in [Chapter 5](#).

### Patient Factors

The choice of treatment for acute pain syndromes and chronic conditions such as osteoarthritis is patient dependent. In addition to nonpharmacologic treatment, oral drug therapy is often employed. One should consider a patient's history (taking note of exclusions for self-treatment), other medications the patient is taking, and any known allergies to medications. Topical analgesics are used as an adjunct or substitute to oral drug therapy. If a counterirritant is selected, one with Category I ingredients should be recommended. Product concentrations are variable; in general, the lowest effective dose should be recommended for the shortest duration needed.

### Patient Preferences

Factors that impact product selection include dosage form, ease of use, cost, and even odor of the preparation. Dosage forms available include solutions, liniments, gels, lotions, ointments, creams, and patches. Oleaginous preparations (ointments and oil-based liniments) have increased absorption compared with solutions, gels, lotions, and creams, but they are greasy and generally less acceptable to patients. The use of patches is becoming more popular because of their simple application and long duration of action. With the exception of patches and solutions, topical products should be rubbed into the skin.

### Complementary Therapies

The most common dietary supplement used for osteoarthritis contains glucosamine and chondroitin. Published data regarding these supplements are conflicting because of population size, trial duration, preparations used, and outcomes measured (i.e., quality of life, pain indices, and radiologic changes). The National Institutes of Health and National Center for Complementary and Alternative Medicine has provided the largest study, the

Glucosamine/Chondroitin Arthritis Intervention Trial (GAIT).<sup>52</sup> Initial results from this 6-month study showed no benefit in mild pain but showed a statistically significant reduction with moderate-severe pain. However, only 22% of patients enrolled in the study were categorized as having moderate-severe pain; therefore, the GAIT trial concluded that further studies are needed because of the small population size. A 2-year follow-up using patients from the GAIT trial showed no clinical difference in reduction of pain and function and joint space width compared with placebo.<sup>53,54</sup>

The new ACR guidelines conditionally recommend that patients with osteoarthritis of the hip and knee should not use glucosamine or chondroitin sulfate.<sup>13</sup> These products and other complementary therapies are discussed in greater detail in [Chapter 51](#).

### Assessment of Musculoskeletal Injuries and Disorders: A Case-Based Approach

Routinely, the health care provider should inventory all patient medications, including pain medications, and should note the patient's satisfaction with or preference for past treatments. In addition, the health care provider should ask about aspects of the patient's medical history that relate directly to the origin or treatment of pain.

Before an attempt is made to treat a pain complaint, the health care provider should qualify and quantify the pain. Inquiry about the cause, duration, location, and severity of pain, as well as factors that relieve and exacerbate the pain, will help assess the pain. [Chapter 2](#) outlines effective strategies for obtaining information from patients about specific complaints. Using a pain scale helps to quantify the intensity of a patient's pain. With the numerical pain scale, the health care provider asks the patient to rank the present pain on a scale of 0-10, with 0 being no pain and 10 being the worst pain the patient can imagine. Typically, mild pain is defined as 1-3, moderate pain 4-6, and severe pain 7-10 on the numerical pain scale.<sup>1</sup> Initially, pain scores establish a baseline for pain before treatment. In addition, a high pain score can be used to screen for patients who would be better served by seeking an appropriate medical evaluation. Pain scores also serve as a measuring device for therapeutic outcomes. Other scales are available for pain rating in children (Wong-Baker FACES Pain Scale), adolescents, people who do not speak English, and other special populations.

A chronic painful condition presents a different set of challenges. An observant health care provider should intervene with a patient who regularly purchases nonprescription analgesics. If additional interviewing indicates an inadequately treated pain problem, additional workup by an appropriate provider should be made. Education should be offered regarding the risks of inadequate treatment as well as the overuse of medications.

Cases 7-1 and 7-2 are examples of the assessment of patients with musculoskeletal injuries and disorders.

## Case 7-1

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (e.g., nature, onset, duration, severity, associated symptoms)	Patient presents with a complaint that his back is really hurting him and that he is having difficulty moving around without pain. He reports that his pain right now is a 4 out of 10.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Yesterday he was working outside in the yard all day for the first time this spring.
c. description of the patient's efforts to relieve the symptom(s)	He has tried a heat patch, which he wore for 8 hours; he has not experienced any significant relief.
d. patient's identity	Alexander Smith
e. age, sex, height, and weight	70 years old, male, 5 ft 11 in., 205 lb
f. patient's occupation	Retired
g. patient's dietary habits	He eats a diet high in carbohydrates and red meat. He does not eat a balanced diet, avoiding vegetables, poultry, and fish.
h. patient's sleep habits	He finds that it is getting more difficult to sleep through the whole night; on average, he sleeps about 7 hours a night.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	He has a history of osteoarthritis, diabetes, coronary artery disease, uncontrolled hypertension, dyslipidemia, and anemia. He occasionally has problems with his back. His current medications include acetaminophen arthritis formulation, 1300 mg every 8 hours, 2-3 doses a day; metformin 1000 mg twice a day; metoprolol succinate 25 mg once daily; enalapril 10 mg once daily; aspirin 81 mg once daily; pravastatin 40 mg once daily; and B12 injections monthly.
j. allergies	Penicillin
k. history of other adverse reactions to medications	None
l. other patient preferences	He prefers patch formulations for convenience.
<b>Assessment and Triage</b>	

2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Patient is experiencing acute back pain as a result of his burst of activity yesterday with his yard work.
3. Identify exclusions for self-treatment (Figure 7-1).	Patient does not have any exclusions for self-care. If his pain were more severe (>6 on pain scale), a referral would be recommended.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer patient to PCP for further assessment and treatment. (2) Continue nondrug measures (heat). (3) Continue APAP alone. (4) Recommend an NSAID. (5) Recommend adjunct topical analgesic, single or combination product (methyl salicylate, trolamine salicylate, camphor, menthol, or capsaicin). (6) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Recommend nondrug measures, including 1-2 days of rest. Recommended therapy would include a topical counterirritant in a patch formulation because the patient prefers that. Continue APAP, which is a regular scheduled medication for his osteoarthritis that is a systemic analgesic. Patient has uncontrolled hypertension, so avoid systemic NSAIDs.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"A topical analgesic medication to treat the pain is appropriate, and we can select a patch formulation."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"An oral nonsteroidal anti-inflammatory should not be used because you regularly have elevated blood pressure readings. A topical analgesic will help treat your muscle pain."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	"Apply Salonpas original patch (methyl salicylate 6.3%, menthol 5.7%, and camphor 1.2%) 3-4 times a day."
b. maximum number of days the therapy should be employed	"This medication can be used for up to 7 days."
c. product administration procedures	"Apply the patch to your back on clean, dry skin where the pain is occurring. A new patch can be applied 3-4 times per day. Do not wear a patch for more than 8 hours. Wash hands before and after you apply the patch. It is not recommended to use heat when you are using this medication."

d. expected time to onset of relief	"You should experience some improvement shortly after application."
e. degree of relief that can be reasonably expected	"This medication will help reduce the pain but not eliminate it."
f. most common side effects	"It is normal to feel warmth in the area where the medication is applied. Some minor skin irritation may occur."
g. side effects that warrant medical intervention should they occur	"Immediately remove the product and contact your primary care provider if you experience any symptoms that would indicate a severe reaction (e.g., excessive redness, blistering, rash, burning, or stinging)."
h. patient options in the event that condition worsens or persists	"If this topical medication does not adequately relieve pain, please contact me to recommend a different topical medication."
i. product storage requirements	"Keep out of children's reach."
j. specific nondrug measures	"Rest for a day or two so as not to further aggravate your condition. Do not use heat over this medicated patch."
Solicit follow-up questions from the patient or caregiver.	"Does the Tylenol that I take for my arthritis help my back?"
Answer the patient's or caregiver's questions.	"Yes, Tylenol is a medication that can help with pain from any cause, but it does not reduce inflammation."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Monitor for a reduction in the patient's reported pain level using a pain scale. In addition, monitor for improved mobility.

Key: APAP = Acetaminophen; NA = not applicable; NKA = no known allergies; NSAID = nonsteroidal anti-inflammatory drug; PCP = primary care provider.

### Case 7-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (e.g., nature, onset, duration, severity, associated symptoms)	Patient presents with a complaint that she hurt her ankle during her basketball game last night. She reports that her pain is an 8 out of 10. She is struggling to walk in the pharmacy and is favoring her right ankle. Upon examination, you observe that her ankle is very swollen and discolored.

b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	During the game last night, she collided with another player, and her ankle rolled when she fell.
c. description of the patient's efforts to relieve the symptom(s)	She has been icing while awake for 15 minutes on and then 15 minutes off. She also slept with her ankle elevated.
d. patient's identity	Madison Jones
e. age, sex, height, and weight	17 years old, female, 5 ft 5 in., 140 lb
f. patient's occupation	High school student
g. patient's dietary habits	She does not eat a regular diet outside of dinner with her family.
h. patient's sleep habits	Sleeping habits are erratic because of her schedule and social activities. She sleeps 8 hours on school nights but likes to sleep in on the weekends.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	She is currently experiencing acne. Her current medications include a multivitamin daily and adapalene gel applied at bedtime.
j. allergies	NKA
k. history of other adverse reactions to medications.	None
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s) ( <a href="#">Table 7-1</a> ).	Patient appears to have at least sprained her ankle but may have a more serious injury such as a fracture or torn tendons around her ankle.
3. Identify exclusions for self-treatment ( <a href="#">Figure 7-1</a> ).	Patient is experiencing pain that is severe (8 out of 10 on pain scale) and is having significant difficulty putting weight on it.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer patient to PCP for further assessment and treatment. (2) Recommend nondrug measures (ice initially). (3) Recommend systemic analgesic. (4) Recommend topical analgesic, single or combination product (methyl salicylate, trolamine salicylate, camphor, menthol, or capsaicin). (5) Take no action.
<b>Plan</b>	

5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Refer patient to PCP for further evaluation because of the severity of pain. Recommend to continue nondrug measures including rest, elevation, compression, and ice (Table 7-2).
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Self-treatment is not appropriate for your condition. You should contact your primary care provider."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	The severity of your pain requires further evaluation by your primary care provider.
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"Do you think they will want me to get an x-ray?"
Answer the patient's or caregiver's questions.	"Your primary care provider may recommend an x-ray to rule out the possibility that you fractured a bone. Your primary care provider will be able to make that determination once he or she examines your ankle."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Follow up with patient to determine the outcome of her visit with her primary care provider.

Key: NA = Not applicable; NKA = no known allergies; PCP = primary care provider.

### Patient Counseling for Musculoskeletal Injuries and Disorders

Consultation with the patient should include explanation of the expected benefit of any recommended medication, the appropriate dose and drug administration schedule, application directions, potential adverse reactions, potential drug-drug or drug-disease interactions, and self-monitoring techniques for assessing response to therapy. Printed materials reinforce verbal information. Many such pamphlets or single-page handouts are available from national professional societies (e.g., [www.arthritis.org](http://www.arthritis.org)). These materials offer advice on exercise, diet, and sleep habits, as well as the advantages and disadvantages of pharmacologic therapy.

In acute pain management, early administration of nonprescription analgesics should be employed to prevent escalating pain, with downward tapering of the analgesic doses as pain severity allows. Patients should be assessed for the appropriateness of nonprescription oral analgesics (Chapter 5).

Patients should be instructed to notify their primary care provider if the pain worsens in quality or severity, or if new acute pain develops. Other sudden uncharacteristic pains may be harbingers of new tissue damage.

The box Patient Education for Musculoskeletal Injuries and Disorders lists specific information about topical analgesics, as well as preventive and nondrug measures to provide patients.

### Evaluation of Patient Outcomes for Musculoskeletal Injuries and Disorders

The primary indicator of treatment effectiveness is the patient's perception of pain relief. If a patient reports the pain is still present or has worsened after 7 days of using topical nonprescription analgesics,<sup>30</sup> the health care provider should refer the patient for further evaluation. In many instances, the lack of a return visit indicates a successful treatment regimen (the provider may call the patient in a few days to determine whether the complaint has resolved). However, a patient who returns with signs of continued swelling, pain, or inflammation should be referred for medical

evaluation. The continued pain may indicate an ongoing process that could lead to long-term disability or decreased mobility.

### Key Points for Musculoskeletal Injuries and Disorders

- Self-treatment of patients presenting with pain secondary to an injury or a disorder of the musculoskeletal system should be limited to those with mild-moderate pain who have no exclusions for self-treatment (Figure 7-1).
- Self-treatment of acute musculoskeletal injuries should include nondrug therapy, such as rest, ice, compression, and elevation (RICE). Heat therapy may also provide benefit after symptoms of inflammation have abated.
- Systemic analgesics are valid first-line agents to treat the majority of musculoskeletal injuries and disorders. Acetaminophen is preferred in noninflammatory diseases, whereas NSAIDs are preferred if inflammation is present. Side effects and drug interactions should be considered before therapy is chosen (see Chapter 5).
- Health care providers should counsel patients on the discussion points listed in Table 7-5 to avoid chemical burns with topical nonprescription analgesics.
- Health care providers should monitor the outcome of self-treatments and advise patients who self-treat their acute musculoskeletal injury with nonprescription topical analgesics to seek medical attention if their symptoms do not improve after 7 days. Patients who experience pain for greater than 10 days, regardless of treatment, should also be referred.

### Patient Education for Musculoskeletal Injuries and Disorders

The objectives of self-treatment are to (1) reduce the severity of pain; (2) reduce the duration of pain, when possible; (3) restore function to the affected area; (4) prevent re-injury and disability; and (5) prevent acute pain from becoming chronic persistent pain. Certain nondrug measures and nonprescription counterirritants can relieve pain symptoms from a sudden and recent muscle, tendon, or ligament injury; an overuse injury (e.g., tendonitis, bursitis, or repetitive stress injury); low back pain; or arthritis. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

### Preventive Measures

- To prevent muscle or joint strains and sprains, do warm-up and stretching exercises before playing sports or exercising, and wrap injured muscle or joint with protective bandage or tape.
- To prevent repetitive strain, exercise the muscles that are vulnerable to the injury, and use ergonomic controls to adjust posture, stresses, motions, and other damaging physical factors.
- To prevent tendonitis and cramps, warm up and stretch muscles before physical activity, drink sufficient fluids, and do not exercise to the point of exhaustion. To help prevent nocturnal leg cramps, raise the foot of the bed. For Achilles tendonitis, wearing better-fitting shoes with heel lifts may help reduce the symptoms.
- To prevent or reduce the occurrence of low back pain, do exercises to strengthen the muscles of the low back and abdomen, and use assistive devices (i.e., cane or walker), if needed.
- To prevent or reduce the occurrence of osteoarthritis, avoid a sedentary lifestyle; keep joints active; lose weight, if overweight; and use assistive devices, if needed.

### Nondrug Measures

- For pain related to muscle or joint injuries, begin treatment with RICE therapy (Table 7-2).
- For periodic muscle cramps, stretch and massage the affected area immediately; then rest or reduce activity of the muscle to allow it to loosen.
- For stiffness, apply heat to the affected area in the form of a warm wet compress, a heating pad, or a hot-water bottle.
- For osteoarthritis, try a combination of nondrug measures, including applying heat or cold to the affected area, supporting the area with splints, and doing range-of-motion and strength-maintenance exercises.

### Nonprescription Medications

- For mild-moderate muscle pain, take a nonprescription systemic analgesic for no longer than 10 days<sup>23</sup> (see Chapter 5 for a listing of nonprescription analgesics), and/or use a topical counterirritant for no longer than 7 days<sup>27</sup> (Table 7-3 provides recommended dosages of counterirritants).
- Do not use counterirritants if your skin is abraded, sunburned, or otherwise damaged.
- When using counterirritants, especially capsaicin, wash your hands after application and before touching your eyes and mucous membranes, or before handling contact lenses.
- Gently rub a thin layer of counterirritant product into affected muscles or joints until you cannot see the product. Thick application of the product does not make the product work better.

- Do not put a tight bandage or dressing over an area treated with a counterirritant. Do not use heat/warming devices with counterirritants.
- Do not treat a child 2 years of age or younger with counterirritants unless a primary care provider supervises the use. Follow age limits on product labeling.
- If you have asthma, and symptoms of wheezing and shortness of breath worsen while you are using a mentholated formulation, stop using it.
- If you are receiving anticoagulation therapy (especially warfarin), do not use products containing salicylates (including aspirin, methyl salicylate, and trolamine salicylate).
- If a counterirritant causes excessive redness and blistering or hives and vomiting, stop using it.

### When to Seek Medical Attention

- A feeling of warmth or coolness is normal; however, if burning pain or blistering occurs, seek medical attention.
- If you experience nausea, vomiting, colic, and other unusual symptoms while using a product containing camphor, seek medical care immediately.
- If the pain has been present for more than 10 days or has worsened, consult a primary care provider.
- If the symptoms persist after more than 7 days of treatment with a topical product, or if the pain is constant and felt in any position, consult a primary care provider.

## Handbook of Nonprescription Drugs > Chapter 8. Vaginal and Vulvovaginal Disorders

### Vaginal and Vulvovaginal Disorders: Introduction

Vaginal symptoms are among the most common health concerns of both reproductive age and older women. Vaginal symptoms may be experienced by all women whether married or single, sexually active or abstinent, homosexual or heterosexual, and premenopausal or postmenopausal.<sup>1</sup> About 65% of women experiencing vaginal symptoms will have one of three common vaginal infections: bacterial vaginosis (BV), vulvovaginal candidiasis (VVC), and trichomoniasis.<sup>1</sup> Infections may also be mixed, with more than one causative organism.

In general, vaginal infections are perceived as minor health problems and patients may consider self-treatment. Women may also self-treat noninfectious vaginal symptoms such as vaginal dryness, atrophic vaginitis, and allergic or chemical dermatologic reactions.<sup>1,2</sup> However, BV and trichomoniasis have been linked to significant health problems such as pelvic inflammatory disease (PID), preterm birth, and facilitation of the transmission of human immunodeficiency virus (HIV).<sup>2,3</sup> Given the number of women with vaginal infections and the approval of nonprescription vaginal antifungal products, health care providers should manage these infections carefully and provide patient education for VVC. Patients need to understand vaginal health to make appropriate decisions about self-care for vaginal symptoms.

The vagina is an elastic fibromuscular tube that extends 8-10 cm from the vulva to the uterus. The upper end of the vagina is closed except for the cervical os, the opening to the cervix. Anatomically, the vagina lies between the urinary bladder and the rectum. At the lower (vulvar) end of the vagina are the Bartholin's glands, which produce secretions in response to sexual stimulation. At puberty, under the influence of estrogen, the vaginal lining changes to stratified squamous epithelium, which contains glycogen. *Lactobacillus* bacteria convert glycogen to lactic acid, which creates an acidic pH of 4-4.5. This acidic pH and the production of hydrogen peroxide by these bacteria help protect the vagina from infection with other bacteria. After menopause, thinning of the vaginal lining occurs, concentrations of lactobacilli decline, and pH rises.<sup>4</sup>

The mature vagina is colonized by many organisms. *Lactobacillus* species predominate, accounting for 90%-95% of the vaginal flora. Another 5-10 species of bacteria, including *Corynebacterium*, *Streptococcus*, *Staphylococcus epidermidis*, *Gardnerella vaginalis*, *Peptostreptococcus*, and *Bacteroides*, are present in small quantities, with anaerobes being more common than aerobes.<sup>2,5</sup> *Candida albicans* and *Escherichia coli* may also be isolated in the absence of active infection in about 20% of women.<sup>5,6</sup>

The vaginal ecosystem is affected by the number and types of endogenous organisms, vaginal pH, and glycogen concentration. Hormonal fluctuations during the menstrual cycle can also influence the vaginal ecosystem in addition to drug therapy, douching, and number of sex partners.

The healthy vagina is cleansed daily by secretions that lubricate the vaginal tract. Normal vaginal discharge, also known as leukorrhea, consists of about 1.5 grams of vaginal fluid daily, which is odorless, clear or white, and viscous or sticky.<sup>6</sup> This discharge consists of endocervical mucus, serum transudate from vaginal capillary beds, endogenous vaginal flora, and epithelial cells.<sup>5,6</sup> An increase in vaginal secretions is normal during ovulation, during pregnancy, following menses, and with sexual excitement or emotional flares. An alteration in vaginal secretions may also occur in response to vaginal irritants such as feminine hygiene deodorant products and vaginal douches, as well as contraceptive products or use of tampons.

### Differentiation of Common Vaginal Infections

The signs and symptoms for different vaginal infections may be similar, and the characteristic symptoms that often help distinguish infections may be absent (Table 8-1). Both patients and providers may have difficulty accurately determining the type of infection solely on the basis of symptoms.<sup>7,8</sup>

**TABLE 8-1 Differentiation of Common Vaginal Infections**

<i>Classic Symptoms</i> <sup>1</sup>	<i>Differentiating Signs and Symptoms</i>	<i>Etiology and Epidemiology</i> <sup>1</sup>
<b><i>Bacterial Vaginosis</i></b>		
Thin (watery), off-white or discolored (green, gray, tan),	Vaginal irritation, dysuria, and itching are less frequent with	Polymicrobial infection resulting from imbalance in normal vaginal flora with

<p>sometimes foamy discharge; unpleasant “fishy” odor that increases after sexual intercourse or with elevated vaginal pH (e.g., menses)</p>	<p>BV than with VVC or trichomoniasis.<sup>18</sup> A foul odor is strongly associated with BV; absence of the odor virtually rules out BV. Increased vaginal discharge (“wetness”) is more common with BV than with VVC or trichomoniasis.</p>	<p>increase in <i>Gardnerella vaginalis</i> and anaerobes (<i>Peptostreptococcus</i>, <i>Mobiluncus</i>, <i>Prevotella</i>, and <i>Mycoplasma hominis</i>) and decrease in lactobacilli Risk factors: new sexual partner, African American race, use of IUD, douching, receptive oral sex, tobacco use, and prior pregnancy Possible protective factors: use of female hormones, including OC, and condoms Responsible for 33% of vaginal symptoms Predominately affects young, sexually active women but can arise spontaneously regardless of sexual activity; found in 12% of virginal adolescents; lower prevalence in postmenopausal women, even with use of hormones</p>
<p><b>Trichomoniasis</b></p>		
<p>Copious, malodorous, yellow-green (or discolored), frothy discharge; pruritus; vaginal irritation; dysuria No symptoms initially in ~50% of affected women Most men are asymptomatic and serve as reservoirs of the infection</p>	<p>Erythema and vulvar edema can occur with this infection.<sup>7</sup> Yellow discharge increases likelihood of trichomoniasis.</p>	<p>STI caused by <i>Trichomonas vaginalis</i> Risk factors: multiple sex partners, new sexual partner, nonuse of barrier contraceptives, and presence of other STIs Responsible for 15%-20% of vaginal infections</p>
<p><b>Vulvovaginal Candidiasis</b></p>		
<p>Thick, white (“cottage cheese”) discharge with no odor; normal pH (see text for detailed information; also referred to as “yeast infection” or “moniliasis”)</p>	<p>Presence of erythema, itching, and/or vulvar edema, and absence of malodor increase likelihood of VVC; thick, “cheesy” discharge is strongly predictive of VVC.<sup>7,19</sup></p>	<p>Organisms: <i>Candida albicans</i>, <i>Candida glabrata</i>, <i>Candida tropicalis</i>, and <i>Saccharomyces</i> Risk factors: medications such as antibiotics and immunosuppressants No identifiable cause for most infections Responsible for 20%-25% of vaginal infections</p>

Key: BV = Bacterial vaginosis; VVC = vulvovaginal candidiasis; IUD = intrauterine device; OC = oral contraceptive; STI = sexually transmitted infection.

Accurately distinguishing VVC from BV and trichomoniasis is especially important because of the availability of nonprescription vaginal antifungal therapy.

Given the availability of nonprescription vaginal antifungal products and the cost and inconvenience of an office evaluation, many patients prefer to self-treat empirically for presumed VVC, which may lead to a potential for inappropriate therapy.<sup>9</sup> Women should be encouraged to ask their pharmacists, who can educate and advise patients on appropriate self-care treatment.

Many women have trouble identifying VVC on the basis of the symptoms alone.<sup>7,10,11</sup> One study found that when women who had previously been diagnosed with VVC read a description of the classic symptoms of the infection, only 35% could accurately recognize it.<sup>12</sup> Similarly, another study reported that many women who purchased nonprescription antifungal products to treat vaginal symptoms actually did not have VVC infections.<sup>11</sup> The symptom most likely to differentiate a *Candida* vaginal infection from that of BV and trichomoniasis is the absence of an offensive odor of the vaginal discharge.<sup>13</sup>

Noninfectious conditions that may be confused with vaginal infections are vulvovaginal irritation or pruritus caused by allergic or hypersensitivity reactions. These reactions may be due to an allergy to latex, spermicides, vaginal lubricants containing propylene glycol, or anesthetics used by men to delay ejaculation.<sup>2</sup> Irritation secondary to douches, feminine hygiene products, soaps and detergents, or frequent use of panty liners or sanitary napkins may also cause these reactions.<sup>2</sup> In addition, urethral irritation and dysuria resulting from vulvovaginitis may be mistaken for a urinary tract infection.

Inappropriate use of vaginal antifungal products has several risks, including unnecessary drug use and a delay in effective treatment for the actual condition. The risks of exposure to the vaginal antifungal products, in the absence of VVC, include local irritation and the cost of therapy.<sup>14</sup> Labeling instructions advise patients to seek help for persistent symptoms, and if these guidelines are followed, the delay in treatment from misdiagnosis will likely present few serious consequences.

One method to assist in appropriate self-care treatment is the use of pH devices. One study evaluated the use of pH devices in symptomatic women. Nearly 57% of women who believed they had a yeast infection did not, which was confirmed by self-testing with the pH device and an examination by a health care provider.<sup>15</sup> The use of pH self-testing devices may be beneficial in reducing inappropriate self-treatment with antifungal products.

Table 8-1 describes the classic symptoms of the three common vaginal infections as well as the symptoms that women typically experience.<sup>1,3,7,16-20</sup>

## Vulvovaginal Candidiasis

Vulvovaginal candidiasis is also referred to as a yeast infection and moniliasis. This condition is second only to BV as the most common vaginal infection, and nearly 75% of women will report at least one VVC infection over their lifetime.<sup>5,21</sup> African American women report three times the number of VVC episodes (17.4% of women) compared with white women (5.8%) or women of other races or ethnic groups (4.8%).<sup>22</sup> Recurrent infections occur in fewer than 5% of women.<sup>3</sup> About 20% of women may be colonized with *Candida albicans* without experiencing vaginal symptoms.<sup>7</sup>

## Pathophysiology of Vulvovaginal Candidiasis

*Candida* fungi are the causative organisms, with about 80%-92% of cases caused by *C. albicans*.<sup>3</sup> The incidence of non-*C. albicans* infections has increased in the past two decades. *Candida glabrata*, *Candida tropicalis*, and *Saccharomyces cerevisiae* now account for about 10% of *Candida* vaginal infections.<sup>3,6</sup> This increase may be a result of the widespread use of nonprescription antifungals, short courses of topical imidazole therapy, and long-term suppressive therapy with imidazole antifungals.<sup>3</sup>

No single causative factor has been identified for most episodes of VVC. Pregnancy, high-dose combined oral contraceptives, and estrogen therapy may increase vaginal susceptibility to *Candida* vaginal infections by increasing the glycogen content of the vagina, although studies are inconsistent. Vaginal pH increases during menstruation, predisposing women to cyclic fungal vaginal infections. During the reproductive years, the vaginal epithelium cells are thick and contain an abundance of glycogen.<sup>23</sup> These cells exfoliate and continually provide the lactobacilli with the glycogen to produce lactic acid.<sup>23</sup> During and after the menopausal transition, the amount of glycogen declines, leading to decreased lactic acid production and an increased vaginal pH, and predisposes patients to vaginal infections. Women with diabetes mellitus are at increased risk for *Candida* vaginal infections, particularly if the glycemic control is poor. Antibiotics may also increase risk of these infections. Between 25% and 70% of women in studies reported developing *Candida* vaginal infections during or just after treatment with antibiotics such as tetracycline, ampicillin/amoxicillin, and cephalosporins.<sup>24,25</sup> The proposed mechanism is a decrease in normal vaginal flora, especially lactobacilli, allowing an overgrowth of *Candida* organisms. However, neither an increase in vaginal *Candida* organisms nor a decrease in lactobacilli occurs in all women who take these antibiotics. In addition, patients who have received an organ transplant or have HIV infection or who are taking systemic corticosteroid, antineoplastic, or immunosuppressant drugs may also be at increased risk for developing *Candida* vaginal infections.

An increased frequency of VVC is associated with the onset of regular sexual activity. However, neither the number of sexual partners nor the frequency of sexual intercourse is related to the occurrence of VVC episodes.<sup>3</sup> Evidence has suggested an increased risk of VVC associated with receptive oral sex.<sup>1</sup> In addition, use of an intrauterine or vaginal sponge contraceptive has increased the risk for VVC.<sup>3</sup>

A consistent association between tight-fitting, nonabsorbent clothing or pantyhose and the development of VVC has not been demonstrated. However, clothing of this type may increase risk by creating a warm and moist environment. Foods that increase the excretion of urinary glucose such as dietary sugars, refined carbohydrates, milk, and artificial sweeteners may increase the risk for *Candida* vaginal infections.<sup>1,16</sup> The consumption of yogurt has been proposed to provide a potential prophylactic benefit against VVC, although further research is needed.<sup>26</sup>

The treatment of *Candida* vaginal infections does not typically include treatment of the male partner. Treatment of male partners has not been shown to prevent recurrence of *Candida* vaginal infections in women. With recurrent infections, male partners may be treated with a topical imidazole. If treatment is necessary, topical imidazoles may be applied to the infected area twice a day for 2-4 weeks.

## Clinical Presentation of Vulvovaginal Candidiasis

The characteristic signs and symptoms of VVC are described in [Table 8-1](#). *Candida* vaginal infections typically do not alter vaginal pH, so a pH greater than 4.5 indicates a bacterial or trichomonal vaginal infection. Vaginal pH testing devices use pH to assist consumers in distinguishing *Candida* vaginal infections that can be self-treated from infections that require medical evaluation and prescription drug therapy. The Vagisil Screening Kit for Vaginal Infections (vaginal swab) uses a color test to determine vaginal pH and is easy for patients to use. Limitations with the product include the fact that testing cannot occur until 72 hours after the use of any vaginal preparation, such as a contraceptive spermicide or antifungal product, and 48 hours after sexual intercourse or douching. In addition, the product cannot be used until 5 days after a menstrual period. This screening kit costs about \$5 per test.

## Treatment of Vulvovaginal Candidiasis

The treatment of VVC is determined by the severity of symptoms and the frequency of episodes. VVC can be categorized as uncomplicated or complicated, with recurrent VVC considered a complicated infection.<sup>13</sup> Complicated infections are reported in about 5% of women and may occur because of host factors such as an inability of normal flora to prevent *Candida* colonization or the presence of fungal organisms that are more resistant to imidazole antifungal therapy.

### Treatment Goals

The goals of therapy for vaginal fungal infections are relief of symptoms, eradication of the infection, and reestablishment of normal vaginal flora. A single course of drug therapy is effective in achieving these goals for most women. However, some women will experience persistent or recurrent infections and will require prolonged therapy or higher dosages of medication.

### General Treatment Approach

Self-treatment of VVC with nonprescription antifungal therapy is appropriate for women with uncomplicated disease with infrequent episodes and mild-moderate symptoms. Women with more severe symptoms, predisposing illnesses or medications, or recurrent infections should be referred for assessment and treatment by their primary care provider.

Recurrent VVC occurs when a woman experiences at least four documented infections in a 1-year period.<sup>3</sup> Patients should be evaluated for the possibility of a mixed infection or a strain other than *C. albicans*. In addition, frequent or recurrent episodes of VVC may be an early sign of HIV infection or diabetes. The Food and Drug Administration (FDA) now requires labels of nonprescription drug products to include a warning similar to the following<sup>27</sup>:

Symptoms that return within 2 months or infections that do not clear up easily with proper treatment require medical evaluation. Possible causes of the infection include pregnancy or a serious underlying medical disorder, such as diabetes or a damaged immune system including damage from infection with HIV, the virus that causes acquired immunodeficiency syndrome.

Preventive measures are not a standard part of therapy for *Candida* vaginal infections.

Women with frequent or unresponsive infections may try dietary changes, as well as other nondrug measures such as the avoidance of nonabsorbent clothing. A 3- to 4-month trial of these approaches is sufficient to determine if they are useful for individual patients.<sup>1</sup> [Figure 8-1](#) outlines the approach to treating the patient with vaginal symptoms.

### Nonpharmacologic Therapy

Decreased consumption of sucrose and refined carbohydrates, as well as consumption of yogurt containing live cultures may potentially decrease VVC, particularly for women who experience recurrent infections.<sup>1,16,26</sup> Discontinuing a drug known to increase susceptibility to *Candida* vaginal infections might be effective in decreasing the incidence. Low-dose oral contraceptives are unlikely to contribute to the occurrence of VVC, but they might be discontinued to determine whether the frequency of infection is altered. Another form of contraception should be recommended before discontinuing the oral contraceptive. Patients taking antibiotics or immunosuppressants should consult their primary care provider regarding these medications.

### Pharmacologic Therapy

#### Vaginal Antifungals

A nonprescription FDA-approved imidazole product is the recommended initial therapy for uncomplicated VVC and relief of external vulvar itching and irritation associated with the infection. Approved drugs include butoconazole, clotrimazole, miconazole, or tioconazole, and they are available as vaginal creams, suppositories, and tablets. [Tables 8-2](#) and [8-3](#) provide proper dosing and administration guidelines, respectively.

The major antifungal effect is through altering the membrane permeability of the fungi. These antifungal agents inhibit cytochrome P450 enzymes in the fungal cell membrane, thereby decreasing synthesis of the fungal sterol ergosterol. The reduced membrane ergosterol content is accompanied by a corresponding increase in lanosterol-like methylated sterols. These sterols cause structural damage to fungal membranes, resulting in the loss of normal membrane function.

Systemic absorption of butoconazole, clotrimazole, miconazole, and tioconazole is about 1.7%, 3%-10%, 1.4%, and a negligible amount of a vaginal dose, respectively.<sup>28</sup> Fungicidal clotrimazole concentrations are detectable in the vaginal fluid for up to 3 days after a single vaginal 500 mg dose.

Adverse effects from topical imidazoles are minimal and include vulvovaginal burning, itching, and irritation in 3%-7% of patients.<sup>29</sup> These adverse effects are more likely to occur with the initial application of the vaginal preparation and are similar to symptoms of the vaginal infection. Abdominal cramps (3%), penile irritation, and allergic reactions (3%-7%) are uncommon, and headache may occur in up to 9% of women.<sup>1</sup>

Because of the limited absorption of topical imidazoles, drug interactions are unlikely. However, a case report documented an interaction between miconazole vaginal suppositories (100-200 mg) and warfarin.<sup>30</sup> In this patient, the international normalized ratio (INR) was significantly increased on two occasions when vaginal miconazole was used. Miconazole and warfarin are both metabolized by CYP2C9; concurrent use may decrease the clearance of warfarin and increase unbound drug. The prescriber should be contacted to consider reducing the dosage of warfarin during concurrent therapy to avoid an increase in INR. The product information warns women using warfarin in combination with these products that bleeding or bruising might occur. Aside from an allergy to imidazoles, contraindications do not exist to the use of topical imidazoles.

### Pharmacotherapeutic Comparison

Studies have shown the imidazoles to be equally effective, with effectiveness rates of about 80%-90%.<sup>3,5</sup> Miconazole single-dose and 7-day treatments have been compared, resulting in similar overall cure rates with significantly faster rates of symptom relief by day 3 in the single-dose group compared with the 7-day treatment group.<sup>31</sup> Butoconazole nitrate 2% single-dose cream has also been compared with miconazole 7-day treatment, resulting in nonsignificant differences in cure rates.<sup>32</sup> Seven-day regimens of clotrimazole and miconazole; 3-day regimens of butoconazole, clotrimazole, and miconazole; and 1-day regimens of clotrimazole, miconazole, and tioconazole are available without a prescription. Monistat 1 has also been approved for insertion in the morning or at bedtime, allowing flexibility for patients. A similar cure rate exists for the daytime and bedtime treatments.<sup>33</sup>

Several other nonprescription vaginal preparations, including Vagisil and Yeast-Gard, containing benzocaine and resorcinol are also available. These agents provide relief of itching, although the underlying cause is not addressed. The use of these agents is rarely, if ever, appropriate given the benefits of the imidazole antifungals, including superior efficacy, improved patient adherence, less frequent local reactions, and shorter treatment durations. These products and medicated douches may be reserved for vaginal and vulvar irritation and itching and should be used for a limited time only or on the advice of a primary care provider (Table 8-4).

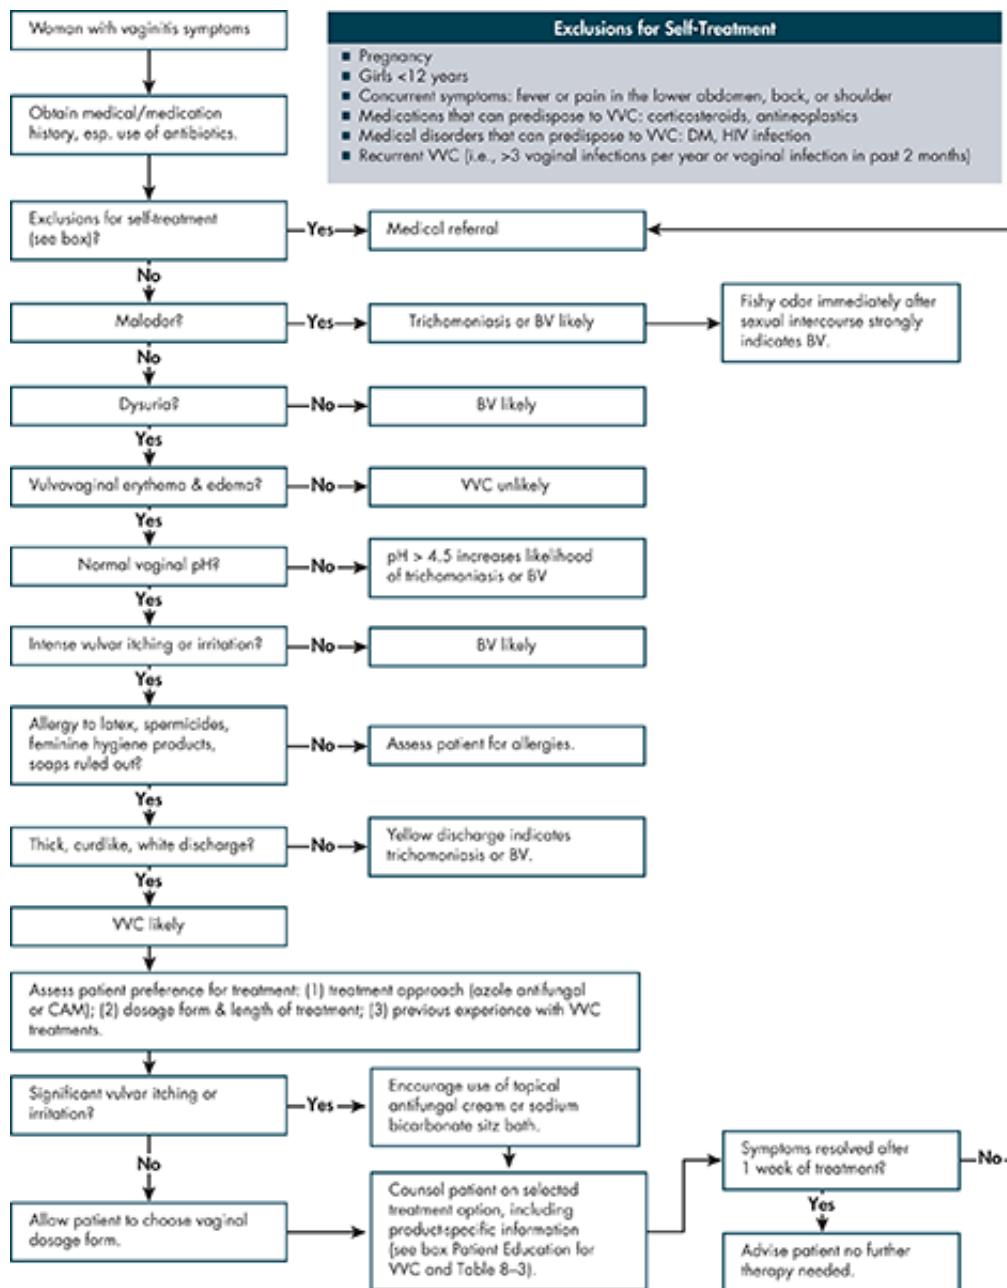

### Product Selection Guidelines

#### Special Populations

Self-treatment of VVC is not appropriate for girls younger than 12 years. This condition is rare in premenarchal girls. Vaginal symptoms in this age group warrant a medical referral to determine the cause because infections in prepubertal children may indicate potential sexual abuse.<sup>34</sup>

Self-care treatment in pregnancy is not appropriate. However, when treatment of VVC is indicated, treatment should consist of butoconazole, clotrimazole, or miconazole. When possible, treatment should be withheld during the first trimester.<sup>34</sup> The health care provider should evaluate for complications such as hyperglycemia and assess for other organisms, given that bacterial vaginosis and trichomoniasis have the potential for adverse pregnancy outcomes.

Breast-feeding women can use any of the nonprescription vaginal antifungals.<sup>29</sup>

Self-care of vulvovaginal candidiasis. Key: CAM = Complementary and alternative medicine; DM = diabetes mellitus; HIV = human immunodeficiency virus; VVC = vulvovaginal candidiasis. (Source: References 7, 18, and 19.)

**TABLE 8-2 Selected Nonprescription Vaginal Antifungal Products and Their Dosages**

Trade Name	Primary Ingredient	Dosage
<b>Butoconazole Nitrate Products</b>		
Gynazole 1	Butoconazole nitrate 2%	Insert cream into vagina daily for 1 day.
<b>Clotrimazole Products</b>		
Gyne-Lotrimin 7 Cream Mycelex-7 Cream	Clotrimazole 1%	Insert cream into vagina daily for 7 days; apply to vulva twice daily as needed for itching.
Mycelex-7 Combination Pack	Tablet: clotrimazole 100 mg Cream: clotrimazole 1%	Insert tablet into vagina daily for 7 days; apply cream to vulva twice daily for itching.

Gyne-Lotrimin 3 Cream	Clotrimazole 2%	Insert cream into vagina daily for 3 days; apply to vulva twice daily for itching.
<b>Miconazole Nitrate Products</b>		
Monistat 1 Combination Pack Day or Night Monistat 1 Daytime Ovule	Cream: miconazole nitrate 2% Suppository: miconazole nitrate 1200 mg	Apply cream to vulva twice daily as needed for itching up to 7 days; insert suppository into vagina daily (morning or at bedtime) for 1 day.
Monistat 3 Combination Pack <sup>a</sup>	Cream: miconazole nitrate 2% Suppository: miconazole nitrate 200 mg	Apply cream to vulva twice daily as needed for itching up to 7 days; insert suppository into vagina daily for 3 days.
Monistat 3 Cream <sup>a</sup>	Miconazole nitrate 4%	Insert cream into vagina daily for 3 days; apply to vulva twice daily as needed for itching.
Monistat 7 Suppository	Miconazole nitrate 100 mg	Insert suppository into vagina daily for 7 days at bedtime.
Monistat 7 Cream Femizol-M Cream	Miconazole nitrate 2%	Insert cream into vagina daily for 7 days; apply to vulva twice daily as needed for itching.
Monistat 7 Combination Pack	Cream: miconazole nitrate 2% Suppository: miconazole nitrate 100 mg	Apply cream to vulva twice daily as needed for itching; insert suppository into vagina daily for 7 days.
<b>Tioconazole Products</b>		
Vagistat-1 Ointment 1-Day Ointment	Tioconazole 6.5%	Insert ointment into vagina daily for 1 day.

<sup>a</sup>Prefilled applicators are available for this product.

No special considerations are necessary to treat older women presenting with a VVC infection.

### Patient Preferences

Selection of cream, tablet, or suppository formulations can be left to patient preference because some women may prefer the convenience of prefilled applicators. Women who have previously experienced VVC prefer shorter courses of therapy than do those who have not had a prior infection.<sup>1</sup> If vulvar symptoms are significant, a cream preparation or the combination of a cream with vaginal suppositories or tablets is preferred. Morning or bedtime dosing is available to provide flexibility for patients.

### Complementary Therapies

An alternative approach to treating VVC is the use of *Lactobacillus* preparations. The rationale for their use is to reestablish normal vaginal flora and inhibit overgrowth of *Candida* organisms. Data on the effectiveness of this approach are limited and inconsistent. One study of five women with positive vaginal cultures for *C. albicans* found four women had negative cultures after administration of *Lactobacillus rhamnosus* GG suppositories for 7 days.<sup>26</sup> Another study examining the usefulness of *Lactobacillus* and other probiotic bacteria administered orally, vaginally, and by both routes found that none of the regimens protected against the development of postantibiotic VVC.<sup>35</sup> However, eating 8 ounces of yogurt with live cultures daily may be of some benefit in preventing recurrent VVC.<sup>26</sup> Nonprescription probiotic feminine supplements may be used to reestablish *Lactobacillus*. RepHresh Pro-B feminine supplement is a product that is easy to use but expensive (about \$25-\$30 for a 30-day supply). Patients take one capsule by mouth daily. (For information on probiotics, see [Chapter 23 \[Table 23-9\]](#) and [Chapter 51](#).) The use of a sodium bicarbonate sitz bath may provide prompt relief of vulvar irritation associated with a *Candida* vaginal infection before antifungal agents can provide benefit.<sup>36</sup> To manage VVC, some women may prefer natural products such as a vaginal preparation of tea tree oil, which has

antibacterial and antifungal properties.<sup>37,38</sup> A 200 mg vaginal suppository containing tea tree oil is available commercially and is used for 6 nights. Allergic dermatitis may occur. (For information on tea tree oil, see [Chapter 51](#).)

**TABLE 8-3 Guidelines for Applying Vaginal Antifungal Products**

1. Start treatment at night before going to bed. Lying down will reduce leakage of the product from the vagina.
2. Wash the entire vaginal area with mild soap and water, and dry completely before applying the product.
3. *Vaginal cream:* (If prefilled applicators are being used, skip to step 4.) Unscrew the cap; place the cap upside down on the end of the tube. Push down firmly until the seal is broken. Attach the applicator to the tube by turning the applicator clockwise. Squeeze the tube from the bottom to force the cream into the applicator. Squeeze until the inside piece of the applicator is pushed out as far as possible and the applicator is completely filled with cream. Remove the applicator from the tube. *Vaginal tablets or suppositories:* Remove the wrapper and place the product into the end of the applicator barrel.

4. While standing with feet slightly apart and knees bent, as shown in drawing A, or while lying on your back with knees bent, as shown in drawing B, gently insert the applicator into the vagina as far as it will go comfortably.

**A**

**B**

Copyright © American Pharmacists Association  
All rights reserved. Any use is subject to the Terms of Use.

5. Push the inside piece of the applicator in and place the cream as far back in the vagina as possible. To deposit vaginal tablets or suppositories, insert the applicator into the vagina and press the plunger until it stops.

6. Remove the applicator from the vagina.
7. After use, recap the tube (if using cream). Then clean the applicator by pulling the two pieces apart and washing them with soap and warm water.
8. If desired, wear a sanitary pad to absorb leakage of the vaginal antifungal. Do not use a tampon to absorb leakage.
9. Continue using the product for the length of time specified in the product instructions. Use the product every day without skipping any days, even during menstrual flow.

**TABLE 8-4 Selected Nonprescription Drug Products for Vaginal Itching and Irritation (Note: List is not all-inclusive.)**

<i>Trade Name</i>	<i>Primary Ingredients</i>
<b><i>Benzocaine Products<sup>a</sup></i></b>	
Vagi-Gard Advanced Sensitive Cream Vagisil Anti-Itch Original Formula	Benzocaine 5%; resorcinol 2%
Vagisil Maximum Strength	Benzocaine 20%; resorcinol 3%
Vagi-Gard Maximum Strength Cream	Benzocaine 20%; benzalkonium chloride 0.13%
Vagi-Gard Cream VH Essentials	Benzocaine 5%; benzalkonium chloride 0.13%
<b><i>Hydrocortisone Products<sup>b</sup></i></b>	
Vagisil Satin Anti-Itch Crème	Hydrocortisone 1%
<b><i>Povidone/Iodine Products</i></b>	
Betadine Medicated Suppository <sup>c</sup>	Povidone/iodine 10%
Betadine Premixed Medicated Disposable Douche Summer's Eve Special Care Medicated Douche	Povidone/iodine 0.3% (in disposable bottles)
<b><i>Homeopathic Products</i></b>	
Yeast-Gard Suppository <sup>d</sup>	<i>Pulsatilla</i> (28×); <i>Candida albicans</i> (28×) <i>Candida parapsilosis</i> (28×)
Yeast-X Suppository <sup>e</sup>	<i>Pulsatilla</i> (28×)
<b><i>Other Products</i></b>	
Summer's Eve Feminine Powder <sup>f</sup> Vagisil Feminine Powder <sup>f</sup>	Cornstarch; aloe; mineral oil

<sup>a</sup> Apply benzocaine products externally.

<sup>b</sup> Apply hydrocortisone products externally; avoid prolonged use; may use concomitantly with antifungal products.

<sup>c</sup> Use 1 povidone/iodine suppository nightly for 7 days.

<sup>d</sup> Use 1 Yeast-Gard suppository daily for 7 days.

<sup>e</sup> Use 1 Yeast-X suppository daily as needed.

<sup>f</sup> Apply feminine powders externally to absorb moisture.

Gentian violet, a dye available in community pharmacies, is an old treatment for VVC. Today, topical gentian violet is used for resistant *Candida* vaginal infections.<sup>39</sup> A tampon may be soaked in gentian violet and inserted into the vagina for several hours or overnight. Often a single application is adequate, but tampons saturated with gentian violet can be used once or twice a day for up to 5 consecutive days. The major disadvantage of using gentian violet is the possible staining of fabrics and skin.<sup>29</sup>

Another option for the treatment of VVC is boric acid 600 mg in a size 0 gelatin capsule inserted vaginally once or twice daily for 14 days. Boric acid 5% in lanolin can be applied topically for vulvar irritation.<sup>3,16,40</sup> Boric acid therapy is useful for non-*C. albicans* infections, which are more likely to be resistant to the imidazole antifungals. Short-term cure rates have been reported to be between 85% and 95% when boric acid is used in women whose infection did not respond to vaginal antifungals.<sup>11,40</sup> For resistant infections, the therapy is used twice weekly for longer durations. Boric acid can be toxic and teratogenic, and human fatalities have been reported from oral ingestion.<sup>40</sup> Boric acid capsules may be compounded in community pharmacies, and patient counseling should be provided to explain that the capsule should not be ingested. In addition, pregnant women should not use boric acid.

### Assessment of Vulvovaginal Candidiasis: A Case-Based Approach

Many episodes of VVC are uncomplicated and can be effectively treated by topical imidazole agents.<sup>3</sup> In particular, otherwise healthy women who experience episodes that are sporadic and uncomplicated and women who predictably experience VVC following a course of antibiotic therapy are the best candidates for self-treatment.<sup>25</sup> Determining the appropriateness of self-care and the likelihood of a *Candida* vaginal infection are important initial steps in advising the woman about the management of vaginal symptoms with nonprescription drug therapy. Health care providers may advise patients when it is appropriate to self-treat for vaginal symptoms consistent with VVC and when medical evaluation, including pelvic examination and laboratory examination of vaginal secretions, is indicated. Self-treatment is most appropriate when the woman meets the following four criteria:

1. Vaginal symptoms are infrequent (i.e., no more than 3 vaginal infections per year and no vaginal infection within the past 2 months).
2. A medical professional diagnosed at least 1 previous episode of VVC.
3. Current symptoms are mild to moderate and consistent with the characteristic signs and symptoms of VVC, particularly in that the discharge does not have a foul odor.
4. If measured, vaginal pH is 4.5 or lower.

Case 8-1 provides an example of the assessment of a patient presenting with a vaginal infection.

### Patient Counseling for Vulvovaginal Candidiasis

Health care providers counseling patients who are considering self-treatment with vaginal antifungals should emphasize limiting self-treatment to the presence of mild-moderate classic symptoms, infrequent vaginal symptoms, and predictable antibiotic-associated VVC. A medical evaluation should be obtained if symptoms persist beyond 1 week after treatment or if they recur within 2 months. Also, if vaginal symptoms occur more than 3 times in a 12-month interval, further evaluation is needed. Women taking warfarin should be referred to their provider.

Patients should be informed that a short course of a nonprescription vaginal antifungal product will kill the “yeast” organisms that caused the infection. Label instructions should be reviewed with the patient, stressing that the antifungal is to be used only once a day for the specified length of time. Patients should be advised that symptomatic relief will likely begin within 2-3 days but that it may take a week for complete resolution of symptoms. The patient should also be advised of signs and symptoms that indicate medical attention is needed. The box Patient Education for Vulvovaginal Candidiasis lists specific information to provide patients.

### Case 8-1

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<i>Information Gathering</i>	

1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient is experiencing vulvovaginal intense itching with a white discharge but no malodor. She also reports that symptoms began yesterday.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient reports experiencing symptoms throughout the day.
c. description of the patient's efforts to relieve the symptoms	Patient reports that she did try nonprescription VH essentials for the itching but had only minimal relief.
d. patient's identity	Amelia Loddy, travel agent
e. age, weight, sex, and height	31 years old, female, 5 ft 5 in., 135 lb
f. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Lo Loestrin Fe 1 daily; daily multivitamin; acetaminophen 325 mg occasionally
g. allergies/other adverse reactions to medications	Sulfa: rash
h. other (describe)	Amelia was diagnosed with a VVC infection twice before per her medical history. Her last vaginal infection was 2 years ago. Her current symptoms are similar to her previous VVC infections.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s) (Table 8-1).	Amelia has itching and a white discharge without malodor, which are symptoms consistent with a <i>Candida</i> vaginal infection.
3. Identify exclusions for self-treatment (Figure 8-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical practitioner is required, and share this information with the patient or caregiver.	Options include: (1) Refer Amelia for medical evaluation with her PCP. (2) Recommend self-treatment with an OTC vaginal antifungal product. (3) Take no action.
<b>Plan</b>	

5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Amelia has classic symptoms associated with VVC. She has had two previous VVC infections. She has no chronic medical problems. She is also a good candidate for self-treatment because she is in a monogamous relationship and is not at risk for STIs. (See <a href="#">Figure 8-1.</a> )
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Several choices of nonprescription vaginal antifungal products are available. Because you have vulvar itching, a cream preparation or a combination pack will provide the best relief of your symptoms." (See the box Patient Education for Vulvovaginal Candidiasis for instructions on proper use.)
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"This treatment is appropriate because you have the characteristic symptoms of vulvovaginal candidiasis, your symptoms are mild to moderate, you have no contraindications to self-treatment, and you have infrequent vaginal infections. See your primary care provider if your symptoms do not improve within 3 days or are not gone within 1 week, if the vaginal discharge changes (particularly if it becomes malodorous), or if symptoms return within the next 2 months."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	"Insert the clotrimazole cream vaginally once daily for 3 days; apply externally to the vulva as needed for itching."
b. maximum number of days the therapy should be employed	"Apply the cream for 3 days."
c. product administration procedures	See <a href="#">Table 8-3.</a>
d. expected time to onset of relief	"Relief should occur in 2-3 days; often some relief occurs within hours of the first application."
e. degree of relief that can be reasonably expected	"All symptoms should be resolved within 1 week after beginning treatment."
f. most common side effects	"Vulvovaginal burning and itching are the most common side effects."
g. side effects that warrant medical intervention should they occur	"Significant stinging, burning, or itching that persists beyond the first 48 hours of treatment should be medically evaluated."
h. patient options in the event that condition worsens or persists	"See your primary care provider if symptoms do not improve in 3 days or worsen."
i. product storage requirements	"The product should be stored in a cool area; storage in the bathroom or

	bedside is appropriate for ease of use.”
j. specific nondrug measures	None
Solicit follow-up questions from patient or caregiver.	(1) “Are any of the nonprescription vaginal antifungal products better than any others? Are some regimens more effective than others?” (2) “Is yogurt consumption helpful in reducing VVC infections?”
Answer patient’s or caregiver’s questions.	(1) “No, all of the products and regimens are equally effective.” (2) “Daily intake of yogurt may provide a prophylactic benefit against VVC infections.”
9. Assess patient outcome.	Ask the patient to call and update you on her treatment outcome. Or you could call her in a week to evaluate the outcome.

Key: VVC = Vulvovaginal candidiasis; PCP = primary care provider; OTC = over-the-counter; STI = sexually transmitted infection.

#### Patient Education for Vulvovaginal Candidiasis

The goals of self-treatment are to cure the vaginal fungal infection and reestablish normal vaginal flora. Carefully following the product instructions and the self-care measures will help ensure optimal therapeutic outcomes.

#### **Nondrug Measures**

- If significant irritation of the vulva is present, use a sodium bicarbonate sitz bath to provide relief and give the antifungal medication time to become effective.
  - Add 1 teaspoon sodium bicarbonate to 1 pint of water.
  - Add 2-4 tablespoons of the solution to 2 inches of bath water.
  - Sit in the sitz bath or bathtub for 15 minutes as needed for symptom control.
- For recurrent infections, try eating yogurt (1 cup per day of live culture yogurt) and decreasing dietary sugar and refined carbohydrates.

#### **Nonprescription Medications**

- Insert the antifungal product into the vagina once a day, preferably at bedtime to minimize leakage from the vagina. Use a sanitary pad or panty liner to avoid staining of underwear.
- [Table 8-3](#) provides instructions on administering vaginal antifungals. Significant relief of symptoms should occur within 24-48 hours, and relief is often apparent within hours after the first dose. However, the length of treatment (particularly for 1- to 3-day treatments) does not directly correspond to the time of resolution of symptoms.
- Continue the therapy for the recommended length of time, even if symptoms are gone. Stopping treatment early is a common reason for recurrence of vaginal symptoms and, possibly, occurrence of difficult-to-treat organisms.
- Vaginal antifungals can be used during a menstrual period. If desired, wait and treat the infection after menses ends. Do not interrupt a course of therapy if menses begins.
- Do not use tampons or douche while using a vaginal antifungal and for 3 days after use.
- Although adverse effects are uncommon, the first dose of the antifungal may cause some vaginal burning and irritation, and a few women (about 1 in 10) experience a headache.
- Refrain from sexual intercourse during treatment with the vaginal antifungal. Vaginal lubricants and vaginal spermicides should not be used at the same time as the vaginal antifungal. Vaginal antifungals can damage latex condoms and diaphragms and may result in unreliable contraceptive effects. Do not use these contraceptives during therapy or for 3 days after therapy because the antifungal medication remains in the vagina for several days.

#### **Consult Physician First**

- Do not use vaginal antifungals if:
  - You have not been medically diagnosed with VVC at least once.
  - You are younger than 12 years old.
  - You are pregnant.
  - You have diabetes mellitus; are human immunodeficiency virus (HIV)-positive or have acquired

immunodeficiency syndrome (AIDS); or have impaired immune function, including use of medications that may impair function of the immune system.

- If you are breast-feeding, consult a primary care provider before using a vaginal antifungal.

### When to Seek Medical Attention

- Seek medical attention if symptoms do not improve within 3 days or symptoms persist beyond 7 days.
- Seek medical attention if vaginal symptoms worsen or change, especially if the vaginal secretions begin to smell bad, become frothy, or become discolored, or if other symptoms (e.g., abdominal tenderness) occur. These events may indicate that the *Candida* (yeast) organisms are resistant to the nonprescription therapy or that another type of vaginal infection is present.

### Evaluation of Patient Outcomes for Vulvovaginal Candidiasis

Symptoms of VVC should improve within 2 or 3 days of initiation of therapy and resolve within 1 week. The length of treatment, particularly for 1- to 3-day treatments, does not directly correspond to the time of resolution of symptoms. The health care provider should advise patients to call if the symptoms persist, and women should understand the importance of adherence. Persistent or new symptoms that are not consistent with VVC are reasons for advising the patient to seek a medical referral.

### Atrophic Vaginitis

Atrophic vaginitis is inflammation of the vagina related to atrophy of the vaginal mucosa secondary to decreased estrogen levels.

Although up to 45% of postmenopausal women may experience symptomatic atrophic vaginitis, only 25% may seek treatment.<sup>41-43</sup> Dyspareunia, or painful intercourse, is a symptom sometimes related to inadequate vaginal lubrication or atrophic vaginitis.

### Pathophysiology of Atrophic Vaginitis

During menopause, the postpartum period, and breast-feeding, the vaginal epithelium becomes thin, and vaginal lubrication declines secondary to a decrease in estrogen levels. Women may experience atrophic vaginitis and dyspareunia during these intervals.<sup>43</sup> Atrophic vaginitis may also occur among women with decreased ovarian estrogen production such as after radiation or chemotherapy. Women taking antiestrogenic drugs such as clomiphene, tamoxifen, raloxifene, danazol, leuprolide, and nafarelin may also develop atrophic vaginitis.<sup>29,44</sup> Low-estrogen oral contraceptives may also cause atrophic vaginitis on rare occasions.<sup>8</sup>

### Clinical Presentation of Atrophic Vaginitis

An early symptom of atrophic vaginitis is a decrease in vaginal lubrication.<sup>44</sup> Other symptoms include vaginal irritation, dryness, burning, itching, leukorrhea, and dyspareunia. A thin, watery (occasionally bloody), or yellow malodorous vaginal discharge or “spotting” may also be present.<sup>3,6,44</sup> Sexual activity may result in vaginal bleeding or spotting. Any new episode of postmenopausal vaginal bleeding should have a medical referral to rule out endometrial cancer.

### Treatment of Atrophic Vaginitis

Self-treatment of atrophic vaginitis is limited to alleviating the primary symptom, vaginal dryness, with lubricant products. Preventing vaginal dryness may necessitate prescription estrogen therapy, a measure that may be considered for women at menopause. Women who are breast-feeding or have recently given birth often have temporary declines in estrogen levels. Vaginal lubricants may be needed only until estrogen levels return to normal.

#### Treatment Goals

The goals of therapy are to reduce or eliminate the symptoms of vaginal dryness, burning, and itching, and eliminate dyspareunia if vaginal dryness is the cause of painful sexual intercourse.

#### General Treatment Approach

Vaginal dryness can often be treated with lubricants such as those listed in [Table 8-5](#). Sexual arousal and intercourse may also improve atrophic vaginitis, and women who are sexually active have fewer symptoms of atrophic vaginitis.<sup>44</sup>

#### TABLE 8-5 Selected Nonprescription Vaginal Lubricants

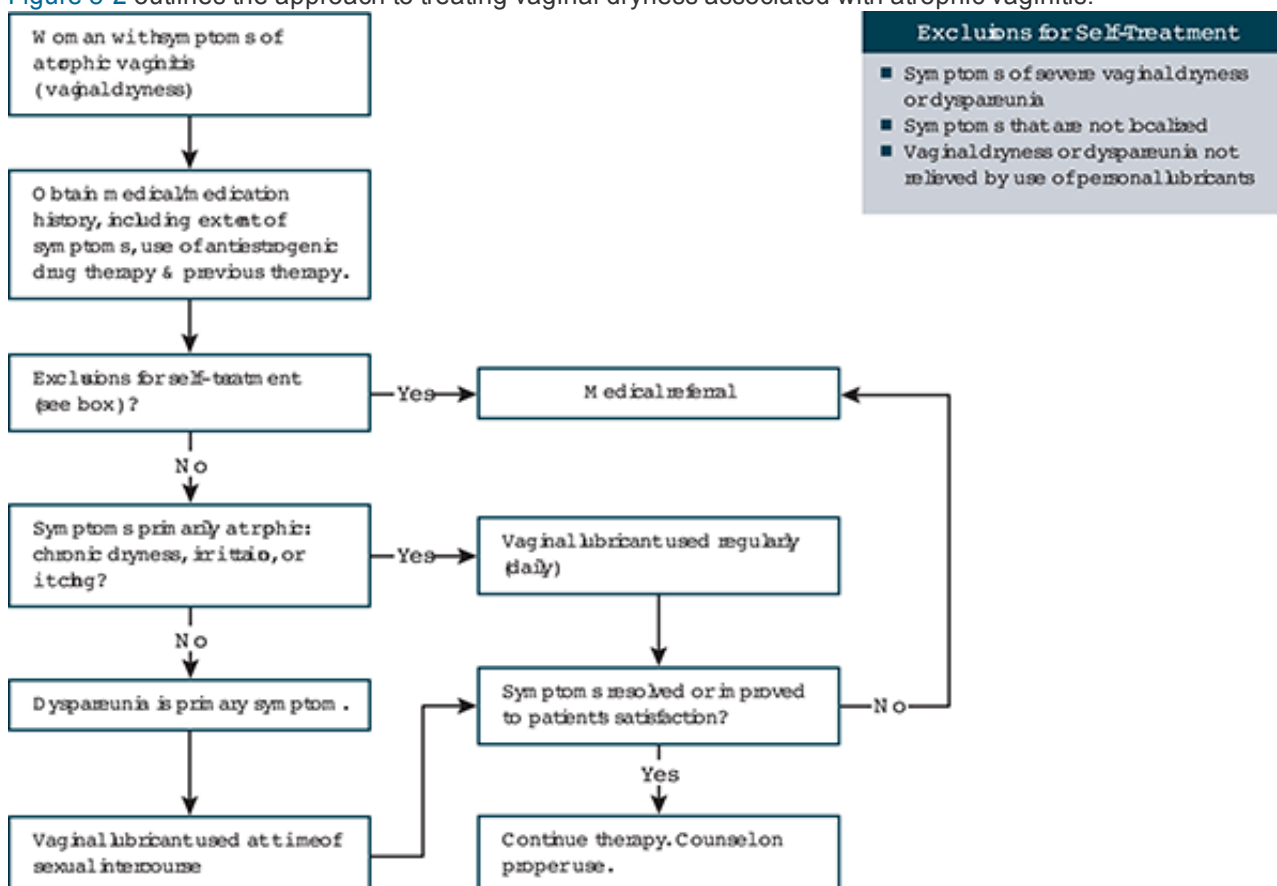

Trade Names	Primary Ingredients
Astroglide; K-Y Personal Lubricant Liquid; Vagisil Intimate Moisturizer Lotion <sup>a</sup>	Glycerin; propylene glycol
H-R Lubricating Jelly	Hydroxypropyl methylcellulose
K-Y Jelly	Glycerin; hydroxyethylcellulose
K-Y Warming Liquid Personal Lubricant	Propylene glycol; glycerin; acacia honey type O
Replens Gel	Glycerin; mineral oil

<sup>a</sup>Fragrance-free formulation.

Self-treatment is appropriate when the symptoms are mild-moderate and confined to the vaginal area and when no bleeding is present. Women with severe vaginal dryness, dyspareunia, or bleeding should be referred for medical evaluation. In addition, products that may aggravate vaginal symptoms such as irritants and allergens such as powders, perfumes, spermicides, and panty liners should be avoided.<sup>44</sup>

Figure 8-2 outlines the approach to treating vaginal dryness associated with atrophic vaginitis.

Self-care of atrophic vaginitis.

## Pharmacologic Therapy

### Vaginal Lubricants

Multiple water-soluble products are available for vaginal lubrication including Astroglide, K-Y Jelly, and Replens. Personal lubricant products temporarily moisten vaginal tissues. These products provide short-term improvement in symptoms such as burning and itching. Personal lubricants can also provide vaginal lubrication to facilitate sexual intercourse.

Petroleum jelly should not be used because it is difficult to remove from the vagina. If the patient is using a latex condom or diaphragm, only water-soluble lubricants should be used because other products may damage the latex

and impair the efficacy of these contraceptive methods. Water-soluble lubricant gels can be applied both externally and internally. Initially, the patient should be instructed to use a liberal quantity of lubricant (up to 2 teaspoons) and then to tailor the quantity and frequency of use to her specific needs. Most lubricant products provide an improvement in symptoms for less than 24 hours.<sup>44</sup> If the patient is treating dyspareunia, the lubricant should be applied to both the vaginal opening and the penis. If the use of lubricants does not produce adequate benefit or is esthetically unappealing to the patient, she should be referred for medical evaluation.

### Assessment of Atrophic Vaginitis: A Case-Based Approach

When discussing symptoms of vaginal dryness during the patient assessment, the health care provider should obtain a description of symptoms, including their association with sexual intercourse and their severity. Information should also be obtained as to whether the woman has recently given birth, is lactating, or is perimenopausal or postmenopausal. The health care provider should ask patients about the use of any vaginal or feminine hygiene products that may cause or worsen vaginal irritation and dyspareunia.

Case 8-2 provides an example of the assessment of a patient presenting with atrophic vaginitis.

#### Case 8-2

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient is experiencing vaginal dryness and significant dyspareunia.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	She reports experiencing these symptoms for a few weeks.
c. description of the patient's efforts to relieve the symptoms.	Patient reports that she has not tried any products.
d. patient's identity	Linda Lewis, yoga instructor
e. age, sex, height, and weight	50 years old, female, 5 ft 4 in., 132 lb
f. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Metoprolol 100 mg twice daily; daily multivitamin
g. allergies/other adverse reactions to medications	NKDA
h. other (describe) _____	Linda is postmenopausal and experiencing vaginal dryness and significant dyspareunia. She reports that she has not tried OTC lubricants, and per her medical history, she has no prior use of estrogen therapy. She also reports a history of a hysterectomy 1 year ago.
<b>Assessment and Triage</b>	

2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Linda is postmenopausal. She has vaginal dryness with significant dyspareunia but no symptoms indicative of other vaginal infections. These symptoms are consistent with atrophic vaginitis.
3. Identify exclusions for self-treatment (Figure 8-2).	She has vaginal dryness with significant dyspareunia as a primary symptom.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical practitioner is required and share this information with the patient or caregiver.	Options include: (1) Suggest that Linda consider using vaginal lubricants for symptom improvement until she can see her PCP. (2) Refer Linda to her PCP for possible vaginal estrogen therapy. (3) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Because Linda has significant and bothersome dyspareunia as a primary symptom, this would qualify as exclusion for self-care. The recommended option for this patient would be to see her PCP to further assess her dyspareunia and explore topical estrogen therapy to relieve her symptoms.
6. Describe the recommended therapeutic approach to the patient or caregiver.	See the box Patient Education for Atrophic Vaginitis.
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Given your significant dyspareunia symptoms and vaginal dryness, I recommend that you follow up with your primary care provider to consider the use of a topical (vaginal) estrogen product, such as tablets. However, OTC lubricants may be used to assist in symptom relief until you see your provider."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from patient or caregiver.	(1) "How much and how often may I use OTC lubricants?" (2) "Will I have to take oral estrogen or will topical estrogen work?"
Answer patient's or caregiver's questions.	(1) "A liberal quantity (2 teaspoons) of OTC lubricants may be used and may be used as frequently, as needed." (2) "Oral estrogen therapy is usually not necessary for the treatment of atrophic vaginitis; vaginal estrogen products (creams or tablets) are options."
9. Assess patient outcome.	Contact the patient in a day or two to ensure she made an appointment for further evaluation and medical care.

Key: NKDA = No known drug allergy; OTC = over-the-counter; PCP = primary care provider.

### Patient Counseling for Atrophic Vaginitis

The health care provider should stress the short-term nature of atrophic vaginitis to women who are breast-feeding or who recently gave birth. Women who are perimenopausal or postmenopausal should know that long-term treatment with vaginal lubricants may be necessary. In either case, the health care provider should explain the proper use of the lubricants for treatment of vaginal dryness or dyspareunia. The box Patient Education for Atrophic Vaginitis lists specific information.

### Evaluation of Patient Outcomes for Atrophic Vaginitis

Symptoms of atrophic vaginitis should improve within a week. The provider should advise the patient to call to discuss treatment effectiveness, if she has any concerns, and to call after 1 week of treatment to report progress in symptom resolution. Symptoms that persist or the presence of bleeding requires medical evaluation.

#### Patient Education for Atrophic Vaginitis

The objective of self-treatment with vaginal lubricants is to relieve vaginal dryness and pain during sexual intercourse related to atrophic vaginitis. Carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

- Apply the vaginal lubricant as frequently as needed for relief of vaginal dryness, irritation, burning, itching, or inadequate vaginal lubrication.
- Begin treatment of atrophic symptoms with a liberal quantity of lubricant (2 teaspoons); tailor subsequent doses to the quantity and frequency of use needed to provide relief.
- If using lubricants at the time of sexual intercourse, apply the lubricant to the vagina, particularly at the vaginal opening, and to the penis.
- Some leakage of product will occur. If desired, use a sanitary napkin or panty liner to avoid staining of underwear.
- Relief of symptoms may be apparent within hours after the first dose. Regular application of a lubricant can reverse atrophic symptoms to some extent.
- If no improvement is noticeable within a week, or if symptoms worsen or there is any vaginal bleeding, see your primary care provider.

### Vaginal Douching

#### Prevalence of Douching

The 2002 National Survey of Family Growth reported that 32% of U.S. women practiced douching in the previous 12 months.<sup>45</sup> Douching rates are influenced by race, geographic region, socioeconomic status, and education.<sup>46</sup> Most women who report douching state they began the practice as adolescents.

The most frequently stated reason for douching is to achieve good vaginal hygiene. Because vaginal douches mechanically irrigate the vagina, clearing away mucus and other accumulated debris, they may be used as cosmetic cleansing agents. Among the women in a focus group study, most considered douching part of normal feminine hygiene, and most reported douching after menstruation and sexual intercourse.<sup>47</sup>

#### Potential Adverse Effects of Douching

Douching may lead to adverse health outcomes. Frequent douching has been associated with an increased risk for PID, reduced fertility, ectopic pregnancy, vaginal infections such as BV, sexually transmitted infections, low birth weight, and cervical cancer.<sup>46,47</sup> Additional problems include irritation or sensitization from douche ingredients and disruption of normal vaginal flora and pH. Local irritation, sensitization, and contact dermatitis are also possible with many antimicrobial agents found in douches.

The effect of douches on vaginal flora varies depending on the douche ingredients and douching frequency. Water/vinegar (acetic acid) douches have minimal effect on lactobacilli but do inhibit some vaginal pathogens, whereas douches containing antiseptics inhibit all vaginal flora.<sup>48,49</sup> Povidone/iodine has a greater potential than water/vinegar douches to reduce total bacteria, but it may allow pathogenic species to proliferate, increasing the risk for vaginal infection.<sup>50</sup> Allergic reactions have been reported with intravaginal povidone/iodine because systemic absorption is possible. This product should not be used by women who are allergic to iodine. [Table 8-4](#) lists examples of douche products that contain povidone/iodine.

#### Proper Use of Douche Equipment

Two types of syringes are available for douching purposes: douche bags and bulb douche syringes. The douche bag, or fountain syringe or folding feminine syringe, holds 1-2 quarts of fluid and comes with tubing and a shutoff valve. Two types of tips are supplied: one for enema use (the shorter rectal nozzle) and one for douching. The two tips are not interchangeable; vaginal infections may occur if a single tip is used for both douching and enemas.

Bulb douche syringes are available as both disposable and nondisposable products. The nondisposable units hold 8-16 ounces of fluid, whereas the disposable units contain 3-9 ounces. The flow rate is regulated by the amount of hand pressure exerted when the bulb is squeezed. Gentle pressure is recommended because excess pressure may force fluid through the cervix, causing uterine inflammation. Instructions on proper use of the device are found in [Table 8-6](#).

**TABLE 8-6 Administration Guidelines for Douches**

<i><b>Bulb Douche Syringe Method</b></i>
• Choose a comfortable douching position. Two positions are recommended: (1) sitting on the toilet or (2) standing in the shower. Whichever position is chosen, remember that douching is easier when relaxed.
• Gently insert the nozzle about 3 inches into the vagina. Avoid closing the lips of the vagina.
• Squeeze bottle gently, letting solution cleanse the vagina and then flow freely from the body.
• After douching, throw away bottle and nozzle, if disposable.
<b>Douche Bag Method</b>
• Fill the douche bag with the prescribed solution or with a warm water and vinegar solution.
• Lie back in the tub with knees bent. Place the douche bag about 1 foot above the height of hips. Do not place or hang the bag any higher because such height will cause the pressure of fluid entering the vagina to be too high.
• Insert the nozzle several inches into the vagina. Aim the nozzle up and back toward the small of the back. While holding the labia closed around the nozzle, release the clamp slowly to allow fluid to enter the vagina. Rotate the tip and allow fluid to enter the vagina until the vagina feels full. Stop the flow of fluid; then hold the fluid in the vagina for about 30-60 seconds. Release and allow the fluid to flow out; repeat until the douche bag is empty.
• Wash the nozzle with mild soap and water.

### **Patient Counseling for Douching**

Health care providers should discuss a woman's reasons for douching. Women should be informed that douching is not necessary to cleanse the vagina and that douching has potential adverse consequences. Douching for routine hygienic purposes should be discouraged, and douching is contraindicated during pregnancy. Douching should be delayed at least 6-8 hours after sexual intercourse if a vaginal spermicide was used as a contraceptive agent. An alternative cleansing method for vaginal and perineal areas should be suggested, such as gently washing the vagina and the vulvar, perineal, and anal regions with the fingers using lukewarm water and mild soap. If a woman is douching to prevent or treat symptoms of a vaginal infection such as an abnormal vaginal discharge, she should be counseled about more effective therapy or referred for medical evaluation, as appropriate.

Patients for whom douches have been prescribed or those who insist on douching for other reasons should be instructed on how to use these products safely, appropriately, and effectively. The box Patient Education for Douching lists specific information to provide these patients.

#### **Patient Education for Douching**

Women should be informed that douching is not necessary for cleansing of the vagina. An alternative cleansing method for vaginal and perineal areas should be suggested, such as gently washing the vagina and the vulvar, perineal, and anal regions with the fingers using lukewarm water and mild soap. Improper methods of douching or too frequent douching can cause vaginal irritation. Douching can also increase the risk for pelvic inflammatory disease and sterility. Strictly following the product instructions and the self-care measures listed here will help avoid these problems.

- Keep all douche equipment clean.
- Use lukewarm water to dilute products.
- Follow the appropriate instructions in [Table 8-6](#) for the method of douching being used.
- Never insert a douche with forceful pressure.
- Do not use these products for birth control.
- Do not douche until at least 8 hours after intercourse during which a diaphragm, cervical cap, or contraceptive jelly, cream, or foam was used.
- Do not douche for at least 3 days after the last dose of vaginal antifungal medication.
- Do not douche for 48 hours before any gynecologic examination.
- Do not douche during pregnancy unless under the supervision of a health care provider.
- Use douches only as directed for routine cleansing.

- Do not douche more often than twice a week, except on the advice of a health care provider.
- If vaginal dryness or irritation occurs, discontinue use of the douche.

### Key Points for Vaginal and Vulvovaginal Disorders

- Vaginal symptoms are often nonspecific, and may be difficult to distinguish between the three common vaginal infections. The symptom most likely to differentiate a *Candida* vaginal infection from BV and trichomoniasis is the absence of an offensive odor to the vaginal secretions. Measurement of vaginal pH (pH > 4.5 indicates a non-*Candida* infection) may also help to distinguish *Candida* and reduce inappropriate use of nonprescription vaginal antifungals.
- *Candida* vaginal infections are typically caused by *C. albicans*, but recently non-*C. albicans* infections have increased. The latter may be more resistant to nonprescription vaginal antifungals.
- Self-treatment for a *Candida* vaginal infection is most appropriate when the symptoms are mild-moderate, when she does not have predisposing illnesses or medications, when she has had one previously diagnosed infection, and when her symptoms are not recurrent. Recurrent infections are defined as more than 3 infections within a 12-month period and symptoms occurring within 2 months of previous vaginal symptoms.
- All of the nonprescription vaginal antifungals are equally effective. Selection of length of regimen or time of day for administration can be determined by patient preference. A medical referral should be made for women taking warfarin. Patients should be informed that symptoms typically improve shortly after application of the nonprescription vaginal antifungals. Symptoms should improve within 2-3 days after initiation of therapy and resolve within a week. The length of the treatment regimen does not directly correspond to resolution of symptoms.
- Use of a sodium bicarbonate sitz bath may provide relief of itching and irritation prior to onset of benefit from the antifungal.
- Eating yogurt with live cultures (8 ounces daily) may benefit some patients in preventing recurrent VVC infections.
- Atrophic vaginitis can occur after menopause, after giving birth, during breast-feeding, or as a result of antiestrogenic medications. Vaginal dryness and dyspareunia can be relieved by use of topical personal lubricant products. If symptoms do not improve within a week, medical evaluation is needed.
- Atrophic vaginitis may cause vaginal bleeding. Any reports of postmenopausal bleeding should have a medical referral to rule out endometrial cancer.
- Douching is not necessary for vaginal cleansing, and adverse consequences of douching can occur. Douching is contraindicated during pregnancy and should be postponed until at least 8 hours after sexual intercourse if a vaginal spermicide was used for contraception.

## Handbook of Nonprescription Drugs &gt; Chapter 9. Disorders Related to Menstruation

**Disorders Related to Menstruation: Introduction**

The menstrual cycle is a regular physiologic event for women that begins in adolescence and usually continues through late middle age. Women are able to self-treat for two common menstrual disorders: primary dysmenorrhea and premenstrual syndrome. Many women use nonprescription products and seek advice from health care providers on how best to manage symptoms of these disorders, including abdominal pain and cramping, irritability, and fluid retention. An understanding of the menstrual cycle will help both patients and health care providers make informed and appropriate decisions about self-care. Health care providers should also be familiar with common menstrual symptoms and disorders, as well as the risks for toxic shock syndrome.

Menstruation results from the monthly cycling of female reproductive hormones. A single menstrual cycle is the time between the onset of one menstrual flow (menstruation or menses) and the onset of the next. The average age of menarche (the initial menstrual cycle) in U.S. women is 12 years, although normal menarche may occur as early as age 11 or as late as age 14.5.<sup>1</sup> The onset of menstruation is influenced by factors such as race, genetics, nutritional status, and body mass. The median menstrual cycle length is 28 days, ranging from 24 to 38 days for adult women; adolescents have a wider cycle length of 20-45 days.<sup>2</sup> Menses lasts 3-7 days, with most blood loss occurring during days 1 and 2.<sup>1,3</sup> The major components of menstrual fluid are blood and endometrial cellular debris; the average blood loss per cycle is 30 mL (10-84 mL).<sup>3</sup> A loss of more than 80 mL per cycle or bleeding lasting longer than 7 days is considered abnormal and may be associated with anemia.

The menstrual cycle (Figure 9-1) results from the hormonal activity of the hypothalamus, pituitary gland, and ovaries; this is known as the hypothalamic-pituitary-ovarian axis. The hypothalamus plays the key role in regulating the menstrual cycle by producing gonadotropin-releasing hormone (GnRH). Low levels of both estradiol and progesterone, present at the end of the previous menstrual cycle, stimulate the hypothalamus to release GnRH, which stimulates pituitary gonadotroph cells to synthesize and secrete luteinizing hormone (LH) and follicle-stimulating hormone (FSH).

Two principal reproductive events, both of which are hormonally controlled, occur during each menstrual cycle. The first event is the maturation and release of an ovum (egg) from the ovaries; the second is the preparation of the endometrial lining of the uterus for the implantation of a fertilized ovum. The events of the menstrual cycle can be described in phases that reflect changes in either the ovary (follicular/ovulatory and luteal phases) or the uterine endometrium (menstrual/proliferative and secretory phases). The follicular/ovulatory phase correlates with the menstrual/proliferative phase, and the luteal phase correlates with the secretory phase.

Cycle day 1 is the first day of menstrual flow and is the beginning of the follicular and menstrual/proliferative phases. The follicular phase can range in length from several days to several weeks, but it lasts an average of 14 days. During the follicular phase, FSH stimulates the maturation of a group of ovarian follicles. These maturing follicles secrete estradiol, which promotes growth of the uterine endometrium.

By about cycle day 8, a single ovarian follicle usually becomes dominant, which typically results in the release or ovulation of only one mature egg. The ovulatory phase of the cycle is about 3 days in length. During this phase, the pituitary gland secretes high levels of LH for a 48-hour period, which is known as the LH surge. The LH surge catalyzes the final steps in the maturation of the ovum and stimulates production of prostaglandins and proteolytic enzymes necessary for ovulation. Estradiol levels also decrease during the LH surge, sometimes resulting in midcycle endometrial bleeding. Ovulation typically occurs 12 hours after the LH surge. Ovulation releases 5-10 mL of follicular fluid, which contains the oocyte mass and prostaglandins; this event may cause abdominal pain (*mittelschmerz*, German for "middle pain") for some women. In adolescents, the LH surge does not occur until 2-5 years after menarche. As a result, 50%-80% of cycles are anovulatory (i.e., no ovulation occurs) and are irregular during the initial years after menarche.

The luteal phase is the time between ovulation and the beginning of menstrual blood flow. After the follicle ruptures, it is referred to as the corpus luteum. The luteal phase is typically consistent in length (about 14 ±2 days) and reflects the 10- to 12-day functional period of the corpus luteum. The corpus luteum secretes progesterone, estradiol, and androgens. The increased levels of estrogen and progesterone alter the uterine endometrial lining. Glands mature, proliferate, and become secretory as the uterus prepares for the implantation of a fertilized egg. Progesterone and estrogen levels increase in the middle of the luteal phase, but LH and FSH levels decline in response to the increased hormone levels. If pregnancy occurs, human chorionic gonadotropin released by the developing placenta supports the function of the corpus luteum until the placenta develops enough to begin secreting estrogen and progesterone. If pregnancy does not occur, the corpus luteum ceases to function. Estrogen and progesterone levels then decline, causing the endometrial lining of the uterus to become edematous and necrotic. The decrease in

progesterone also leads to prostaglandin synthesis. Following prostaglandin-initiated vasoconstriction and uterine contractions, sloughing of the outer two endometrial layers occurs. The decline in estrogen and progesterone results in an increase in GnRH and in the renewed production of LH and FSH, which begins a new menstrual cycle.

## Dysmenorrhea

Dysmenorrhea (difficult or painful menstruation) is the most common gynecologic problem among adolescents and young adult women. Dysmenorrhea is divided into primary and secondary disorders by etiology. Primary dysmenorrhea is associated with cramp-like lower abdominal pain at the time of menstruation in the absence of pelvic disease. Secondary dysmenorrhea is typically associated with pelvic pathology. The prevalence of dysmenorrhea is highest in adolescence, with up to 93% of young women being affected.<sup>4-6</sup> Primary dysmenorrhea usually develops within 6-12 months after menarche, generally affecting women during their teens and early 20s.<sup>7</sup> Primary dysmenorrhea occurs only during ovulatory cycles. Its prevalence increases between early and older adolescence as the regularity of ovulation increases<sup>4</sup> and decreases after age 24.<sup>7,8</sup>

Severe menstrual pain is reported by 14%-23% of teens.<sup>9</sup> Dysmenorrhea is the leading cause of school absenteeism and lost working hours among adolescent girls and young women. About 26% of adolescent girls report dysmenorrhea-related school absenteeism, which increases to 50% in girls who report severe pain.<sup>6,9</sup> In addition,

adolescents with severe menstrual pain reported that the pain interfered with other life activities such as social activities, sports, work, and relationships with friends and family.<sup>4,9</sup> Similarly, an estimated 600 million work hours are lost annually because of dysmenorrhea.<sup>8</sup>

The decreased prevalence and severity of dysmenorrhea in women in their mid-20s and older may be partially explained by oral contraceptive (OC) use (an effective therapy for dysmenorrhea) and pregnancy. The use of OCs decreases the amount of endometrium, resulting in lower prostaglandin production. During the last trimester of pregnancy, uterine adrenergic nerves virtually disappear, and only a portion of the nerves regenerate after childbirth. For many women, this phenomenon results in a decreased prevalence of dysmenorrhea following childbirth.

Factors other than young age and nulliparity can increase the risk for or severity of dysmenorrhea. These include early menarche (prior to age 12); heavy menstrual flow; tobacco smoking; low fish consumption; a body mass index of less than 20 kg/m<sup>2</sup> or greater than 30 kg/m<sup>2</sup>; premenstrual symptoms; and stress, anxiety, and depression.<sup>5,6</sup>

Obesity is linked to early menarche and can predispose to primary dysmenorrhea.<sup>8</sup> In addition, factors such as attempting to lose weight and stress related to social, emotional, or family issues can all make dysmenorrhea pain more bothersome.<sup>6,8,10</sup>

### Pathophysiology of Primary Dysmenorrhea

The cause of primary dysmenorrhea is not fully understood. However, prostaglandins and leukotrienes contribute substantially to the occurrence and severity of dysmenorrhea.<sup>4,5,8</sup> Nitric oxide and vasopressin may also be involved.<sup>5,8</sup> Ovulation increases serum progesterone, which leads to increases in arachidonic acid. During menstruation, arachidonic acid is converted to prostaglandins and leukotrienes, which are then released. Prostaglandin levels are two to four times greater in women with dysmenorrhea than in women without dysmenorrhea; the severity of dysmenorrhea is proportional to the endometrial concentration of the prostaglandin F<sub>2a</sub> (PGF<sub>2a</sub>).<sup>7</sup> Leukotrienes (inflammatory mediators known to cause vasoconstriction and uterine contractions) are elevated in women with dysmenorrhea; levels are correlated with both occurrence and severity. Leukotrienes may contribute significantly to dysmenorrhea in women who do not respond to nonsteroidal anti-inflammatory drugs (NSAIDs).<sup>8</sup> Nitric oxide has also been linked to dysmenorrhea because transdermal nitroglycerine patches increase nitric oxide and decrease dysmenorrhea-related pain. Nitric oxide is the substance that promotes uterine quiescence during pregnancy, and use of nitric oxide during premature labor can stop uterine contractility.<sup>8</sup> Circulating levels of vasopressin (a substance that can produce dysrhythmic uterine contractions) are higher in women with dysmenorrhea than in asymptomatic individuals. However, the role of vasopressin in the etiology of primary dysmenorrhea remains controversial.<sup>4,5</sup>

Prostaglandins stimulate uterine contractions. Normal contractions and vasoconstriction help expel menstrual fluids and control bleeding as the endometrium sloughs. However, the increased levels of prostaglandins and leukotrienes present with dysmenorrhea can lead to strong uterine contractions similar to those experienced during labor and excessive vasoconstriction, resulting in uterine ischemia and pain. In women without dysmenorrhea, uterine contractions are rhythmic, and contraction pressure reaches 120 mm Hg. In contrast, women with dysmenorrhea have more frequent contractions, with pressures up to 180 mm Hg that contribute to ischemia and tissue hypoxia and, thus, pain.<sup>11</sup>

### Clinical Presentation of Primary Dysmenorrhea

The pain with primary dysmenorrhea is cyclic in nature and is directly related to the onset of menstruation (Table 9-1). Pain is typically experienced as a continuous dull ache with spasmodic cramping in the lower midabdominal or suprapubic region that may radiate to the lower back and upper thighs. The uterine contractions can force prostaglandins and leukotrienes into the systemic circulation, causing additional symptoms such as nausea, vomiting, fatigue, dizziness, bloating, diarrhea, and headache.<sup>4</sup> A large study of adolescents found that 78% reported fatigue, 71% cramping, 64% headaches, 58% lower back pain, and 37% nausea at the time of menstruation.<sup>9</sup> The onset of pain is several hours prior to or coincident with the onset of menses and usually lasts 1-3 days, typically peaking in the first 24-48 hours.<sup>6,10</sup> For this reason, women with regular periods may wish to begin treatment before the onset of menses to prevent dysmenorrhea. This clinical presentation can be adequate for the diagnosis of primary dysmenorrhea, if the pain is mild-moderate and the patient responds to NSAID therapy.<sup>4,6,7</sup>

Secondary dysmenorrhea is suggested if the symptoms initially begin years after menarche (at age 25 or older), if pelvic pain occurs at times other than during menses, if the woman has irregular menstrual cycles or has menorrhagia (excessively prolonged or profuse menses), metrorrhagia (irregular uterine bleeding usually between menstrual periods), or a history of pelvic inflammatory disease (PID), dyspareunia, or infertility.<sup>4,5,9</sup> Endometriosis (growth of cells similar to endometrial cells in locations outside the uterus) is the most common cause of secondary

dysmenorrhea. Adolescents are being diagnosed increasingly with secondary dysmenorrhea, which accounts for symptoms in 47%-73% of teens with severe menstrual pain and no response to NSAIDs or OCs.<sup>2,9</sup> Secondary dysmenorrhea may also be caused by the presence of an intrauterine contraceptive (IUC).

**TABLE 9-1 Differentiation of Primary and Secondary Dysmenorrhea**

	<i>Primary Dysmenorrhea</i>	<i>Secondary Dysmenorrhea</i>
Age at onset of dysmenorrhea symptoms	As soon as 6-12 months after menarche but typically several years after menarche; age 13-17 years for most girls	Mid- to late-20s or older; usually 30s and 40s for women with secondary dysmenorrhea
Menses	More likely to be regular with normal blood loss	More likely to be irregular; menorrhagia and metrorrhagia more common
Pattern and duration of dysmenorrhea pain	Onset just prior to or coincident with onset of menses; pain with each or most menses, lasting only 2-3 days	Pattern and duration vary with cause; change in pain pattern or intensity may also indicate secondary disease
Pain at other times of menstrual cycle	No	Yes; may occur before, during, or after menses
Response to NSAIDs and/or OCs	Yes	No
Other symptoms	Fatigue, headache, nausea, change in appetite, backache, dizziness, irritability, and depression may occur at same time as dysmenorrhea pain	Vary according to cause of the secondary dysmenorrhea; may include dyspareunia, pelvic tenderness

Key: NSAID = Nonsteroidal anti-inflammatory drug; OC = oral contraceptive.

Source: References 4 and 9.

### Treatment of Primary Dysmenorrhea

Many women self-treat for dysmenorrhea using nonprescription products. In a study of adolescents, 66% self-treated with NSAIDs; fewer used acetaminophen or aspirin.<sup>9</sup> Among those who self-treated, 85% reported moderate-to-high effectiveness from the analgesic. Other studies have found that self-care may result in use of low or mistimed doses or use of less effective medications, thus increasing the likelihood of school absence and other activity limitations.<sup>4</sup> Inadequate management of dysmenorrhea pain can lead to increased pain sensitivity at times other than during menses and to increased sensitivity to non-uterine pain, thus having important implications for pain perception and quality of life throughout life.<sup>12</sup>

#### Treatment Goals

The goals of treating primary dysmenorrhea are to provide relief or a significant improvement in symptoms and minimize the disruption of usual activities.

#### General Treatment Approach

An important initial step in managing dysmenorrhea is distinguishing between primary and secondary dysmenorrhea. Self-care is appropriate for an otherwise healthy young woman who has a history consistent with primary dysmenorrhea and who is not sexually active or for a woman who has been diagnosed with primary dysmenorrhea.<sup>4</sup> Adolescents with pelvic pain who are sexually active and thus at risk for PID and women with characteristics indicating secondary dysmenorrhea should be referred for medical evaluation. Table 9-1 compares primary and secondary dysmenorrhea. An estimated 80%-90% of women with primary dysmenorrhea can be successfully treated with NSAIDs, OCs, or both. Other treatment options include nonpharmacologic measures (e.g., use of topical heat; dietary supplementation with omega-3 fatty acids). These fatty acids are found in fish and fish oil and compete with arachidonic acid in the cyclooxygenase and lipoxygenase pathways, leading to a decrease in the

production of the proinflammatory cytokines. Increased consumption of fish rich in omega-3 fatty acids (e.g., tuna, salmon, and sardines) or use of fish oil may reduce symptoms.<sup>10</sup> Cholecalciferol, also known as vitamin D<sub>3</sub>, is known to decrease the production of prostaglandins and increase prostaglandin inactivation.<sup>13</sup> One small study found a reduction in dysmenorrhea pain among women with low serum vitamin D levels who were given a single 300,000 IU dose of cholecalciferol 5 days prior to menses.<sup>14</sup> Women should be counseled to ingest vitamin D<sub>3</sub> 600 IU daily. These measures often serve as adjuncts to drug therapy, although topical heat may be adequate as a sole therapy for some women. [Figure 9-2](#) presents an algorithm for managing primary dysmenorrhea. A patient with more severe dysmenorrhea, a change in the pattern or intensity of pain, or inadequate response or intolerance to NSAIDs should be referred to her primary care provider. An estimated 10%-25% of women do not respond to NSAIDs, cannot tolerate therapy, or prefer not to use medication for dysmenorrhea.<sup>10</sup> [Figure 9-2](#) lists exclusions for self-care.

### Nonpharmacologic Therapy

Many women use nonpharmacologic measures to help manage dysmenorrhea and menstrual discomfort. A study of adolescents found that common nonpharmacologic measures included sleep, hot baths or a heating pad, and exercise.<sup>4</sup> The use of heat is a commonly recommended nondrug therapy. An abdominal heat patch has been tested for the treatment of dysmenorrhea.<sup>15</sup> The heat patch was significantly better and provided 14% greater pain relief than placebo or acetaminophen. The analgesic effect of the heat patch had a faster onset than drug therapy and was additive to the relief provided by ibuprofen. Evidence regarding the benefit of exercise is conflicting; however, participation in regular exercise may lessen the symptoms of primary dysmenorrhea for some women.<sup>4,5</sup> Nonpharmacologic therapy may be especially useful for women who cannot tolerate or do not respond to nonprescription medications.

Smoking and exposure to secondhand smoke have been associated with more severe dysmenorrhea.<sup>4</sup> The severity of dysmenorrhea symptoms reportedly increases with the number of cigarettes smoked per day. The basis for this effect is unknown, but nicotine-induced vasoconstriction may be involved. Discontinuing tobacco smoking or avoiding exposure to tobacco smoke may improve symptoms.

### Pharmacologic Therapy

Unfortunately, many women and adolescents with dysmenorrhea remain untreated or are inadequately treated. They continue to experience pain and limitations in their daily activity. The following sections outline the uses and properties of the four nonprescription analgesic medications commonly used by women to treat dysmenorrhea: acetaminophen, aspirin, ibuprofen, and naproxen sodium. [Table 9-2](#) lists their dosages for dysmenorrhea. [Chapter 5](#) provides further discussion of their adverse effects, contraindications, and drug interactions.

#### Aspirin

Aspirin may be adequate for treating mild symptoms of dysmenorrhea. In low dosages, aspirin has only a limited effect on prostaglandin synthesis and is only moderately effective in treating more than minimal symptoms of dysmenorrhea. Aspirin may also increase menstrual flow.

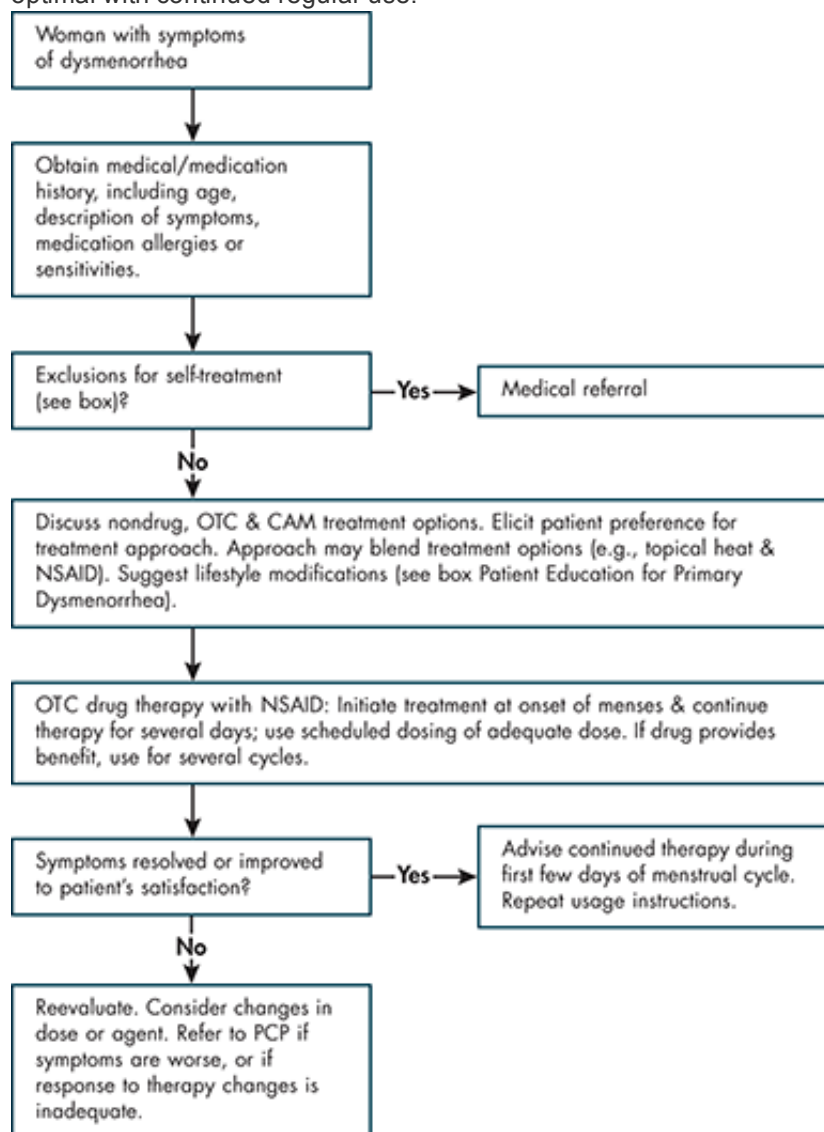

#### Acetaminophen

Acetaminophen may also be adequate for treating mild symptoms of dysmenorrhea. Acetaminophen is a weak inhibitor of prostaglandin synthesis; the reduction of PGF<sub>2a</sub> levels is much greater with nonsalicylate NSAIDs than with acetaminophen.<sup>16</sup> Even in dosages of 4 grams daily, acetaminophen is less effective than ibuprofen; lower dosages are less likely to be effective.<sup>16</sup>

#### Nonsalicylate NSAIDs

Nonsalicylate NSAIDs, the first-line treatment for primary dysmenorrhea, include ibuprofen 200 mg and naproxen sodium 220 mg. In clinical trials, these NSAIDs were effective in 66%-90% of patients. Relief of dysmenorrhea typically occurs within the first cycle of use.<sup>10</sup> However, dosages used in clinical trials and dosages of prescription drugs for the treatment of dysmenorrhea are often higher than the labeled nonprescription dosages. Therefore, providers may recommend prescription therapy, or they may recommend that a patient use a prescription dosage of an NSAID using nonprescription products if the lower dosage does not provide adequate symptom relief. Therapy with nonsalicylate NSAIDs should begin at the onset of menses or pain. If inadequate pain relief occurs, treatment beginning 1-2 days before expected menses may improve symptomatic relief.<sup>5</sup> If the possibility of pregnancy exists, therapy should be initiated only after menses begins. Patients should be instructed that the NSAID

is used to prevent cramps and to relieve pain. Optimal pain relief is achieved when these agents are taken on a schedule, rather than on an as-needed basis. Therefore, ibuprofen should be taken every 4-6 hours and naproxen sodium every 8-12 hours for the first 48-72 hours of menstrual flow because that time frame correlates with maximum prostaglandin release (Table 9-2). The therapeutic effect is usually apparent within 30-60 minutes, and benefit will be optimal with continued regular use.

#### Exclusions for Self-Treatment<sup>o</sup>

- Severe dysmenorrhea and/or menorrhagia
- Dysmenorrhea symptoms inconsistent with primary dysmenorrhea (e.g., onset after age 25, dysmenorrhea pain at times other than onset of menses)
- History of PID, infertility, irregular menstrual cycles, endometriosis, ovarian cysts
- Use of IUC
- Allergy to aspirin or NSAIDs; intolerance for NSAIDs
- Use of warfarin, heparin, or lithium
- Active GI disease (PUD, GERD, ulcerative colitis)
- Bleeding disorder

<sup>o</sup> Women who are lactating should avoid use of herbs. Selected drug interactions and disease interactions are listed in Figure 9-3, but this list is not comprehensive.

Copyright © American Pharmacists Association  
All rights reserved. Any use is subject to the Terms of Use.

Self-care of primary dysmenorrhea. Key: CAM = Complementary and alternative medicine; GERD = gastroesophageal reflux disease; GI = gastrointestinal; IUC = intrauterine contraceptive; NSAID = nonsteroidal anti-inflammatory drug; OTC = over-the-counter; PID = pelvic inflammatory disease; PCP = primary care provider; PUD = peptic ulcer disease.

A patient with dysmenorrhea may respond better to one NSAID than to another. If the maximum nonprescription dosage of one agent does not provide adequate benefit, then switching to another agent is recommended. The analgesic effect for most of these NSAIDs plateaus, so further dosage increases may increase the risk of adverse effects rather than provide additional benefit. Therapy with NSAIDs should be undertaken for three to six menstrual cycles, with changes made in the agent, dosage, or both before judging the effectiveness of these agents for a particular patient. If nonprescription NSAID therapy does not provide an adequate therapeutic effect, alternative therapies that may provide relief from primary dysmenorrhea include prescription NSAIDs; prescription dosages of nonprescription NSAIDs; or use of a combined OC or a progestin implant (Implanon, Nexplanon), estrogen plus progestin vaginal ring (NuvaRing), or the levonorgestrel IUC (Mirena, Skyla).<sup>17</sup>

Adverse effects from a few days of intermittent use usually include gastrointestinal (GI) symptoms such as upset stomach, vomiting, heartburn, abdominal pain, diarrhea, constipation, and anorexia. Adverse effects may also include headache and dizziness. Some GI adverse effects may be decreased by taking the drugs with food.

#### Pharmacotherapeutic Comparison

A Cochrane review indicated that ibuprofen and naproxen are considered first-line agents for dysmenorrhea because of their effectiveness and tolerability.<sup>18</sup> Cost and patient preference as to the number of doses and tablets to

take should guide agent selection. Because of restrictions on taking medications to school, adolescents may benefit from naproxen's longer duration of action. Women at risk of GI ulceration should consider the use of a gastroprotective agent or another therapeutic option (e.g., an oral contraceptive). Acetaminophen may provide some relief for patients with hypersensitivity or intolerance to aspirin and for patients with intolerance to the GI and platelet-inhibition adverse effects of aspirin and NSAIDs.

**TABLE 9-2 Treatment of Dysmenorrhea with Nonprescription Medications**

<b>Agent</b>	<b>Recommended Nonprescription Dosage (maximum daily dosage)</b>
Acetaminophen	650-1000 mg every 4-6 hours (4000 mg) <sup>a</sup>
Aspirin	650-1000 mg every 4-6 hours (4000 mg)
Ibuprofen	200-400 mg every 4-6 hours <sup>b</sup> (1200 mg)
Naproxen sodium	220-440 mg initially; then 220 mg every 8-12 hours (660 mg)

<sup>a</sup> See Table 5-3 for information on the manufacturer's voluntary reduction of maximum daily dosages of Tylenol products sold in the United States.

<sup>b</sup> If 200 mg every 4-6 hours is ineffective, the recommended dosage for dysmenorrhea (400 mg every 6 hours while awake) should be taken.

#### Product Selection Guidelines

#### Special Populations

The Food and Drug Administration (FDA) recommends that aspirin and combination products containing aspirin not be given to children and adolescents under 19 years of age during episodes of febrile illnesses because of the association between aspirin use and Reye's syndrome in this age group. Pregnant or menopausal women will not experience dysmenorrhea. Women attempting to become pregnant should avoid use of NSAIDs in the periconception time, as these agents may impair implantation of the blastocyst.<sup>19</sup> Acetaminophen and ibuprofen can safely be taken by breast-feeding women, as the amounts of both medications are low in breast milk.<sup>20</sup> Women who are breast-feeding should avoid use of aspirin; if a dose of aspirin is taken, a woman should wait 1-2 hours before breast-feeding.<sup>20</sup> Naproxen sodium is a less optimal choice for breast-feeding women; although levels in breast milk are low, this medication has a long half-life, and a report of a serious adverse reaction in a neonate has been published.<sup>20</sup> A nonpharmacologic approach (e.g., topical heat) may also be a good choice for breast-feeding women.

#### Patient Factors

Given that NSAIDs are used only temporarily and intermittently, the risk for GI toxicity (e.g., irritation, bleeding, or ulceration) is limited. However, patients who have active peptic ulcer disease, those at risk for GI bleeding, or those with a history of GI ulcers should discuss use of NSAIDs with their primary care provider. They may attempt to treat dysmenorrhea with acetaminophen, nonpharmacologic therapy, or an OC. NSAIDs can also inhibit platelet activity and increase bleeding time. Women on anticoagulants should avoid NSAID use, and women on other agents that may increase bleeding should use NSAIDs cautiously. Women who consume 3 or more alcohol-containing beverages daily should discuss use of acetaminophen or aspirin with their primary care provider because additive liver or GI toxicity, respectively, may occur.

#### Patient Preferences

Women may prefer to use an NSAID that they are familiar with, or they may prefer to try another agent if adverse effects were experienced previously. Preferences may also be based on tablet/capsule preferences or cost of products.

#### Complementary Therapies

Small studies have suggested that intake of several vitamins or minerals (e.g., vitamin B<sub>1</sub>, vitamin E, or magnesium) may decrease dysmenorrhea.<sup>10</sup> Additionally, data from several randomized controlled trials have found acupuncture to be an easily teachable, effective nonpharmacologic therapy for relieving primary dysmenorrhea.<sup>21</sup> All of these

potential therapies need further study and verification.

### Assessment of Primary Dysmenorrhea: A Case-Based Approach

Before recommending any product to a patient experiencing symptoms of dysmenorrhea, the health care provider should ascertain that the symptoms (particularly the onset and duration of pain in relation to the onset of menses) are consistent with primary dysmenorrhea ([Table 9-1](#)).

Case 9-1 illustrates the assessment of a patient with dysmenorrhea.

### Patient Counseling for Primary Dysmenorrhea

Adolescents and young women who experience primary dysmenorrhea symptoms should be educated about this condition so they (1) realize primary dysmenorrhea is normal, (2) recognize typical symptoms and symptoms that are inconsistent with primary dysmenorrhea and when to seek medical evaluation, (3) understand that NSAIDs are preferred therapy because of their efficacy, and (4) know how to use these agents for greatest benefit. Patients should also be advised that nonprescription NSAIDs can be appropriate for initial therapy, but that not all women will respond. If response to the first agent is not adequate, another NSAID and/or nondrug intervention can be tried. The health care provider should explain the proper use of these agents and their potential adverse effects. The Patient Education for Primary Dysmenorrhea box lists specific information to provide patients.

### Evaluation of Patient Outcomes for Primary Dysmenorrhea

Patient monitoring is accomplished by having the patient report whether her symptoms are improved or resolved. Symptoms should improve within an hour or so of taking an NSAID. The optimal effect of drug therapy may not be seen until the woman has used the medication on a scheduled basis. If inadequate pain relief occurs, treatment beginning 1-2 days before expected menses may improve symptomatic relief. The patient with persistent symptoms should be advised to try another nonprescription NSAID, to add adjunct therapy, or to see a primary care provider for evaluation.

### Case 9-1

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient is experiencing very painful menstrual cramps. She has had bad menstrual cramps for years. The cramps occur during menses but can also occur at other times of the month. She also has heavy bleeding during her periods.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	A hot bath can help sometimes, but even NSAIDs do not always relieve her pain.
c. description of the patient's efforts to relieve the symptoms	She has tried ibuprofen 400 mg three times daily; she has even tried 600 mg doses. She also tried naproxen sodium. She has some left-over acetaminophen with codeine from a dental procedure that she takes when the pain is really bad.
d. patient's identity	Marion Chandler
e. age, sex, height, and weight	27 years old, female, 5 ft 7 in., 140 lb

f. patient's occupation	Elementary school teacher
g. patient's dietary habits	She reports she eats a good diet overall, but will eat pizza or fast-food when busy. Also, she likes chocolate.
h. patient's sleep habits	She sleeps about 8 hours a night; sleep is only a problem if the pain is really bad.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Migraine headache: Excedrin, 2 tablets as needed Contraception: Loestrin 1.5/30, 1 daily for 3 weeks monthly Multiple vitamin, 1 daily Calcium/vitamin D 500 mg/400 IU, 1 daily
j. allergies	None
k. history of other adverse reactions to medications	None
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Ms. Chandler has symptoms that are not consistent with primary dysmenorrhea; they are more consistent with secondary dysmenorrhea.
3. Identify exclusions for self-treatment (Figure 9-2).	Abdominal pain at times other than at the onset of menses; menorrhagia; severity of cramps; lack of alleviation or improvement in symptoms by NSAIDs and oral contraceptive
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer patient to an appropriate health care provider. (2) Recommend self-care with nonprescription and nondrug measures. (3) Recommend self-care until patient can see an appropriate health care provider. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	She should be referred for medical evaluation.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Your symptoms are not consistent with primary dysmenorrhea. Therefore, there is not a nonprescription drug therapy that will address your symptoms. I advise you to see your primary care provider for a medical evaluation."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic	"You have tried both nonprescription NSAIDs, and neither has relieved your pain adequately. Also, you are taking an oral contraceptive; OCs typically improve primary dysmenorrhea. But you are still experiencing pain while taking the OC. Because you have had very bad cramps for a long time and

alternatives.	neither NSAIDs nor your OC have relieved your pain, I recommend you have this pain evaluated.”
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	“My mother has had menstrual problems—could this be genetic?”
Answer the patient’s or caregiver’s questions.	“It is possible—some gynecologic conditions are known to have genetic causes. Tell your primary care provider about your mother’s history. Once your primary care provider determines the cause of your symptoms, he or she will be able to tell you if a genetic effect is possible.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	NA

Key: NA = Not applicable; NSAID = nonsteroidal anti-inflammatory drug; OC = oral contraceptive.

#### Patient Education for Primary Dysmenorrhea

The objective of self-treatment is to relieve or significantly improve symptoms of dysmenorrhea so as to limit discomfort and disruption of usual activities. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Nonpharmacologic Measures

- If effective, apply topical heat to the abdomen, lower back, or other painful area.
- Stop smoking cigarettes and avoid second-hand smoke.
- Consider eating more fish high in omega-3 fatty acids or taking a fish oil supplement.
- Participate in regular exercise if it lessens the symptoms.

#### Nonprescription Medications

- Ibuprofen and naproxen sodium are the best type of nonprescription medication for primary dysmenorrhea. The medications stop or prevent strong uterine contractions (cramping).
- Start taking the medication when the menstrual period begins or when menstrual pain or other symptoms begin. Then take the medication at regular intervals following the product instructions, rather than just when the symptoms are present. See [Table 9-2](#) for recommended NSAID dosages.
- Take the NSAID with food to limit upset stomach and heartburn.
- Do not take NSAIDs if you are allergic to aspirin or any NSAID, or if you have peptic ulcer disease, gastroesophageal reflux disease, colitis, or any bleeding disorder.
- If you have hypertension, asthma, or heart failure, watch for early symptoms that the NSAID is causing fluid retention.
- Do not take a nonsalicylate NSAID if you are also taking anticoagulants or lithium.
- If abdominal pain occurs at times other than just before or during the first few days of menses, seek medical attention.

#### When to Seek Medical Attention

- Seek medical attention if the pain intensity increases or if new symptoms occur.

#### Premenstrual Syndrome

Premenstrual syndrome (PMS) is defined as a cyclic disorder composed of a combination of physical, emotional/mood, and behavioral symptoms that occur during the luteal phase of the menstrual cycle. Symptoms

improve significantly or disappear by the end of menses and are absent during the first week following menses. The diagnosis of PMS can be made on the basis of symptoms that occur cyclically. Premenstrual dysphoric disorder (PMDD) is a severe form of PMS. The diagnosis of PMDD requires that a specific constellation of symptoms occurs on a cyclical basis and that symptoms are severe enough to interfere with social and/or occupational functioning.<sup>22,23</sup> In addition, the American Congress of Obstetricians and Gynecologists has defined moderate-severe PMS as a condition having at least one psychological or physical symptom resulting in significant impairment and substantiated by prospective symptom ratings.<sup>23</sup>

Almost all women experience some mild physical or mood changes before the onset of menses, and these are normal signs of ovulatory cycles.<sup>4,23</sup> The changes may include physical symptoms; food cravings; and emotional lability, irritability, or lowered mood. In addition, some women report positive changes (e.g., increased energy, creativity, work productivity, and sexual desire).<sup>22</sup>

The number and severity of symptoms and the extent to which they interfere with functioning distinguish typical premenstrual symptoms, PMS, moderate-severe PMS, and PMDD<sup>24</sup> (Table 9-3). Sixty percent to 80% of women with premenstrual symptoms experience only mild (primarily physical) symptoms that do not interfere with their lives.<sup>25</sup> An estimated 20%-25% of women experience clinically significant symptoms, and 3%-8% report symptoms that cause significant impairment that interferes with relationships, lifestyle, or work.<sup>24</sup>

PMS can occur any time after menarche. Symptoms usually originate when women are in their teens to early 20s; typically, women wait about a decade to seek care.<sup>4,25,26</sup> PMS symptoms occur only during ovulatory cycles. Symptoms disappear during events that interrupt ovulation (e.g., pregnancy and breast-feeding); PMS symptoms disappear at menopause. The use of OCs can cause or exacerbate PMS symptoms, and use of hormone therapy in postmenopausal women may result in recurrence of PMS symptoms.<sup>26</sup>

Many factors contribute to the development of PMS and PMDD. Genetic factors likely play a role. Twin studies have shown that PMS is inherited, with women whose mothers had PMS being more likely to develop PMS.<sup>26,27</sup> In addition, genetic differences exist in the serotonergic 5-HT<sub>1A</sub> receptor and the estrogen alpha-receptor gene in women with and without PMS symptoms.<sup>23,27</sup> Stress and prior traumatic events (including sexual abuse) are risk factors for PMS/PMDD. Different coping strategies for handling stress, as well as altered psychological and physiologic responses to stress, have been shown in individuals with a history of life stress and abuse.<sup>23,27</sup> Sociocultural factors can also influence the experience of premenstrual symptoms. Exposure to negative expectations about premenstrual symptoms can lead women to interpret normal symptoms more negatively.<sup>27</sup>

### Pathophysiology of PMS

The etiology of PMS is not fully understood. The current consensus is that the fluctuations of estrogen and progesterone caused by normal ovarian function are the cyclic trigger for PMS/PMDD symptoms. Although triggered by hormonal fluctuations, no known hormonal imbalances are present in women with PMS. Some women are biologically vulnerable or predisposed to experience PMS because of a neurotransmitter sensitivity to physiologic changes in hormone levels.<sup>4,23,25,27</sup> Serotonin, which is involved in mood and behavior regulation, is affected by estrogen and progesterone levels. Reduced levels of serotonin and serotonin effect in the brain may be linked to certain PMS symptoms (e.g., poor impulse control, irritability, carbohydrate craving, and dysphoria).<sup>4,26</sup> Other neurotransmitters and systems that may be important are allopregnanolone and gamma-aminobutyric acid (GABA) receptors. Allopregnanolone is a progesterone metabolite that binds the GABA receptor, leading to an anxiolytic action.<sup>25</sup> Women with PMS may be less sensitive to the sedating effects of allopregnanolone during the luteal phase and may have different GABA receptor sensitivity.<sup>23,25,27</sup> These alterations may result in luteal phase symptoms (e.g., anxiety and irritability).<sup>26</sup> In addition, selective serotonin reuptake inhibitors (SSRIs), which are known to relieve PMS/PMDD, affect the synthesis of allopregnanolone. Therefore, for symptoms severe enough to warrant prescription drug therapy, treatment is based on medications that affect the levels of serotonin or suppress ovulation and interrupt hormonal cycling.

The pathophysiology of physical symptoms of PMS (e.g., breast tenderness, bloating, and joint/muscle pain) is not as well studied. Women with PMDD have lower beta-endorphin levels, leading to a lower tolerance for discomfort and pain.<sup>23</sup> Studies of fluid retention and breast enlargement have not found tissue changes; abdominal bloating often occurs without weight gain.<sup>23</sup>

**TABLE 9-3 Differentiation of PMS and PMDD from Other Conditions with Luteal Phase Symptoms**

Typical premenstrual symptoms	Mild physical (breast tenderness, bloating, lower backache, food cravings) or mood (irritability, emotional lability, lowered mood, increased energy or creativity) changes before the onset of menses that do not interfere with normal life functions
-------------------------------	---

Premenstrual syndrome	At least one mood (depression, irritability, anger, anxiety) or physical (breast tenderness, abdominal bloating) symptom during the 5 days prior to menses. Symptoms are virtually absent during cycle days 5-10. The symptom or symptoms have a negative effect on social functioning or lifestyle, but the severity is mild-moderate.
Moderate-severe premenstrual syndrome	At least one mood or physical symptom that results in significant impairment of daily activities or relationships.
Premenstrual dysphoric disorder	Five or more symptoms (mood or physical) are present the last week of the luteal phase of the menstrual cycle, with at least one symptom being significant depression, anxiety, affective lability, or anger. The intensity of the symptoms interferes with work, school, social activities, and social relationships. Symptoms should be absent the week after menses and must not be an exacerbation of the symptoms of another disorder such as depression, panic disorder, or personality disorder.
Premenstrual exacerbation	A worsening of the symptoms of other, typically psychiatric disorders such as depression and anxiety or panic disorders. Conditions such as asthma, endometriosis, hypothyroidism, irritable bowel syndrome, attention-deficit disorder, diabetes mellitus, rheumatoid arthritis, migraine headaches, seizure disorders, and perimenopause can also worsen premenstrually. However, symptoms do not occur only during the luteal phase of the menstrual cycle; there is no symptom-free interval.

Source: References 4, 23, and 30.

Exogenous hormones may influence premenstrual symptoms. Women taking either OCs or postmenopausal hormone therapy may experience adverse effects similar to PMS symptoms as a result of altered hormone levels.<sup>22,26</sup> Conversely, 71% of women reported that the use of their OC had no effect on their PMS symptoms.<sup>4</sup> Certain OCs have been found useful in reducing the symptoms of PMS/PMDD: OCs containing the progestin drospirenone; those with a lower estrogen dose; those with a shortened hormone-free interval between pill packs; and those with continuous or extended cycles.<sup>4,17</sup>

### Clinical Presentation of PMS

The symptoms of PMS or PMDD are not unique to these conditions; however, the occurrence of specific symptoms and their fluctuation with the phases of the menstrual cycle are diagnostic. Premenstrual symptoms typically begin or intensify about a week prior to the onset of menses, peak near the onset of menses, and resolve within several days after the beginning of menses.<sup>23,26</sup> Symptoms typically are consistent from month to month.<sup>23</sup> A woman with PMS or PMDD should experience essentially a symptom-free interval during days 5-10 of her menstrual cycle. Common symptoms of PMS are listed in [Table 9-4](#). Women seeking symptom relief typically report multiple emotional, physical, and behavioral symptoms. Mood and behavioral symptoms are the most upsetting.<sup>26</sup> Most women rate their symptoms as mild-moderate and do not feel that they interfere with their life. Mood symptoms tend to cause more distress than physical symptoms because of their impact on relationships. A large cross-sectional study conducted in multiple countries found that the most common PMS symptoms reported by women included abdominal bloating, cramps or abdominal pain, irritability, breast tenderness, and joint or back pain.<sup>28</sup> These symptoms may be the ones most often reported to providers and may blur the distinction between dysmenorrhea and PMS. In addition, the presence of dysmenorrhea may be associated with a greater severity of PMS.<sup>29</sup>

**TABLE 9-4 Common Premenstrual Syndrome Symptoms**

<b>Most Common Negative Symptoms</b>
Fatigue, lack of energy
Irritability
Labile mood with alternating sadness and anger
Depression
Anxiety, feeling stressed
Crying spells, oversensitivity

Difficulty concentrating
Abdominal bloating, edema of extremities
Breast tenderness
Appetite changes and food cravings
Headache
Gastrointestinal upset
<b>Most Common Positive Symptoms</b>
Increased energy, more efficient at work
Increased libido, more affectionate
Increased sense of control, more self-assured

*Source:* Adapted from Reference 22.

Symptoms of PMDD are similar to those of PMS. Compared with PMS, women with moderate-severe PMS and PMDD experience more symptoms, more severe symptoms, and symptoms that impair personal relationships and the ability to function well at work to a greater extent. Among women with PMDD, the most common symptoms are affective in nature. The diagnosis of PMDD requires that a patient experiences marked anger or irritability, or depressed mood, anxiety, or emotional lability.<sup>30</sup> Other symptoms of PMDD include difficulty concentrating, lethargy, hypersomnia or insomnia, and physical symptoms such as breast tenderness and bloating. The severity of symptoms must cause significant impairment in the ability to function socially or at work during the week prior to menses.<sup>30</sup> A daily rating of symptoms for several cycles establishes a diagnosis of moderate-severe PMS or PMDD, and these types of symptoms should have occurred during most menstrual cycles over the past year. PMDD symptoms during the last 7 days of the cycle should be at least 30% worse than those experienced during the mid-follicular phase (days 3-9 of the menstrual cycle).

PMS/PMDD should be distinguished from typical premenstrual symptoms and also from premenstrual exacerbations of other disorders, particularly mood disorders. Some medical conditions can be aggravated during the premenstrual phase.<sup>26,30</sup> In addition, mood disorders not occurring solely during the luteal phase must be distinguished from cyclic mood symptoms (Table 9-3).

Lack of a symptom-free interval suggests that the patient has a psychiatric disorder (e.g., anxiety or panic disorder) or another health condition (e.g., the perimenopause or menopausal transition), rather than PMS.

### Treatment of PMS

PMS is a multisymptom disorder involving emotional, behavioral, and physical symptoms. A single therapeutic agent is unlikely to address all symptoms. Thus, treatment should be selected to address the patient's most bothersome symptoms. A symptom log/calendar is a useful tool for documenting the most bothersome symptom(s) and the cyclic nature of this disorder. This information will also be useful in evaluating the efficacy of treatment. Women with severe symptoms are less likely to have symptoms alleviated solely by use of nonprescription therapies. In addition, PMS symptoms are chronic and, in most cases, will continue until menopause. Therefore, the cost of therapy, the possibility that a woman may become pregnant, and the likelihood of adverse effects are important considerations in selecting therapy.

### Treatment Goals

The two intended outcomes for women with PMS or PMDD are patient education to better understand PMS and to improve or resolve symptoms to reduce the impact on activities and interpersonal relationships. Typically, therapy is considered effective if symptoms are reduced by 50% or more.

### General Treatment Approach

Women with mild-moderate PMS symptoms often do not require pharmacologic therapy. In these cases, initial treatment is generally conservative, consisting of education and nondrug measures (e.g., dietary modifications, physical exercise, and stress management). Women should be educated about the syndrome and encouraged to identify techniques for coping with PMS symptoms and stress. Many women are engaged in multiple social roles, which can increase stress. Knowledge of this disorder can allow a woman to exert some control over her symptoms

by anticipating and planning. For example, she might schedule more challenging tasks during the first half of the cycle, thus limiting the influence of this condition on her social and work functioning.

In addition to education, treatment options include lifestyle modifications (e.g., diet and exercise). Nonpharmacologic approaches that can be considered include light therapy, cognitive-behavioral therapy, and acupuncture.<sup>26</sup> Supplements with evidence of potential benefit include calcium, pyridoxine, and chastetree berry (*Vitex agnus-castus*).<sup>26,27</sup> Preliminary data suggest a potential benefit from ginkgo, magnesium pyrrolidone, St. John's wort, and saffron.<sup>31</sup>

Prescription drug therapy should be considered if the treatments outlined in Figure 9-3 are ineffective or if the patient suffers from moderate-severe PMS or PMDD. SSRIs used daily or only during the luteal phase of the menstrual cycle are considered first-line prescription therapy. Agents that suppress ovulation (e.g., OCs and GnRH agonists such as leuprolide) are also used. Newer OCs containing drospirenone, shortened hormone-free intervals, or extended cycling may also be considered first-line therapy for women who prefer a gynecologic approach rather than a psychological approach.<sup>32</sup> Finally, hysterectomy with bilateral oophorectomy is effective for refractory severe symptoms.<sup>33</sup> Surgery may be appealing for women experiencing significant adverse drug reactions and/or costs.<sup>33</sup>

### Nonpharmacologic Therapy

Several nonpharmacologic therapies may improve PMS symptoms. These include aerobic exercise, dietary modifications, and cognitive-behavioral therapy.<sup>26</sup> Exercise can increase endorphin levels and may help decrease PMS symptoms.<sup>23,26</sup> Although the benefit of dietary changes is unproven, many health care providers recommend eating a balanced diet while also avoiding salty foods and simple sugars (which may cause fluid retention) and avoiding caffeine and alcohol (which can increase irritability).<sup>26,27</sup> Cravings for foods high in carbohydrates, which contain the serotonin precursor tryptophan, are common in women with PMS. Two studies of a carbohydrate-rich beverage that increased tryptophan levels demonstrated an improvement in emotional symptoms in women with PMS.<sup>27</sup> Consuming foods rich in complex carbohydrates (e.g., whole-grain foods) during the premenstrual interval may reduce symptoms.<sup>23,27</sup>

Stress is reported to increase PMS symptoms. Cognitive-behavioral therapy, which emphasizes relaxation techniques and coping skills, may help reduce symptoms.<sup>26,27</sup> These approaches may be helpful used singly or as adjuncts to other therapies. Data also exist suggesting a possible benefit with light therapy, acupuncture, and massage.<sup>26</sup>

### Pharmacologic Therapy

A survey of women with PMS found that 80% use some nonprescription therapy, including vitamins, minerals, and herbs; a number of products have claims for the management of PMS yet little supporting evidence.<sup>31</sup>

#### Pyridoxine

Pyridoxine has been suggested as a therapy for PMS. Trials have reported mixed results with no dose-response relationship shown, and no trials were performed in women with PMDD.<sup>27,31</sup> One double-blind, placebo-controlled trial found pyridoxine 80 mg daily improved mood symptoms to a greater extent than placebo.<sup>27</sup> The dosage of pyridoxine should be limited to 100 mg daily because of the risk for peripheral neuropathy with higher dosages.<sup>26</sup>

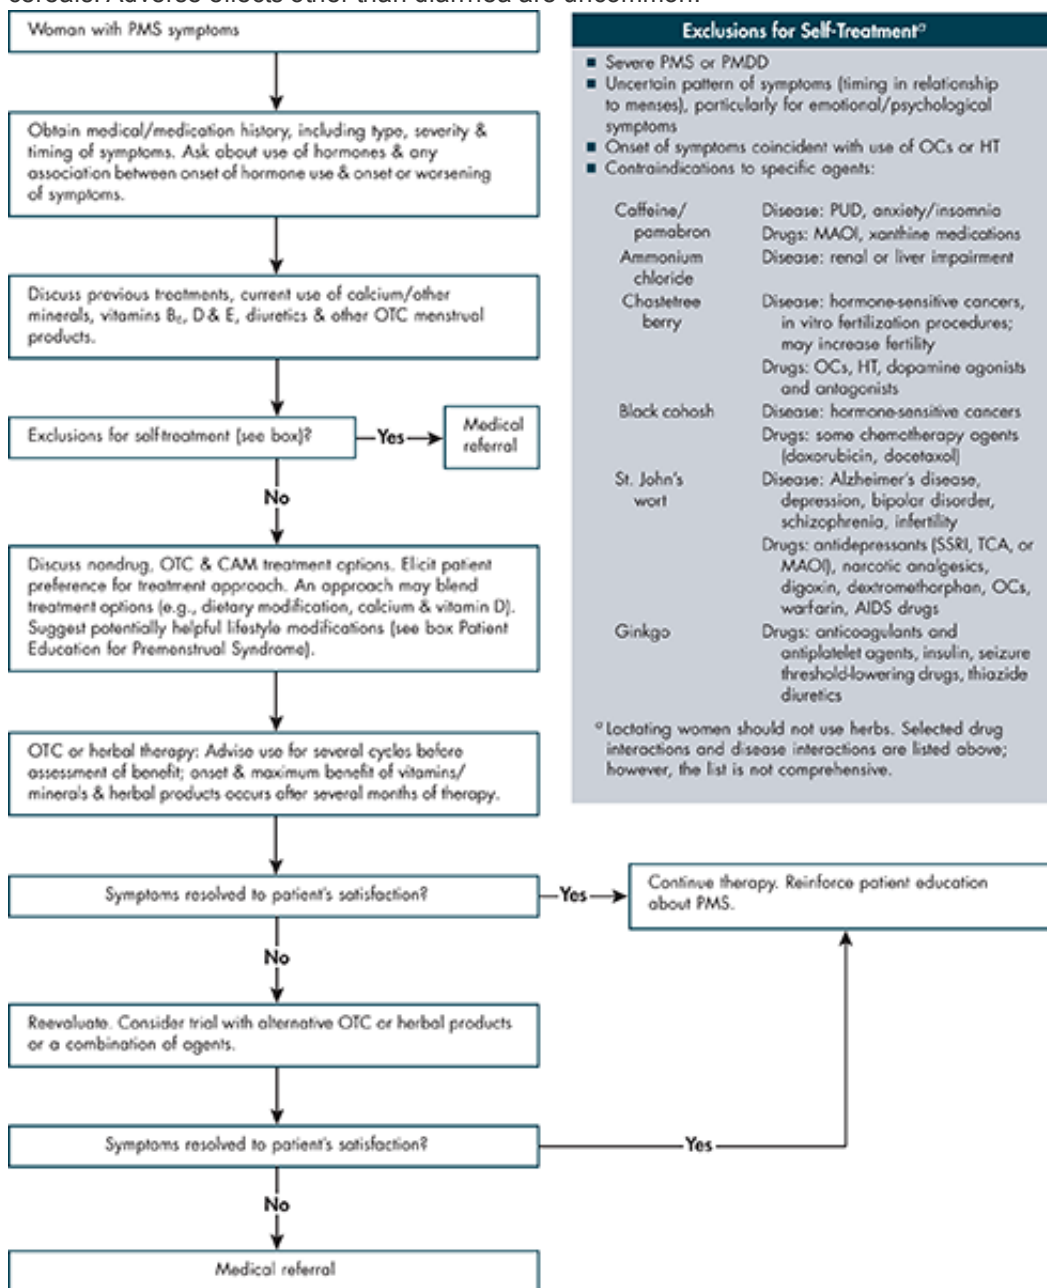

#### Calcium and Vitamin D

Several randomized trials have evaluated the effect of calcium supplementation on PMS symptoms. The largest trial studied the effect of calcium in a dosage of 600 mg twice daily in 466 women with moderate-severe PMS.<sup>34</sup> Symptoms were significantly reduced by the second month of therapy, and by the third month, calcium had reduced overall symptoms by 48%. Emotional symptoms such as mood swings, depression, and anger, as well as food cravings and physical symptoms, were all reduced. More than 50% of the women taking calcium had a greater than 50% improvement in symptoms; 29% had a greater than 75% improvement in symptoms. Few women experienced adverse effects from calcium; 5 withdrew from the study because of nausea, and 1 woman each in the calcium and placebo groups developed kidney stones. The dosage of calcium used in the trial is consistent with the recommended daily calcium intake for women of reproductive age, which is between 1000 and 1300 mg daily. Similar improvements were noted in smaller studies.<sup>24,31,35</sup> An additional study reported that high dietary intake of both calcium and vitamin D may prevent the development of PMS symptoms.<sup>36</sup> Reduced levels of vitamin D secondary to alterations in calcium and vitamin D metabolism during the luteal phase may trigger PMDD symptoms.<sup>23</sup> Data show an inverse relationship between both milk consumption and a high intake of vitamin D, and

PMS.<sup>4</sup> Additionally, all health care providers should be reinforcing adequate calcium and vitamin D intake in women to help prevent osteoporosis.

## Magnesium

Magnesium deficiency may lead to some PMS-type symptoms (e.g., irritability), and low magnesium levels in red blood cells have been found in women with PMS. Affective symptoms associated with PMS were reduced by magnesium pyrrolidone carboxylic acid in a dosage of 360 mg daily administered during the luteal phase.<sup>31,37</sup> In contrast, two trials of magnesium oxide found no benefit. The dosage of magnesium pyrrolidone used in the trial was similar to the recommended dietary allowance of magnesium for women (310-360 mg). About 50% of women regularly consume less than that amount, and obtaining adequate magnesium from food sources may be difficult. Food sources of magnesium include spinach, Swiss chard, nuts, legumes (e.g., beans and peas), and whole-grain cereals. Adverse effects other than diarrhea are uncommon.

Self-care of premenstrual syndrome. Key: AIDS = Acquired immunodeficiency syndrome; CAM = complementary and alternative medicine; HT = hormone therapy; MAOI = monoamine oxidase inhibitor; OC = oral contraceptive; OTC = over-the-counter; PMDD = premenstrual dysphoric disorder; PMS = premenstrual syndrome; PUD = peptic ulcer disease; SSRI = selective serotonin reuptake inhibitor; TCA = tricyclic antidepressant.

## Nonsteroidal Anti-Inflammatory Drugs

NSAIDs have been shown to reduce some of the physical symptoms (e.g., headache and muscle/joint pains) and

mood symptoms associated with PMS when taken for several days prior to the onset of and during the first several days of menses.<sup>26</sup> The benefit from these agents may be a result of the coexistence of dysmenorrhea and PMS or PMS manifesting primarily as physical symptoms.

### Diuretics

A common premenstrual complaint is the subjective sensation of fluid accumulation, particularly abdominal bloating. However, most women do not experience any true sodium or water retention and do not experience weight gain.<sup>38</sup> Two factors may explain the sense of abdominal bloating. First, a distinction must be made between fluid redistribution (where weight does not change) and fluid retention (which can be detected by weight gain). The abdominal bloating and swelling observed with PMS are primarily caused by a fluid shift to this area. As a result, diuretics that are indicated for relieving fluid retention are unlikely to be helpful for most women with PMS. Second, abdominal distension may occur secondary to relaxation of the gut muscle caused by progesterone.<sup>38</sup> For women who have true water retention and the resultant weight gain, a diuretic may be useful.

FDA has approved three nonprescription diuretics as useful for relieving water retention, weight gain, bloating, swelling, and the feeling of fullness: ammonium chloride, caffeine, and pamabrom. The latter agent is the most common diuretic in nonprescription menstrual products (Table 9-5).

**TABLE 9-5 Selected Combination Nonprescription Menstrual Products**

<i>Trade Name</i>	<i>Diuretic (per tablet/capsule)</i>	<i>Analgesic and/or Antihistamine (per tablet/capsule)</i>
Aqua-Ban Diuretic Maximum Strength Tablets; Diurex Water Caplets	Pamabrom 50 mg	
Diurex Original Formula Water Pills	Caffeine 50 mg	Magnesium salicylate 162.5 mg
Pamprin Multisymptom; Premsyn PMS	Pamabrom 25 mg	Acetaminophen 500 mg; pyrilamine maleate 15 mg
Pamprin Max	Caffeine 65 mg	Acetaminophen 250 mg; aspirin 250 mg
Pamprin All Day; Midol Extended Relief	None	Naproxen sodium 220 mg
Pamprin Cramp	Pamabrom 25 mg	Acetaminophen 250 mg; magnesium salicylate 250 mg
Midol Complete	Caffeine 60 mg	Acetaminophen 500 mg; pyrilamine maleate 15 mg
Midol Liquid Gel	None	Ibuprofen 200 mg
Midol Teen	Pamabrom 25 mg	Acetaminophen 500 mg
Midol PM	None	Acetaminophen 500 mg; diphenhydramine 38 mg

Ammonium chloride is an acid-forming salt with a short duration of effect. The drug is taken in oral dosages of up to 3 g/day, divided into three doses, for no more than 6 consecutive days. Larger dosages of ammonium chloride can produce significant gastrointestinal and central nervous system adverse effects. Ammonium chloride is contraindicated in patients with renal or liver impairment because metabolic acidosis may result. Ammonium chloride is no longer available as a nonprescription drug but can be obtained as a dietary supplement.

Caffeine promotes diuresis by inhibiting the renal tubular reabsorption of sodium and water. In doses of 100-200 mg every 3-4 hours, caffeine is safe and effective, although patients may develop tolerance to its diuretic effect. Caffeine may also cause anxiety, restlessness, or insomnia, and it may worsen PMS by causing irritability. Additive adverse effects (e.g., nervousness, irritability, or tachycardia) might occur if other caffeine-containing medications, foods, or beverages (especially "energy drinks") are consumed concurrently. Caffeine may also cause GI irritation; thus, it can cause or worsen dyspepsia. Patients taking monoamine oxidase inhibitors (MAOIs) or theophylline should also avoid diuretics that contain caffeine.

Pamabrom, a derivative of theophylline, is used in combination products (along with analgesics and antihistamines) marketed for the treatment of PMS. Pamabrom may be taken in dosages of up to 50 mg 4 times daily.

### Combination Products

Multi-ingredient nonprescription products are marketed for women with PMS-type symptoms. Two of the most commonly used product brand names are Midol and Pamprin. Some of these products contain acetaminophen, caffeine/pamabrom, and pyrilamine, whereas others contain only an NSAID or a combination of an analgesic with a diuretic or an antihistamine (Table 9-5). Pain is a relatively uncommon symptom of PMS, and no evidence exists that the sedative effect of an antihistamine such as pyrilamine will provide benefit to women experiencing the emotional symptoms of PMS. Therefore, these types of nonprescription products should not be recommended. More appropriate recommendations are the use of more definitive agents, such as those previously discussed, or referral for prescription drug therapy.

### Pharmacotherapeutic Comparison

Calcium can be suggested for the initial treatment of PMS symptoms. If this agent provides inadequate relief, another agent or a combination of two or more agents may be tried. Women who experience bloating with documented weight gain might try pamabrom or caffeine. Caffeine and pamabrom may not be an appropriate choice for women who experience irritability as a PMS symptom. Both caffeine and pamabrom should be used cautiously in patients who have a history of peptic ulcer disease or who are taking MAOIs or other xanthine medications. NSAIDs should be reserved for women who experience both PMS and dysmenorrhea or other pain. Use of combination products containing antihistamines should be discouraged because drowsiness may impair job performance, schoolwork, and driving.

### Product Selection Guidelines

#### Special Populations

PMS does not occur during pregnancy or after menopause. Adolescents and adult women can be treated similarly; they should initially attempt to manage their symptoms with lifestyle changes and with therapies such as calcium supplementation. Adolescents should avoid combination products containing aspirin (see Dysmenorrhea, Special Populations). Women who are breast-feeding should avoid all herbal products because information about their safety for nursing infants is limited. Vitamins and minerals in the dosages used for PMS are generally compatible with breast-feeding, and magnesium use is unlikely to cause diarrhea in infants.<sup>20</sup> Diuretics should be avoided during breast-feeding, as caffeine appears in breast milk about 1 hour after maternal ingestion. Caffeine may cause fussiness and poor sleep in infants, especially if consumed in high dosages or if the infant is preterm or younger than 3 weeks of age.<sup>20</sup>

#### Patient Factors

Patients using proton pump inhibitors and H<sub>2</sub>-receptor antagonists should use calcium citrate rather than calcium carbonate products because the carbonate products are less soluble with a higher gastric pH.

#### Patient Preferences

Patient preferences for PMS treatment can be accommodated. Women preferring to use dietary supplements should discuss their use with a health care provider to ensure that drug-drug or drug-disease interactions do not exist.

#### Complementary Therapies

Trials have been conducted with botanical therapies, including chastetree berry (*Vitex agnus-castus*), St. John's wort (*Hypericum perforatum*), ginkgo (*Ginkgo biloba*), and saffron (*Crocus sativus*).<sup>31</sup> The first three dietary supplements are discussed in depth in Chapter 51.

Chastetree berry has shown efficacy in improving mild-moderate PMS symptoms, but trials have used different formulations of chastetree berry. Two trials using a standardized fruit extract ZE 440 of chastetree berry found a significant reduction in PMS symptoms (including mood, irritability/anger, pain/headache, breast tenderness, and fluid retention).<sup>39</sup> Two randomized, double-blind, placebo-controlled trials found that chastetree berry extract reduced many common PMS symptoms and did not cause any serious adverse effects.<sup>40-42</sup> Symptoms were significantly lower by the end of the third cycle of use. In a trial in women diagnosed with PMDD, chastetree berry was compared with fluoxetine; a similar percentage of patients improved on both agents. Chastetree berry was shown to decrease irritability, breast tenderness, swelling, food cravings, and cramps. In contrast, fluoxetine improved more mood symptoms; symptoms with a 50% reduction included depression, irritability, insomnia, nervous tension, feeling out of control, breast tenderness, and aches. Chastetree berry was well tolerated; nausea and headache were the most common adverse effects. Chastetree berry may offer more benefit for patients with mild-moderate PMS and for women experiencing breast pain.<sup>39,43</sup> Chastetree berry may affect estrogen receptors and inhibit prolactin.<sup>39</sup> Women who are pregnant or lactating should avoid chastetree berry, and it should be used cautiously by women

taking hormones or who have hormone-sensitive cancers.

One randomized trial of St. John's wort reported a reduction in anxiety-related symptoms in women with PMS, although its effect was not different from placebo.<sup>31</sup> St. John's wort may improve mild-moderate depression. St. John's wort has many clinically significant drug interactions, including reducing the effectiveness of OCs. A placebo-controlled randomized trial evaluated ginkgo in a dosage of 160-320 mg daily in 165 women with PMS. Symptoms of anxiety, irritability, and depression associated with PMS were improved with ginkgo, although statistical significance was not demonstrated. However, ginkgo provided a statistically significant reduction in breast pain.<sup>31</sup> Ginkgo has antiplatelet effects and may increase the risk of bleeding. In one randomized trial, 30 mg saffron extract daily was found to significantly reduce PMS symptoms and depression symptoms compared with placebo.<sup>31</sup>

### Assessment of PMS: A Case-Based Approach

The health care provider should obtain a complete description of the patient's symptoms and their timing to determine whether the patient has PMS/PMDD or another disorder with PMS-type symptoms. The severity of PMS symptoms is another factor in self-treatment. As with any disorder, the health care provider should explore the use of medications that might be causing the symptoms or that might potentially interact with nonprescription agents used to treat PMS. Previous treatments for the symptoms should also be explored.

Case 9-2 illustrates the assessment of a patient with PMS.

### Patient Counseling for PMS

Educating women with PMS about the timing of symptoms using a symptom log and calendar and educating women about what might control those symptoms may increase compliance with recommended therapies. Health care providers should be prepared to discuss the treatment of behavioral and physical symptoms of mild-moderate PMS. If the patient wants to use nonprescription medications or vitamins, the proper use and potential adverse effects of these agents should be explained. The patient should also be advised that treatment measures must be implemented during every menstrual cycle because it may take several cycles for symptomatic relief to occur. The Patient Education for Premenstrual Syndrome box lists specific information to provide patients.

### Case 9-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient reports that she experiences moodiness (irritability) along with breast tenderness every month. Symptoms occur every month during the week prior to her period.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	"It seems worse if I am feeling stressed—like around the holidays, or if there is something going on at work that is stressful."
c. description of the patient's efforts to relieve the symptoms	"Usually, I just try not to act too grumpy, even if I feel that way. I have not tried anything to address my breast tenderness."
d. patient's identity	Ruby Wilcox
e. age, sex, height, and weight	22 years old, female, 5 ft 4 in., 118 lb

f. patient's occupation	Team leader, cable TV/Internet/phone company
g. patient's dietary habits	Vegetarian
h. patient's sleep habits	She estimates she gets about 7 hours of sleep nightly; she has no problem falling asleep.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	No chronic health problems Tension headaches: ibuprofen 400 mg Colds: <i>Echinacea</i> extract and zinc lozenges Contraception: NuvaRing Dietary supplements: vitamin B-complex, B <sub>12</sub> , flaxseed oil, probiotic blend (all taken once daily)
j. allergies	Allergic to cats (sneezes, itchy eyes)
k. history of other adverse reactions to medications	NKDA
l. other (describe) _____	None
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	The symptoms she describes are consistent with mild PMS. The time frame for the occurrence of symptoms is also consistent with PMS.
3. Identify exclusions for self-treatment (Figure 9-3).	Patient does not have any exclusions for self-treatment. Her symptoms are mild, she likely is not pregnant (using contraceptive), and she has no major medical conditions.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer patient to an appropriate health care provider. (2) Recommend self-care with nonprescription and nondrug measures. (3) Recommend self-care until patient can see an appropriate health care provider. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Recommend self-care with nonprescription and nondrug measures.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"The symptoms you describe are consistent with PMS. Your symptoms are mild, and there are several nonprescription vitamins and minerals that might provide improvement in your symptoms. The best studied approach is the use of calcium in a dose of 1200 mg daily. I suggest you try taking calcium 500-600 mg twice daily." [Assuming that the patient is obtaining some calcium from foods, you could also ask explicitly about calcium-containing foods in her diet.]

	“Also, you should consume vitamin D daily through foods or a supplement—it will help with the absorption of calcium and also has some additive benefits with calcium in the management of PMS. The dose of vitamin D I recommend for you is 600 IU daily.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“This approach is recommended because there is evidence for its benefit, it is a safe supplement, and women need calcium to protect against osteoporosis.”
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	“Calcium should be taken in a dose of 600 mg or less at one time, as that is the highest dose the body can absorb at one time. You are not likely to experience side effects from calcium, but some women experience gastrointestinal distress or constipation. Let me know if that occurs, and I can suggest how to manage those side effects. If you add vitamin D to your regimen also, I suggest a daily dose of 600 IU.”
Solicit follow-up questions from the patient or caregiver.	“How long will it take for the calcium to be effective?”
Answer the patient’s or caregiver’s questions.	“You should take calcium for at least 3 months to determine if it will be beneficial for you. Clinical studies found that some symptoms were improved by the second month of calcium use, but the best effect in reducing symptoms was seen after 3 months of use.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	“Try calcium therapy for 3 months; if you still have bothersome symptoms, let me know. There are other nonprescription therapies that may be helpful.”

Key: NKDA = No known drug allergies.

#### Patient Education for Premenstrual Syndrome

The objective of self-treatment is to achieve relief from or significant improvement in PMS symptoms to limit discomfort, distress, and the disruption of personal relationships or usual activities. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### **Nondrug Measures**

- Try to avoid stress, develop effective coping mechanisms for managing stress, and learn relaxation techniques.
- If possible, participate in regular aerobic exercise.
- During the 7-14 days before your menstrual period, reduce intake of salt, caffeine, chocolate, and alcoholic beverages. Eating foods rich in carbohydrates and low in protein during the premenstrual interval may also reduce symptoms.

#### **Nonprescription Medications**

- Nonprescription medications and lifestyle modifications may not improve symptoms for all women, and it may take several months to determine whether these therapies are working.
- Therapy with one nonprescription medication may improve only some of the symptoms; several medications may be needed for optimal symptom control. However, only add one agent at a time so that it is possible to determine which agent causes benefit or adverse effects.
- Follow the guidelines here for the agents that best control your symptoms:
  - Take 1200 mg of elemental calcium daily in divided doses. Calcium can be obtained from food or from supplements. Take no more than 500-600 mg at one time. Calcium may cause stomach upset (if this

occurs, take with food) or constipation.

- Take at least 600 IU of vitamin D daily.
- Take 300-360 mg of magnesium pyrrolidone daily during the premenstrual interval only. Magnesium may cause diarrhea.
- Take up to 100 mg of pyridoxine daily. Do not exceed this dosage, or neurologic symptoms caused by vitamin B<sub>6</sub> toxicity may occur.

### When to Seek Medical Attention

- If you are taking vitamin B<sub>6</sub> and develop neurologic symptoms (e.g., a sensation of pricking, tingling, or creeping on the skin; bone pain; muscle weakness; or stinging, burning, or itching sensations), stop taking the vitamin and seek medical attention.
- If the PMS symptoms do not improve, or if they worsen, a medical evaluation is suggested.

### Evaluation of Patient Outcomes for PMS

Monitoring is accomplished by having the patient report whether the symptoms are resolved. It may take several menstrual cycles to ascertain whether lifestyle changes or nonprescription therapies are reducing the symptoms of PMS. Comparing the occurrence of symptoms before and after vitamin or medication use can help determine the value of a therapy. Women should be encouraged to contact their health care provider to discuss treatment effectiveness and to clarify information or answer any questions. Reasons for advising the patient to see a provider include persistent symptoms, symptoms that the patient reports are disruptive to personal relationships, or symptoms that affect the patient's ability to engage in usual activities or function productively at work.

### Toxic Shock Syndrome

Toxic shock syndrome (TSS) is a term originally coined in 1978 to describe a severe multisystem illness characterized by high fever, profound hypotension, severe diarrhea, mental confusion, renal failure, erythroderma, and skin desquamation. In 1980, these symptoms were recognized as affecting a relatively large number of young, previously healthy, menstruating women. TSS is commonly divided into menstrual and nonmenstrual cases.

Menstrual TSS affects primarily young women between 13 and 19 years of age.<sup>44</sup> Almost all cases of menstrual TSS have been associated with menstruation and tampon use (especially the use of high-absorbency tampons).<sup>44</sup> The decrease in cases of menstrual TSS has been attributed to several factors, including removal of superabsorbent tampons from the market; a change in the composition of tampons; an increased awareness of the recommendations to change tampons frequently and to alternate tampon and pad use; and FDA-required standardized labeling of tampons.<sup>44</sup>

The strongest predictor of risk for menstrual TSS is the use of tampons. Women who currently use tampons still have a 33-fold greater risk for TSS than nonusers. The greatest risk is associated with the use of higher absorbency tampons; for every 1 gram increase in absorbency, the risk for TSS increases 34%-37%. Continuous uninterrupted use of tampons for at least 1 day during menses has also been shown to correlate with an increased risk for menstrual TSS. In addition, using tampons between menstrual periods (to manage vaginal discharge or nonmenstrual bleeding) can increase the likelihood of vaginal ulcers and the risk of TSS.<sup>45</sup> Besides tampons, TSS has been associated with the use of barrier contraceptives, including diaphragms, cervical caps and cervical sponges, and IUCs.

### Pathophysiology of Menstrual TSS

Menstrual TSS is caused by the toxin-producing strains of *Staphylococcus aureus*.<sup>46</sup> TSS is an inflammatory immune response to the enterotoxins produced by these bacteria. Toxin-producing strains of *S. aureus* produce the superantigen toxin TSST-1. Most adults have a protective level of antibodies against the TSST-1 toxin. Younger people who lack this antibody protection and who become infected with a toxin-producing strain of *S. aureus* may develop TSS.<sup>46</sup>

TSS develops in three phases: proliferation of toxin-producing bacteria, production of toxin, and engagement of the immune system. Menstrual blood can serve as a medium for bacterial growth, and the retention of blood in the vagina by the tampon can increase bacterial proliferation. Also, some tampons contain fibers that inhibit lactobacilli, thereby diminishing their ability to limit the proliferation of *S. aureus*.

Four conditions promote toxin production: elevated protein levels, neutral pH, elevated carbon dioxide levels, and elevated oxygen levels.<sup>44</sup> During menses, menstrual blood provides an increase in protein and also increases vaginal pH to 7, or neutral pH. Tampon use may create the environment for TSS by introducing oxygen into the vagina; oxygen is trapped within the tampon, and higher-absorbency tampons carry more oxygen into the

vagina.<sup>44,46</sup> Oxygen is a critical factor for the production of TSST-1.<sup>47</sup> After the introduction of a tampon, the vagina takes hours to return to its anaerobic state, with elevated carbon dioxide levels. In addition, tampons, IUCs, and contraceptive sponges create microtrauma, which increases exposure of the toxins to the circulatory and immune systems. Exposure of immune cells to TSST-1 initiates the inflammatory cascade involving interleukin-1 and tumor necrosis factor. This inflammatory response results in the signs and symptoms of TSS.

### Clinical Presentation of Menstrual TSS

By definition, menstrual TSS occurs within 2 days of the onset of menses, during menses, or within 2 days after menses. Prodromal symptoms (including malaise, myalgias, and chills) occur for 2-3 days prior to TSS.<sup>46</sup> GI symptoms (e.g., vomiting, diarrhea, and abdominal pain) typically occur early in the illness and affect almost all patients. After that period of time, TSS evolves rapidly into high fever, myalgias, vomiting and diarrhea, erythroderma, decreased urine output, severe hypotension, and shock. Neurologic manifestations (e.g., headache, confusion, agitation, lethargy, and seizures) also occur in almost all cases. Acute renal failure, cardiac involvement, and adult respiratory distress syndrome are also common.

Dermatologic manifestations are characteristic of TSS; both early rash and subsequent skin desquamation are required for a definite diagnosis. The early rash is often described as a sunburn-like, diffuse, macular erythroderma that is not pruritic. About 5-12 days after the onset of TSS, desquamation of the skin on the patient's face, trunk, and extremities (including the soles of the feet and the palms of the hands) occurs.

### Prevention of Menstrual TSS

Women can almost entirely prevent menstrual TSS by using sanitary pads instead of tampons during their menstrual cycle. Women who use tampons can reduce the risk of developing TSS by following the guidelines in the box Patient Education for Toxic Shock Syndrome. The addition of substances to tampons that will inhibit production of the TSST-1 exotoxin is being explored.<sup>47</sup>

Women who have had TSS are at risk for recurrence; TSS recurs in about 28%-64% of women with menstrual TSS.<sup>46</sup> Recurrence rates are lower for women who are treated with antibiotics during TSS. Prevention of TSS for these patients includes avoiding tampons, IUCs, diaphragms, cervical caps, and contraceptive sponges.

#### Patient Education for Toxic Shock Syndrome

The objective of self-treatment is to reduce the risk of developing toxic shock syndrome (TSS) associated with the use of tampons or contraceptive devices. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

- To reduce the risk of TSS to almost zero, use sanitary pads instead of tampons during your period.
- To lower the risk of TSS while using tampons, use the lowest-absorbency tampons compatible with your needs. Also, alternate the use of menstrual pads with the use of tampons (e.g., use pads at night) so that tampons are not used continuously for 24 hours.
- Change tampons four to six times a day and at least every 6 hours; overnight use should be no longer than 8 hours.
- Wash your hands with soap before inserting anything into the vagina (e.g., tampon, diaphragm, contraceptive sponge, or vaginal medication). The bacteria causing TSS are usually found on the skin.
- Do not leave a contraceptive sponge, diaphragm, or cervical cap in place in the vagina longer than recommended; do not use any of them during menstruation.
- Do not use tampons, contraceptive sponges, or a cervical cap during the first 12 weeks after childbirth. It may also be best to avoid using a diaphragm.
- Read the insert on TSS enclosed in the tampon package, and become familiar with the early symptoms of this disorder.

### When to Seek Medical Attention

- If you develop symptoms of TSS (high fever, muscle aches, a sunburn-like rash appearing after a day or two, weakness, fatigue, nausea, vomiting, and diarrhea), remove the tampon or contraceptive device immediately and seek emergency medical treatment. If left untreated, TSS can cause shock and even death.

### Assessment of Menstrual TSS: A Case-Based Approach

Obtaining prompt medical attention is a very important aspect of care for patients with symptoms consistent with TSS. A health care provider can be alert to symptoms of TSS when patients seek nonprescription therapy for a severe "flu" with symptoms such as fever, vomiting, diarrhea, and dizziness, or when patients seek help for an unusual skin rash that occurs in conjunction with the previously described symptoms. If TSS is suspected, the patient should be advised to seek medical care immediately; additionally, the patient should be advised to avoid use of NSAIDs for fever and

myalgias because these agents may increase the progression of TSS by increasing the production of tumor necrosis factor.

### Patient Counseling for Menstrual TSS

Tampons are used by women of all ages during the reproductive years. Health care providers should counsel patients about the prevention of TSS as outlined in the box Patient Education for Toxic Shock Syndrome. In particular, health care providers should emphasize the importance of washing the hands before inserting a tampon, which removes organisms causing TSS from the skin. Similarly, about 18%-36% of women report that they do not always change a tampon at least every 6 hours; health care providers should counsel patients to change tampons frequently, according to product instructions; to alternate the use of tampons with the use of sanitary pads over a 24-hour period; and to use the lowest-absorbency tampons compatible with their needs. The health care provider should emphasize, however, that the risk for this condition is quite small. If a patient presents with early symptoms of TSS, she should be advised to remove the tampon or any barrier contraceptive device and to seek emergency medical treatment.

### Key Points for Disorders Related to Menstruation

- Self-care is appropriate for an otherwise healthy young woman whose history is consistent with primary dysmenorrhea and who is not sexually active, or for a woman diagnosed with primary dysmenorrhea. Adolescents with pelvic pain who are sexually active and thus at risk for PID and women with characteristics indicating secondary dysmenorrhea should be referred for medical evaluation.
- NSAIDs are the drugs of choice for the management of primary dysmenorrhea. These medications should be taken at the onset of or just prior to menses and should be used in scheduled doses for several days for optimum reduction in pain and cramping.
- The use of local topical heat can also provide relief from dysmenorrhea. Its analgesic effect has a faster onset than drug therapy, and it can add to the relief provided by an NSAID. Nonpharmacologic therapy may be especially useful for women who cannot tolerate or who prefer not to use drug therapy or who do not respond to nonprescription NSAIDs.
- PMS/PMDD should be distinguished from typical premenstrual symptoms and also from premenstrual exacerbations of other disorders, particularly mood disorders.
- PMS/PMDD symptoms typically begin or intensify about a week prior to the onset of menses, peak the 2 days before menses, and resolve within several days to a week after the beginning of menses. A woman with PMS or PMDD experiences a symptom-free interval during days 4-12 of her menstrual cycle.
- PMS symptoms are chronic and, in most cases, will continue until menopause. Therefore, the cost of therapy, the possibility that a woman may become pregnant, and the likelihood of adverse effects from therapy are important considerations in selecting therapy.
- Several dietary supplements (particularly calcium, pyridoxine, and chastetree berry) might be suggested to reduce the symptoms of PMS. Moderate-severe PMS and PMDD symptoms warrant prescription drug therapy.
- TSS has been linked to tampon use. To lower the risk for TSS while using tampons, women should use the lowest-absorbency tampons compatible with their needs and should alternate the use of sanitary pads with the use of tampons over a 24-hour period.

**Handbook of Nonprescription Drugs** > Chapter 10. Prevention of Pregnancy and Sexually Transmitted Infections**Update: FDA Approves Gardasil 9 for Prevention of Certain Cancers Caused by Five Additional Types of HPV**

Content Update for [Chapter 10](#), "Prevention of Pregnancy and Sexually Transmitted Infections." Posted April 1, 2015.

In December 2014, the Food and Drug Administration approved a new 9-valent form of the Gardasil vaccine. Gardasil 9 (human papillomavirus 9-valent vaccine, recombinant) provides protection against oncogenic human papillomavirus (HPV) types 31, 33, 45, 52, and 58 in addition to HPV 6, 11, 16, and 18, which the quadrivalent product covers. The five new HPV types cause an estimated 20% of cervical cancers.<sup>1</sup> The vaccine is for use in girls and women ages 9–26 years and boys ages 9–15 years.

A recent international study of 14,215 women between ages 16 and 26 years (mean, 21.9 years) compared the 9-valent and quadrivalent vaccines. The study showed that among women without prior HPV exposure, Gardasil 9 was 96.7% effective in reducing the risk of high-grade cervical, vulvar, and vaginal disease due to the protection it provided against the five additional HPV types. The new vaccine also produced antibody responses to HPV 6, 11, 16, and 18 that were assessed as non-inferior to those produced by the quadrivalent product. However, local injection reactions were more common with the 9-valent vaccine.<sup>2</sup>

At the February 2015 meeting of the Centers for Disease Control and Prevention (CDC) Advisory Committee on Immunization Practices (ACIP), the group did not express a preference for the use of the 9-valent product over the other currently available vaccines. This topic and the use of the 9-valent vaccine in individuals who have received the quadrivalent product will be discussed at the June ACIP meeting.<sup>3</sup> Currently, either vaccine can be used to complete the series and, of note, the ACIP recommended the use of the vaccines in young men up to age 21, which differs from the product labeling.

**Prevention of Pregnancy and Sexually Transmitted Infections: Introduction**

Unprotected sexual activity can result in unintended pregnancy and sexually transmitted infections (STIs), either of which can exact high physical, psychological, and financial tolls on those affected. This chapter discusses how vaccines and properly used nonprescription contraceptive products or methods can reduce the risks of such adverse outcomes.

An estimated 49% of pregnancies in the United States are unintended.<sup>1</sup> The National Survey of Family Growth (NSFG) found that among U.S. women with unintended pregnancies, about half had used a method of contraception during the month they conceived, a result that is indicative of a high level of inconsistent or incorrect use.<sup>1</sup>

In the United States alone, the Centers for Disease Control and Prevention (CDC) estimate that more than 19.7 million persons are infected annually with new STIs, with medical costs estimated at \$16 billion a year.<sup>2</sup> Of particular concern is the high risk of pregnancy and STIs in adolescents. The NSFG found that about 40% of teenagers had experienced sexual intercourse.<sup>3</sup> Among sexually active female teenagers, about one-fifth of those at risk for an unintended pregnancy did not use contraception.<sup>4</sup> Low levels of contraceptive use in this population may be due to lack of knowledge and planning, denial, and infrequent or unpredictable intercourse. The teenage pregnancy rate in the United States is one of the highest among developed countries.<sup>3</sup> However, as of 2011, birth rates for U.S. teenagers had reached historic lows for all age and ethnic groups.<sup>5</sup>

Repeat pregnancies are common and are often associated with inadequate contraceptive use after the first pregnancy.<sup>6</sup>

Adolescents are particularly vulnerable to STIs, with one in four teenage girls infected with one or more STIs.<sup>7</sup> Reasons for infections include having multiple sexual partners, unprotected intercourse, an inherent biological susceptibility to infection, and barriers to health care utilization.<sup>8</sup>

Perimenopausal women are also at risk of unintended pregnancies. The NSFG found that among women age 40 years or older, 38% of pregnancies were unplanned.<sup>1</sup> Postmenopausal women and older men in sexual relationships that are not mutually monogamous are also at increased risk of STIs.<sup>9</sup>

The availability and relatively low cost of nonprescription methods of contraception for pregnancy and STI prevention are important, especially for those who are unwilling or unable to access family planning services or use prescription contraceptives. Even if a prescription product is chosen as the primary contraceptive method, low-cost and low-risk

nonprescription methods may be appropriate at different times during a person's life. The widespread accessibility of pharmacist-administered immunizations offers another opportunity for STI prevention.

*Editor's Note:* This chapter is based on the 17th edition chapter of the same title, which was written by Louise Parent-Stevens and Mitzi Wasik.

### Pathophysiology of Pregnancy and STIs

Pregnancy can result only when a viable egg is available for fertilization by a sperm. (See [Chapter 9](#) for discussion of the reproductive process.) Conception may occur during a 6-day window that begins 5 days before ovulation through the day of ovulation. The estimated risk of pregnancy from unprotected sexual intercourse during this period ranges from 5% to 45%, with peak risk occurring the day before ovulation.<sup>10</sup> Pregnancy can occur despite contraceptive use if the product is used incorrectly or it fails (e.g., condom breakage).

STIs are contracted through contact with infected genital tissues, mucous membranes, and/or body fluids. [Table 10-1](#) summarizes the major infections.<sup>8</sup> Although STIs affect both sexes, women are more likely to develop reproductive consequences, including pelvic inflammatory disease, chronic pelvic pain, ectopic pregnancy, malignancies, and infertility. This likelihood is possibly related to difficulties in diagnosis, lack of patient recognition of symptoms, and a higher probability of asymptomatic infection.<sup>11</sup> Pregnancy-related complications also increase as a consequence of STIs.<sup>11</sup> Transmission rates also differ between sexes. For example, about 50% of women become infected with gonorrhea after a single exposure with an infected man, whereas only about 25% of men contract gonorrhea from a single exposure with an infected woman.<sup>11</sup>

### Prevention of STIs and Pregnancy

#### Vaccines for STI Prevention

#### Human Papillomavirus Vaccine

Human papillomavirus (HPV) is a virus that may be transmitted by sexual contact and is a major cause of cervical cancer and genital warts.<sup>8,12</sup> With more than 100 different types of HPV identified, HPV types 16 and 18 are responsible for 70% of cervical cancers, and types 6 and 11 are responsible for 90% of genital warts.<sup>13</sup> HPV is also responsible for a subset of vaginal, vulvar, penile, anal, and some head and neck cancers and is the most common STI in this country.<sup>13</sup> In 2008, about 14 million new cases of HPV were reported in the United States.<sup>2,14</sup> At least 80% of all sexually active men and women will be infected with genital HPV at some point in their lives, with the highest risk of infection occurring during the first few years after they become sexually active.<sup>12</sup>

**TABLE 10-1 Sexually Transmitted Infections**

<i>Disease [Scientific Name] (Type)</i>	<i>Incubation Period</i>	<i>Symptoms</i>	<i>Diagnosis/Treatment</i>	<i>Complications</i>	<i>Congenital Transmission/Neonatal Complications</i>
<b>Noncurable but Vaccine-Preventable STIs</b>					
Genital warts [Human papillomavirus <sup>a</sup> ] (DNA virus)	2-4 months (average)	Asx infections common; warts on external genitalia, rectum, anus, perineum, mouth, larynx, vagina, urethra, cervix	Colposcopy; serology; molecular- based assays/cytoablation (chemical or physical); antivirals; antimetabolites; immunomodulators	Cervical dysplasia/neoplasia, anogenital cancers, oropharyngeal cancer	Yes/respiratory papillomatosis
Hepatitis B [Hepatitis B virus] (virus)	6 weeks- 6 months	Acute, self-limited, mild	Serology/antivirals	Cirrhosis, hepatocellular cancer	Yes
<b>Curable STIs</b>					
Genital chlamydia [ <i>Chlamydia trachomatis</i> ] (bacterium)	7-35 days	M: range from asx to urethritis, proctitis, urogenital discharge, itching, dysuria F: range from asx to vaginal discharge, postcoital bleeding, cervicitis	EIA, NAAT/antibiotics	PID, ectopic pregnancy, infertility	Yes/neonatal conjunctivitis, pneumonia

Gonorrhea [ <i>Neisseria gonorrhoeae</i> ] (bacterium)	Up to 14 days	Urethritis, cervicitis, proctitis, pharyngitis M: mucopurulent urethral discharge F: often asx	Gram stain; EIA; culture; NAAT/antibiotics	Septic arthritis, perihepatitis, endocarditis, meningitis, PID, infertility, ectopic pregnancy	Yes/sepsis, meningitis, arthritis, ophthalmia neonatorum
Nongonococcal urethritis (men) [Various, including <i>Chlamydia trachomatis</i> , <i>Ureaplasma urealyticum</i> , <i>Mycoplasma</i> sp.] (bacteria)	1-2 weeks	M: nonspecific urethritis, discharge, dysuria, pruritus	NAAT; culture/antibiotics	Epididymitis, proctitis, proctocolitis, Reiter's syndrome	—
Syphilis [ <i>Treponema pallidum</i> ] (spirochete)	3 weeks	Primary syphilis: chancre	Darkfield microscopy; direct fluorescent antibody test; treponemal and nontreponemal serologic tests/antibiotics	Secondary syphilis: rash, lymphadenopathy Tertiary syphilis: cardiovascular, gummatous lesions Neurosyphilis: CNS infection	Yes/fetal death, prematurity, congenital syphilis
Trichomoniasis [ <i>Trichomonas vaginalis</i> ] (protozoan)	Unknown	M: commonly asx F: ~50% asx, malodorous, frothy green vaginal discharge, itching, dyspareunia, postcoital bleeding	Microscopic exam of vaginal fluids; nucleic acid probe test; PCR/antibiotics	Pregnancy: preterm labor, low birth weight	Yes
<b>Noncurable STIs</b>					
AIDS [HIV] (virus)	Up to 10 years	After initial flu-like illness, asx until OIs occur	Serologic antibody testing, NAAT/antivirals; prophylaxis for OIs	OIs, malignancies, death	Yes, also transmitted via breast milk
Genital herpes [HSV-1, HSV-2] (virus)	2-14 days	Asx or vesicular/ulcerative lesions on mucous membranes	Culture; serology; PCR assay/antivirals	Disseminated infection, pneumonitis, hepatitis, meningitis/encephalitis	Yes
Hepatitis C [hepatitis C virus] (virus) <sup>b</sup>	8-9 weeks	Asx or mild clinical illness	Serology/antivirals	Cirrhosis, hepatocellular cancer	Yes

Key: AIDS = Acquired immunodeficiency syndrome; Asx = asymptomatic; CNS = central nervous system; EIA = enzyme immunoassay; F = female; HIV = human immunodeficiency virus; HPV = human papillomavirus; HSV = herpes simplex virus; M = male; NAAT = nucleic acid amplification test; OI = opportunistic infection; PCR = polymerase chain reaction; PID = pelvic inflammatory disease.

<sup>a</sup> Self-clearance of HPV virus may occur.

<sup>b</sup> Compared with transmission through blood exposure, sexual transmission of hepatitis C is inefficient but may still occur.

Source: Reference 8.

The available vaccines may decrease the risk of HPV. Two vaccines, Gardasil (quadrivalent HPV vaccine) and Cervarix (bivalent HPV vaccine), target the oncogenic strains 16 and 18, with the quadrivalent HPV vaccine also providing protection against genital wart strains 6 and 11 of HPV. The quadrivalent HPV vaccine is indicated for girls and boys ages 9-26 years to prevent cervical, vaginal, vulvar, and anal cancers, with an administration schedule of 0, 2, and 6 months. The bivalent

vaccine is indicated for girls and women ages 9-25 years to prevent cervical cancer, with an administration schedule of 0, 1, and 6 months. Completion of the entire series is essential for the individual to obtain the highest immunity. One study found that girls ages 9-13 years who received two doses of the HPV vaccine had less immunity at 18 months after administration compared with those who had received the full three doses within 6 months.<sup>15</sup> The current age range for both vaccines is wide. This wide range is due to the “catch up” series which may be used in women up to 25 or 26 years of age (depending on the agent used) and in men up to 21 years of age (may be up to 26 years of age in men having sex with men). The vaccines work best prior to HPV exposure from sexual contact but previous sexual intercourse does not preclude an individual from receiving the vaccine.<sup>13</sup> The current recommendation of the Advisory Committee on Immunization Practices (ACIP) is for all girls 11-12 years of age (and boys, if receiving the quadrivalent HPV vaccine) to receive the HPV vaccine. If appropriate, vaccines can be given as early as 9 years of age.<sup>13</sup>

The adverse effects of the Gardasil and Cervarix vaccines are similar and may include irritation at the site of administration, malaise, and syncope. Because of the risk of syncope, particularly in younger girls, patients should be monitored for at least 15 minutes after administration of the vaccine.<sup>13</sup>

### Hepatitis B Vaccine

Infection with the hepatitis B virus is associated with long-term complications such as hepatitis, cirrhosis, hepatic carcinoma, and death. The virus can be transmitted through contact with blood and other body fluids, and sexual transmission is estimated to cause 19,000 new infections annually.<sup>2</sup>

The hepatitis B vaccine is an inactivated injectable formulation with an administration schedule of 0, 1, and 6 months.<sup>13</sup> Recommended as a routine vaccination for all infants starting at birth, the vaccine is also provided to children and adolescents who did not receive the vaccine as an infant or did not complete the series. Adults who meet risk criteria and who were not previously vaccinated should also receive the three-dose series. Potential candidates for the vaccine include patients with multiple sexual partners; injection drug users; health care and emergency response personnel; patients with diabetes, end-stage renal disease, human immunodeficiency virus (HIV) infection, or liver disease; international travelers; and residents of correctional, drug abuse, or HIV treatment facilities.<sup>13</sup>

Pharmacist-administered vaccination has become more common. Depending on state laws and regulations, those vaccines are available for administration in the pharmacy for the entire series. States may limit the age range to which a pharmacist may administer vaccines, but if no barriers exist, pharmacists should offer their services to increase the number of vaccinated individuals.

### Contraception for Pregnancy and STI Prevention

The goal of contraceptive use is to prevent unintended pregnancy and STIs with minimal adverse effects. No method of birth control except abstinence is perfect, and contraceptive choices may change during a person’s life.

The effectiveness of a contraceptive method in preventing pregnancy is reported in two ways: the accidental pregnancy rate in the first year of *perfect* use (method-related failure rate) and the rate in the first year of *typical* use (use-related failure rate; [Table 10-2](#)).<sup>4,16-19</sup> The pregnancy rate with perfect use is difficult to measure and indicates the method’s theoretical effectiveness. Perfect use assumes accurate and consistent use of the method every time intercourse occurs. The more realistic rate of typical use includes pregnancies that may have occurred because of inconsistent or incorrect use of the method. Reported use-related failure rates vary, depending on the population studied. Effectiveness increases the longer a particular method is used. Decreased coital frequency and declining fertility in older users may contribute to increased effectiveness rates in this population.<sup>17</sup>

**TABLE 10-2 Failure and Use Rates of Various Contraceptive Methods**

<i>Method</i>	<i>Accidental Pregnancy in the First Year of Use</i>		<i>% of Women Using Method<sup>c</sup></i>
	<i>Typical Use<sup>a</sup></i>	<i>(%)Perfect Use<sup>b</sup></i>	
No method	85	85	37.8
Withdrawal	22	4	3.2
Fertility awareness-based methods	24		0.7
Calendar method	13	5	
Cervical mucus method	22	3	
Symptothermal method	13-20	0.4	

Lactational amenorrhea method (first 6 months postpartum)	2	0.5	
Standard days method	12	5	
TwoDay method	14	3.5	
Spermicides (foam, creams, gels, vaginal suppositories, vaginal film)	28	18	<0.3
Contraceptive sponge	24 (parous women) 12 (nulliparous women)	20 (parous women) 9 (nulliparous women)	<0.3
Male condom (without spermicide)	18	2	10.2
Female condom (without spermicide)	21	5	<0.3
Prescription methods	0.05-9	≤0.6	29.6
Sterilization (male/female)	≤0.5	≤0.5	22.7

<sup>a</sup> Among typical couples who initiate use of a method (not necessarily for the first time), the percentage who experience an accidental pregnancy during the first year if they do not stop use for any other reason.

<sup>b</sup> Among typical couples who initiate use of a method (not necessarily for the first time) and who use it consistently and correctly, the percentage who experience an accidental pregnancy during the first year if they do not stop use for any other reason.

<sup>c</sup> Percentage of women ages 15-44 years.

Source: References 4 and 16-19.

The most effective way for an individual to avoid contracting an STI is either to abstain from risky sexual activity or to be involved in a long-term mutually monogamous sexual relationship with an uninfected partner.<sup>8</sup> In the absence of those options, preventive strategies in conjunction with use of selected contraceptives may provide the best method for reducing risk of infection (Table 10-3<sup>8,11</sup> and Figure 10-1).<sup>8,11,20-23</sup>

**TABLE 10-3 Prevention Strategies for STIs**

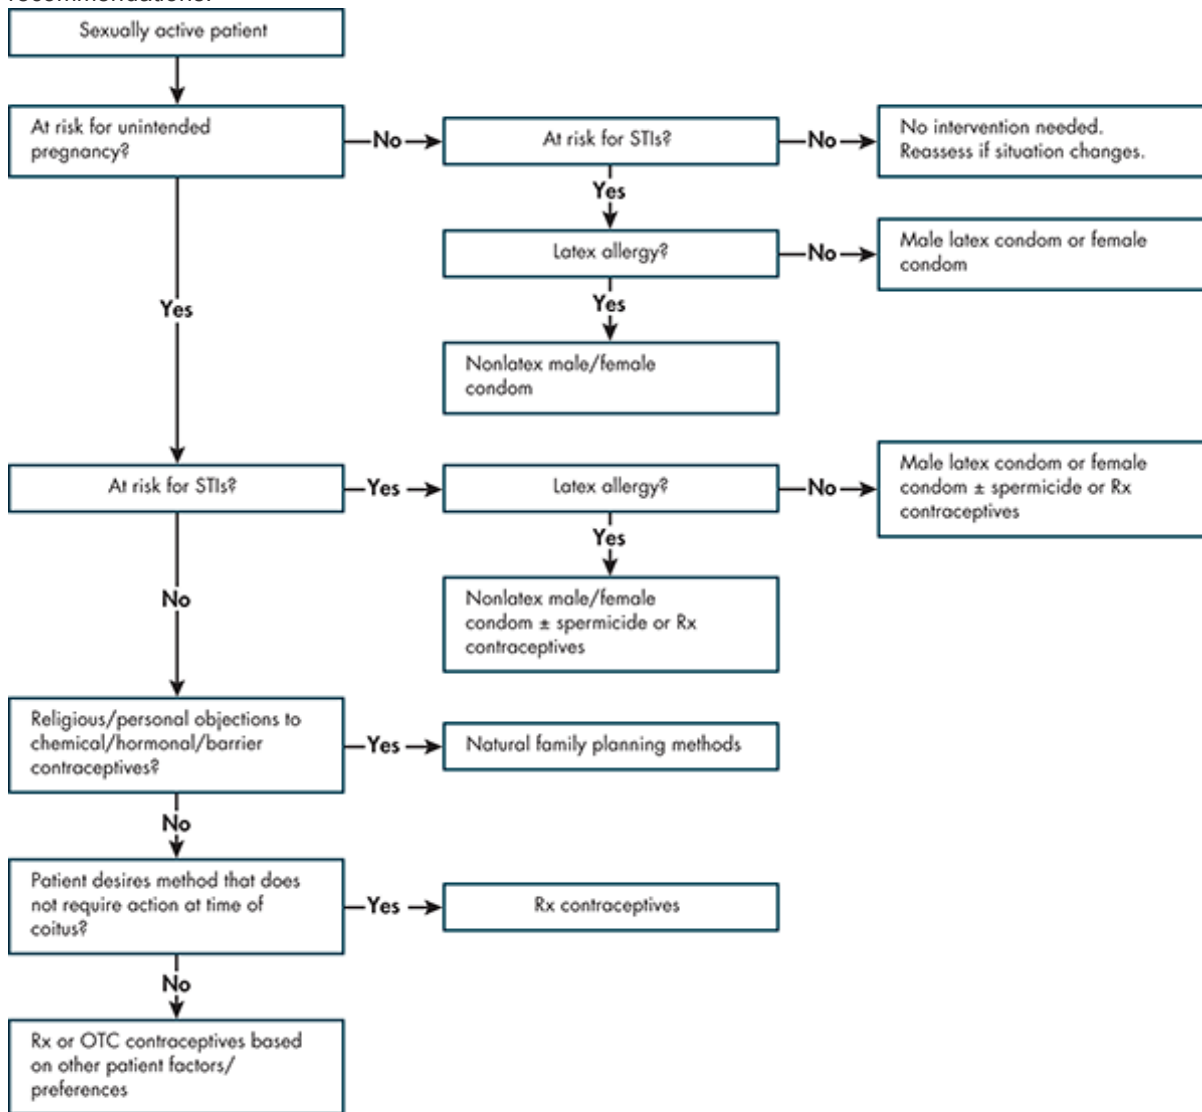

• Abstain from sexual activity.
• Avoid intercourse with a known infected partner.
• Avoid intercourse with an individual having multiple sex partners.
• Use a new condom with each episode of anal, oral, or vaginal intercourse.
• Seek a mutually monogamous relationship with an uninfected partner.
• Discuss partner's past sexual experiences.
• Examine partner for genital lesions.
• Practice genital self-examination.
• Avoid sexual activity involving direct contact with blood, semen, or other body fluids.
• Avoid sharing sexual devices that come in contact with semen or other body fluids.
• Choose safe and effective methods (e.g., mechanical barriers) to reduce the risk of STIs (consider adding more effective methods of pregnancy prevention when necessary).
• Avoid sexual activity if signs/symptoms of an STI are present.
• Consider vaccination if at high risk of a vaccine-preventable STI (e.g., HBV and HPV).

Key: HBV = Hepatitis B virus; HPV = human papillomavirus; STI = sexually transmitted infection.

### Selection of a Contraceptive Method

The acceptability of any given contraceptive method is vital for correct and consistent use of the method. Factors that affect acceptability include the user’s religious beliefs and future reproductive plans, product effectiveness, partner’s preference and support, degree of interruption of spontaneity, ease of use, product accessibility, and cost. To help patients make informed decisions, health care providers should be aware of each method’s safety, including potential adverse effects on future fertility and on the fetus, if unintended conception does occur, and the effectiveness, accessibility, and relative cost of different contraceptive methods. The algorithm in Figure 10-1 can assist the provider in making appropriate contraceptive recommendations.

Prevention of unintended pregnancy and sexually transmitted infections. Key: OTC = Over-the-counter; Rx = prescription; STI = sexually transmitted infection.

### Nonprescription Contraceptive Products

#### Male Condoms

Condoms, also known as rubbers, sheaths, prophylactics, safes, skins, or pros, are the most important barrier contraceptive device that helps protect against STIs.<sup>17</sup> Male condoms are available in latex, polyurethane, polyisoprene, and lamb cecum (natural membrane or skin) (Table 10-4).

**TABLE 10-4 Selected Male Condoms**

Synthetic, nonlatex condoms	Durex Avanti BARE (polyisoprene), Trojan Supra (polyurethane), Lifestyles Skyn (polyisoprene)
-----------------------------	---

Natural membrane condoms	Trojan Naturalamb (lamb cecum)
Latex condoms	Beyond Seven, Billy Boy, Crown, Durex, Kimono, LifeStyles, One Next Generation, Sir Richard's Condom Company, Sensis, Trojan

Latex condoms come in various sizes, colors, styles, shapes, and thicknesses and are degraded by oil-based lubricants. Other features include reservoir tips, ribs, studs, spermicide coating with nonoxynol-9, and lubrication. Latex condoms range in price from \$0.25 to \$1.50 each.<sup>24</sup>

Polyurethane condoms conduct heat well, are available prelubricated, and are not subject to degradation by oil-based products, but are not as elastic as latex condoms.<sup>25</sup> Another form of condoms include those made of polyisoprene which are more elastic than those made of polyurethane but can be damaged by oil-based lubricants. At a cost of \$1.50-\$2.50 each, polyurethane and polyisoprene condoms are more expensive than latex condoms.<sup>24</sup>

Lamb cecum condoms are labeled only for pregnancy prevention because the presence of pores in the membrane may allow passage of viral organisms, including HIV and hepatitis B virus.<sup>20</sup> These condoms conduct heat well, are very strong, and are not degraded by oil-based lubricants. With a price of about \$3.00 each, these condoms are also more expensive than latex condoms.<sup>24</sup>

Condoms are regulated by the Food and Drug Administration (FDA) as medical devices and must meet performance standards for strength and integrity. The true incidence of condom breakage is unknown, and breakage rates from studies vary widely, ranging from 0% to 22%.<sup>26</sup> In some studies, a limited group of patients reported multiple instances of breakage, indicating that breakage may be related as much to the individual user as it is to manufacturing defects. Behaviors that have been associated with an increased risk of condom breakage are (1) incorrect placement of the condom/failure to squeeze air from the receptacle tip; (2) use of an oil-based lubricant with latex condoms; (3) reuse of condoms; (4) increased duration, intensity, or frequency of coitus; (5) prior history of condom breakage or slippage; (6) history of STI; (7) contact with sharp objects; and (8) self-reported problems with fit of a condom.<sup>20,26-28</sup> One study found a decreased incidence of breakage with continued use, indicating that correct use may improve with experience.<sup>26</sup> The benefit of using additional lubrication with lubricated condoms is unclear. One study found that use of additional lubricant increased the risk of condom slippage. However, another study found that use of an additional water-based lubricant was associated with decreased breakage rates but caused no increase in condom slippage rates.<sup>28</sup> A review of comparative studies found that nonlatex synthetic condoms had a significantly higher breakage rate compared with latex condoms.<sup>25,29,30</sup> Two studies also reported a significantly higher pregnancy rate with nonlatex condoms compared with latex condoms.<sup>30,31</sup> Because of these reports, nonlatex condoms should be reserved for use by individuals with intolerance to latex condoms.

The use-related failure rate for condoms is about 15 pregnancies per 100 women during the first year of use, but that rate improves with increasing duration of use (Table 10-2).

Studies support the finding that consistent use of condoms protects against trichomoniasis, bacterial vaginosis, and gonorrhea infections in women, and syphilis, chlamydia, HPV, and herpes simplex virus infections in both men and women.<sup>20</sup> Nonoxynol-9-coated (spermicide-coated) male condoms are no more effective than untreated condoms at preventing STIs. Use of nonoxynol-9-treated condoms is discouraged because of the potential risk of irritation from the spermicide in both men and women, resulting in possible increased risk of infection.<sup>20</sup>

Proper use of condoms is essential to their preventing pregnancy and STIs (Table 10-5). A man using a polyurethane condom should be advised that it is not as elastic as the latex condom and will not fit as snugly. A space must be left at the tip when using condoms without a reservoir.

**TABLE 10-5 Usage Guidelines for Male Condoms**

<ul style="list-style-type: none"> <li>• Use only condoms that are fresh (not previously opened), that are within their expiration date, and that have been stored in a dry, cool place (not a wallet or car glove compartment).</li> </ul>
<ul style="list-style-type: none"> <li>• Do not attempt to test the condom for leaks before using; this step weakens the condom.</li> </ul>
<ul style="list-style-type: none"> <li>• Be aware that long fingernails or jewelry may easily tear condoms.</li> </ul>
<ul style="list-style-type: none"> <li>• As shown in drawing A, unroll the condom onto the erect penis before the penis comes into any contact with the vagina. If you start to put the condom on backward, discard that condom and use a fresh one. (Note: Preejaculate secretions may contain sperm.)</li> </ul>
<ul style="list-style-type: none"> <li>• If you are not using a reservoir-tipped condom, leave one-half inch of space between the end of the condom and the tip of the penis by pinching the top of the condom as you unroll it (drawing B). This method leaves space for the ejaculate (drawing C) and decreases the risk of breakage.</li> </ul>
<ul style="list-style-type: none"> <li>• If your partner has vaginal dryness, use additional lubrication, if desired. This step will help decrease the risk of tears and breakage. Use only water-based lubricants; oil-based lubricants weaken latex condoms and increase the chance of breakage. Spermicidal agents may be used as lubricants with condoms (Table 10-8) and the combination may increase contraceptive effectiveness.</li> </ul>

- After ejaculation, withdraw the penis immediately. To prevent the condom from slipping off, hold on to the rim of the condom as you withdraw.

- Check the condom for tears and then discard in a trash can, not a toilet.

- If a tear or break occurs, immediately insert spermicidal foam or jelly containing a high concentration of spermicide into the vagina. Do not use suppositories or a vaginal film in these cases because the delay time for dissolution may decrease the product's efficacy. Do not douche because sperm that are present may be forced into the cervical canal.

Copyright © American Pharmacists Association  
All rights reserved. Any use is subject to the Terms of Use.

Prelubricated condoms are a good choice when lubrication is desired. Additional lubrication for use with any latex condom should be selected from products that do not harm or weaken the strength and integrity of the condom (Table 10-6).

Packaged condoms should be kept in their sealed packages until time of use and protected from light and excessive heat, which can rapidly decrease the integrity of the latex. FDA requires that latex condoms be labeled with an expiration date or date of manufacture. The shelf life of packaged condoms under optimal conditions is 3-5 years. Condoms showing signs of discoloration, brittleness, or stickiness should be discarded, even if they are within their expiration date.

The most frequent complaint about condoms is decreased sensitivity of the glans penis, resulting in decreased sexual pleasure for the man. Contact dermatitis caused by latex allergy can occur in the male or female partner, and may be characterized by immediate localized itching and swelling (urticarial reaction) or by a delayed eczematous reaction. In individuals with severe sensitivity, the reaction may include systemic symptoms. Spermicide-treated condoms may enhance latex allergy or cause the sensitivity reactions itself.<sup>32</sup>

For most people, condoms are an effective, acceptable, inexpensive, safe, and nontoxic method of birth control. Given the range of condoms available, men should be encouraged to try a different style or brand if they are dissatisfied with a condom used previously. Before recommending a latex condom, providers should assess for latex allergy. The sensitizers in latex condoms are usually antioxidants or accelerators used in processing the rubber. Some men may be sensitized to components of the lubricant or spermicide. Because manufacturers use different processes, changing brands or using a condom without spermicide may resolve the problem.<sup>20</sup> If switching brands does not eliminate the irritation, the man may use nonlatex synthetic condoms. Natural skin condoms may also be used if the individual recognizes the limitations of the product in preventing STIs.

**TABLE 10-6 Selected Lubricants/Products That Are Safe or Unsafe to Use with Latex Condoms**

<i>Safe</i>	<i>Unsafe</i>
Contraceptive foams/gels	Topical oils (e.g., baby oil, mineral oil, massage oil)
Water-based personal lubricants, such as K-Y Jelly	Edible oils/fats (e.g., olive, peanut, corn, canola, and safflower oils; butter; margarine)
Egg white	Hemorrhoidal ointments
Glycerin (USP)	Petroleum jelly (e.g., Vaseline)
Replens Inserts	Vaginal creams (e.g., Monistat, Estrace, Vagisil, Premarin)
Saliva	
Water	

Source: Reference 20.

The use of very thin or ridged condoms, nonlatex synthetic condoms, or natural membrane condoms in a monogamous relationship with a partner screened for STI exposure may alleviate complaints of decreased sensitivity.

Female Condoms

A female condom is another nonprescription contraceptive product. The first female condom, known as the polyurethane F.C. Female Condom (FC1), was approved by FDA in 1993.<sup>33</sup> The FC1 was prelubricated, came with additional lubricant, and resisted degradation by oil-based lubricants. A second-generation female condom, the FC2, made of nitrile, a synthetic latex, was approved in 2009 and replaced the polyurethane condom as supplies of FC1 were exhausted.<sup>34</sup> Although production of the FC1 stopped in 2009, the product has a shelf life of 5 years so existing supplies may still be available. The female condom consists of an outer ring, a sheath or pouch that fits over the vaginal mucosa, and an inner ring that secures the sheath by fitting like a diaphragm over the cervix. The female condom is designed for onetime use only and, at a cost of \$2.00 each, is more expensive than the latex male condom.<sup>24</sup>

The breakage rate of the female condom has been shown to be lower than that of latex male condoms, but slippage rates of female condoms may be higher, especially with initial use.<sup>27</sup> The 6-month pregnancy failure rate among all users of the FC1 is 12.4%, similar to that for users of diaphragms and cervical caps. Among perfect users, however, 6-month pregnancy failure rates of 0.8%-2.5% have been documented. The extrapolated annual pregnancy failure rate for the FC1 is 21% for all users and 5% for perfect users (Table 10-2).<sup>1,21,33,34</sup> Although specific data regarding failure rates for the FC2 are not available, it is considered non-inferior to the FC1.<sup>34</sup>

The female condom is an effective barrier to sexually transmitted bacteria and viruses, and appears to be similar in efficacy to latex male condoms in decreasing the risk of STIs.<sup>22</sup>

Table 10-7 provides instructions for proper use of the female condom.<sup>35</sup> Skills in correctly using the female condom improve with practice and continued use.<sup>36</sup> The condom may be inserted up to 8 hours before intercourse, but it is effective immediately on insertion.

Fresh condoms can be stored at room temperature in their unopened packages. Before inserting the female condom, the woman should ensure that the product is within its expiration date.

The most common complaints about the female condom are vaginal irritation and increased noise ("squeaking"). Additional lubrication may resolve those problems. Some women may complain of decreased sensation or discomfort caused by the outer ring during intercourse.

The female condom provides a method for women to protect themselves against pregnancy. It is thinner than many latex condoms and has a lower breakage rate than the male condom.<sup>22</sup> Compared with vaginal spermicides, the female condom can be inserted much earlier before intercourse and is less messy to use. However, some women may find the female condom cumbersome and unattractive. The female condom should not be used together with the male condom. Use of the two products together may cause friction and increase the risk of breakage for either product.<sup>35</sup>

#### TABLE 10-7 Usage Guidelines for Female Condoms

• Remove the condom from the package. One end of the condom is closed to form a pouch, as shown in drawing A.
• Gently rub the sides together to evenly distribute the lubricant. If needed, add additional lubrication at this point.
• Add a drop of lubricant on the outside of the pouch to improve the ease of insertion if needed. Oil- or water-based lubricants can be used with this condom.
• To place the pouch properly, grasp the inner ring between the thumb and middle finger of one hand. Place the index finger on the sheath between the other two fingers. (See drawing B.)
• Be careful that sharp fingernails or jewelry does not tear the condom.
• Squeeze the inner ring and with your other hand, spread the lips of the vagina. Then insert the squeezed condom into the vagina as far as possible. (See drawing C.)
• Be sure that the inner ring is placed beyond the pubic (pelvic) bone, that the pouch is not twisted, and that the outer ring is outside the vagina, as shown in drawing D.
• During intercourse, make sure that the penis enters the vagina inside the pouch and that the outer ring remains outside the vagina.
• If desired, add more lubricant during intercourse, without removing the condom.
• If you notice the female condom slipping out of the vagina during intercourse or the outer ring is going into the vagina, stop intercourse. Remove the female condom and insert a new condom.
• Remove the pouch before standing by twisting the outer ring and pulling gently. (See drawing E.)
• Discard the used condom in a trash can, not a toilet.
• Insert a new condom for each act of intercourse.
• Do not use a male condom with the female condom. The increased friction could cause displacement of the female condom.

Source: Reference 35.

### Vaginal Spermicides

Vaginal spermicides use surface-active agents to immobilize and kill sperm. For gels and foams, the spermicide vehicle also acts as a physical barrier against sperm. The effective spermicides include nonoxynol-9, octoxynol-9, and menfegol, but in the United States, all products contain nonoxynol-9 (Table 10-8). Vaginal spermicide products differ in application method and onset and duration of action (Table 10-9). The cost of vaginal spermicides ranges from \$1.00 to \$3.00 per dose.<sup>24</sup> Vaginal gels (jellies) provide additional lubrication and are safe to use with latex condoms. For convenience, applicators may be prefilled before use. Prefilled unit-dose applicators are also available for some products. When selecting an agent to use without a diaphragm or cervical cap, a product with a higher concentration of spermicide, rather than one with a lower concentration labeled for use with barrier methods, should be chosen. Products with a higher concentration of spermicide may be used alone or with a diaphragm or cervical cap.

**TABLE 10-8 Selected Nonprescription Vaginal Spermicides Containing Nonoxynol-9**

Spermicidal foams	VCF Vaginal Contraceptive Foam 12.5%, 85 mg
Spermicidal gels/jellies	Conceptrol Gel 4%, 100 mg Ortho Options Gynol II Vaginal Contraceptive Jelly <sup>a</sup> 2%, 100 mg Ortho Options Gynol II Extra Strength Vaginal Contraceptive Jelly 3%, 150 mg
Spermicidal suppositories	Encare Vaginal Contraceptive Inserts 100 mg
Spermicidal film	VCF Vaginal Contraceptive Film 28%, 72 mg
Spermicidal sponge	Today Contraceptive Sponge 1000 mg

<sup>a</sup> Product formulated for use with a diaphragm or cervical cap; it should not be used alone.

Vaginal foams distribute more evenly and adhere better to the cervical area and vaginal walls but provide less lubrication than jellies. A new canister should always be available because it is difficult to know when the canister is nearly empty. Vaginal suppositories are solid or semisolid dosage forms that are activated by moisture in the vaginal tract. Incomplete dissolution of the suppository may result in an unpleasant, gritty sensation. Although vaginal suppositories do not require refrigeration, in warmer climates, refrigeration may be desirable to prevent softening.

**TABLE 10-9 Administration Guidelines for Vaginal Spermicides**

<i>Dosage Form</i>	<i>Application Method</i>	<i>Onset/Duration of Action</i>	<i>Application Time before Intercourse</i>	<i>Reapplication Requirements</i>
Vaginal gel alone	Insert full dose near cervix.	Immediate/1 hour	Up to 30-60 minutes	Reapply for each coital act.
Vaginal gel used with diaphragm/cervical cap	Fill barrier device one-third full with gel and place it near cervix. Leave barrier in place for at least 6 hours after intercourse.	Immediate/diaphragm: 6 hours; cervical cap: 48 hours	Up to 1 hour	Diaphragm: for each coital act that occurs within 6 hours of initial insertion of device, reapply spermicide without removing device; for coitus after 6 hours of initial insertion, remove and wash

				device, fill with new spermicide, and re-insert device. Cervical cap: remove and wash device; then reapply spermicide for each coital act that occurs 48 hours after initial insertion of device.
Vaginal foam	Insert full dose near cervix.	Immediate/1 hour	Up to 1 hour	Reapply for each coital act.
Vaginal suppository	Insert suppository near cervix.	10-15 minutes/1 hour	10-15 minutes	Reapply for each coital act.
Vaginal contraceptive film	Drape film over fingertip; place film near cervix.	15 minutes/1-3 hours (brand-dependent)	15 minutes	Reapply for each coital act.
Vaginal contraceptive sponge	Moisten with tap water, insert convex side against cervix.	Immediate/24 hours	Can be inserted up to 24 hours before intercourse.	Leave in for ≥6 hours after intercourse, but no longer than 30 hours total; polyester loop to facilitate removal.

Vaginal contraceptive film contains nonoxynol-9 in paper-thin, 2-inch-square sheets. The film is activated by vaginal secretions. One film is used for each act of intercourse. The practice of inserting the film by placing it over the penis should be avoided because this method does not ensure proper placement and does not allow adequate time for dissolution. In one comparison of spermicide dosage formulations, the film was rated the most difficult to use but the least messy.<sup>37</sup> Similarly designed vaginal films for cleansing or lubrication do not contain spermicide and should not be used for contraception. Patients should be advised to verify that they are using the correct vaginal film product if they desire contraception. Spermicides used alone have a relatively high typical rate of usage failure among first-year users (Table 10-2). A review of clinical trials found a similar pregnancy rate between dosage forms containing 100-150 mg nonoxynol-9 per dose.<sup>38</sup> A gel containing 52.5 mg nonoxynol-9 per dose, which is not available in the United States, was significantly less effective at preventing pregnancy than the higher-dose formulations.<sup>38</sup> Efficacy improves greatly if spermicides are used with barrier methods, such as diaphragms, cervical caps, or condoms.

Although nonoxynol-9 can inactivate many sexually transmitted pathogens in vitro, clinical studies do not support a protective effect of vaginal spermicides against STI transmission.<sup>21,39</sup> Higher rates of genital lesions, especially in frequent users, have been reported, raising concerns about an increased risk of STI transmission.<sup>21,39</sup> In 2007, FDA ruled that vaginal spermicide products must carry a label stating that the product does not protect against HIV and other STIs.<sup>39</sup> If a risk of STIs exists, spermicides should only be recommended in conjunction with condom use.

Table 10-9 provides guidelines for the proper administration of vaginal spermicides. When using any vaginal spermicide, a woman should delay douching for at least 6 hours after intercourse. Although allergic reactions are rare, either partner may experience such reactions to spermicides. Couples having oral-genital sex may find the taste of some products unpleasant. Frequent use or use of high-concentration products may irritate or damage vaginal and cervical epithelium,<sup>39</sup> which may be associated with an increased risk for STIs. Despite initial concerns about a possible association between spermicide use and birth defects or miscarriage should an unintended pregnancy occur, current data do not support an increased risk of either attributable to spermicides.<sup>40</sup>

The relatively low effectiveness of spermicides when used alone is their major disadvantage. However, studies suggest that simultaneous use of condoms and spermicides provides efficacy rates similar to those of oral contraceptives and intrauterine contraceptives (IUCs).<sup>17</sup> Their availability and ease of use make spermicides a good choice for women who need a backup method. Spermicides are not recommended for women with anatomic abnormalities that would prevent the proper placement of the spermicide near the cervical opening. Product selection can be based on patient preference and specific product characteristics.

#### Contraceptive Sponge

The contraceptive sponge marketed as the Today Sponge is a small, circular, disposable sponge made of polyurethane permeated with the spermicide nonoxynol-9. The sponge is believed to act as a contraceptive by serving as a mechanical barrier, providing a spermicide, and absorbing semen. The contraceptive sponge ranges in price from \$5 to \$8 per sponge.<sup>24</sup> In two large trials, the failure rate for the contraceptive sponge ranged from 17.4 to 24.5 pregnancies per 100 women in the first year of use.<sup>41</sup> Women who had given birth previously (parous women) had a significantly higher pregnancy rate while using the sponge, compared with women who had never given birth (nulliparous women). That finding may be related to poor fit in women who have delivered vaginally. If the sponge becomes dislodged during intercourse, its efficacy may be decreased.

The contraceptive sponge does not protect against STIs. One study found an increased risk of HIV infection in women with

frequent sponge use, possibly because of an increased incidence of vaginal ulceration from the spermicide.<sup>23</sup>

A woman must be able to locate her cervix and must be comfortable in doing so to place the sponge correctly. Table 10-9 provides instructions for proper use. The sponge has a loop attached to the convex side to facilitate removal. Some women have difficulty removing the sponge, and it has been known to fragment on removal. The sponge may be inserted up to 24 hours prior to intercourse but must remain in place for 6 hours after intercourse. The sponge should be stored in its unopened package in a cool place and used before its expiration date.

Vaginal dryness is reported among sponge users. Although the incidence is rare, the contraceptive sponge has been associated with an increased risk of toxic shock syndrome (TSS).<sup>21</sup> Women should take special care to wash their hands before inserting the sponge. The sponge should not be used during menstruation, less than 6 weeks postpartum, or in women with a history of TSS. Use should not exceed the maximum recommended retention time of 30 hours. Women should also be advised to make sure the entire sponge is removed because fragments left in the vagina may serve as a source for infection.

The contraceptive sponge is convenient, safe, and portable. Contraindications for use include spermicide sensitivity, anatomic abnormalities of the vagina, and a history of TSS. The contraceptive sponge should not be routinely recommended to parous women because possible problems with adequate cervical coverage may lead to increased risk of pregnancy.

## Emergency Contraception

Emergency contraception (EC) involves the use of hormones in the form of oral tablets or a non-hormonal copper IUC to prevent pregnancy within 3-5 days after unprotected sexual intercourse. Hormones used in EC may include only progestin (synthetic progesterone), estrogen in combination with a progestin, or a selective progesterone receptor modulator. Currently OTC and prescription oral tablet formulations are available. The prescription product, ella, contains 30 mg of ulipristal acetate and is a selective progesterone-receptor modulator that can be taken up to 120 hours after unprotected intercourse. Ulipristal will not be discussed in this chapter because of its prescription-only status, but it follows counseling points similar to those used for progestin-only products. Nonprescription EC products that contain estrogen and progestin together are not available; therefore, this chapter will focus on progestin-only products.

Emergency contraceptive products should be recommended for girls and women of reproductive age who have had recent unprotected intercourse or experienced method failure, such as condom breakage.<sup>16,42,43</sup> Some women may be seeking EC in the case of sexual assault. In addition to providing EC for immediate use, pharmacy staff should refer the individual to health care providers who can evaluate the individual for STIs and report the incident to the authorities as required by state law.

EC products reduce the expected number of pregnancies by at least 89% for levonorgestrel users and 74% for combination oral contraceptive users.<sup>43</sup> The efficacy of EC is due primarily to the suppression of ovulation. Other possible mechanisms of action include interference with transport of sperm or egg, including thickening of cervical mucus.<sup>16,42,43</sup>

Current options on the market include levonorgestrel-containing tablets, available as one-tablet formulations in the generic branded products Next Choice One Dose and My Way or the branded product Plan B One-Step and two-tablet formulations as an unbranded generic product. Progestin-only products cost between \$40 and \$50 for single incident use.<sup>24</sup>

Levonorgestrel-containing EC products were made available OTC to women 18 years of age or older in 2006 and in 2009 to women 17 years of age or older. In 2011, FDA recommended EC to be available OTC to all women. Concerns about the lack of safety data in young girls and political pressure led to the limitation of its use to girls ages 17 years or older.<sup>44</sup> In April 2013, a U.S. district judge reversed the age limitations of levonorgestrel-containing EC products, making them OTC for all ages.<sup>45</sup> In July 2013, FDA granted Teva, the manufacturer of Plan B One-Step, exclusivity to market the one-tablet formulation OTC for 3 years to all ages.<sup>45,46</sup> Thus, other formulations are available OTC to those 17 years of age or older and by prescription to those younger than 17 years.

Next Choice One Dose, My Way, and Plan B One-Step each contain one tablet of levonorgestrel 1.5 mg labeled to be taken as a single dose within 72 hours after unprotected intercourse or contraceptive failure, but studies have shown effectiveness up to 120 hours after intercourse, though efficacy declines with more time post coitus.<sup>43</sup> Therefore, women presenting within 120 hours of unprotected sex should be offered EC. Various generic formulations may contain two pills, each containing 0.75 mg of levonorgestrel, taken 12 hours apart or together within the same time frame after unprotected intercourse. Both methods of administration have equal effectiveness, although taking the full dose of 1.5 mg immediately is preferred because of simplicity and adherence.<sup>43</sup>

Oral contraceptives containing levonorgestrel or D,L-norgestrel may also be used but are not the preferred regimen because of the availability of the dedicated products for EC.<sup>42</sup> EC using combined oral contraceptive tablets is given in two doses.<sup>43</sup> For optimal efficacy, the first dose of the combined regimen should be given as soon as possible after unprotected intercourse, and the second dose 12 hours later. Only certain combined hormonal contraceptive products are appropriate for EC use. Women should check with their providers to determine which combined hormonal product could be used if needed. Because of the increased access to Next Choice One Dose, My Way, and Plan B One-Step as nonprescription products, using progestin-only EC is preferred to using combined oral contraceptives as EC.

The most common adverse effects reported with EC use are nausea and vomiting.<sup>16,43</sup> Nausea occurs in about 50% of women using combination oral contraceptives for EC and about 25% of women using progestin-only products. Vomiting occurs in about 20% and 5% of combination oral contraceptive and progestin-only EC users, respectively. An antiemetic is usually not necessary for progestin-only EC but may be recommended 60 minutes before each dose when using

combination oral contraceptive regimen.<sup>16,43</sup> However, if a woman vomits within 1 to 2 hours of taking the dose, she should repeat the dose.<sup>16,43</sup> Headaches, breast tenderness, and dizziness have also been reported by users of both products. Progestin-only EC has been found to be more effective and better tolerated than combination oral contraceptives. Patients presenting between 5 and 7 days after unprotected intercourse should be referred to a physician for possible insertion of a copper IUC.<sup>16</sup> Although a copper IUC is usually placed up to 5 days after unprotected intercourse, the IUC can be inserted up to 8 days after intercourse if ovulation is known to have occurred more than 72 hours after intercourse.<sup>16</sup> Therefore, if intercourse occurred 3 days prior to ovulation, the patient could potentially still have an IUC placed up to 120 hours after ovulation, though in practice it is usually placed up to 5 days after unprotected intercourse.<sup>16</sup> [Table 10-10](#) provides patient counseling points and information about EC products.

**TABLE 10-10 Counseling Points for Emergency Contraception**

<ul style="list-style-type: none"> <li>Identify whether patient has had recent unprotected sex within the past 120 hours or is at risk for unprotected sex and does not want to get pregnant.</li> </ul>
<ul style="list-style-type: none"> <li>Identify whether patient is appropriate for EC available as nonprescription products.</li> </ul>
<ul style="list-style-type: none"> <li>Explain how to take EC: Both doses of generic levonorgestrel EC may be given at the same time or as 2 doses taken 12 hours apart. Plan B One-Step, My Way, or Next Choice One Dose is given as a single dose and should be taken as soon as possible. EC is most effective when taken as soon as possible after unprotected intercourse. The method is effective when taken up to 120 hours after unprotected intercourse though package labeling states within 72 hours.</li> </ul>
<ul style="list-style-type: none"> <li>Recommend an antiemetic for women using combination oral contraceptive pills for EC.</li> </ul>
<ul style="list-style-type: none"> <li>Discuss adverse effects of EC, which may include a change in menstrual cycle depending on when emergency contraception is used. Patients may experience their next menstrual cycles early or late or have no change. If a menstrual cycle has not occurred more than 21 days after use of ECPs, the patient should take a pregnancy test.</li> </ul>
<ul style="list-style-type: none"> <li>Emphasize that EC is not to be used as a regular contraceptive method.</li> </ul>
<ul style="list-style-type: none"> <li>Recommend that a sexually active woman begin using regular contraception after taking EC. Barrier methods should be used with each subsequent act of intercourse. Hormonal contraceptive methods may be started with the next menses or may be started the day after taking EC, including 7 days of a backup method.</li> </ul>
<ul style="list-style-type: none"> <li>Explain that EC does not protect against STIs.</li> </ul>
<ul style="list-style-type: none"> <li>Explain that EC is not 100% effective. Recommend using a pregnancy test if menses is more than 21 days late.</li> </ul>
<ul style="list-style-type: none"> <li>Provide written instructions.</li> </ul>

Key: EC = Emergency contraception; ECP = emergency contraceptive pill; STI = sexually transmitted infection.

### Fertility Awareness-Based Methods

Examples of contraceptive methods that do not use a chemical or barrier to prevent conception include calendar methods, cervical mucus methods, symptothermal method, and the lactational amenorrhea method (LAM). These fertility awareness-based (FAB) methods use various techniques to determine a woman's fertile phase of the menstrual cycle. The techniques are typically chosen because they pose no health risks to the couple or to the fetus should pregnancy occur or because of decreased cost or religious reasons. In some cases, FAB methods are used because of a lack of access to or knowledge of other methods of contraception. Disadvantages of FAB methods include lack of STI protection, lower efficacy than with some other contraceptive methods, and the need for periods of abstinence or the use of another method of contraception, such as condoms, during fertile days.<sup>18</sup>

#### Calendar Methods

Calendar methods use a woman's monthly menstrual cycle length to calculate the fertile period. These methods factor in the viabilities of ovum (up to 24 hours) and sperm (up to 6 days).<sup>10,18</sup> Menstrual cycles may vary, and therefore, cycle lengths should be recorded for 6-12 cycles to predict the likely range of fertile days. The Calendar Rhythm Method calculates the first fertile day in a woman's menstrual cycle by subtracting 18 from the number of days in her shortest cycle. The last fertile day is calculated by subtracting 11 from the number of days in her longest cycle. Women who have irregular cycles are not optimal candidates for this method as an overestimation of unsafe fertile days could occur.<sup>18</sup> The Standard Days Method is a calendar method recommended only for women with cycles between 26 and 32 days in length. Counting the first day of menstruation as day 1, a woman should avoid intercourse on days 8 through 19 of her menstrual cycle or use another method of contraception, such as condoms, during this time. Software applications are available to facilitate the tracking of

cycle days.<sup>18</sup>

### Cervical Mucus Methods

Cervical mucus methods rely on rather consistent changes in cervical mucus that take place during a normal menstrual cycle.<sup>18</sup> Individuals should be encouraged to work with trained instructors to ensure proper interpretation of mucus as well as to avoid intercourse during the first cycle. Examples of cervical mucus methods include the Billings Ovulation Method, the Creighton Model, and the TwoDay Method.

With the Billings Ovulation Method, the woman observes the cervical mucus on a daily basis and charts its character and quantity. After menstruation, most women notice a sensation of vaginal dryness. About 5-6 days before ovulation, estrogen levels rise, causing the cervical mucus to increase in quantity and elasticity and to become clear, resembling raw egg white. The peak symptom, the last day of the clear, stretchy, estrogenic mucus, has been shown to occur within a day of ovulation for most women. With the postovulatory rise in progesterone, the mucus becomes thick and sticky or is absent. The woman is considered fertile from the first day after menstruation on which mucus is detected until 4 days after appearance of the peak symptom, during which time intercourse should be avoided.<sup>18,47</sup> With experience and assistance, a woman learns to differentiate other vaginal secretions, such as seminal fluid or an infectious discharge, from normal mucus, enabling her to seek early treatment for an infection. Women should be informed that vaginal foams, gels, creams, and douches will interfere with cervical mucus. The Creighton Model involves similar principles, but uses more standardized definitions of cervical secretions, involves the male partner, and requires extensive patient training from certified instructors.<sup>47</sup>

Another method of monitoring cervical secretions is called the TwoDay Method.<sup>18,47</sup> The woman should monitor for secretions on a daily basis, and if she notes any secretions that day or the day before, she is likely to be fertile. If she does not note any secretions, she is unlikely to be fertile. The TwoDay Method is a simple method that does not require keeping records or logs. However, training the woman to identify cervical secretions correctly is still important.<sup>47</sup>

### Symptothermal Method

The symptothermal method combines methods of fertility awareness to determine the fertile period. Tracking changes in cervical mucus is combined with basal body temperature (BBT) monitoring.<sup>10,18</sup> Observation of the cervical mucus is used to identify the onset of the fertile period, and BBT charting is used to identify the end of the fertile period.<sup>18</sup> Monitoring of BBT can also be used to predict ovulation for conception, which is discussed further in [Chapter 48](#).

To monitor BBT, the woman measures and charts her body temperature every morning, preferably with a digital thermometer calibrated in increments of 0.1°F (0.05°C), to detect small changes in body temperature.<sup>18</sup> The temperature must be obtained before getting out of bed at the same time every day and is recorded on a chart ([Figure 10-2](#)). At least 3 hours of uninterrupted sleep are required for a reliable reading. The temperature may be taken orally, vaginally, or rectally, but the same site must be used each day.

Symptothermal variations during a model menstrual cycle. (Source: Reprinted with permission from Jennings VH, Arevalo M, Kowal D. Fertility awareness-based methods. In: Hatcher RA, Trussell J, Stewart F, et al., eds. *Contraceptive Technology*. 18th rev ed. New York, NY: Ardent Media; 2004:327.)

In some women, the onset of ovulation may be detected by a drop in BBT 12-24 hours before ovulation. At the time of ovulation, BBT rises by at least 0.4°F (0.2°C) above the lowest point (the nadir).<sup>18</sup> The safe (infertile) period begins once there have been 3 consecutive days of rising temperature and lasts until the end of menses. Some women do not have a definite or significant temperature dip or rise with ovulation. Stress, inadequate sleep, travel, fever, lactation, or perimenopause may affect BBT.<sup>18</sup> For women who work rotating shifts, an accurate record of BBT may be difficult to maintain. At such times, couples should use an alternative method of contraception.

Home Tests for Ovulation Prediction

Ovulation prediction tests are designed to aid couples in conceiving by detecting the surge in luteinizing hormone that occurs shortly before ovulation (see Chapter 48). These kits detect an increase in urinary excretion of the hormone, which usually occurs 8-40 hours before actual ovulation. These ovulation predictors do not give warning of impending ovulation with enough accuracy to be effective contraceptive agents and are not recommended for use other than as an aid for couples desiring pregnancy.<sup>18</sup>

Lactational Amenorrhea Method

In many developing countries, the LAM is used as a contraceptive method for spacing the birth of children. When an infant younger than 6 months of age receives at least 90% of his nutrition from breastfeeding, and the mother is amenorrheic, the LAM offers more than 98% protection against pregnancy.<sup>16,19</sup> Because the suckling action of the infant on the breast at frequent intervals is necessary for the LAM to be effective, milk extraction through a breast pump does not offer the same protection against pregnancy.<sup>19</sup> Although menstrual periods in lactating women may be anovulatory, ovulation may occur before the return of menses. With the LAM, the risk of pregnancy increases after the initial 6 months postpartum as supplementation becomes more commonplace in older infants. In general, if a breastfeeding woman is having menstrual periods, is supplementing her infant's diet, or is more than 6 months postpartum, she should use an additional method of contraception.<sup>16,19</sup> For a woman who is breastfeeding an infant almost exclusively, studies have reported pregnancy rates of 0.5%-2% for the 6-month period after delivery. Once supplemental feedings begin, the efficacy rate decreases significantly.<sup>19</sup>

Effectiveness of Fertility Awareness-Based Methods

Overall, the pregnancy rate for typical use of FAB methods is about 24% (Table 10-2).<sup>17</sup> Compared with condoms, hormonal

methods, or the nonhormonal IUC, the risk of pregnancy is higher with any of the FAB methods alone. Consequently, family planners do not recommend using a single method; instead, they suggest using a combination of methods. FAB methods that specifically identify preovulatory and postovulatory changes, such as the symptothermal method, have much better outcomes; with perfect use, the annual failure rate is less than 5%.<sup>17</sup> FAB methods also do not provide any protection against STIs and should be recommended solely for couples in mutually monogamous relationships.

#### Coitus Interruptus

Coitus interruptus (withdrawal) involves coital activity until ejaculation is imminent, followed by withdrawal of the stimulated penis and ejaculation away from the vagina or vulva. Method failures (pregnancy even when the method is used correctly and consistently) occur in part because involuntary preejaculation secretions may contain millions of sperm. Disadvantages of this method include the requirement of considerable self-control by the man, the potential for diminished pleasure for the couple because of interrupted lovemaking, and no STI protection. This method has failure rates of 4% with perfect use and 22% with typical use, comparable to those of other barrier methods.<sup>48</sup>

#### Assessment of the Prevention of Pregnancy and STIs: A Case-Based Approach

Before advising a couple on contraception and STI prevention, the health care provider must first identify their level of knowledge about these issues because they must understand their risk of pregnancy and STIs to select an appropriate product or method. Individuals who prefer FAB methods must understand the reproductive cycle before they can use these methods effectively. Those who prefer nonprescription contraceptive products must know how to use them properly and be prepared to use them with every act of intercourse. The provider should identify individual preferences for products or methods on the basis of the timing of use or religious or cultural practices.

Case 10-1 illustrates the assessment of a woman who is seeking advice on contraception, whereas Case 10-2 deals with the use of emergency contraception.

#### Case 10-1

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient is asking for a recommendation for a contraceptive method. She has not used contraception in the past as she has not been sexually active. However, she plans to begin having intercourse with her current boyfriend. She is not sure of his sexual history but expresses interest in a method whose use she can control. She does not have access to a physician at this time because of insurance issues.
b. patient's identity	Jennifer Grayson
c. age, sex, height, and weight	23 years old, woman, 5 ft 3 in., 115 lb
d. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	None; no history of sexual partners
e. allergies	NKA
<b>Assessment and Triage</b>	

2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Risk of undesired pregnancy and STI
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Recommend use of a male or female condom to provide STI protection in addition to contraception. (2) Refer patient for a prescription hormonal method of contraception to be used in combination with a male or female condom.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Nonlatex female condom because patient prefers female-controlled method and does not have medical insurance at this time.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Use the nonlatex female condom with each act of sexual intercourse."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"There are various OTC contraceptive options whose use are controlled by the woman, including the female condom, contraceptive sponge, and various forms of spermicides. In addition, many prescription hormonal contraceptive products are available. They are more effective than the OTC methods for pregnancy prevention, and I can provide you information on low-cost clinics in the area that may better fit your financial needs for medical care. In the meantime, of the OTC methods, only the female condom provides protection from STIs, which is important to consider when beginning a sexual relationship. This method would be important to continue using even if you started a hormonal method in the future for this reason."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	"Use a fresh condom with each act of sexual intercourse."
b. product administration	See <a href="#">Table 10-7</a> .

procedures	
c. expected time to onset of relief	“Female condoms are effective immediately once correctly inserted. Although most women insert them between 2 and 20 minutes prior to intercourse, they can be inserted up to 8 hours prior to intercourse.”
d. degree of relief that can be reasonably expected	See <a href="#">Table 10-2</a> for efficacy rates.
e. most common side effects	“Vaginal irritation and increased noise (possible squeaking) are the most common side effects.”
f. patient options in the event that condition worsens or persists	“Consult your primary care provider.”
g. product storage requirements	See <a href="#">Table 10-7</a> .
Solicit follow-up questions from the patient or caregiver.	“May I use lubricants or vaginal spermicides with the female condom?”
Answer the patient’s or caregiver’s questions.	“Yes. The female condom comes with its own lubricant, but additional lubrication can also be used. Nitrile and/or the previously marketed polyurethane female condoms are not affected by oil-based lubricants.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Ask the patient to call the pharmacy if she has further questions.

Key: NKA = No known allergies; OTC = over-the-counter; PCP = primary care provider; STI = sexually transmitted infection.

### Case 10-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient’s symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient had unprotected intercourse with a partner 3 days ago. This is her third time in 6 weeks requesting EC, involving two sexual partners.
b. patient’s identity	Cindy Smith
c. age, sex, height, and weight	22 years old, woman, 5 ft 3 in., 120 lb
d. patient’s occupation	College student

e. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Occasional tension headaches: naproxen 220 mg 1 tablet orally as needed for headache; multivitamin 1 tablet daily
f. allergies	None
g. history of other adverse effects to medications	None
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Elevated risk of pregnancy and STI due to unprotected intercourse with multiple partners
3. Identify exclusions for self-treatment.	Patient has no exclusions for self-treatment with EC but should see her health care provider for STI screening and for possible longer-term prescription contraceptive method.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Recommend that the patient purchase OTC EC at her local pharmacy. (2) Recommend that the patient purchase OTC EC at her local pharmacy. Also refer patient to see her provider for selection of a longer-term prescription contraceptive method and STI screening. (3) Recommend that the patient obtain a prescription for ella (ulipristal acetate). (4) Recommend that the patient obtain a prescription for an oral contraceptive pill that can be used as EC. (5) Recommend that the patient see her provider for evaluation and possible insertion of a copper intrauterine contraceptive. (6) Recommend against use of OTC EC because of overuse.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The patient prefers to purchase EC at her local pharmacy and considers obtaining a prescription for a regular method of contraception. OTC EC should not be denied to the patient because of multiple uses.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should take Next Choice One Dose, My Way, or Plan B One-Step (levonorgestrel 1.5 mg), 1 tablet by mouth. It is recommended to take the product as soon as possible within 72 hours of unprotected intercourse, but the product can still be effective up to 120 hours after intercourse."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Over-the-counter emergency contraception is up to 89% effective in preventing pregnancy and works better the sooner it is taken. It is not intended to be a regular form of birth control. For more effective and less expensive ways of contraception, you should see your provider to obtain a prescription for a more regular form of contraception. Emergency contraception does not protect against sexually transmitted infections. Because you have had unprotected intercourse, you should be screened."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient	See <a href="#">Table 10-10</a> .

or caregiver.	
Solicit follow-up questions from the patient or caregiver.	(1) "How effective is emergency contraception?" (2) "May I start taking birth control pills after I use emergency contraception?"
Answer the patient's or caregiver's questions.	See <a href="#">Table 10-10</a> .
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact the patient in a day or two to ensure she made an appointment and sought the discussed medical care.

Key: EC = Emergency contraception; OTC = over-the-counter; PCP = primary care provider; STIs = sexually transmitted infections.

### Patient Counseling for Prevention of Pregnancy and STIs

As the most accessible health care provider, pharmacists are in a unique position to lower the incidence and consequences of unintended pregnancy and STIs in their communities. The pharmacist should seek opportunities to discuss specific diseases or prevention strategies with individuals who may be at high risk of unintended pregnancy and STIs. If possible, consultation involving both partners can improve the understanding and acceptance of selected contraceptive methods. Providers must be familiar with the proper use of available nonprescription contraceptive products and provide opportunities for consultation by removing barriers that may prevent open conversations. Contraceptive products and information as well as STI-related patient information should be available in an area where the individual can browse and the pharmacist can easily interact with the individual, such as near the prescription counter.

In addition to an educational role, the provider may be able to assist an individual in gaining access to other needed medical and social supportive services. In cases of suspected domestic violence or sexual abuse, pharmacists should act on their role as mandatory reporters. A private area for education and counseling is important if adequate discussion is to take place. Special efforts should be made to offer contraceptive information and services to adolescents. Providers who are uncomfortable discussing reproductive health in a nonjudgmental manner with young people should refer adolescents to a clinic that specializes in services to young people. Adolescents need clear, accurate information on all aspects of reproductive health. The provider should keep in mind that misconceptions about STI and pregnancy risk and proper contraceptive use are common, especially among adolescents; therefore, adequate education is very important. FAB methods are recommended for couples in a stable relationship. These methods, especially the symptothermal and cervical mucus methods, require extensive training and support from health care professionals who have experience with FAB methods. In addition to stocking spermicidal products, BBT thermometers, and monitoring charts, the pharmacist may serve as a referral for individuals who want to use these methods of family planning. A pharmacist with the proper training might consider counseling patients on FAB methods as a unique practice possibility.

### Evaluation of Patient Outcomes for Prevention of Pregnancy and STIs

Many sexually active persons are at risk of unintended pregnancy or STIs. The most important factor affecting the ability of a contraceptive to prevent pregnancy and STIs is correct and consistent use with each sexual encounter. Although any of the methods can be used for pregnancy prevention, male condoms (except for lamb cecum) and the female condom are the preferred methods for prevention of STIs. Individuals who experience an adverse effect after use of a nonprescription contraceptive should switch to an alternative brand or agent. If the symptoms do not resolve or if they recur with the use of other agents, the individuals should seek medical attention. A sexually active woman who misses a menstrual period should be encouraged to perform a home pregnancy test or seek medical attention. Symptoms of an STI in a sexually active individual require medical referral ([Table 10-1](#)).

### Key Points for Prevention of Pregnancy and STIs

- No method of contraception except abstinence is completely effective at preventing unintended pregnancy and STIs.
- The HPV vaccine is an effective method of preventing HPV-related consequences, including genital warts and cervical, vaginal, vulvar, penile, and anal cancers.
- Selection of a contraceptive product or method must be based on individual risk of undesired outcomes (pregnancy and STI) and efficacy, safety, and acceptability.
- Efficacy of nonprescription contraceptives is significantly increased by correct and consistent use of the product/method with each sexual encounter (Tables 10-5 through 10-9).
- Male condoms (latex) and female condoms are the preferred contraceptive products for individuals at risk for STIs. Nonlatex condoms other than lamb cecum may be used in persons with latex hypersensitivity for STI prevention.
- Spermicides decrease risk of unintended pregnancy but may increase risk of STIs.

- Vaginal spermicides are available in different dosage forms to improve patient acceptability.
- EC is an effective method of postcoital contraception that can decrease risk of unintended pregnancy, but the risk of STIs is not decreased. EC should not be used as routine contraception.
- FAB methods are an inexpensive, modestly effective method of contraception that can be used by couples in a mutually monogamous relationship.

## Handbook of Nonprescription Drugs &gt; Chapter 11. Colds and Allergy

**Update: Flonase Allergy Relief (fluticasone propionate) OTC Granted Market Exclusivity for Ocular Indication until 2017**

Content Update for [Chapter 11](#), "Colds and Allergy." Posted April 1, 2015.

In November 2014, the Food and Drug Administration (FDA) granted GlaxoSmithKline (GSK) limited market exclusivity through July 23, 2017 for Flonase (fluticasone propionate) Allergy Relief.<sup>1</sup> Originally approved in July 2014, Flonase Allergy Relief is an over-the-counter (OTC) intranasal glucocorticoid used to treat nasal and ocular symptoms caused by allergic rhinitis.<sup>2</sup> Flonase is approved for OTC use to treat allergic rhinitis in children  $\geq 4$  years of age and adults.<sup>2</sup> The exclusivity is based on data about Flonase's effectiveness in treating ocular symptoms and allows GSK to promote its product as the first and only product that can treat nasal and ocular symptoms.<sup>1,3</sup> The Hatch-Waxman Amendments to the Food, Drug and Cosmetic Act allow FDA to grant manufacturers exclusivity.<sup>4</sup> After a drug is approved by FDA Center for Drug Evaluation and Research officials, a separate FDA exclusivity board considers the evidence supporting exclusivity and issues a decision whether to grant exclusivity.<sup>4</sup> One way the board can grant exclusivity is by allowing a "label carve-out," as occurred in this situation.<sup>4</sup> Through this label carve-out, FDA grants exclusivity for treating ocular symptoms to GSK but allows generic manufacturers to launch and promote fluticasone products over the next 3 years.<sup>1,4,5</sup> However, generic labeling cannot make the same claims about treating ocular symptoms.<sup>1,4</sup> Once the exclusivity period ends, generic manufacturers can submit a request to FDA to update their labels to match that of the brand-name product label and to include the ocular indication.<sup>1,4</sup>

**Colds and Allergy: Introduction**

Colds and allergic rhinitis are two of the most common conditions for which patients access the health care system. This chapter reviews the role of the plethora of nonprescription products that patients may use to self-treat symptoms associated with those two disorders.

**Colds**

A cold, also known as the common cold, is a viral infection of the upper respiratory tract. According to some estimates, one billion cases of colds occur annually, making this illness one of the top five diagnosed in the United States.<sup>1</sup> Children usually have 6-10 colds per year.<sup>1</sup> Adults younger than 60 years typically have 2-4 colds per year, whereas adults older than 60 years usually have 1 cold per year.<sup>1</sup> Colds may occur at any time, but in the United States, the cold season occurs from late August through early April.<sup>1</sup> Colds are the leading cause of work and school absenteeism. Colds are usually self-limiting; however, because symptoms are bothersome, patients frequently self-medicate and spend an estimated \$7 billion annually on nonprescription cold and cough products.<sup>2</sup>

**Pathophysiology of Colds**

Colds are limited to the upper respiratory tract and primarily affect the following respiratory structures: pharynx, nasopharynx, nose, cavernous sinusoids, and paranasal sinuses. The respiratory tract's intricate host-defense system usually protects the body from infectious and foreign particles. The respiratory tract, especially the nose, is well perfused and innervated. The nose contains sensory, cholinergic, and sympathetic nerves. When stimulated by an infectious (i.e., a cold) or allergic (i.e., allergic rhinitis) process, those nerves play a role in the resulting symptoms and are also targets for some nonprescription therapies. Stimulation of sensory fibers by mechanical and thermal stimuli or by mediators such as histamine and bradykinin results in sneezing. Cholinergic and sympathetic nerves are involved in congestion because they innervate glands and arteries that supply the glands. Cholinergic stimulation dilates arterial blood flow, whereas sympathetic stimulation constricts arterial blood flow. The sensory, cholinergic, and sympathetic nerves also respond to a variety of neuropeptide neurotransmitters.

More than 200 viruses cause colds. The majority of colds in children and adults are caused by rhinoviruses.<sup>1</sup> Other viruses known to cause colds include coronaviruses, parainfluenza, adenoviruses, echoviruses, respiratory syncytial viruses, and coxsackieviruses. Viral and bacterial coinfection (usually with group A beta-hemolytic streptococci) occurs but is rare. Rhinoviruses bind to intercellular adhesion molecule-1 receptors on respiratory epithelial cells in the nose and nasopharynx.<sup>3</sup> Once inside the epithelial cells, the virus replicates and infection spreads to other cells.<sup>3</sup> Peak viral concentrations occur 2-4 days after initial inoculation, and viruses are present in the nasopharynx for 16-18 days.<sup>3</sup> Infected cells release chemokine "distress signals," and cytokines then activate inflammatory mediators and neurogenic reflexes. These activation processes result in recruitment of additional inflammatory mediators, vasodilatation, transudation of plasma, glandular secretion, and stimulation of pain nerve fibers and sneeze and cough reflexes. Inflammatory mediators and parasympathetic nervous system reflex mechanisms cause hypersecretion of watery nasal fluid. Viral infection ends once enough neutralizing antibody (secretory immunoglobulin A [IgA] or serum IgG) leaks into the mucosa to end viral replication.

The most efficient mode of viral transmission is self-inoculation of the nasal mucosa or conjunctiva after contact with viral-laden secretions on animate (e.g., hands) or inanimate (e.g., doorknobs and telephones) objects. Aerosol transmission is also common. Increased susceptibility to colds has been linked to higher exposure rates (e.g., increased population density in classrooms or day care centers); allergic disorders affecting the nose or pharynx; less diverse social networks; and a weakened immune system due to smoking, a sedentary lifestyle, chronic (i.e.,  $\geq 1$  month) psychological stress, or sleep deprivation (e.g., poor sleep quality or  $< 7$  hours of sleep per night).<sup>1,4,5</sup> There is conflicting information about increased susceptibility due to cold environments, sudden chilling, or exposure to central heating (i.e., low humidity).<sup>1,6</sup> Walking outside barefoot, teething, or suffering from enlarged tonsils or adenoids has not been shown to increase susceptibility to viral upper respiratory infections.<sup>1</sup>

**Clinical Presentation of Colds**

A predictable sequence of symptoms appears 1-3 days after infection.<sup>7</sup> Sore throat is the first symptom to appear, followed by nasal symptoms, which dominate 2-3 days later. Cough, although an infrequent symptom ( $< 20\%$ ), appears by day 4 or 5. Physical assessment of a patient with a cold may yield the following findings: slightly red pharynx with evidence of postnasal drainage, nasal obstruction, and mildly to moderately tender sinuses on palpation. During the first 2 days of a cold, patients may report clear, thin, and/or watery nasal secretions. As the cold progresses, the secretions become thicker and the color may change to yellow or green. When the cold begins to resolve, the secretions again become clear, thin, and/or watery. Patients may have low-grade fever, but colds are rarely associated with a fever above 100°F (37.8°C). Rhinovirus cold symptoms persist for about 7-14 days.<sup>7</sup> Signs and symptoms of a cold may be confused with symptoms of influenza and other respiratory illnesses ([Table 11-1](#)).

Most people do not have complications from colds. However, complications of colds may be severe and, rarely, life-threatening. Complications include sinusitis, middle ear infections, bronchitis, pneumonia, and exacerbations of asthma or chronic obstructive pulmonary disease.

**TABLE 11-1 Differentiation of Colds and Other Respiratory Disorders**

Illness	Signs and Symptoms
Allergic rhinitis	Watery eyes; itchy nose, eyes, or throat; repetitive sneezing; nasal congestion; watery rhinorrhea; red, irritated eyes with conjunctival injection
Asthma	Cough, dyspnea, wheezing
Bacterial throat	Sore throat (moderate-severe pain), fever, exudate, tender anterior cervical adenopathy

infection	
Colds	Sore throat (mild-moderate pain), nasal congestion, rhinorrhea, sneezing common; low-grade fever, chills, headache, malaise, myalgia, and cough possible
Croup	Fever, rhinitis, and pharyngitis initially, progressing to cough (may be "barking" cough), stridor, and dyspnea
Influenza	Myalgia, arthralgia, fever $\geq 100^{\circ}\text{F}$ - $102^{\circ}\text{F}$ ( $37.8^{\circ}\text{C}$ - $38.9^{\circ}\text{C}$ ), sore throat, nonproductive cough, moderate-severe fatigue
Otitis media	Ear popping, ear fullness, otalgia, otorrhea, hearing loss, dizziness
Pneumonia or bronchitis	Chest tightness, wheezing, dyspnea, productive cough, changes in sputum color, persistent fever
Sinusitis	Tenderness over the sinuses, facial pain aggravated by Valsalva's maneuver or postural changes, fever $\geq 101.5^{\circ}\text{F}$ ( $38.6^{\circ}\text{C}$ ), tooth pain, halitosis, upper respiratory tract symptoms for $\geq 7$ days with poor response to decongestants
West Nile virus infection	Fever, headache, fatigue, rash, swollen lymph glands, and eye pain initially, possibly progressing to GI distress, CNS changes, seizures, or paralysis
Whooping cough	Initial catarrhal phase (rhinorrhea, mild cough, sneezing) of 1-2 weeks, followed by 1-6 weeks of paroxysmal coughing

Key: CNS = Central nervous system; GI = gastrointestinal.

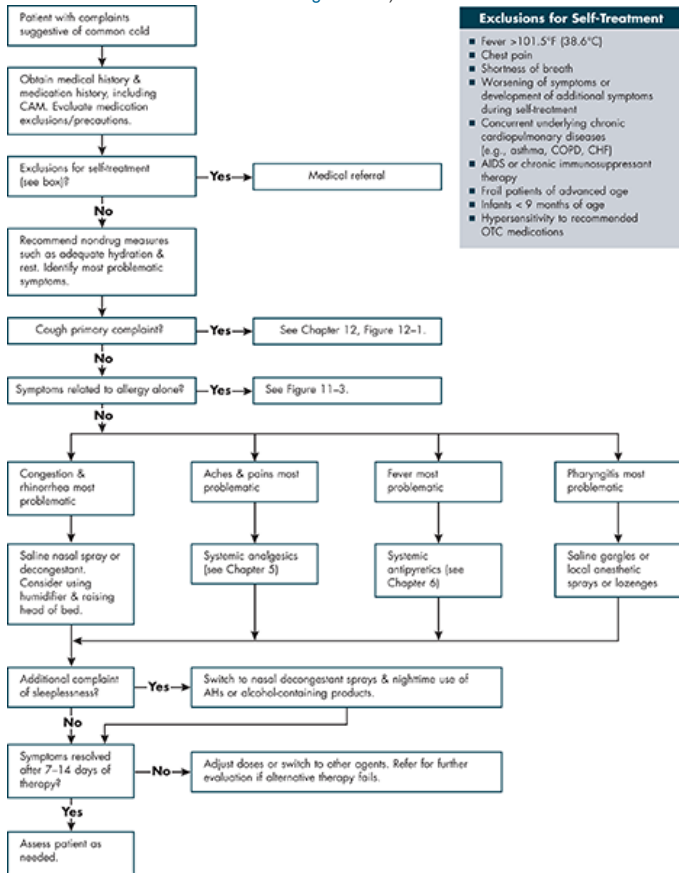

**Treatment of Colds**

Treatment Goals

Because there is no known cure for colds, the goal of therapy is to reduce bothersome symptoms and prevent transmission of cold viruses to others.

General Treatment Approach

Antibiotics are ineffective against viral infections and the mainstay of treatment is nonpharmacologic therapy. If a patient desires to self-treat, a stepwise approach using single-entity products targeting specific symptoms is preferred over the use of combination products (Figure 11-1) because symptoms appear, peak, and resolve at different times.<sup>7</sup> Patient education regarding the administration of intranasal drugs (Table 11-2) and ocular drugs (see Chapter 27) is important. Not all patients should self-treat colds (see the exclusions for self-treatment listed in Figure 11-1).

Self-care of the common cold. Key: AH = Antihistamine; AIDS = acquired immunodeficiency syndrome; CAM = complementary and alternative medicine; CHF = congestive heart failure; COPD = chronic obstructive pulmonary disorder; OTC = over-the-counter. (Source: Adapted from Reference 7.)

**TABLE 11-2 Administration Guidelines for Nasal Dosage Formulations**

<i>General Instructions</i>
• Clear nasal passages before administering the product.
• Wash your hands before and after use.
• Gently depress the other side of the nose with finger to close off the nostril not receiving the medication.
• Aim tip of product away from nasal septum to avoid accidental damage to the septum.
• Breathe through mouth and wait a few minutes after using the medication before blowing the nose.

**Nasal Sprays**

- Gently insert the bottle tip into one nostril, as shown in drawing A.
- Keep head upright. Sniff deeply while squeezing the bottle. Repeat with other nostril.

**A**

Copyright © American Pharmacists Association  
All rights reserved. Any use is subject to the Terms of Use.

**Nasal Inhalers**

- Warm the inhaler in hand just before use.
- Gently insert the inhaler tip into one nostril, as shown in drawing C. Sniff deeply while inhaling.
- Wipe the inhaler after each use. Discard after 2-3 months even if the inhaler still smells medicinal.

**C**

Copyright © American Pharmacists Association  
All rights reserved. Any use is subject to the Terms of Use.

**Pump Nasal Sprays**

- Prime the pump before using it the first time. Hold the bottle with the nozzle placed between the first two fingers and the thumb placed on the bottom of the bottle.
- Tilt the head forward.
- Gently insert the nozzle tip into one nostril (see drawing B). Sniff deeply while depressing the pump once.
- Repeat with other nostril.

**Nasal Drops**

- Lie on bed with head tilted back and over the side of the bed, as shown in drawing D.
- Squeeze the bulb to withdraw medication from the bottle.
- Place the recommended number of drops into one nostril. Gently tilt head from side to side.
- Repeat with other nostril. Lie on bed for a couple of minutes after placing drops in the nose.
- Do not rinse the dropper.

*Note:* Do not share the drug with anyone. Discard solutions if discolored or if contamination is suspected. Remove caps before use and replace tightly after each use. Do not use expired products.

#### Nonpharmacologic Therapy

Although evidence of efficacy is lacking, popular therapies include increased fluid intake, adequate rest, a nutritious diet as tolerated, and increased humidification with steamy showers, vaporizers, or humidifiers. Vaporizers superheat water to produce steam and can accommodate medications such as Vicks Vapo Steam (camphor 6.2%). In contrast, humidifiers use fans or ultrasonic technology to produce a cool mist and cannot accommodate additives. Saline nasal sprays or drops moisten irritated mucosal membranes and loosen encrusted mucus; salt gargles may ease sore throats. Food products such as tea with lemon and honey, chicken soup, and hot broths are soothing. Limited evidence suggests that a number of substances in chicken soup could have anti-inflammatory activity.<sup>8</sup> Milk products should not be withheld given the lack of evidence that milk increases cough or congestion. Medical devices, such as Breathe Right nasal strips, are marketed for temporary relief from nasal congestion and stuffiness resulting from colds and allergies. Those devices lift the nares open, thus enlarging the anterior nasal passages. Aromatic oil (camphor, menthol, and eucalyptus) products such as Theraflu Vapor Patch (ages ≥ 12 years) and Vicks VapoRub (ages ≥ 2 years) ease nasal congestion and improve sleep by producing a soothing sensation.<sup>9</sup> Children should be supervised closely when these products are used because aromatic oils can irritate the eyes and skin and ingesting large quantities can be toxic.

Non-drug therapy for infants includes upright positioning to enhance nasal drainage. Because children typically cannot blow their own noses until about 4 years of age, carefully clearing the nasal passages with a bulb syringe may be necessary if accumulation of mucus interferes with sleeping or eating. To use the syringe and avoid harm to the child, the caregiver should squeeze the large end of the bulb *before* inserting it, continue to squeeze the bulb while gently inserting the tip into the infant's nose, and then slowly release the squeezing pressure to draw out fluid. After the pressure is completely released, the syringe is removed from the infant's nose and the fluid expelled from the syringe by again compressing the bulb.

Proper hand hygiene reduces the transmission of cold viruses. The Centers for Disease Control and Prevention (CDC) encourages frequent hand cleansing with soap or soap substitutes (e.g., hand sanitizers).<sup>1</sup> Not all hand sanitizers are effective at eradicating rhinoviruses from hands. Alcohol-based products containing isopropanol or ethanol (60%-80% concentration) are preferred but are short-acting and require frequent reapplication.<sup>10</sup> Chlorhexidine, povidone-iodine, and quaternary ammonium compounds are also effective alone or in combination with alcohol-based products.<sup>10</sup> Alcohol-based nasal sanitizers (e.g., Nozin) are also available but lack evidence of efficacy and safety. Use of antiviral disinfectants such as Lysol (kills >99% of rhinoviruses after 1 minute) and antiviral tissues such as Kleenex Anti-Viral (tissue layer containing citric acid and sodium lauryl sulphate) may also help prevent transmission to others.

#### Pharmacologic Therapy

##### Decongestants

Decongestants specifically treat sinus and nasal congestion. Decongestants are adrenergic agonists (sympathomimetics). Stimulation of alpha-adrenergic receptors constricts blood vessels, thereby decreasing sinusoid vessel engorgement and mucosal edema. There are three types of decongestants. Direct-acting decongestants (e.g., phenylephrine, oxymetazoline, and tetrahydrozoline) bind directly to adrenergic receptors. Indirect-acting decongestants (e.g., ephedrine) displace norepinephrine from storage vesicles in prejunctional nerve terminals and tachyphylaxis can develop as stored neurotransmitter is depleted. Mixed decongestants (e.g., pseudoephedrine) have both direct and indirect activity.

Systemic nonprescription decongestants include pseudoephedrine and phenylephrine. Intranasal nonprescription decongestants include the short-acting decongestants ephedrine, levmetamfetamine (l-desoxyephedrine), naphazoline, phenylephrine, and propylhexedrine, and the long-acting decongestants xylometazoline (8-10 hours) and oxymetazoline (12 hours). Ophthalmic nonprescription decongestants are also available (see [Chapter 27](#)).

Systemic decongestants are rapidly metabolized by monoamine oxidase (MAO) and catechol-O-methyltransferase in the gastrointestinal (GI) mucosa, liver, and other tissues. Pseudoephedrine is well absorbed after oral administration; phenylephrine has a low oral bioavailability (about 38%). Both pseudoephedrine and phenylephrine have short half-lives (pseudoephedrine, 6 hours; phenylephrine, 2.5 hours), and peak concentrations for both drugs occur at 0.5-2 hours after oral administration.

Decongestants are indicated for temporary relief of nasal and eustachian tube congestion and for cough associated with postnasal drip. Nonprescription decongestants are not approved by the Food and Drug Administration (FDA) to self-treat nasal congestion associated with sinusitis.

FDA-approved dosages for decongestants are listed in [Tables 11-3<sup>11,12</sup>](#) and [11-4<sup>11</sup>](#). Nonprescription decongestants are marketed in a variety of dosage formulations, and many combination products are available ([Table 11-5](#)).

**TABLE 11-3 Dosage Guidelines for Nonprescription Systemic Nasal Decongestants**

*Dosage (maximum daily dosage)*

Drug	Adults/Children ≥12 Years	Children 6 to <12 Years	Children 2 to <6 Years <sup>a</sup>
Phenylephrine HCl	10 mg every 4 hours (60 mg)	5 mg every 4 hours (30 mg)	2.5 mg every 4 hours (15 mg)
Phenylephrine bitartrate	15.6 mg every 4 hours (62.4 mg)	7.8 mg every 4 hours (31.2 mg)	Not recommended for children < 6 years except under advice of PCP
Pseudoephedrine	60 mg every 4-6 hours (240 mg)	30 mg every 4-6 hours (120 mg)	15 mg every 4-6 hours (60 mg)

<sup>a</sup> FDA has advised that cough and cold medications not be used in children under 2 years of age.<sup>12</sup> Manufacturers have voluntarily updated cough and cold product labels to state "do not use" in children under 4 years of age.<sup>26</sup> These actions have not changed the official monograph for cold, cough, allergy, bronchodilator, and antiasthmatic drug products.<sup>12</sup>

Source: Reference 11.

Key: PCP = Primary care provider.

**TABLE 11-4 Dosage Guidelines for Nonprescription Topical Nasal Decongestants**

Drug	Concentration (%)	Adults/Children ≥12 Years	Children 6 to <12 Years	Children 2 to <6 Years <sup>a</sup>
<b>Sprays/Drops</b>				
Ephedrine <sup>b</sup>	0.5	2-3 drops/sprays in each nostril not more often than every 4 hours	1-2 drops/sprays in each nostril not more often than every 4 hours	Not recommended for children < 6 years except under advice of PCP
Naphazoline	0.05	1-2 drops/sprays in each nostril not more often than every 6 hours	Not recommended for children < 12 years except under advice of PCP	Not recommended for children < 6 years except under advice of PCP
	0.025	—	1-2 drops/sprays in each nostril not more often than every 6 hours	Not recommended for children < 6 years except under advice of PCP
Oxymetazoline	0.05	2-3 drops/sprays in each nostril not more often than every 10-12 hours (max: 2 doses/24 hours)	2-3 drops/sprays in each nostril not more often than every 10-12 hours (max: 2 doses/24 hours)	Not recommended for children < 6 years except under advice of PCP
	0.025	—	—	2-3 drops/sprays in each nostril not more often than every 10-12 hours (max: 2 doses/24 hours)
Phenylephrine	1.0	2-3 drops/sprays in each nostril not more often than every 4 hours	Not recommended for children < 12 years except under advice of PCP	Not recommended for children < 6 years except under advice of PCP
	0.5	2-3 drops/sprays in each nostril not more often than every 4 hours	Not recommended for children < 12 years except under advice of PCP	Not recommended for children < 6 years except under advice of PCP
	0.25	2-3 drops/sprays in each nostril not more often than every 4 hours	2-3 drops/sprays in each nostril not more often than every 4 hours	Not recommended for children < 6 years except under advice of PCP
	0.125	—	—	2-3 drops/sprays in each nostril not more often than every 4 hours
Xylometazoline <sup>b</sup>	0.1	2-3 drops/sprays in each nostril not more often than every 8-10 hours	Not recommended for children < 12 years except under advice of PCP	Not recommended for children < 6 years except under advice of PCP
	0.05	—	2-3 drops/sprays in each nostril not more often than every 8-10 hours	2-3 drops/sprays in each nostril not more often than every 8-10 hours (max: 3 doses/24 hours)

Key: Max = Maximum; PCP = primary care provider.

<sup>a</sup> No recommended dosages exist for children < 2 years, except under the advice and supervision of a PCP.

<sup>b</sup> Products approved by FDA but not currently marketed in the United States

Source: Reference 11.

Adhering to FDA-approved doses of decongestant products is very important, given that acute overdose can be life-threatening, especially in children. Systemic decongestant overdoses cause excessive central nervous system (CNS) stimulation, paradoxical CNS depression, cardiovascular collapse, shock, and coma. Treatment of decongestant overdoses is supportive.

Adverse effects associated with decongestants include cardiovascular stimulation (e.g., elevated blood pressure, tachycardia, palpitation, or arrhythmias) and CNS stimulation (e.g., restlessness, insomnia, anxiety, tremors, fear, or hallucinations). Children and older adults are more likely than other age groups to experience adverse effects. Adverse effects are more common with systemic decongestants because topical decongestants are minimally absorbed. However, accidental ingestion of nasal or ocular decongestants can cause serious adverse effects such as nausea, vomiting, drooling, hypotension, hyperthermia, lethargy, sedation, and coma. Adverse effects specifically related to topical decongestants include propellant- or vehicle-associated effects (e.g., burning, stinging, or local dryness) and trauma from the tip of the administration device. Rhinitis medicamentosa (RM; i.e., rebound congestion) has been associated with topical decongestants. The exact cause is unknown, but short-acting products, preservative agents (e.g., benzalkonium chloride), and long duration of therapy have been suspected to contribute to the problem.<sup>13</sup> Currently, therapy of 3-5 days is the accepted duration to avoid RM. However, controversy exists and some studies show that durations of 10 days to 8 weeks appear to be safe and do not cause RM.<sup>13</sup> Further investigation is needed to determine the optimal duration of treatment. Treatment of RM consists of slowly withdrawing the topical decongestant (one nostril at a time); replacing the decongestant with topical normal saline, which soothes the irritated nasal mucosa; and, if needed, using topical corticosteroids and systemic decongestants. Two to 6 weeks of withdrawal measures may be necessary before mucous membranes return to normal. A nonprescription kit, RhinoStat, has been advertised to assist health care providers and patients with management of RM. The product creates a patient-specific mixture of the patient's topical decongestant product and a diluent; however, the kit is not FDA approved. Decongestants interact with numerous drugs, as summarized in Table 11-6. Decongestants are contraindicated in patients receiving concomitant MAO inhibitors (MAOIs). Decongestants may exacerbate diseases sensitive to adrenergic stimulation, such as hypertension, coronary heart disease, ischemic heart disease, diabetes mellitus, hyperthyroidism, elevated intraocular pressure, and prostatic hypertrophy. Patients with hypertension should use decongestants only with medical advice. No clear evidence exists that any one agent is safer than other agents in patients with hypertension. Products specifically marketed for patients with hypertension (e.g., Coricidin HBP) do not contain decongestants. Those products usually contain a combination of ingredients that may or may not be appropriate depending on a patient's symptoms. Health care providers should be aware of patients wishing to purchase large quantities of pseudoephedrine that may be used illegally to produce methamphetamine. In 2005, passage of the Combat Methamphetamine Epidemic Act changed the classification of pseudoephedrine to "scheduled listed chemical products."<sup>14</sup> That change in classification allowed limits to be placed on sales. All pseudoephedrine products must now be kept in secure areas (e.g., behind a pharmacy counter or in a locked cabinet), and purchases are limited to 3.6 grams per day and 9 grams per month per patient.<sup>14</sup> The following information from each sale must be entered into a written or electronic logbook: product name, quantity sold, patient's name and address, and time and date of sale.<sup>14</sup> Patients must show valid identification to purchase pseudoephedrine and then sign the logbook.

Some states and corporations have enacted stricter guidelines regarding the sale of pseudoephedrine.

**TABLE 11-5 Selected Nonprescription Products for Nasal Decongestion**

<i>Trade Name</i>	<i>Primary Ingredients</i>
<b>Topical Decongestants</b>	
Afrin Original Nasal Spray	Oxymetazoline HCl 0.05%
Vicks Sinex Nasal Spray	Oxymetazoline HCl 0.05%
Zicam Extreme Congestion Relief Nasal Gel	Oxymetazoline HCl 0.05%
4-Way Fast Acting	Phenylephrine HCl 1%
Neo-Synephrine Regular Strength Nasal Spray	Phenylephrine HCl 0.5%
Little Noses Decongestant Nose Drops	Phenylephrine HCl 0.125%
Otrivin Nasal Spray (Canada)	Xylometazoline 0.1%
<b>Nasal Decongestant Inhalers</b>	
Benzedrex Inhaler	Propylhexedrine 250 mg
Vicks Vapo Inhaler	Levmetamfetamine (l-desoxyephedrine) 50 mg/inhaler
<b>Systemic Decongestants</b>	
Sudafed PE Congestion	Phenylephrine HCl 10 mg
Sudafed 24 Hour Long Acting	Pseudoephedrine HCl 240 mg
Sudafed 12 Hour	Pseudoephedrine HCl 120 mg
Nexafed <sup>a</sup>	Pseudoephedrine HCl 30 mg
Zephrex-D <sup>b</sup>	Pseudoephedrine HCl 30 mg
<b>Combination Products</b>	
Sudafed PE Pressure + Pain	Phenylephrine HCl 5 mg; acetaminophen 325 mg
Alka-Seltzer Plus Sinus	Phenylephrine bitartrate 7.8 mg; aspirin 325 mg
Vicks Dayquil Liquicaps	Phenylephrine HCl 5 mg; acetaminophen 325 mg; dextromethorphan hydrobromide 10 mg
Tylenol Cold Multi-Symptom Nighttime Cool Burst Liquid	Phenylephrine HCl 5 mg/15 mL; acetaminophen 325 mg/15 mL; dextromethorphan hydrobromide 10 mg/15 mL; doxylamine succinate 6.25 mg/15 mL
Triaminic Chest & Nasal Congestion Liquid	Phenylephrine HCl 2.5 mg/5 mL; guaifenesin 50 mg/5 mL
Aleve-D Sinus & Cold	Pseudoephedrine HCl 120 mg; naproxen sodium 220 mg
Mucinex D	Pseudoephedrine HCl 60 mg; guaifenesin 600 mg
<b>Other Products</b>	
Ocean Premium Saline Nasal Spray	Sodium chloride 0.65%
Vicks VapoRub	Camphor (4.8%); eucalyptus (1.2%); menthol (2.6%)

<sup>a</sup> Meth-detering technology (Impede).

<sup>b</sup> Meth-detering technology (Tarex).

#### Antihistamines

Reviews have shown that monotherapy with nonprescription antihistamines is not effective in reducing rhinorrhea and sneezing due to colds.<sup>15,16</sup> However, a combination of first-generation (sedating) antihistamines and decongestants showed some benefit in adults, but the significance of the data is questionable.<sup>15,16</sup> Apart from questions of efficacy, an important issue is whether potential benefits of sedating antihistamines outweigh known risks associated with these drugs. (See the discussion of antihistamines in the Allergic Rhinitis section.)

**TABLE 11-6 Decongestant and Antihistamine Drug Interactions**

<i>Drug/Drug Class</i>	<i>Effect (drug-specific data)</i>
<b>Decongestants</b>	
Antacids	Decreased elimination (pseudoephedrine)
Furazolidone; linezolid; MAOIs (e.g., phenelzine, selegiline); procarbazine	Severe hypertension; headache; hyperpyrexia
TCAs (amitriptyline, nortriptyline, imipramine)	Increased blood pressure (direct-acting decongestants); decreased decongestant activity (indirect-acting decongestants)
<b>Antihistamines</b>	
Amiodarone	Increased risk of QT interval prolongation (loratadine)
Antacids (aluminum and magnesium salts); rifampin	Decreased efficacy (fexofenadine)
CNS depressants (alcohol, sedatives)	Increased sedation (sedating antihistamines; cetirizine)
Cholinesterase inhibitors (e.g., donepezil, rivastigmine)	Worsened symptoms of Alzheimer's disease (sedating antihistamines)
Erythromycin; ketoconazole	Increased fexofenadine plasma concentration
Phenytoin	Decreased phenytoin elimination (chlorpheniramine)

Key: CNS = Central nervous system; MAOI = monoamine oxidase inhibitor; TCA = tricyclic antidepressant.

### Local Anesthetics

A variety of products containing local anesthetics (e.g., benzocaine or dyclonine hydrochloride) is available for the temporary relief of sore throats (Table 11-7). Local anesthetic products may be used every 2-4 hours. Health care providers should counsel patients with a history of allergic reactions to anesthetics to avoid products containing benzocaine. Benzocaine has also been associated with methemoglobinemia, especially in children younger than 2 years, and should be avoided in this age group. Some products contain local antiseptics (e.g., cetylpyridinium chloride or hexylresorcinol) and/or menthol or camphor. Local antiseptics are not effective for viral infections. Emerging evidence suggests that menthol and camphor may provide pain relief via stimulation of the TRPM8 or "menthol" receptor.<sup>17</sup>

**TABLE 11-7 Selected Nonprescription Products for Sore Throat**

Trade Name	Primary Ingredients
<b>Lozenges</b>	
Cepacol Sore Throat Sugar Free	Benzocaine 15 mg
Chloraseptic Sore Throat	Benzocaine 6 mg; menthol 10 mg
Halls Fruit Breezers	Pectin 7 mg
Sucrets Classic	Dyclonine HCl 2 mg
Vicks VapoDrops	Menthol 1.7 mg (cherry) Menthol 3.3 mg (menthol)
<b>Throat Sprays</b>	
Cepacol Ultra Sore Throat Spray	Benzocaine 5%; glycerin 33%
Chloraseptic Sore Throat	Phenol 1.4%
<b>Alternative Formulations</b>	
Chloraseptic Sore Throat Lollipops <sup>a</sup>	Benzocaine 6 mg

<sup>a</sup> Indicated for children ≥ 3 years of age.

### Systemic Analgesics

Systemic analgesics (e.g., aspirin, acetaminophen, ibuprofen, or naproxen) are effective for aches or fever sometimes associated with colds. Concerns that use of aspirin and acetaminophen may increase viral shedding and prolong illness have not been proved.<sup>18</sup> Aspirin-containing products should not be used in children with viral illnesses because of the risk of Reye's syndrome. (See Chapter 5 for a complete discussion of those products, including the manufacturer's voluntary reduction of maximum daily dosages of Tylenol products sold in the United States [see section Acetaminophen and Table 5-3] and developments in liquid infant acetaminophen products [see section Patient Factors].)

### Antitussives and Protussives (Expectorants)

When present, cough associated with colds is usually nonproductive. The use of antitussives (codeine or dextromethorphan) has questionable efficacy in colds and is not recommended.<sup>19</sup> Guaifenesin, an expectorant, has not been proved effective in natural colds.<sup>20</sup> (See Chapter 12 for a complete discussion of those products).

### Combination Products

Decongestants and antihistamines are marketed in many combinations, including combinations with analgesics, expectorants, and antitussives. Products are also marketed for daytime or nighttime use. Products for nighttime use usually contain a sedating antihistamine, whereas daytime products do not. Combination products are convenient, but the convenience must be weighed against the risks of taking unnecessary drugs.

### Pharmacotherapeutic Comparison

As stated earlier, evidence does not support the use of antihistamines, antitussives, and expectorants for treatment of symptoms related to colds. Local anesthetics and systemic analgesics have good evidence for treatment of pain related to sore throat or fever related to colds.

Topical decongestants are convenient dosage forms and are effective in relieving nasal congestion; however, their use is limited to 3-5 days owing to concerns about RM. The major differences in topical decongestants are duration of action, dosage formulation (e.g., mist versus spray versus drops), moisture content, and preservative content. Although many manufacturers have reformulated products with phenylephrine as a response to pseudoephedrine regulations, controversy exists with regard to comparison of the safety and efficacy of the systemic decongestants. Clear evidence that oral phenylephrine is safer than pseudoephedrine has yet to be presented.<sup>21,22</sup> Strong evidence supports the efficacy of oral dosage forms of pseudoephedrine, whereas efficacy of the current FDA-approved dose of phenylephrine has been highly debated.<sup>21,23</sup>

### Product Selection Guidelines

#### Special Populations

Drug use during pregnancy and lactation is a balance between risk and benefit. Because most colds are self-limiting with bothersome rather than life-threatening symptoms, many health care providers recommend nondrug therapy. When drugs are considered, those with a long record of safety in animals and humans are preferred. To minimize possible adverse effects on the fetus or newborn, pregnant or lactating women should be advised to avoid products labeled as "extra strength," "maximum strength," or "long-acting," as well as combination products. Systemic decongestants should be avoided as human data suggest risk based on theoretically decreased fetal blood flow.<sup>24,25</sup> Also, pseudoephedrine has been linked to abdominal wall defects (gastroschisis) in newborns.<sup>24,25</sup> There is no clear association between birth defects and the use of intranasal decongestants during pregnancy.<sup>24,25</sup> Oxymetazoline is poorly absorbed after intranasal administration and is the preferred topical decongestant during pregnancy.

The American Academy of Pediatrics has found pseudoephedrine to be compatible with breast-feeding and to be the preferred decongestant for lactating mothers.<sup>25</sup> No human data are available for intranasal phenylephrine and oxymetazoline, so they are considered "probably compatible" in lactating mothers.<sup>25</sup> Because decongestants may decrease milk production, lactating mothers should monitor their milk production and drink extra fluids as needed. Dextromethorphan, guaifenesin, benzocaine, camphor (topical), and menthol (topical) have low risks of birth defects and have been found to be compatible with breast-feeding.<sup>25</sup>

Using nonprescription cold products in children is controversial owing to the lack of clinical evidence of safety and efficacy in this age group. Currently, FDA does not recommend nonprescription cold medications for children younger than 2 years because of the lack of efficacy and risk of misuse or overuse leading to adverse events and death.<sup>12</sup> Manufacturers have voluntarily updated product labeling to include the statement "Do not use in children under four years of age" and added warnings to antihistamine-containing products against their use for sedation purposes.<sup>26</sup> FDA continues to monitor and review the use of nonprescription cold medications in children between the ages of 2 and 11 years.<sup>12</sup> Health care providers should emphasize nondrug measures in children and, if pharmacotherapy is deemed necessary, parents should follow dosing instructions carefully and avoid combination products to avoid overdose. To address the issue of inaccurate dosing, FDA released guidelines in May 2011 for liquid nonprescription drug products that include any type of dispensing device (dropper, cup, syringe, or spoon).<sup>27,28</sup> These products include liquid analgesics, liquid cough and cold products, and lactase replacement drops. The key points of the guidelines are as follows:

- A dosing device should be included with all oral liquid nonprescription products.

- The device should be calibrated to the dose recommended in the product directions.
- The device should be used only with the product in which it is packaged.
- The markings remain visible even when the liquid is in the device.

### Patient Factors

As discussed earlier, it may be difficult to differentiate cold symptoms from some acute and chronic disorders (Table 11-1). If duration of symptoms is longer than 7-14 days or a chronic condition is suspected, patients should not self-treat. Patients with chronic conditions exacerbated by, or those overly sensitive to, adrenergic stimulation should avoid decongestants. Health care providers should educate patients who participate in organized sports that oral decongestants are considered "doping" products and should be used only in accordance with sport regulations.

### Patient Preferences

Lozenges, soft chews, and nasal drug delivery forms may be preferred by patients who have difficulty swallowing or when access to water is not convenient. However, nasal delivery forms may be difficult to use for patients with severe arthritis or coordination problems.

For patients who prefer a nasal delivery form, each form has distinct advantages and disadvantages. Nasal sprays are simple to use, cover a large surface area, are relatively inexpensive, and have a fast onset of action. The disadvantages include imprecise dosage, a tendency for the tip to become clogged with repeated use, and a high risk of contamination from aspiration of nasal mucus into the bottle. Metered pump sprays deliver a more precise dose. Nasal drops are preferred for small children but can be difficult to use, cover a limited surface area, and pass easily into the larynx. There is also a high risk of contamination because of the tendency to touch the dropper to the nose during administration. Nasal inhalers are small and unobtrusive, but they require an unobstructed airway and sufficient airflow to distribute the drug to the nasal mucosa. Nasal inhalers lose efficacy after 2-3 months even when tightly capped because of dissipation of the active ingredient. Nasal polyps, enlarged turbinates, and abnormalities such as septal deviation may reduce the efficacy of topical dosage forms.

### Complementary Therapies

Numerous complementary therapies are marketed for the treatment of colds (Table 11-8; see also Chapter 51).<sup>29-32</sup> Zinc and high-dose vitamin C are popular therapies.

**TABLE 11-8 Selected Complementary Therapies for Colds and Allergies**

Agent	Risks	Effectiveness
<i>Botanical Natural Products (Scientific Name)</i>		
African geranium [umckaloabo, active ingredient in Umcka ColdCare products] ( <i>Pelargonium sidoides</i> )	Allergic reactions or GI disturbances	Some evidence for alleviating symptoms of acute rhinosinusitis associated with colds in adults
Ephedra [ma huang] ( <i>Ephedra sinica</i> )	Tachycardia, hypertension, heart attack, stroke, seizure	Effective decongestant
Goldenseal ( <i>Hydrastis canadensis</i> )	Potentially toxic, especially in patients with glucose-6-dehydrogenase deficiency	Some evidence of anti-inflammatory effects of active ingredient berberine for treatment of pulmonary inflammation

Key: GI = Gastrointestinal.

High local concentrations of zinc ions purportedly block the adhesion of human rhinovirus to the nasal epithelium and are also thought to inhibit viral replication by disrupting viral capsid formation. However, in vitro studies have shown only a modest antiviral effect. Formulations include tablets, capsules, chews, lozenges, syrups, and oral sprays.

Nasal formulations were removed from the market because of anosmia (loss of smell).<sup>33</sup> Oral formulations may be associated with GI adverse effects (e.g., nausea, upset stomach, and bitter taste). Since the 1980s, the effectiveness of zinc has been highly debated. A meta-analysis of 17 trials concluded that oral zinc (lozenges or syrup) was effective in reducing cold symptoms or duration of the cold if started within 24 hours of symptom onset and administered every 2 hours while patient is awake. The study also reported prophylaxis with zinc for at least 5 months reduced the incidence of colds in healthy patients.<sup>34</sup>

The efficacy and safety of high-dose (e.g.,  $\geq 2$  g/day) vitamin C (ascorbic acid) supplementation for prophylaxis and treatment of colds have been debated for more than 70 years. An analysis of 29 trials showed that, although routine use of high-dose vitamin C does not appear to prevent colds in the general population, it did reduce the duration by about 8% in adults and 14% in children.<sup>35</sup> In contrast, high-dose vitamin C prophylaxis was effective in preventing colds in a subgroup of patients subjected to severe physical stress (e.g., marathon runners).<sup>35</sup> Using vitamin C as treatment after the onset of a cold was not effective at reducing severity or duration of symptoms.<sup>35</sup> Regular use of high doses may increase the risk of kidney stones in men.<sup>36</sup> The clinical significance and risk-benefit ratio of these results are debatable. Doses of 4 g/day or greater are associated with diarrhea and other GI symptoms and, therefore, should not be recommended.

Products that claim to strengthen the immune system such as Airborne, Emergen-C Immune+, vitamin D, etc. are available but have not been proved to be effective in preventing colds. Various probiotic products are available and emerging research suggests that they may help support the immune system and prevent colds.<sup>37</sup> (See Chapters 23 and 51 for a complete discussion of those products.)

### Assessment of Colds: A Case-Based Approach

After asking questions about the patient's symptoms, medical history, medication use (current and past), and the efficacy of past self-treatment of colds, the health care provider should conduct a brief physical assessment (Table 11-9). If the assessment and patient's answers do not reveal exclusions for self-treatment, the provider should recommend medications that target the patient's most troublesome symptoms.

**TABLE 11-9 Physical Assessment of Patient Presenting with Cold Symptoms**

1. Observe patient (look and listen for signs of chronic conditions, such as red, watery eyes; wheezing; productive cough; barrel chest; poorly perfused areas; enlarged lymph nodes; rash).
<b>If equipment and privacy allow, conduct the following:</b>
2. Obtain vitals (temperature, respiratory rate, pulse, and blood pressure).
3. Palpate sinuses and neck, and observe any pain/tenderness.
4. Visually examine throat for redness or exudates. If bacterial pharyngitis is suspected, run rapid strep test.
5. Auscultate chest to detect wheezing, crackles, and rapid or irregular heartbeat.

Case 11-1 is an example of assessment of a patient with a cold.

### Case 11-1

Relevant Evaluation Criteria	Scenario/Model Outcome
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	

a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of nasal congestion and fatigue. Patient had sore throat 3 days ago; then congestion started and has progressively worsened.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Congestion is worse in the morning when patient wakes up, then improves during the day. Congestion worsens again at night.
c. description of the patient's efforts to relieve the symptoms	Patient has tried hot showers, warm compresses, and a Neti pot rinse.
d. patient's identity	Toby Lewis
e. age, sex, height, and weight	19 years old, male, 6 ft, 200 lb
f. patient's occupation	College student
g. patient's dietary habits	Patient has a healthy, low-carbohydrate, low-fat diet. Occasionally patient consumes junk food and alcohol on weekends.
h. patient's sleep habits	Erratic because of studying late at night and social engagements
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Type 1 diabetes; Lantus 40 units at bedtime; Humalog 5 units with meals; Men's One A Day multivitamin once a day; creatine-protein shake every morning
j. allergies	None
k. history of other adverse reactions to medications	None
l. other (describe) _____	Patient's temperature currently is 100°F (37.8°C), and blood pressure is 118/78 mm Hg. Patient's fasting blood glucose was 100 mg/dL this morning.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Onset of congestion after sore throat resolution, lack of high fever, indicative of a cold
3. Identify exclusions for self-treatment (Figure 11-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Recommend separate OTC products for each symptom: nasal saline or decongestant (topical or systemic) for congestion. (2) Recommend that patient see his PCP for further evaluation and treatment. (3) Recommend self-care until patient can consult his PCP. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Recommend that patient use a nasal decongestant to relieve his congestion. Recommend oxymetazoline spray 0.05% 2-3 sprays in each nostril every 10-12 hours (max two doses in 24 hours). Do not use for more than 5 days.
6. Describe the recommended therapeutic approach to the patient or caregiver.	There are no exclusions for self-care. Because congestion is the only symptom, monotherapy with a decongestant is indicated.
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Decongestants may raise your blood glucose. Nasal formulations are not absorbed as much as oral formulations and may reduce the risk."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	"Use 2-3 sprays of oxymetazoline in each nostril every 10-12 hours. Nasal congestion should significantly diminish in 10 minutes, and relief should last 10-12 hours after each administration. Nasal congestion will be temporarily relieved but may persist for 7-14 days. Do not use the nasal spray longer than 5 days. Most common adverse effects are nasal stinging or burning, sneezing, dryness. Monitor your blood glucose closely as this medication may raise it. A PCP should be consulted if congestion worsens or if headache or fever develops with treatment or lasts longer than 7-14 days. Store at room temperature with the cap tightly closed."
Solicit follow-up questions from the patient or caregiver.	"Is it OK for me to drink alcohol?"

Answer the patient's or caregiver's questions.	"Alcohol may worsen your congestion, so you should avoid drinking alcohol while you are sick."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Follow up with a phone call in 7 days.

Key: OTC = Over-the-counter; PCP = primary care provider.

### Patient Counseling for Colds

Nondrug measures may be effective in relieving the discomfort of cold symptoms. The provider should explain the appropriate nondrug measures for the patient's particular symptoms. For patients who prefer to use nonprescription medications, the purpose of each medication should be described, and the patient should be counseled to use only medications that target his or her specific symptoms. Patients need an explanation of possible adverse effects, drug interactions, and precautions or warnings. Finally, the provider should explain the signs and symptoms that indicate the disorder is worsening and that medical care should be sought. (See the box Patient Education for Colds.)

### Evaluation of Patient Outcomes for Colds

Given that most colds are self-limiting, symptoms will usually resolve on their own in 7-14 days. For the majority of patients, targeted nonprescription therapy will relieve their cold symptoms. Patients should be monitored for worsening symptoms and progression of complications by measuring their temperature, assessing nasal secretions, assessing respirations for wheezing or shortness of breath, identifying productive cough, and asking about facial or neck pain. If complications are suspected, medical referral is necessary. Referral to a primary care provider (PCP) is also required for patients who meet the exclusions for self-treatment in [Figure 11-1](#) or the warnings listed in the box Patient Education for Colds. Follow-up usually is not necessary for patients with uncomplicated colds, but telephone follow-up in 7-14 days may be deemed appropriate.

The objectives of self-treatment are to (1) reduce symptoms, (2) improve functioning and sense of well-being, and (3) prevent spread of the disease. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

### Nondrug Measures

- To prevent spreading a cold to others, follow these steps:
  - Frequently wash your hands with soap for at least 20 seconds.
  - Use facial tissues to cover your mouth and nose when coughing or sneezing, and then promptly throw the tissues away.
  - Use antiviral products such as Lysol to clean surfaces (e.g., doorknobs or telephones) that you may have touched.
- The following measures may provide relief or speed up recovery from a cold:
  - Getting adequate rest may help you recover more quickly.
  - Drinking fluids and using a humidifier or vaporizer may loosen mucus and promote sinus drainage.
  - Sucking on hard candy, gargling with salt water ( $\frac{1}{2}$  to 1 teaspoon of salt per 8 ounces of warm water), or drinking fruit juices or hot tea with lemon may soothe a sore throat.

### Nonprescription Medications

- Ask a health care provider to help you select medications that target the most bothersome symptoms.

### Sore Throat and Cough

- Sore throat may be treated with anesthetic products and/or systemic pain relievers:
  - Allow lozenges, troches, and orally disintegrating strips to dissolve slowly in the mouth; do not chew or bite these products.
  - Benzocaine and dyclonine may numb the mouth and tongue. If these effects occur, do not eat or drink until they go away.
  - Seek medical attention if any of the following occur after using benzocaine products: pale, gray- or blue-colored skin, lips, and nail beds; headache; lightheadedness; shortness of breath; fatigue; and rapid heart rate.
- Cough related to a runny nose (postnasal drip) may be treated with a sedating antihistamine and decongestant combination.

### Rhinorrhea (Runny Nose) and Sneezing

- See the box Patient Education for Allergic Rhinitis for treatment of rhinorrhea (runny nose) and sneezing.

### Nasal Congestion

- Nasal congestion may be treated with topical or systemic decongestants, which constrict blood vessels in the nose to reduce congestion.
  - Systemic decongestants include pseudoephedrine and phenylephrine. Dosages are listed in [Table 11-3](#).
  - Topical decongestants include ephedrine, naphazoline, oxymetazoline, phenylephrine, and xylometazoline. Dosages are listed in [Table 11-4](#).
- Decongestants have the following adverse effects:
  - The most common adverse effects caused by systemic decongestants are cardiovascular stimulation (e.g., elevated blood pressure, rapid heart rate, palpitations, arrhythmias) and central nervous system stimulation (e.g., restlessness, insomnia, anxiety, tremors, fear, hallucinations).
  - Topical decongestants may cause any of the adverse effects listed for systemic decongestants. However, less of the topical medication gets into the body, so adverse effects are less common.
  - Topical decongestants may irritate the nose, or the bottle tip can injure the nose if used forcefully.
  - Topical decongestants may cause rebound congestion if used longer than 3-5 days.
- Note the following precautions for use of decongestants in persons with other medical conditions:
  - Persons with high blood pressure should use decongestants only with medical advice.
  - Persons with thyroid disorders, heart disease, glaucoma, or an enlarged prostate may experience worsening symptoms of their underlying disease if they take decongestants.
  - Persons with diabetes need to closely monitor their blood glucose concentrations and may need to adjust their dose of insulin if they take decongestants.
- Note the following drug interactions for decongestants:
  - Persons taking MAOIs (e.g., selegiline or phenelzine), certain antibiotics (linezolid and furazolidone), and the anticancer drug procarbazine should not take decongestants.
  - Persons taking tricyclic antidepressants should use decongestants with caution as these medications may increase or decrease blood pressure, depending on the specific decongestant.
  - Large amounts of some antacids or medicines that increase pH decrease the elimination of pseudoephedrine.
- Store all medications according to the manufacturer's recommendations. Do not use expired medications.

### When to Seek Medical Attention

- Seek medical attention for the following situations:
  - Sore throat persists more than several days, is severe, or is associated with persistent fever, headache, or nausea or vomiting.
  - Cough does not improve within 7-14 days.
  - Symptoms worsen while nonprescription medications are being taken.
  - Signs and symptoms of bacterial infections develop (e.g., thick nasal or respiratory secretions that are not clear; temperature higher than 101.5°F [38.6°C]; shortness of breath; chest congestion; wheezing, rash, or significant ear pain).

### Note About Pediatric Dosing

- Manufacturers of cough and cold medications have revised the labeling to state that these products should not be used in children younger than 4 years. Health care providers should stress this information to caregivers of infants and young children.

## Allergic Rhinitis

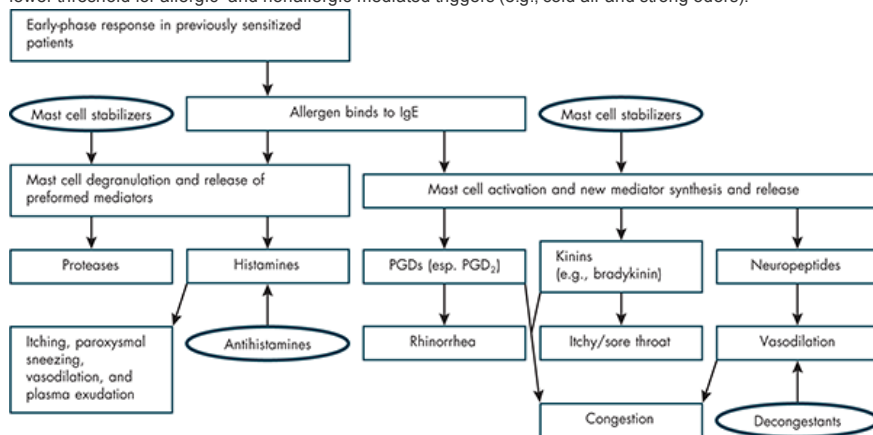

Allergic rhinitis, a systemic disease with prominent nasal symptoms, is a worldwide problem that affects adults and children. An estimated 20% of adults and 40% of children in the United States have this disease, and the number of newly diagnosed cases in the country has been steadily increasing over the past 3 decades.<sup>38</sup> An estimated 8% of adults and 11% of children in the United States are newly diagnosed with allergic rhinitis annually.<sup>38</sup> Annual direct costs (e.g., medications and office visits) are estimated to be \$3.4 billion.<sup>39</sup> Addition of indirect costs (e.g., lost school- and workdays) increases this estimate to \$11 billion.<sup>39</sup> Impaired quality of life creates additional significant, but yet to be quantified, intangible costs.

Symptoms of allergic rhinitis generally begin after the second year of life, and the disease is prevalent in children and adults ages 18-64 years.<sup>40</sup> After age 65 years, the number of cases decreases. The prevalence of allergic rhinitis is higher in the southern United States.<sup>40</sup>

### Pathophysiology of Allergic Rhinitis

Allergic rhinitis affects the upper respiratory system. (The section Colds provides a detailed discussion of the respiratory anatomy and physiology.) Risk factors for developing allergic rhinitis include family history of atopy (allergic disorders) in one or both parents; filaggrin (skin barrier protein) gene mutation; elevated serum IgE greater than 100 IU/mL before age 6 years; higher socioeconomic class; eczema; and positive reaction to allergy skin tests.<sup>41</sup> Emerging evidence also suggests that diet may be a risk factor in children and adolescents. Children who consume three or more fast-food meals per week showed an increased incidence of allergic disorders.<sup>42</sup> The exact mechanism for that increase is not known but is thought to be related to higher content of fatty acids, especially trans-fatty acids, which trigger an immune response.<sup>42</sup> Allergic rhinitis is triggered by indoor and outdoor environmental allergens. Common outdoor aeroallergens (airborne environmental allergens) include pollen and mold spores. Other nonairborne pollens have also been implicated. Pollutants (e.g., ozone and diesel exhaust particles) are considered environmental triggers and are becoming more of a concern in highly populated areas. Common indoor aeroallergens include house-dust mites, cockroaches, mold spores, cigarette smoke, and pet dander. Occupational aeroallergens include the following: wool dust, latex, resins, biologic enzymes, organic dusts (e.g., flour), and various chemicals (e.g., isocyanate and glutaraldehyde).

The pathogenesis of allergic rhinitis is complex, involving numerous cells and mediators, and consists of four phases.<sup>43</sup> First is the sensitization phase, which occurs on initial allergen exposure. The allergen stimulates beta-lymphocyte-mediated IgE production. Second is the early phase, occurring within minutes of subsequent allergen exposure. The early phase consists of rapid release of preformed mast cell mediators (e.g., histamine and proteases), as well as the production of additional mediators (e.g., prostaglandins, kinins, leukotrienes, and neuropeptides). Figure 11-2 shows mediator-specific symptoms. The third phase is cellular recruitment. Circulating leukocytes, especially eosinophils, are attracted to the nasal mucosa and release more inflammatory mediators. Fourth is the late phase, which begins 2-4 hours after allergen exposure; symptoms include mucus hypersecretion secondary to submucosal gland hypertrophy and congestion. Continued persistent inflammation "primes" the tissue, resulting in a lower threshold for allergic- and nonallergic-mediated triggers (e.g., cold air and strong odors).

### Clinical Presentation of Allergic Rhinitis

Allergic rhinitis has been classified as seasonal allergic rhinitis ("hay fever") and perennial allergic rhinitis. New classifications, intermittent allergic rhinitis (IAR) and persistent allergic rhinitis (PER), were proposed in the late 1990s and are now the more accepted terminology.<sup>41,44</sup> Classification depends on the timing and duration of symptoms. Symptoms can be further classified as mild or moderate-severe (Table 11-10).<sup>41</sup> Symptoms of allergic rhinitis and common physical findings in these patients are summarized in Table 11-11<sup>41,43</sup> and can be used to differentiate allergic from nonallergic rhinitis. Table 11-12 lists causes of nonallergic rhinitis.<sup>41,43</sup> Systemic symptoms include fatigue, irritability, malaise, and cognitive impairment.

**TABLE 11-10 Classification of Allergic Rhinitis**

<i>Duration</i>	<i>Severity</i>
<b>Intermittent</b>	<b>Mild</b>
Symptoms occur ≤4 days per week OR ≤4 weeks.	Symptoms do not impair sleep or daily activities <sup>a</sup> ; no troublesome symptoms.
	<b>Moderate-Severe</b>
	One or more of the following occurs: impairment of sleep; impairment of daily activities <sup>a</sup> ; troublesome symptoms.
<b>Persistent</b>	<b>Mild</b>
Symptoms occur ≥4 days per week AND ≥4 weeks.	Symptoms do not impair sleep or daily activities <sup>a</sup> ; no troublesome symptoms.
	<b>Moderate-Severe</b>
	One or more of the following occurs: impairment of sleep; impairment of daily activities <sup>a</sup> ; troublesome symptoms.

<sup>a</sup> Daily activities include work, school, sports, and leisure.

Source: Reference 41.

**TABLE 11-11 Differentiation of Allergic Rhinitis from Nonallergic Rhinitis**

<i>Symptoms/Findings</i>	<i>Allergic Rhinitis</i>	<i>Nonallergic Rhinitis<sup>a</sup></i>
Symptom presentation	Bilateral symptoms that are worst upon awakening, improve during the day, then may worsen at night	Unilateral symptoms common but can be bilateral; constant day and night
Sneezing	Frequent, paroxysmal	Little or none

Rhinorrhea	Anterior, watery	Posterior, watery or thick and/or mucopurulent (associated with an infection)
Pruritus (itching) of eyes, nose, and/or palate	Frequent	Not present
Nasal obstruction	Variable	Usually present and often severe
Conjunctivitis (red, irritated eyes with prominent conjunctival blood vessels)	Frequent	Not present
Pain	Sinus pain due to congestion may be present; throat pain due to postnasal drip irritation may be present.	Variable depending on cause
Anosmia	Rare	Frequent
Epistaxis	Rare	Recurrent
Facial, nasal, or throat features	<p>"Allergic shiners" (periorbital darkening secondary to venous congestion)</p> <p>"Dennie's lines" (wrinkles beneath the lower eyelids)</p> <p>"Allergic crease" (horizontal crease just about bulbar portion of the nose secondary to the "allergic salute")</p> <p>"Allergic salute" (patient will rub the tip of the nose upward with the palm of the hand)</p> <p>"Allergic gape" (open-mouth breathing secondary to nasal obstruction)</p> <p>Nonexudative cobblestone appearance of posterior oropharynx</p>	<p>Nasal polyps</p> <p>Nasal septal deviation</p> <p>Enlarged tonsils and/or adenoids</p>

<sup>a</sup> Depending on the cause of the nonallergic rhinitis, not all symptoms may be exhibited.

Source: References 41 and 43.

Acute complications of allergic rhinitis include sinusitis and otitis media with effusion. Chronic complications include nasal polyps, sleep apnea, sinusitis, and hyposmia (diminished sense of smell).<sup>39,41</sup> Allergic rhinitis and asthma share a common pathology, and allergic rhinitis has been implicated in the development of asthma and exacerbations of preexisting asthma in children and adults. Depression, anxiety, delayed speech development, and facial or dental abnormalities have also been linked to allergic rhinitis.<sup>39,41</sup>

#### Treatment of Allergic Rhinitis

##### Treatment Goals

Allergic rhinitis cannot be cured. The goals of therapy are to reduce symptoms and improve the patient's functional status and sense of well-being. Treatment is individualized to provide optimal symptomatic relief and/or control.

##### General Treatment Approach

Allergic rhinitis is treated in three steps: allergen avoidance, pharmacotherapy, and immunotherapy.<sup>41,43</sup> Health care providers should maximize each step before going on to the next intervention. Patient education is an important part of all three steps, especially regarding the administration of nonprescription medications (for instructions, see [Table 11-2](#) for intranasal preparations and [Chapter 27](#) for ocular drugs). The algorithm in [Figure 11-3](#) outlines the self-treatment of IAR and PER and lists exclusions for self-treatment.<sup>41,44</sup> Because allergen avoidance is usually not sufficient to provide complete relief of allergic rhinitis, targeted therapy with single-entity drugs is usually initiated. Nonprescription therapy with intranasal corticosteroids, antihistamines, or decongestants usually treats most symptoms. Drugs with different mechanisms of action or delivery systems may be added if single-drug therapy does not provide adequate relief, or if symptoms are already moderately severe, particularly intense, or long-lasting.

**TABLE 11-12 Causes of Nonallergic Rhinitis**

<i>Hormonal</i>
Pregnancy, puberty, thyroid disorders
<b>Structural</b>
Septal deviation, adenoid hypertrophy
<b>Drug-Induced</b>
Cocaine, beta-blockers, ACEIs, chlorpromazine, clonidine, reserpine, hydralazine, oral contraceptives, aspirin or other NSAIDs, overuse of topical decongestants
<b>Systemic Inflammatory</b>
Eosinophilic nonallergic rhinitis (NARES)
<b>Lesions</b>
Nasal polyps, neoplasms
<b>Traumatic</b>
Recent facial or head trauma
<b>Autonomic (Vasomotor)</b>
Age-related; physical or chemical agent causes parasympathetic hyperactivity

Key: ACEI = Angiotensin-converting enzyme inhibitor; NSAID = nonsteroidal anti-inflammatory drug.

Source: References 41 and 43.

Self-care of allergic rhinitis. Key: ADR = Adverse drug reaction; AH = antihistamine; COPD = chronic obstructive pulmonary disorder; HCP = health care provider; IAR = intermittent allergic rhinitis; INCS = intranasal corticosteroids; PER = persistent allergic rhinitis; PCP = primary care provider; Rx = prescription. (Source: References 41, 43, and 44.)

##### Nonpharmacologic Therapy

Allergen avoidance is the primary nonpharmacologic measure for allergic rhinitis. Avoidance strategies depend on the specific allergen. House-dust mites (*Dermatophagoides* spp.), found in all but the driest regions of the United States, thrive in warm, humid environments. The main allergen is a fecal glycoprotein, but other mite proteins and proteases are also allergenic. Avoidance strategies, targeted at reducing the mite population, include lowering the household humidity to less than 40%, applying acaricides, and reducing mite-harboring dust by removing carpets, upholstered furniture, stuffed animals, and bookshelves from the patient's bedroom and other rooms if possible. Mite populations in

bedding are reduced by encasing the mattress, box springs, and pillows with mite-impermeable materials. Bedding that cannot be encased should be washed at least weekly in hot (130°F [54.4°C]) water. Bedding that cannot be encased or laundered should be discarded.

Outdoor mold spores are prevalent in late summer and fall, especially on calm, clear, dry days. *Alternaria* and *Cladosporium* are common outdoor mold allergens; *Penicillium* and *Aspergillus* are common indoor molds. Avoiding activities that disturb decaying plant material (e.g., raking leaves) lessens exposure to outdoor mold. Indoor mold exposure is minimized by lowering household humidity, removing houseplants, venting food preparation areas and bathrooms, repairing damp basements or crawl spaces, and frequently applying fungicide to obviously moldy areas.

Cat-derived allergens (Fel d1; proteins secreted through sebaceous glands in the skin) are small and light, and they stay airborne for several hours. Cat allergens can be found in the house months after the cat is removed. Although unproved, weekly cat baths may reduce the allergen load.

Cockroaches are major urban allergens. To eliminate cockroaches, patients should be encouraged to keep kitchen areas clean, keep food stored tightly sealed, and treat infested areas with baits or pesticides.

Pollutants (e.g., ozone and diesel fumes) are an additional concern in urban environments. Pollutants such as diesel exhaust particles are especially irritating to the respiratory tract and have been shown to increase the severity of allergic rhinitis.<sup>41</sup> Patients whose allergies are triggered by air pollutants should be aware of the air quality index (AQI; a measure of five major air pollutants per 24 hours) and plan outdoor activities when the AQI is low.

In general, trees pollinate in spring, grasses in early summer, and ragweed from mid-August to the first fall frost. Knowledge of pollen counts (the number of pollen grains per cubic meter per 24 hours) helps patients plan outdoor activities. Most patients are symptomatic when pollen counts are very high, and only very sensitive patients have symptoms when pollen counts are low. Pollen counts are highest early in the morning and lowest after rainstorms clear the air. Avoiding outdoor activities when pollen counts are high and closing house and car windows reduce pollen exposure.

Ventilation systems with high-efficiency particulate air (HEPA) filters remove pollen, mold spores, and cat allergens from household air but not fecal particles from house-dust mites, which settle to the floor too quickly to be filtered. Filters need to be changed regularly to maintain effectiveness. The systems are expensive and not effective for all patients. HEPA filters are also found in some vacuum cleaners. Weekly vacuuming of carpets, drapes, and upholstery with a HEPA filter-equipped vacuum cleaner may help reduce household allergens, including house-dust mites.<sup>43</sup>

Nasal wetting agents (e.g., saline, propylene, and polyethylene glycol sprays or gels) or nasal irrigation with warm saline (isotonic or hypertonic) delivered via a syringe or Neti pot may relieve nasal mucosal irritation and dryness, thus decreasing nasal stuffiness, rhinorrhea, and sneezing. That process also aids in the removal of dried, encrusted, or thick mucus from the nose. No significant adverse effects have been noted with nasal wetting agents. Mild stinging or burning has been noted with saline irrigation. Only distilled, sterile, or boiled tap water should be used to prepare nasal irrigation solutions because of the risk of rare but serious infections.

#### Pharmacologic Therapy

Intranasal corticosteroids (INCS) have been shown to be the most effective treatment for most symptoms of allergic rhinitis.<sup>43,44</sup> However, until October 2013, INCS were only available by prescription.<sup>45</sup> Other nonprescription options include ocular and oral antihistamines, topical and oral decongestants, and mast cell stabilizers. INCS, antihistamines, and mast cell stabilizers should be used regularly rather than episodically. Patients should start taking those products at least 1 week before symptoms typically appear or as soon as possible before expected allergen exposures. Length of therapy with those medications should be individualized according to duration and severity of symptoms, pattern of allergen exposure (episodic or continuous), and geographical location.

#### Intranasal Corticosteroids

INCS, also known as glucocorticoids, are very effective treatments for nasal symptoms such as itching, rhinitis, sneezing, and congestion as they inhibit multiple cell types and mediators, including histamine, and effectively stop the "allergic cascade."<sup>44</sup> Triamcinolone acetonide (Nasacort Allergy 24 HR) and fluticasone propionate (Flonase Allergy Relief) are currently the only two INCS approved for nonprescription use.<sup>45</sup>

Intranasal triamcinolone acetonide and fluticasone propionate have minimal systemic absorption. However, patients who are sensitive to INCS or use higher-than-recommended doses may experience systemic effects.

Both triamcinolone acetonide and fluticasone propionate are approved for nonprescription use to treat nasal allergy symptoms (nasal congestion, runny nose, sneezing, and itchy nose). Triamcinolone acetonide is approved for use in adults and children ages 2 years and older, whereas fluticasone propionate is approved for use in adults and children ages 4 years and older.<sup>45</sup>

The dosage of triamcinolone acetonide for children ages 2-5 years is 1 spray in each nostril daily (110 mcg/day). Children ages 6-12 years should be started on the same dosage; if symptoms are not relieved, 2 sprays in each nostril daily (220 mcg/day) may be used. The approved adult dosage is 220 mcg/day; once symptom control is achieved, some adults may be able to titrate down to 110 mcg/day. The dosage of fluticasone propionate for children ages 4-11 years is 1 spray in each nostril daily (100 mcg/day). Adults and children ages 12 years and older should use 2 sprays in each nostril daily (200 mcg/day) for 1 week; if complete symptom control is achieved, they can titrate down to 1 spray in each nostril daily. Complete symptom control may not be seen for up to 1 week. Patients should be instructed to shake the bottle well before each use and discard the product after a total of 60 or 120 doses, depending on which size was purchased, even if the bottle does not feel completely empty.

Triamcinolone acetonide and fluticasone propionate are usually well tolerated. Side effects are usually minor and include nasal discomfort, bleeding, or sneezing. More serious side effects include changes in vision, glaucoma, cataracts, increased risk of infection, and growth inhibition in children. No drug interactions have been reported with either medication.

#### Antihistamines

Antihistamines are one of the most frequently prescribed drug classes in the United States.<sup>46</sup> These drugs are classified as sedating (first-generation, nonselective) or nonsedating (second-generation, peripherally selective). The role of sedating antihistamines in treating allergic rhinitis is controversial. Sedating antihistamines are effective, readily available without a prescription, and relatively inexpensive. However, these antihistamines expose patients to risks of anticholinergic effects and should be used with caution.

Antihistamines compete with histamine at central and peripheral histamine<sub>1</sub> (H<sub>1</sub>)-receptor sites, preventing the histamine-receptor interaction and subsequent mediator release. In addition, second-generation antihistamines inhibit the release of mast cell mediators and may decrease cellular recruitment.

Differences among antihistamines relate to the rapidity and degree to which they penetrate the blood-brain barrier as well as to their receptor specificity. Sedating antihistamines are highly lipophilic molecules that readily cross the blood-brain barrier. Nonsedating antihistamines, large protein-bound lipophobic molecules with charged side chains, do not readily cross the blood-brain barrier. Both types of antihistamines are highly selective for H<sub>1</sub> receptors but have little effect on H<sub>2</sub>, H<sub>3</sub>, or H<sub>4</sub> receptors. The sedating antihistamines have anticholinergic, antiserotonin, and anti-alpha-adrenergic effects.

Each antihistamine chemical class (Table 11-13) differs slightly in terms of its activity and adverse effect profile.<sup>47,48</sup> Most sedating antihistamines are well absorbed after oral administration with time to peak plasma concentrations in the range of 1.5-3 hours. Protein binding is in the range of 78%-99%, and sedating antihistamines undergo significant first-pass metabolism through the cytochrome P450 system. Half-lives vary widely, for example, 2-10 hours for diphenhydramine versus 20-24 hours for chlorpheniramine.

**TABLE 11-13 Antihistamine Classes**

Class (specific drug entities)	Properties
Alkylamines (brompheniramine, chlorpheniramine, dexbrompheniramine, dexchlorpheniramine, pheniramine, triprolidine)	Moderately sedating; strong anticholinergic effects; higher risk of paradoxical CNS stimulation compared with other classes
Ethanolamines (clemastine, diphenhydramine, doxylamine)	Highly sedating; strong anticholinergic effects; large doses cause seizures and arrhythmias
Ethylenediamines (pyrilamine, triprolidine, thonzylamine)	Weak CNS effects; increased GI effects
Phenothiazines (promethazine)	Highly sedating; strong anticholinergic effects; block alpha-adrenergic receptors; more likely to cause hypotension; akathisia and dystonic reactions may occur
Piperidines (fexofenadine, loratadine, phenindamine)	Nonsedating
Piperazines (cetirizine, chlorcyclizine, hydroxyzine, levocetirizine, meclizine)	Minimally to moderately sedating

Source: References 46 and 47.

Key: CNS = Central nervous system; GI = gastrointestinal.

The nonsedating antihistamines are also rapidly absorbed after oral administration, with time to peak plasma concentrations in the range of 1-3 hours. Loratadine has the highest protein binding at 97% and is extensively metabolized by the liver to an active metabolite (descarboethoxyloratadine), whereas cetirizine and fexofenadine are minimally metabolized. Half-lives range from 8 hours (loratadine and cetirizine) to 14 hours (fexofenadine). Antihistamines are indicated for relief of symptoms of allergic rhinitis (e.g., itching, sneezing, and rhinorrhea) and other types of immediate hypersensitivity reactions. FDA-approved dosages for systemic antihistamines are listed in [Table 11-14](#).<sup>11</sup> Nonprescription antihistamines are marketed as immediate- and sustained-release tablets and capsules, chewable tablets, oral disintegrating tablets, solutions, and syrups. Alcohol-, sucrose-, and dye-free formulations are available. (See [Chapter 27](#) for ocular antihistamines.)

**TABLE 11-14 Dosage Guidelines for Systemic Nonprescription Antihistamines**

Drug	Dosage (maximum daily dosage)		
	Adults/Children ≥12 Years	Children 6 to <12 Years	Children 2 to <6 Years <sup>a</sup>
Brompheniramine maleate	4 mg every 4-6 hours (24 mg)	2 mg every 4-6 hours (12 mg)	1 mg every 4-6 hours (6 mg)
Cetirizine HCl <sup>b</sup>	10 mg every 24 hours	5-10 mg every 24 hours (10 mg)	2.5 mg every 12 hours or 2.5-5.0 mg every 24 hours (5 mg)
Chlorcyclizine HCl <sup>c</sup>	25 mg every 6-8 hours (75 mg)	Not recommended for children < 12 years except under advice of PCP	—
Chlorpheniramine maleate	4 mg every 4-6 hours (24 mg)	2 mg every 4-6 hours (12 mg)	1 mg every 4-6 hours (6 mg)
Clemastine fumarate	1.34 mg every 12 hours (2.68 mg)	Not recommended for children < 12 years except under advice of PCP	—
Dexbrompheniramine maleate	2 mg every 4-6 hours (12 mg)	1 mg every 4-6 hours (6 mg)	0.5 mg every 4-6 hours (3 mg)
Dexchlorpheniramine maleate	2 mg every 4-6 hours (12 mg)	1 mg every 4-6 hours (6 mg)	—
Diphenhydramine citrate	38-76 mg every 4-6 hours (456 mg)	19-38 mg every 4-6 hours (228 mg)	9.5 mg every 4-6 hours (57 mg)
Diphenhydramine HCl	25-50 mg every 4-6 hours (300 mg)	12.5-25 mg every 4-6 hours (150 mg)	6.25 mg every 4-6 hours (37.5 mg)
Doxylamine succinate	7.5-12.5 mg every 4-6 hours (75 mg)	3.75-6.25 mg every 4-6 hours (37.5 mg)	1.9-3.125 mg every 4-6 hours (18.75 mg)
Fexofenadine <sup>d</sup>	60 mg every 12 hours or 180 mg every 24 hours (180 mg)	30 mg every 12 hours (60 mg)	30 mg every 12 hours (60 mg)
Loratadine	10 mg every 24 hours (10 mg)	10 mg every 24 hours (10 mg)	5 mg every 24 hours (5 mg)
Phenindamine tartrate <sup>c</sup>	25 mg every 4-6 hours (150 mg)	12.5 mg every 4-6 hours (75 mg)	6.25 mg every 4-6 hours (37.5 mg)
Pheniramine maleate	12.5-25 mg every 4-6 hours (150 mg)	6.25-12.5 mg every 4-6 hours (75 mg)	3.125-6.25 mg every 4-6 hours (37.5 mg)
Pyrilamine maleate	25-50 mg every 6-8 hours (200 mg)	12.5-25 mg every 6-8 hours (100 mg)	6.25-12.5 mg every 6-8 hours (50 mg)
Thonzylamine HCl <sup>c</sup>	50-100 mg every 4-6 hours (600 mg)	25-50 mg every 4-6 hours (300 mg)	12.5-25.0 mg every 4-6 hours (150 mg)
Triprolidine HCl <sup>c</sup>	2.5 mg every 4-6 hours (10 mg)	1.25 mg every 4-6 hours (5 mg)	Age 4-6 years: 0.938 mg every 4-6 hours (3.744 mg)
			Age 2 to <4 years: 0.625 mg every 4-6 hours (2.5 mg)
			4 months to <2 years: 0.313 mg every 4-6 hours (1.25 mg)

Key: PCP = Primary care provider.

<sup>a</sup> With the exception of cetirizine, fexofenadine, and loratadine, these products are not recommended for children younger than 6 years, except with the advice and supervision of a PCP. FDA recommends that the labels on nonprescription products not provide dosing information for children younger than 6 years.

<sup>b</sup> For adults older than 65 years, 10 mg cetirizine is not recommended, except with the advice and supervision of a PCP.

<sup>c</sup> Drug is FDA approved but not currently marketed in the United States.

<sup>d</sup> For adults older than 65 years, fexofenadine is not recommended, except with the advice and supervision of a PCP.

Source: Reference 11.

Sedating antihistamine overdoses are characterized by excessive H<sub>1</sub>-receptor and cholinergic-receptor blockade and by alpha-adrenergic and serotonergic activity.<sup>47</sup> Overdoses also cause excessive blockade of fast sodium channels and potassium channels, thus leading to cardiac symptoms (tachycardia and conduction abnormalities, including torsades de pointes).<sup>47</sup> CNS symptoms include toxic psychosis, hallucinations, agitation, lethargy, tremor, insomnia, or tonic-clonic seizures. Children tend to be more sensitive to CNS excitatory effects and adults are more likely to experience CNS depression.<sup>47</sup> Peripheral symptoms include hyperpyrexia, mydriasis, vasodilation, decreased exocrine secretion, urinary retention, decreased GI motility, dystonic reactions, and rhabdomyolysis. Overdoses of nonsedating antihistamines are characterized by drowsiness, restlessness/hyperactivity, and tachycardia. Treatment of antihistamine overdoses is supportive.

The adverse effect profile of systemic antihistamines varies widely and depends on the receptor activity, chemical structure, and lipophilicity of the drug. The primary adverse effects, CNS effects (depression and stimulation) and anticholinergic effects, are common with first-generation antihistamines but are rarely seen with second-generation agents. CNS-depressive effects include sedation and impaired performance (e.g., impaired driving performance, poor work performance, incoordination, reduced motor skills, and impaired information processing).<sup>48</sup> CNS-stimulatory effects include anxiety, hallucinations, appetite stimulation, muscle dyskinesias, and activation of epileptogenic foci. Adverse effects associated with cholinergic blockade include dryness of the eyes and mucous membranes (mouth, nose, vagina); blurred vision; urinary hesitancy and retention; constipation; and reflex tachycardia.

Antihistamines interact with numerous drugs ([Table 11-6](#)). All antihistamines decrease or prevent immediate dermal reactivity and should be discontinued at least 4 days before scheduled allergy skin testing. Fexofenadine should not be taken with any fruit juices (e.g., grapefruit, apple, or orange). Fruit juice is thought to reduce absorption of fexofenadine by directly inhibiting intestinal organic anion transporting polypeptides (OATPs), specifically OATP1A2.<sup>49</sup> Separating fexofenadine dose and fruit juice

consumption by at least 2 hours will avoid this interaction.<sup>49</sup>

Sedating antihistamines are contraindicated in newborns or premature infants, lactating women, and patients with narrow-angle glaucoma. Additional contraindications include acute asthma exacerbation, stenosing peptic ulcer, symptomatic prostatic hypertrophy, bladder-neck and pyloroduodenal obstruction, and concomitant use of MAOIs.

Formulations of 12- and 24-hour sustained-release loratadine/pseudoephedrine combination products are contraindicated in patients with esophageal narrowing, abnormal esophageal peristalsis, or a history of difficulty swallowing tablets.

Patients with lower respiratory tract diseases (e.g., emphysema and chronic bronchitis) should use sedating antihistamines with caution. Patients requiring mental alertness should not use sedating antihistamines and should use cetirizine with caution. Patients may be impaired even if they do not feel drowsy or if they have taken the dose the evening before. The sedating antihistamines are photosensitizing drugs. Patients should be advised to use sunscreens and wear protective clothing.

#### Combination Products

Antihistamines are marketed in combination with decongestants and analgesics. Those combinations are also available in sustained-release formulations, allowing convenient dosage regimens. However, these combination products should be used with caution because of the increased risk of adverse effects, especially insomnia, which compounds daytime fatigue already associated with this disease.

#### Decongestants

Congestion is a common allergic rhinitis symptom controllable with systemic decongestants or short-term ( $\leq 5$  days) topical nasal decongestants. (See discussion of decongestants in the section Colds.)

#### Cromolyn Sodium

Cromolyn is a mast cell stabilizer indicated for preventing and treating the symptoms of allergic rhinitis. Cromolyn is thought to work by blocking the influx of calcium into mast cells thereby preventing mediator release. Less than 7% of an intranasal cromolyn dose is absorbed systemically, and what little is absorbed has no systemic activity. The absorbed drug is rapidly excreted unchanged in the feces and urine, with a half-life of 1-2 hours.

Cromolyn is approved for patients ages 2 years or older; the recommended dosage is 1 spray in each nostril 3-6 times daily at regular intervals.<sup>11</sup> Treatment is more effective if started before symptoms begin. It may take 3-7 days for initial treatment efficacy to become apparent and 2-4 weeks of continued therapy to achieve maximal therapeutic benefit. Sneezing is the most common side effect reported for intranasal cromolyn. Other adverse effects include nasal stinging and burning. No drug interactions have been reported with intranasal cromolyn.

#### Pharmacotherapeutic Comparison

INCS have been shown to be the most effective treatment for moderate-severe IAR and both types of PER. Monotherapy with INCS is considered first-line.<sup>41,43,44</sup> If additional symptom control is needed, combination therapy with antihistamines, decongestants, or mast cell stabilizers can be initiated. Sedating antihistamines are effective, and some evidence does suggest that this group of drugs may be more effective than nonsedating antihistamines in treating symptoms of allergic rhinitis.<sup>50</sup> However, this evidence is based on trials using the maximum daily dosage (50 mg) of diphenhydramine.<sup>50</sup> Sedating antihistamines have a quick onset of action but also have shorter duration of action and require multiple daily doses. The risks of cognition impairment and sedation have been well established with this class of drugs.<sup>48</sup> The World Health Organization and numerous health care providers now recommend nonsedating antihistamines as the nonprescription therapy of choice on the basis of their efficacy and safety profile, quick onset of action, and long duration, which allows once-daily dosing.<sup>41,49</sup>

Cetirizine has been shown to be a more potent antihistamine than loratadine or fexofenadine.<sup>49</sup> However, unlike loratadine and fexofenadine, cetirizine causes sedation (in about 10% of patients).

#### Product Selection Guidelines

##### Special Populations

Because pregnancy is a common cause of nonallergic rhinitis, pregnant women should be referred for differential diagnosis. If allergic rhinitis is confirmed and nonprescription therapy is approved by a PCP, several treatment choices are available.<sup>24,25</sup> Intranasal cromolyn is considered compatible with pregnancy and is a first-line option.<sup>24,25</sup>

Diphenhydramine and chlorpheniramine are considered compatible with pregnancy.<sup>25</sup> Chlorpheniramine is the first-generation antihistamine of choice in pregnancy because of its long history of safety.<sup>24</sup> If chlorpheniramine is not tolerated, loratadine and cetirizine are considered to have low risk and are preferred alternatives.<sup>24,49</sup> Fexofenadine is considered to have moderate risk.<sup>25</sup> Intranasal fluticasone propionate is considered compatible with pregnancy.<sup>25</sup> Systemic use of triamcinolone acetonide has been linked to cleft palate and low birth weight; however, intranasal use is considered probably compatible with pregnancy because of minimal systemic absorption.<sup>25</sup>

Lactating women diagnosed with allergic rhinitis and approved for self-treatment by a PCP have fewer options. Because of its limited systemic absorption, intranasal cromolyn is a good choice, and there are no reports of adverse effects on nursing infants.<sup>25</sup> Triamcinolone acetonide has a low molecular weight and is thought to be excreted in breast milk. However, there are no reports of intranasal triamcinolone acetonide or fluticasone propionate causing harm in nursing infants.<sup>25</sup> Antihistamines are contraindicated during lactation because of their ability to pass into breast milk. There have been reports of drowsiness and irritability in infants after mothers took clemastine.<sup>25</sup> Short-acting chlorpheniramine, fexofenadine, or loratadine seems to be the best option if an oral antihistamine is needed, but the antihistamine should be used with caution and under the supervision of a PCP. If an oral antihistamine is used during lactation, the mother should avoid long-acting and high-dose antihistamines and should take the dose at bedtime after the last feeding of the day.<sup>25</sup>

Because of concerns of undiagnosed asthma, children younger than 12 years should be referred to a PCP for differential diagnosis.<sup>41</sup> If nonprescription therapy is approved by a PCP, several treatment choices are available for children.<sup>41,49</sup> Intranasal cromolyn and triamcinolone acetonide are safe for children ages 2 years and older, and intranasal fluticasone propionate is safe for children 4 years and older. However, these products may be difficult for children to self-administer. In addition, triamcinolone acetonide and fluticasone propionate have been linked to growth inhibition in children; FDA-mandated labeling for the nonprescription products encourages parents to speak to a health care provider if they plan to use these products in children longer than 2 months per year.<sup>45</sup> Loratadine is the nonprescription antihistamine of choice, followed by fexofenadine and cetirizine. Sedating antihistamines should be avoided in children because of paradoxical excitation and risk for serious adverse events with misuse.<sup>49</sup> Sedating antihistamines should be avoided in elderly patients as they are more likely than younger adults to be taking concomitant medications with anticholinergic properties and have increased risk of CNS-depressive adverse effects, including confusion as well as hypotension.<sup>51</sup> Those adverse effects contribute to a higher risk of falling in the elderly.<sup>51</sup> Loratadine and intranasal cromolyn are drugs of choice in the older population. Dosages of fexofenadine should be adjusted in patients with renal impairment, whereas loratadine and cetirizine should be adjusted in patients with renal and/or hepatic impairment.

##### Patient Factors and Preferences

The duration of treatment and the presence of concomitant symptoms will determine which product is selected (Table 11-15). Product selection may also be based on side effect profiles and cost. For example, all first-generation antihistamines are sedating, but the degree of sedation depends on chemical class (Table 11-13). Nonsedating antihistamines are more expensive but have less risk of sedation and impairment, which may justify the additional cost. Some patients report that antihistamines are less effective after prolonged use. This decline is most likely not indicative of true tolerance but rather stems from several factors, including patient nonadherence, an increase in antigen exposure, worsening of disease, limited effectiveness of antihistamines in severe disease, or the development of similar symptoms from unrelated diseases. Chemical class differences make it reasonable to suggest switching to a different class of antihistamine if a patient has a less-than-optimal response to one class of antihistamine.

**TABLE 11-15 Selected Nonprescription Products for Allergic Rhinitis**

Trade Name	Primary Ingredients
<b>Systemic First-Generation Antihistamine Products</b>	
Chlor-Trimeton Allergy (4, 8, or 12 Hour) Tablets	Chlorpheniramine 4, 8, or 12 mg, respectively
Dayhist Allergy Tablets	Clemastine fumarate 1.34 mg
Benadryl Allergy Tablets	Diphenhydramine HCl 25 mg
Children's Benadryl Allergy Relief Syrup	Diphenhydramine HCl 12.5 mg/5 mL

Kids-EEZE Allergy Soft Chews	Diphenhydramine HCl 12.5 mg
<b>Systemic Second-Generation Antihistamine Products</b>	
Zyrtec Tablets	Cetirizine 10 mg
Children's Zyrtec Syrup	Cetirizine 5 mg/5 mL
Allegra Allergy 24 hour Tablets	Fexofenadine 180 mg
Children's Allegra Orally Disintegrating Tablets <sup>a</sup>	Fexofenadine 30 mg
Claritin Non-Drowsy Tablets	Loratadine 10 mg
Alavert Orally Disintegrating Tablets	Loratadine 10 mg
<b>Combination Systemic Products</b>	
Dimetapp Cold and Allergy Syrup	Brompheniramine 1 mg/5 mL; phenylephrine 2.5 mg/5 mL
Zyrtec D Tablets	Cetirizine 5 mg; pseudoephedrine HCl 120 mg
Actifed Cold and Allergy Tablets	Chlorpheniramine 4 mg; phenylephrine 10 mg
Advil Allergy Sinus Caplets	Chlorpheniramine 2 mg; pseudoephedrine HCl 30 mg; ibuprofen 200 mg
Allegra D 12-Hour Tablets	Fexofenadine 60 mg; pseudoephedrine HCl 120 mg
Claritin-D 24 Hour Tablets	Loratadine 10 mg; pseudoephedrine sulfate 240 mg
<b>Nasal Products</b>	
Nasacort Allergy 24 HR	Triamcinolone acetonide 55 mcg/spray
Ayr Saline Nasal Gel	Sodium chloride; aloe; propylene glycol; glycerin
NasalCrom Spray	Cromolyn sodium 5.2 mg/spray
Ocean Spray	Sodium chloride 0.65%

<sup>a</sup> Contains phenylalanine.

#### Complementary Therapies

Ephedra (ma huang) and feverfew are commonly suggested herbal remedies for allergic rhinitis. Ephedra-containing products are banned by FDA owing to their serious adverse effects (e.g., stroke). Parthenolide, feverfew's biologically active component, may have anti-inflammatory properties, but its safety and efficacy in allergic rhinitis are unproved. (For further discussion of these types of products, see [Chapter 51](#).) Capsaicin-based nasal sprays (e.g., Allergy Buster) are marketed for allergy sufferers, but despite these products being studied since the 1990s, many questions remain about their safety and efficacy. Using local honey or homeopathic products containing known allergens (e.g., bioAllers Animal Hair and Dander Allergy Relief Liquid contains cat, cattle, dog, horse, and sheep wool extracts) to induce long-term resistance by repeated exposure to controlled amounts of allergen has not been proven safe or effective. Safety and efficacy data are also lacking for symptom-specific homeopathic remedies such as sabadilla for nasal and ocular symptoms (red, watery eyes) and wyethia for itching.

#### Assessment of Allergic Rhinitis: A Case-Based Approach

Asking the patient for a detailed description of symptoms and obtaining the patient's medical and medication use (previous and current) history are essential to determining whether the patient has allergic rhinitis or rhinitis related to other causes and is eligible for self-care ([Tables 11-11](#) and [11-12](#)).

The medical history may uncover other respiratory illnesses that complicate treatment of allergic rhinitis. The patient's current medication use will also alert the health care provider to possible interactions with nonprescription allergy medications. The provider should also ask the patient whether nonprescription products used to treat IAR or PER were effective and without adverse effects.

Case 11-2 presents an example of the assessment of a patient with allergic rhinitis.

#### Case 11-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient has had postnasal drip and moderate congestion for 7 days.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Symptoms are constant day and night, but congestion seems worse at night. Symptoms started one week into second trimester.
c. description of the patient's efforts to relieve the symptoms	Patient has not tried anything.
d. patient's identity	Sarah Connor
e. age, sex, height, and weight	28 years old, female, 5 ft 7 in., 180 lb
f. patient's occupation	Teacher
g. patient's dietary habits	Vegetarian
h. patient's sleep habits	Patient usually sleeps 7-8 hours at night, but congestion has been disrupting sleep.

i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Prenatal vitamin 1 tablet every morning
j. allergies	Penicillin
k. history of other adverse reactions to medications	None
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Allergic rhinitis symptoms tend to include sneezing, itchy nose or eyes, and anterior runny nose. Patient's symptoms (postnasal drip and congestion) are more indicative of nonallergic rhinitis. Also, because her symptoms started in second trimester, she may have hormonal nonallergic rhinitis.
3. Identify exclusions for self-treatment (Figure 11-3).	Pregnancy, nonallergic rhinitis symptoms
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Recommend a separate OTC product for each symptom: nonsedating or sedating antihistamine for postnasal drip and topical or systemic decongestant for congestion. Or because the patient has multiple symptoms, a combination product may be appropriate. (2) Refer patient to her PCP for evaluation and treatment. (3) Recommend self-care until patient can consult her PCP. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Patient should consult a health care provider for evaluation and treatment.
6. Describe the recommended therapeutic approach to the patient or caregiver.	Patient should consult a health care provider for evaluation and treatment.
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	Because patient's symptoms seem to be related to her pregnancy and not allergies, patient needs to consult a health care provider.
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"Can I use a Neti pot to help with the congestion?"
Answer the patient's or caregiver's questions.	"Yes. The Neti pot may help wash away some of the mucus in your nose. Be sure to use distilled, sterile, or boiled tap water in the Neti pot to avoid rare but serious infections."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact patient in 1 week to ensure that she made an appointment and sought medical care.

Key: OTC = Over-the-counter; PCP = primary care provider.

#### Patient Counseling for Allergic Rhinitis

The provider should stress that the best method of treating allergic rhinitis is to avoid allergens. Many patients, however, have no control over their work environment or are unable to implement all the preventive measures at home. These patients usually rely on allergy medications for symptom control. The patient should be advised about proper use of recommended medication(s) and about possible adverse effects, drug-drug and drug-disease interactions, and other precautions and warnings. Patients should also know the signs and symptoms that indicate the disorder has progressed to the point where medical care is needed. The box Patient Education for Allergic Rhinitis lists specific information to provide patients.

#### Evaluation of Patient Outcomes for Allergic Rhinitis

Many patients achieve symptomatic relief with initial nonprescription drug therapy in 3-4 days, but complete relief of symptoms may take 2-4 weeks. After this time frame, the health care provider should follow up with a telephone call or a scheduled appointment to determine whether symptom control has been achieved or the patient is encountering any adverse effects or problems. Patients who respond poorly to treatment should be assessed to determine whether they are complying with allergen avoidance strategies and medication regimens. Options for patients who do not achieve relief include increasing current medications to maximally effective dosages or changing to a different medication or dosage formulation. Patients who do not respond to nonprescription therapy should be referred back to their PCPs for prescription medications such as systemic corticosteroids, leukotriene inhibitors, anticholinergics, or immunotherapy. Patients should also be reassessed, and the diagnosis of allergic rhinitis may need to be reconsidered. Patients who develop any of the warning signs or symptoms listed in the box Patient Education for Allergic Rhinitis should be referred to a PCP.

#### Patient Education for Allergic Rhinitis

The primary objective of self-treatment is to prevent or reduce symptoms, which in turn will improve functioning and a sense of well-being. For some patients, prescription therapy such as short-course oral corticosteroids may help control symptoms, whereas other therapy is initiated when symptoms are especially severe. For most patients, carefully following instructions for nonprescription allergy medications and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Nondrug Measures

- Avoidance of allergens is important regardless of whether allergy medications are being taken.
- For symptoms that develop mainly when outdoors:
  - Frequently check local pollen counts and air quality index.
  - Keep house and car windows shut; avoid yard work and outdoor sports on days with high levels of pollen (spring/summer), mold (late summer/fall), or pollution.
- For symptoms that occur mainly when indoors:
  - Try to remove the symptom trigger(s) (e.g., cats, house-dust mites, tobacco smoke, and molds) from rooms.
  - Lower the humidity in the home to reduce molds. Use lower settings on humidifiers, repair damp basements and crawl spaces, vent kitchens and bathrooms, and remove house plants.

- Wash bedding in hot water (130°F [54.4°C]) every week, and encase mattresses and pillows in coverings resistant to house-dust mites.
- Nasal saline solutions may relieve nasal irritation and dryness, and aid in the removal of dried, encrusted, or thick mucus from the nose.

### Nonprescription Medications

- Ask a health care provider for help in selecting an allergy medication that treats the most bothersome symptoms. If needed, additional medications can be added for other symptoms:
  - Intranasal steroids (triamcinolone acetonide) are effective for itchy eyes and noses, sneezing, runny nose, and congestion.
  - Antihistamines are effective for itching, sneezing, and runny nose but, with the exception of newer agents (fexofenadine), have little effect on nasal congestion.
  - Decongestants are effective for nasal congestion but have little effect on other symptoms.
  - Combination therapy with an antihistamine and a decongestant is common.
  - Intranasal and ocular preparations are available to reduce nasal and eye symptoms, respectively.
  - Intranasal cromolyn is the preferred initial drug of choice during pregnancy and lactation. This medication is not absorbed into the body.
  - For intranasal products, follow the dosing and administration directions carefully. See [Table 11-2](#).
  - The most common adverse effects of nasal preparations include nasal stinging and burning.
- Allergy medications are more effective if they are used regularly rather than episodically:
  - If you have intermittent allergies, start allergy medications as soon as possible, before exposure to allergen.
  - If you have persistent allergies, take allergy medications on a regular basis

### Nasal Congestion

- See the box Patient Education for Colds for information about relieving nasal congestion.

### Rhinorrhea (Runny Nose) and Sneezing

- Many factors cause a runny nose and depending on the factors, nonprescription steroids or antihistamines may only partially treat this symptom. Because some nonprescription antihistamines may make you very drowsy, the potential benefits of the medication must be weighed against the potential risks.
- Sneezing is a common and sometimes bothersome symptom. Sneezing may be reduced with nonprescription intranasal steroids or antihistamines. The potential benefits of using antihistamines must be weighed against the potential risks.
- Intranasal steroids and oral antihistamines are the preferred initial treatment for runny nose and sneezing in persons who are eligible for self-care (see exclusions in [Figure 11-3](#)).
- There are two types of antihistamines, sedating and nonsedating. Cetirizine, fexofenadine, and loratadine are nonsedating antihistamines and usually do not cause significant drowsiness.
- Note the following adverse effects for antihistamines:
  - The sedating antihistamines cause drowsiness and impair mental alertness. Mental alertness is impaired even if you do not feel drowsy or if you took the dose the prior evening. While taking these medications, do not drive a vehicle, operate machinery, or engage in other activities that require alertness.
  - Sedating antihistamines may cause sensitivity to sunlight. Use sunscreens and wear protective clothing when outdoors.
  - Use of sedating antihistamines may cause dryness in your mouth, nose, and other areas of your body.
  - Children and elderly persons may experience unexpected excitement with sedating antihistamines.
  - Elderly persons should avoid sedating antihistamines and may need lower doses of nonsedating antihistamines because they are more sensitive to the effects of these medications and take other medications that interact.
- Do not use antihistamines:
  - If you are allergic to antihistamines or similar medications.
  - If you are breast-feeding.
- Do not give antihistamines to newborns or premature infants unless directed to do so by a primary care provider.
- Note the following precautions for use of nonprescription antihistamines:
  - Persons with glaucoma, stenosing peptic ulcer, symptomatic enlarged prostate, bladder-neck obstruction, or stomach-intestinal blockage should not use sedating (first-generation) antihistamines.
  - Persons with lower respiratory tract disease (e.g., emphysema or chronic bronchitis) should use sedating antihistamines with caution.
  - Persons with esophageal narrowing, abnormal esophageal peristalsis, or problems swallowing tablets should not take the 12- or 24-hour sustained-release dosage forms of loratadine combined with pseudoephedrine. There have been reports of esophageal obstruction and perforation with these sustained-release dosage forms.
- Sedating antihistamines interact with the following drugs:
  - Alcohol, sedatives, and other central nervous system depressants may cause additive depressive effects when taken with sedating antihistamines.
  - Sedating antihistamines may block the effects of some drugs used to treat Alzheimer's disease (e.g., donepezil).
  - Chlorpheniramine may increase the adverse effects of phenytoin.
- Nonsedating antihistamines interact with the following drugs:
  - Fexofenadine interacts with ketoconazole, erythromycin, rifampin, and antacids. Also avoid taking with fruit juice.
  - Loratadine interacts with amiodarone.
  - Avoid taking cetirizine with alcohol.
- Store all medications according to the manufacturer's instructions.

### When to Seek Medical Attention

- Seek medical attention in the following situations:
  - Your allergy symptoms worsen while you are taking nonprescription medications or do not improve after 2-4 weeks of treatment.
  - You develop signs or symptoms of secondary bacterial infections (e.g., thick nasal or respiratory secretions that are not clear, temperature higher than 101.5°F [38.6°C], shortness of breath, chest congestion, wheezing, significant ear pain, rash).

### Key Points for Disorders Related to Colds and Allergic Rhinitis

- Colds are self-limiting, viral infections characterized by initial sore throat followed by nasal symptoms and nonproductive cough.
- Medical referral is appropriate for patients with suspected colds who are immunocompromised, have underlying cardiopulmonary diseases, or have alarm symptoms (high fever, chest pain, shortness of breath, or wheezing).
- Treatment for colds is symptomatic and targeted at the most bothersome symptoms.
- Decongestants are the most common nonprescription treatment for congestion related to colds and allergic rhinitis, but they should be used cautiously in patients with hypertension, diabetes, and other chronic diseases.
- Therapy for allergic rhinitis is sequential and consists of allergen avoidance, pharmacotherapy, and allergen immunotherapy.
- Medical referral is appropriate for patients with symptoms suggestive of nonallergic rhinitis, otitis media, sinusitis, or lower respiratory tract problems such as pneumonia, asthma, or bronchitis, and for those patients who fail to respond to nonprescription medications.
- Antihistamines are commonly used to control allergic rhinitis symptoms. Nonsedating (second-generation) antihistamines are preferred over sedating (first-generation) antihistamines on the basis of safety and efficacy data.

## Handbook of Nonprescription Drugs &gt; Chapter 12. Cough

**Cough: Introduction**

Cough is an important defensive respiratory reflex with potentially significant adverse physical and psychological consequences and economic impact. Cough is the most common symptom for which patients seek medical care.<sup>1</sup> Cough is also a common reason for emergency department visits. In 2010, cough was the second most common reason for children younger than 15 years to visit emergency departments and the seventh most common reason for adults.<sup>2</sup> Americans spend more than \$4 billion annually on nonprescription cough/cold and related medications, more than any other nonprescription sales category.<sup>3</sup>

**Pathophysiology of Cough**

Cough is initiated by stimulation of chemically and mechanically sensitive, vagally mediated sensory pathways in laryngeal, esophageal, and tracheobronchial airway epithelium.<sup>4,5</sup> The number of afferent nerves activated and the intensity of activation may influence the cough threshold.<sup>6</sup> Receptors in the larynx and proximal large airways are more sensitive to mechanical stimulation, whereas laryngeal receptors are more sensitive to chemical stimulation.<sup>7</sup> A complex medullary brainstem network ("cough control center") processes the sensory input and stimulates the motor efferents. Voluntary cough is controlled by the cerebral cortex.<sup>8</sup> Viruses promote cough by a different though not well-understood mechanism.<sup>9</sup> A cough starts with a deep inspiration followed by closure of the glottis and forceful contraction of the chest wall, abdominal wall, and diaphragmatic muscles against the closed glottis; pressure within the thoracic cavity may reach 300 mm Hg.<sup>4</sup> When the glottis opens, air is expelled with a velocity of about 11-15 m/s, propelling mucus, cellular debris, and foreign material out of the respiratory system.<sup>10</sup> Cough may occur in epochs ("coughing fits"). Cough, classified as acute (duration of less than 3 weeks), subacute (duration of 3-8 weeks), or chronic (duration of more than 8 weeks), is a symptom of diverse infectious and noninfectious disorders (Table 12-1).<sup>11</sup> In children, cough may also be a symptom of aspiration caused by poor coordination of sucking and swallowing or esophageal motility disorders.<sup>12</sup> Angiotensin-converting enzyme inhibitors cause dry cough in approximately 20% of treated patients.<sup>13</sup> Systemic and ophthalmic beta-adrenergic blockers may cause cough in patients with obstructive airway diseases (e.g., asthma or chronic obstructive pulmonary disease [COPD]).

**TABLE 12-1 Etiology of Cough**

<i>Classification</i>	<i>Etiology</i>
Acute	Viral URTI, pneumonia, acute left ventricular failure, asthma, foreign body aspiration
Subacute	Postinfectious cough, bacterial sinusitis, asthma
Chronic	UACS, asthma, GERD, COPD (chronic bronchitis), ACEIs, bronchogenic carcinoma, carcinomatosis, sarcoidosis, left ventricular failure, aspiration secondary to pharyngeal dysfunction

Key: ACEI = Angiotensin-converting enzyme inhibitor; COPD = chronic obstructive pulmonary disease; GERD = gastroesophageal reflux disease; UACS = upper airway cough syndrome; URTI = upper respiratory tract infection.

Source: Reference 11.

**Clinical Presentation of Cough**

Coughs are described as productive or nonproductive. A productive cough (a wet or "chesty" cough) expels secretions from the lower respiratory tract that, if retained, could impair ventilation and the lungs' ability to resist infection. Productive coughs may be effective (secretions easily expelled) or ineffective (secretions present but difficult to expel). The appearance of the secretions is not always a reliable diagnostic indicator, but secretions are typically clear with bronchitis and purulent with bacterial infection. Anaerobic bacterial infections are associated with a distinct malodor. Nonproductive coughs (a dry or "hacking" cough), which are associated with viral and atypical bacterial infections, gastroesophageal reflux disease (GERD), cardiac disease, and some medications, serve no useful physiologic purpose.

Common complications of cough include exhaustion, insomnia, musculoskeletal pain, hoarseness, excessive perspiration, and urinary incontinence. Less common complications include cardiac dysrhythmias, syncope, stroke, and rib fractures. Mechanical irritation from coughing may cause sore throat. Cough may cause prolonged absence from work or school, withdrawal from social activities, and fear that the cough is a symptom of a serious illness, such as cancer or tuberculosis.

**Treatment of Cough****Treatment Goals**

The primary goal of self-treatment of cough is to reduce the number and severity of cough episodes. The second goal is to prevent complications. Cough treatment is symptomatic; the underlying disorder must be treated to stop the cough.

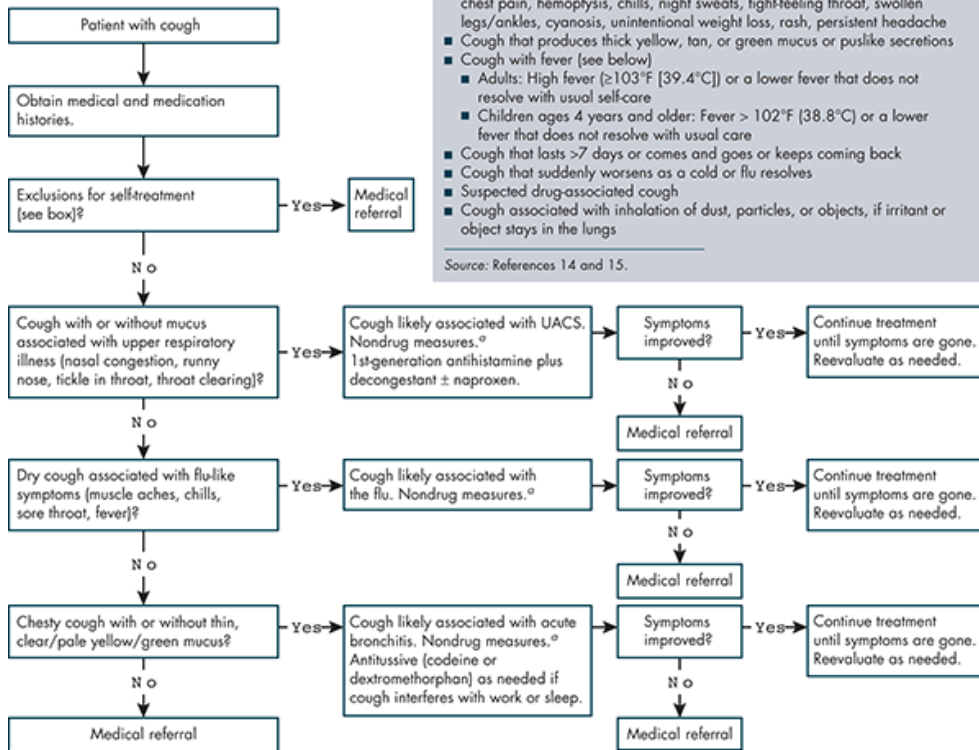

**General Treatment Approach**

Selection of a medication for self-care of cough depends on the nature and etiology of the cough. Figure 12-1 lists exclusions for self-care. These exclusions are based on the presence of signs and symptoms of potentially serious medical conditions associated with cough that require medical evaluation.<sup>14,15</sup> Antitussives (cough suppressants) control or eliminate cough and are the drugs of choice for nonproductive coughs. Antitussives should not be used to treat productive cough unless the potential benefit outweighs the risk (e.g., significant nocturnal cough). Suppression of productive coughs may lead to retention of lower respiratory tract secretions, increasing the risk of airway obstruction and secondary bacterial infection. Protussives (expectorants) change the consistency of mucus and increase the volume of expectorated sputum and may provide some relief for coughs that expel thick, tenacious secretions from the lungs with difficulty.

**Exclusions for Self-Treatment**

- Children < 4 years of age
- History of symptoms of chronic disease associated with cough (e.g., asthma, COPD, chronic bronchitis, CHF)
- Cough accompanied by one or more of the following: shortness of breath, chest pain, hemoptysis, chills, night sweats, tight-feeling throat, swollen legs/ankles, cyanosis, unintentional weight loss, rash, persistent headache
- Cough that produces thick yellow, tan, or green mucus or puslike secretions
- Cough with fever (see below)
  - Adults: High fever ( $\geq 103^{\circ}\text{F}$  [ $39.4^{\circ}\text{C}$ ]) or a lower fever that does not resolve with usual self-care
  - Children ages 4 years and older: Fever  $> 102^{\circ}\text{F}$  ( $38.8^{\circ}\text{C}$ ) or a lower fever that does not resolve with usual care
- Cough that lasts  $> 7$  days or comes and goes or keeps coming back
- Cough that suddenly worsens as a cold or flu resolves
- Suspected drug-associated cough
- Cough associated with inhalation of dust, particles, or objects, if irritant or object stays in the lungs

Self-care of cough. Key: CHF = Congestive heart failure; COPD = chronic obstructive pulmonary disease; UACS = upper airway cough syndrome.

Cough medications are marketed in a variety of dosage forms (syrups, liquids, solutions, suspensions, tablets, capsules, lozenges, oral granules, topical ointments and creams, topical patches, and vaporizer solutions). Generic formulations are widely available. The Food and Drug Administration (FDA) allows various combinations of antitussives, protussives, analgesics, decongestants, and antihistamines. However, combinations of antitussives and protussives are potentially counterproductive.

**Nonpharmacologic Therapy**

Nonpharmacologic therapy includes nonmedicated lozenges, humidification, interventions to promote nasal drainage, and hydration. Nonmedicated lozenges may reduce cough by decreasing throat irritation. Humidifiers (ultrasonic, impeller, and evaporative) increase the amount of moisture in inspired air, which may soothe irritated airways. However, high humidity may increase environmental mold, dust mites, minerals, and microorganisms. Vaporizers (humidifiers with a medication well or cup for volatile inhalants) produce a medicated vapor. Cool-mist humidifiers and vaporizers are preferred because fewer bacteria grow at the cooler temperatures and there is less risk of scalding if they are tipped over. Humidifiers and vaporizers must be cleaned daily and disinfected weekly. Babies and young children up to about 2 years of age cannot blow their noses; a rubber bulb nasal syringe may be used to clear the nasal passages and reduce cough if postnasal drip causes cough. Propping infants upright when they sleep and raising the head of the bed at night promotes drainage of nasal secretions. Less viscous and thus easier-to-expel secretions are formed when a person is well hydrated. Cautious hydration is recommended for patients with lower respiratory tract infections, heart failure, renal failure, or other conditions potentially exacerbated by overhydration.

**Pharmacologic Therapy**

Table 12-2 lists examples of antitussive and expectorant products.

**TABLE 12-2 Selected Nonprescription Products for Cough**

Primary Ingredients	Trade Name
<b>Single-Ingredient Products</b>	
Dextromethorphan	DayQuil Cough, Delysm Adult 12 Hour Cough, Robitussin Long-Acting CoughGels, Hold DM
Guaifenesin	Mucinex, Robitussin Mucus + Chest Congestion
Menthol	Vicks VapoDrops, Hall's Ice Blue Drops
<b>Combination Products</b>	
Dextromethorphan and guaifenesin	Robitussin Cough + Chest Congestion DM, Mucinex-DM, DayQuil Mucus Control
Codeine and guaifenesin	Guaiatussin AC, Cheratussin AC
Camphor, menthol, and eucalyptus oil	Vicks VapoRub, Mentholatum for Kids

**Oral Antitussives**

FDA-approved nonprescription oral antitussives include codeine (codeine, codeine phosphate, codeine sulfate), dextromethorphan (dextromethorphan,

dextromethorphan hydrobromide), diphenhydramine (diphenhydramine citrate, diphenhydramine hydrochloride), and chlorphedianol hydrochloride.<sup>16</sup>

### Codeine

At antitussive dosages, codeine is a Schedule C-V narcotic available without a prescription in 30 states (9 of the 30 states limit sales to products sold by a pharmacist in a pharmacy).<sup>17</sup> Codeine-containing Schedule C-V products must contain one or more noncodeine active ingredients and no more than 200 mg of codeine per 100 milliliters.<sup>18</sup> Abuse of the combination of codeine and promethazine hydrochloride, known by the street names of "purple drank" and "lean," is a common problem.<sup>19</sup>

Codeine acts centrally on the medulla to increase the cough threshold. Codeine is methylmorphine; morphine may be the active antitussive. Codeine is well absorbed orally with a 15- to 30-minute onset of action and a 4- to 6-hour duration of effect. The elimination half-life is 2.5-3 hours. Ten percent of a codeine dose is demethylated in the liver to form morphine. Approximately 3%-16% of codeine is eliminated unchanged in the urine.

Codeine is indicated for the suppression of nonproductive cough caused by chemical or mechanical respiratory tract irritation. Codeine's efficacy and safety as an antitussive drug in children are not established; pediatric dosage guidelines are extrapolated from the adult literature. Table 12-3 lists FDA-approved codeine dosages.<sup>16</sup> Reduced doses are appropriate for patients of advanced age and the debilitated. Codeine is available as oral solutions, liquids, suspensions, and syrups in combination with other active ingredients, including guaifenesin, antihistamines, and decongestants. Alcohol-, dye-, gluten-, and sucrose-free formulations are available.

Usual antitussive codeine dosages have low toxicity and little risk of addiction. The most common side effects associated with antitussive codeine dosages are nausea, vomiting, sedation, dizziness, and constipation. The lethal dose of codeine in adults is 0.5-1 gram, with death from marked respiratory depression and cardiopulmonary collapse. Concomitant use of codeine and central nervous system (CNS) depressants (e.g., barbiturates, sedatives, or alcohol) causes additive CNS depression. Codeine is contraindicated in patients with known codeine hypersensitivity and during labor when a premature birth is anticipated. Patients with impaired respiratory reserve (e.g., asthma or COPD) or preexisting respiratory depression, drug addicts, and individuals who take other respiratory depressants or sedatives, including alcohol, should use codeine with caution.

### Dextromethorphan

Considered approximately equipotent with codeine, dextromethorphan is a nonopioid with no analgesic, sedative, respiratory depressant, or addictive properties at usual antitussive doses. Dextromethorphan, the methylated dextrorotatory analogue of levorphanol (a codeine analogue), acts centrally in the medulla to increase the cough threshold. It is well absorbed orally with a 15- to 30-minute onset of action and a 3- to 6-hour duration of effect.

Dextromethorphan exhibits polymorphic metabolism, with a usual elimination half-life of 1.2-2.2 hours. However, the half-life may be as long as 45 hours in people with a poor metabolism phenotype.

Dextromethorphan is indicated for the suppression of nonproductive cough caused by chemical or mechanical respiratory tract irritation. The efficacy and safety of dextromethorphan as an antitussive drug in children have not been established.<sup>20</sup> Table 12-3 lists FDA-approved dextromethorphan dosages.<sup>16</sup> Dextromethorphan is marketed in the form of syrups, liquids, solutions, extended-release oral suspensions, liquid-filled gelcaps, tablets, capsules, powders, and lozenges. Alcohol-, sucrose-, gluten-, and dye-free formulations are available.

**TABLE 12-3 Dosage Guidelines for Nonprescription Oral Antitussives and Expectorants**

Drug	Dosage (maximum daily dosage)		
	Adults/Children ≥12 Years	Children 6 to <12 Years	Children 2 to <6 Years <sup>a</sup>
Chlophedianol <sup>b,c</sup>	25 mg every 6-8 hours (100 mg)	12.5 mg every 6-8 hours (50 mg)	12.5 mg every 6-8 hours (50 mg)
Codeine <sup>b-d</sup>	10-20 mg every 4-6 hours (120 mg)	5-10 mg every 4-6 hours (60 mg)	1 mg/kg/day in 4 equal divided dosages or by average body weight
Dextromethorphan hydrobromide <sup>b</sup>	10-20 mg every 4 hours or 30 mg every 6-8 hours (120 mg)	5-10 mg every 4 hours or 15 mg every 6-8 hours (60 mg)	2.5-5 mg every 4 hours or 7.5 mg every 6-8 hours (30 mg)
Diphenhydramine citrate <sup>b,c</sup>	38 mg every 4 hours (228 mg)	19 mg every 4 hours (114 mg)	9.5 mg every 4 hours (57 mg)
Diphenhydramine HCl <sup>b,c</sup>	25 mg every 4 hours (150 mg)	12.5 mg every 4 hours (75 mg)	6.25 mg every 4 hours (37.5 mg)
Guaifenesin <sup>b</sup>	200-400 mg every 4 hours (2.4 g)	100-200 mg every 4 hours (1.2 g)	50-100 mg every 4 hours (600 mg)

<sup>a</sup> The Consumer Health Care Products Association announced in October 2008 that manufacturers were voluntarily updating cough and cold product labels to state "do not use" in children under 4 years of age.<sup>41</sup> FDA announced that it would not object to the more restrictive labeling.<sup>42</sup> These actions have not changed the official monograph for cold, cough, allergy, bronchodilator, and antiasthmatic drug products.<sup>16</sup>

<sup>b</sup> Not recommended for use in children younger than 2 years; no FDA-approved dosing recommendations.

<sup>c</sup> FDA recommends that the labels on nonprescription products not provide dosage information for children younger than 6 years.

<sup>d</sup> Codeine may be dosed by average body weight: 2 years of age (average body weight of 12 kg) = 3 mg every 4-6 hours (maximum in 24 hours: 12 mg); 3 years of age (average body weight of 14 kg) = 3.5 mg every 4-6 hours (maximum in 24 hours: 14 mg); 4 years of age (average body weight of 16 kg) = 4 mg every 4-6 hours (maximum in 24 hours: 16 mg); 5 years of age (average body weight of 18 kg) = 4.5 mg every 4-6 hours (maximum in 24 hours: 18 mg). A dispensing device such as a dropper calibrated for age or weight should be dispensed along with the product when it is intended for use in children 2 to <6 years of age to prevent possible overdose from an improperly measured dose.

Source: Reference 16.

Dextromethorphan has a wide margin of safety. Side effects with usual doses are uncommon but may include drowsiness, nausea or vomiting, stomach discomfort, or constipation. Dextromethorphan overdoses cause confusion, excitation, nervousness, irritability, restlessness, drowsiness, as well as severe nausea and vomiting; respiratory depression may occur with very high doses. Additive CNS depression occurs with alcohol, antihistamines, and psychotropic medications. The combination of monoamine oxidase inhibitors (MAOIs) and dextromethorphan may cause serotonergic syndrome (e.g., increased blood pressure, hyperpyrexia, arrhythmias, and myoclonus). Dextromethorphan should not be taken for at least 14 days after the MAOI is discontinued. Patients who have known hypersensitivity to dextromethorphan or who have a prior history of dextromethorphan dependence should not take it. Dextromethorphan is abused for its phencyclidine-like euphoric effect ("robo-tripping")<sup>21,22</sup>; abuse may be associated with psychosis and mania.

Dextromethorphan abuse is especially common among male adolescents.<sup>23</sup> In 2010, at the request of the Drug Enforcement Administration, FDA's Drug Safety and Risk Management Advisory Committee considered, but voted against, recommending that dextromethorphan be scheduled in the Controlled

Substances Act.<sup>24</sup>

### Diphenhydramine

Diphenhydramine, a nonselective (first-generation) antihistamine with significant sedating and anticholinergic properties, acts centrally in the medulla to increase the cough threshold. Second-generation antihistamines (e.g., loratadine and fexofenadine) lack antitussive activity. Diphenhydramine is well absorbed following oral administration, with a bioavailability of 40%-70%, an onset of action of about 15 minutes, and a duration of action of about 4-6 hours. The volume of distribution is 3.3-4.5 L/kg. Diphenhydramine is hepatically metabolized to N-dealkylated urine and acidic metabolites with a clearance of 0.4-0.7 L/kg per hour. Less than 4% is excreted unchanged in the urine.

Diphenhydramine is indicated for the suppression of nonproductive cough caused by chemical or mechanical respiratory tract irritation. [Table 12-3](#) lists FDA-approved diphenhydramine dosages.<sup>16</sup> A common ingredient in cold and allergy products, diphenhydramine is available in multiple dosage formulations, including an alcohol-free syrup specifically indicated for cough. Symptoms of diphenhydramine overdose include mild to severe CNS depression (e.g., mental confusion, sedation, or respiratory depression), hypotension, and CNS stimulation (e.g., hallucinations or convulsions). Side effects of diphenhydramine include drowsiness, disturbed coordination, respiratory depression, blurred vision, urinary retention, dry mouth, and dry respiratory secretions. Uncommon side effects reported with diphenhydramine include acute dystonic reactions such as oculogyric crisis (rotation of the eyeballs), torticollis (contraction of neck muscles), and catatonia-like states, as well as allergic and photoallergic reactions. Diphenhydramine may cause excitability, especially in children. Diphenhydramine potentiates the depressant effects of narcotics, nonnarcotic analgesics, benzodiazepines, tranquilizers, and alcohol on the CNS, and it intensifies the anticholinergic effect of MAOIs and other anticholinergics. Diphenhydramine is contraindicated in patients with known hypersensitivity to diphenhydramine or structurally similar antihistamines. Diphenhydramine should be used with caution in patients with diseases potentially exacerbated by drugs with anticholinergic activity, including narrow-angle glaucoma, stenosing peptic ulcer, pyloroduodenal obstruction, symptomatic prostatic hypertrophy, bladder-neck obstruction, asthma and other lower respiratory tract disease, elevated intraocular pressure, hyperthyroidism, cardiovascular disease, or hypertension. Because of the increased risk of toxicity, diphenhydramine-containing antitussives should not be used with any other diphenhydramine-containing product, including topical products.

### Chlophedianol

Chlophedianol is a centrally acting oral antitussive originally marketed in 1960 as a prescription antitussive. Reintroduced as a nonprescription product in late 2009, chlophedianol is an alkylamine antihistamine derivative with antitussive, moderate local anesthetic, and mild anticholinergic effects.

Chlophedianol is indicated for the suppression of nonproductive cough caused by chemical or mechanical respiratory tract irritation. [Table 12-3](#) lists the FDA-approved chlophedianol dosage.<sup>16</sup> Chlophedianol is marketed in the form of oral liquids, solutions, and syrups. Sugar-, alcohol-, dye-, and gluten-free products are available.

Published data for chlophedianol are limited. It has a slower onset of maximal effect (4 hours vs. 30 minutes) and a longer duration of action than does codeine.<sup>25</sup> Chlophedianol is metabolized hepatically and eliminated renally. Side effects include excitation, hyperirritability, nightmares, hallucinations, hypersensitivity, and urticaria. Dry mouth, vertigo, visual disturbances, nausea, vomiting, and drowsiness have been associated with large doses. If the patient takes MAOIs, chlophedianol should not be administered for at least 14 days after the MAOIs are halted. Chlophedianol is contraindicated in patients with known chlophedianol hypersensitivity.

### Protussives (Expectorants)

Guaifenesin (glyceryl guaiacolate), the only FDA-approved expectorant, is indicated for the symptomatic relief of acute, ineffective productive cough.<sup>16</sup> Guaifenesin is not indicated for chronic cough associated with chronic lower respiratory tract diseases such as asthma, COPD, emphysema, or smoker's cough. Guaifenesin loosens and thins lower respiratory tract secretions, making minimally productive coughs more productive. However, few data support its efficacy, especially at nonprescription dosages. Although the pharmacokinetics of guaifenesin is not well described, guaifenesin appears to be well absorbed after oral administration, with a half-life of about 1 hour.

[Table 12-3](#) lists FDA-approved dosages of guaifenesin.<sup>16</sup> Guaifenesin is marketed as oral liquids, syrups, caplets, granules, and immediate-release and extended-release tablets. Alcohol-, sucrose-, and dye-free formulations are also available. Most reports of guaifenesin overdosages involve combinations of drugs and therefore are difficult to assess. However, signs and symptoms of overdosages appear to be extensions of the side effects.

Guaifenesin is generally well tolerated. Side effects include nausea, vomiting, dizziness, headache, rash, diarrhea, drowsiness, and stomach pain. Large doses, either singly or in combination with ephedrine or pseudoephedrine, have been associated with renal calculi.<sup>26</sup> Guaifenesin is contraindicated in patients with a known hypersensitivity to guaifenesin.

### Topical Antitussives

Camphor and menthol are the only FDA-approved topical antitussives.<sup>16</sup> Other volatile oils (e.g., eucalyptus), common in many cough and cold preparations, impart a strong medicinal odor to products but are not FDA-approved antitussives. At subtherapeutic doses, menthol is a common flavoring agent. Although the mechanism of action is not well described, inhaled camphor and menthol vapors stimulate sensory nerve endings within the nose and mucosa, creating a local anesthetic sensation and a sense of improved airflow. However, there is little objective evidence of clinical efficacy. A possible drug interaction with menthol cough drops and warfarin resulting in reduced warfarin response has been reported.<sup>27</sup> [Table 12-4](#) provides administration guidelines for these agents.

**TABLE 12-4 Administration Guidelines for Nonprescription Topical Antitussives (Adults and Children ≥ 2 Years<sup>a</sup>)**

<b>Formulation</b>	<b>Administration</b>
Ointments <sup>b</sup>	Rub on the throat and chest in a thick layer; application may be repeated up to 3 times daily or as directed by primary care provider; loosen clothing around throat and chest so vapors reach the nose and mouth; cover with a warm, dry cloth (optional). Do not use in the nostrils, under the nose, by the mouth, on damaged skin, or with tight bandages.
Lozenges <sup>c</sup>	Allow lozenge to dissolve slowly in mouth; repeat hourly or as needed or as directed by a primary care provider.
Inhalation <sup>d</sup>	For products intended to be added directly to cold water for use in a steam vaporizer: add measured solution to cold water; place the mixture in the vaporizer; breathe in the medicated vapors up to 3 times daily. For products to be placed in the medication chamber of a hot steam vaporizer: place water in vaporizer; place solution in medication chamber; breathe in the medicated vapors up to 3 times daily.

<sup>a</sup> For children ages < 2 years, consult a primary care provider.

<sup>b</sup> Camphor 4.7%-5.3%; menthol 2.6%-2.8%.

<sup>c</sup> Menthol lozenges, 5-10 mg lozenge; repeat hourly as needed.

<sup>d</sup> Camphor 6.2%; menthol 3.2%.

Source: Reference 16.

Camphor- and menthol-containing ointments, creams, and solutions may splatter and cause serious burns if used near an open flame or placed in hot water or in a microwave oven. Camphor and menthol vapors may be ciliotoxic and proinflammatory, especially in young children.<sup>28</sup> These products are also toxic if ingested. Toxicities include burning sensations in the mouth, nausea and vomiting, epigastric distress, restlessness, excitation, delirium, seizures, and death. Ingestion of as little as 4 teaspoons of products containing 5% camphor may be lethal for children.<sup>29</sup>

#### Product Selection Guidelines

##### Efficacy

Although antitussives and expectorants have been marketed for decades, efficacy has been difficult to prove and may depend on the etiology of the cough. There is no good evidence that dextromethorphan, codeine, diphenhydramine, or guaifenesin are effective treatments of acute cough in adults or children<sup>30-33</sup>; there is even less evidence for the efficacy of menthol, camphor, and chlophedianol. There is also a lack of evidence for or against the efficacy of nonprescription antitussives as adjuncts to antibiotics for the treatment of acute pneumonia.<sup>34</sup> Factors such as taste, smell, color, viscosity, sugar content, and personal expectation may contribute to a large placebo response (up to 85%).<sup>35</sup> Proof of efficacy will require data from well-designed trials of subjects with natural disease who are assessed with standardized objective outcome parameters.

The American College of Chest Physicians (ACCP) published updated evidence-based diagnosis and management of cough guidelines in 2006<sup>36</sup>; similar international guidelines are available.<sup>37,38</sup> The ACCP guidelines state that central cough suppressants are ineffective in cough associated with the common cold, and they recommend a combination of a first-generation antihistamine plus a decongestant to treat the virus-induced postnasal drip that is most likely the cause of the cough (see [Chapter 11](#)).<sup>39</sup> Also, because viral infection increases upper airway afferent nerve sensitivity, the guidelines suggest that the anti-inflammatory naproxen may reduce viral-associated cough.<sup>39</sup> The guidelines also recommend empiric treatment of cough associated with chronic upper airway cough syndrome, for which the etiology is unclear, with a first-generation antihistamine/decongestant combination (see [Chapter 11](#)).<sup>40</sup> The guidelines recommend codeine or dextromethorphan for the short-term symptomatic relief of cough associated with acute and chronic bronchitis and postinfectious subacute cough. Guaifenesin is not recommended for any indication. The guidelines do not address chlophedianol.

##### Dosage Formulations

Cough products are marketed in a variety of dosage formulations. Efficacy appears to be the same for all dosage formulations; patients may select a dosage formulation on the basis of preference and convenience. Most products are formulated for dosage intervals of 4-6 hours, but some liquid dosage forms are specifically formulated for an extended dosage interval. For example, some dextromethorphan products are formulated with polymer complexes (e.g., sulfonated styrene-divinylbenzene copolymer; polistirex), conferring an extended dosage interval (8-12 hours). Patients treating nocturnal cough may prefer a product with an extended dosage interval.

##### Special Populations

In January 2008, FDA issued a public health advisory recommending that nonprescription cough and cold medicines “. . . not be used to treat infants and children under 2 years of age because several serious and potentially life-threatening side effects can occur.”<sup>41</sup> In October 2008, the Consumer Healthcare Products Association (CHPA) announced that manufacturers were voluntarily updating cough and cold product labels to state “do not use” in children under 4 years of age.<sup>42</sup> FDA announced that it would not object to the more restrictive labeling.<sup>43</sup> To address the issue of inaccurate dosing, FDA released guidelines in May 2011 for liquid nonprescription drug products that include any type of dispensing device (dropper, cup, syringe, or spoon).<sup>44,45</sup> These products include liquid analgesics, liquid cough and cold products, and lactase replacement drops. The key points of the guidance are recommendations that

- A dosing device be included with all oral liquid nonprescription products.
- The device be calibrated to the dose recommended in the product directions.
- The device be used only with the product in which it is packaged.
- The markings remain visible even when the liquid is in the device.

The agency continues to assess the safety and efficacy of nonprescription cough and cold medications in children.

Codeine (Pregnancy Category C) should be used during pregnancy only if the potential benefits outweigh the risks. Nonteratogenic concerns include the risk of neonatal respiratory depression if codeine is taken close to the time of delivery and neonatal withdrawal if codeine is used regularly during the pregnancy. Codeine is excreted in breast milk and is associated with drowsiness in nursing infants.<sup>46,47</sup> Because the elderly may be more susceptible to the sedating effects of codeine, the dose should be started at the lower end of the dosage range and titrated as tolerated, with careful monitoring.

Dextromethorphan (Pregnancy Category C) is viewed as probably safe for use during pregnancy.<sup>48</sup> It is not known whether dextromethorphan is excreted in breast milk. Because the elderly may be more susceptible to the sedating effects of dextromethorphan, the dose should be started at the lower end of the dosage range and titrated as tolerated, with careful monitoring.

Diphenhydramine (Pregnancy Category B) is excreted in breast milk and may cause unusual excitation and irritability in the infant; it may also decrease the flow of milk. Compared with the general population, the elderly are more likely to experience dizziness, excessive sedation, syncope, confusion, and hypotension with diphenhydramine. The 2012 American Geriatrics Society Beers Criteria identify diphenhydramine, along with four other nonprescription first-generation H<sub>1</sub>-antihistamines and seven prescription first-generation H<sub>1</sub>-antihistamines, as potentially inappropriate medications in older adults.<sup>49</sup>

Children and the elderly may experience paradoxical excitation, restlessness, and irritability with diphenhydramine. Dosing for the latter group should be started at the lower end of the dosage range and titrated as tolerated, with careful monitoring.

There are no controlled data regarding the use of guaifenesin (Pregnancy Category C) or chlophedianol (Pregnancy Category N) during pregnancy or breast-feeding. There are no special considerations for use of guaifenesin by the elderly. Chlophedianol should be used with caution in sedated or debilitated patients.

##### Patient Factors

Cough is a symptom of many acute and chronic diseases. Patients with identified exclusions for self-care ([Figure 12-1](#)) should be referred for further evaluation. Patients with known, or signs and symptoms of, chronic diseases associated with cough ([Table 12-5](#)) should not attempt to self-treat cough, even cough caused by an acute viral upper respiratory tract infection (URTI) because the acute infection may exacerbate the underlying disease. Patients with smoker's cough should be counseled regarding smoking cessation options; antitussives and expectorants are not indicated (see [Chapter 47](#)). Dextromethorphan, diphenhydramine, and chlophedianol should not be taken concurrently with MAOIs. Diphenhydramine is highly sedating and should be avoided by patients at risk from the anticholinergic properties of the drug. First-generation antihistamines and decongestants should be used only if the potential benefit outweighs the risk (see [Chapter 11](#)).

##### Complementary Therapies

Hundreds of herbal and other complementary therapies are marketed for cough. However, evidence does not support the use of complementary therapies for treating cough, and some products have potential safety issues. (See [Chapter 51](#) for information on those therapies.) For example, honey, a common but unproven home remedy, should not be given to children younger than 1 year owing to the risk of botulism from ingestion of honey contaminated with *Clostridium botulinum*.<sup>50</sup>

#### Assessment of Cough: A Case-Based Approach

Before recommending any treatment, the health care provider needs to inquire about the duration of the cough, whether the cough is productive, and whether it is associated with a chronic illness (Table 12-5). The provider should also obtain a list of all the patient's current medications to identify possible drug-drug or drug-disease interactions. In addition, the provider should find out how the patient has treated the current cough, as well as previous coughs, and whether these treatments were satisfactory or effective.

**TABLE 12-5 Signs and Symptoms of Diseases Associated with Cough**

<i>Disease</i>	<i>Signs and Symptoms</i>
Acute bronchitis	Purulent sputum; cough that lasts 1-3 weeks; mild dyspnea, mild bronchospasm and wheezing; usually afebrile though may have a low-grade fever
Asthma	Wheezing or chest tightness; shortness of breath, coughing predominantly at night; cough in response to specific irritants, such as dust, smoke, or pollen
CHF	Fatigue; dependent edema, breathlessness
Chronic bronchitis	Productive cough most days of the month at least 3 months of the year for at least 2 consecutive years
COPD	Persistent, progressive dyspnea; chronic cough (may be intermittent or unproductive), chronic sputum production
GERD	Heartburn; sour taste in mouth; worsening of symptoms when supine; improvement with acid-lowering drugs
Lower respiratory tract infection	Fever (mild to high); thick, purulent, discolored phlegm; tachypnea, tachycardia
UACS	Mucus drainage from nose; frequent throat clearing
Viral URTI	Sneezing; sore throat; rhinorrhea; low-grade temperature

Key: CHF = Congestive heart failure; COPD = chronic obstructive pulmonary disease; GERD = gastroesophageal reflux disease; UACS = upper airway cough syndrome; URTI = upper respiratory tract infection.

Cases 12-1 and 12-2 provide examples of the assessment of patients with cough.

#### Case 12-1

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient has been coughing for about a week. The cough started about 3 days after she got a cold. Her cold symptoms (sore throat, nasal congestion, rhinorrhea) are mostly resolved, but the dry, hacking, nonproductive cough persists.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The cough is worse at night or when she lies down.
c. description of the patient's efforts to relieve the symptoms	The patient tried menthol cough drops and a combination of dextromethorphan and guaifenesin cough syrup without relief.
d. patient's identity	Janet Carter
e. age, sex, height, and weight	25 years old, female, 5 ft 5 in., 125 lb
f. patient's occupation	High school math teacher
g. patient's dietary habits	Generally eats a well-balanced diet with lots of fresh fruits and vegetables.
h. patient's sleep habits	Sleeps 8-9 hours a night.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	No concurrent medical conditions. No routine nonprescription medications or dietary supplements. Is currently taking Yasmin (ethinyl estradiol 30 mcg, drospirenone 3 mg) for oral contraception; started about 5 years ago.
j. allergies	NKA
k. history of other adverse reactions to medications	None
l. other (describe) _____	None
<b>Assessment and Triage</b>	

2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Janet is likely experiencing UACS secondary to the upper respiratory tract viral infection.
3. Identify exclusions for self-treatment (Figure 12-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Take no action. (2) Recommend that the patient see her PCP for further evaluation and treatment. (3) Recommend nondrug treatment (inhale warm steamy vapors, elevate head of bed at night to promote nasal and sinus drainage). (4) Recommend self-care with a first-generation antihistamine and decongestant combination product.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Janet should treat her cough with a first-generation oral antihistamine (e.g., diphenhydramine) and decongestant (e.g., pseudoephedrine, phenylephrine) combination product; elevating the head of the bed at night or inhaling warm steamy vapors may provide some nondrug symptomatic relief.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"The upper airway cough syndrome is treated by a combination of the drying effects of an oral first-generation antihistamine and decongestant action of an oral decongestant."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Centrally active antitussives such as dextromethorphan and codeine and the expectorant guaifenesin have little efficacy in cough associated with viral infections such as the common cold."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	See the box Patient Education for Cough.
Solicit follow-up questions from the patient or caregiver.	"How long can I take the antihistamine/decongestant medication?"
Answer the patient's or caregiver's questions.	"You may take the antihistamine/decongestant medication as needed for relief of symptoms until the cough resolves. Contact your PCP if the cough persists for longer than 7 days; if you develop a high fever 103°F (39.4°C); or if you cough up blood, develop chest pain, or have trouble breathing."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Ask Janet to call to update you on her response to treatment.

Key: NKA = No known allergies; UACS = upper airway cough syndrome; PCP = primary care provider.

### Case 12-2

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient has a cough that is slowly getting worse. He states that he has had a cough for "years." Initially the cough was a dry morning cough, but over the past few months it has become productive of clear phlegm and persists throughout the day and night.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The cough is worse in the morning when he gets up and persists throughout the day and night. The patient thinks it may be a smoker's cough.
c. description of the patient's efforts to relieve the symptoms	The patient has tried hard candy, menthol cough drops, Echinacea cough drops, and horehound drops, but nothing stops the cough.
d. patient's identity	Martin Lansford

e. age, sex, height, and weight	45 years old, male, 5 ft 11 in., 75 kg
f. patient's occupation	Accountant
g. patient's dietary habits	Mostly eats a meat and potatoes diet with little fresh fruit or vegetables.
h. patient's sleep habits	Sleeps 9 hours a night.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Intermittent heartburn and/or sour taste in mouth; has symptoms 3-4 times per year. The patient takes Prilosec (omeprazole) 20 mg once a day for 3-5 days 3-4 times per year. He has no other known medical condition and is not taking any routine nonprescription or dietary supplements.
j. allergies	None
k. history of other adverse reactions to medications	None
l. other (describe) _____	The patient started smoking at age 16 years. He currently smokes 2 ppd.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	The cough appears to be a smoker's cough, but may be a symptom of chronic bronchitis or COPD. Heartburn and dyspepsia may be symptoms of GERD; GERD may cause chronic cough.
3. Identify exclusions for self-treatment (Figure 12-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Take no action. (2) Recommend that the patient see his PCP for further evaluation and treatment. (3) Recommend nondrug treatment (nonmedicated lozenges, inhale warm steamy vapors). (4) Recommend self-care with a nonprescription centrally acting antitussive or expectorant. (5) Recommend that the patient stop smoking.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Martin should be referred to his PCP for further evaluation and treatment of his chronic cough. Centrally acting antitussives (e.g., codeine, dextromethorphan) and expectorants (e.g., guaifenesin) are not effective for the management of smoker's cough, COPD, or chronic obstructive pulmonary disease. Recommend smoking cessation.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should consult with your primary care provider about your chronic cough."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Chronic productive cough is a symptom associated with smoking but also with several chronic medical conditions such as chronic bronchitis and COPD. Chronic cough is also a symptom of lung cancer. Heartburn may trigger cough." (See Chapter 13 for information on the assessment and self-care of heartburn and dyspepsia.)
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"What are my choices if I decide to stop smoking?"
Answer the patient's or caregiver's questions.	"Nonprescription nicotine replacement choices include nicotine-containing patches, gums, and lozenges. Prescription medications include nicotine-containing nasal sprays and inhalers and medications that reduce nicotine cravings such as bupropion and varenicline. Individual or group counseling are also available to help you quit smoking." (See Chapter 47 for information on self-care assessment of and medications for smoking cessation.)
<b>Evaluation of Patient Outcome</b>	

9. Assess patient outcome.

Ask Martin to call you after he is evaluated by his PCP to update you on his medical condition and decision regarding smoking cessation.

Key: COPD = Chronic obstructive pulmonary disease; GERD = gastroesophageal reflux disease; PCP = primary care provider; ppd = packs of cigarettes smoked per day.

### Patient Counseling for Cough

The provider should explain the appropriate drug and nondrug measures for treating the patient's type of cough. After a product is recommended, the dosage guidelines; drug administration techniques (for topical drugs); and possible side effects, drug-drug interactions, and precautions or warnings should be fully explained. The provider should ensure that the patient understands when self-care of the cough should be discontinued and medical care sought. For patients with underlying medical disorders, the provider should explain which nonprescription medications are contraindicated and what symptoms indicate the need to seek medical care. The box Patient Education for Cough lists specific information for patients.

#### Patient Education for Cough

The goal of self-treatment is to reduce the number and severity of cough episodes and prevent complications. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Nondrug Measures

- Stay well hydrated.
- Reduce throat irritation by slowly dissolving nonmedicated lozenges and candies in the mouth.
- Use humidifiers and vaporizers to increase the moisture in the air and possibly soothe irritated airways.
- Treat the underlying cause of cough (e.g., nasal congestion).

#### Nonprescription Medications

- Cough is a symptom of an underlying disorder. Contact your primary care provider if you have any of the exclusions for self-care listed in [Figure 12-1](#).
- Select a product on the basis of the active ingredients and dosage formulation. Brand names frequently change and may not clearly represent the active ingredients.
- Slowly dissolve medicated lozenges in your mouth; do not chew.
- Swallow tablets and capsules whole; do not crush or chew.
- Follow the recommended dosing guidelines for each medication.
- Store all these medications according to the manufacturer's recommendations. Do not use any expired drug.

#### Cough Suppressants (Antitussives)

- Cough suppressants control or eliminate cough and are the drugs of choice for nonproductive coughs.
- Oral nonprescription cough suppressants include codeine (available without a prescription in some states), dextromethorphan, diphenhydramine, and chlorpheniramine.
- Topical nonprescription antitussives include camphor and menthol.
- Do not heat, microwave, or add topical antitussives to hot water. Do not use topical antitussives near an open flame. Topical antitussive ointments and liquids are toxic if ingested.
- The most common side effects of codeine include nausea, vomiting, sedation, dizziness, and constipation.
- Dextromethorphan's side effects are uncommon but may include drowsiness, nausea, vomiting, stomach discomfort, and constipation.
- The most common diphenhydramine side effects include drowsiness, disturbed coordination, decreased respiration, blurred vision, difficult urination, and dry mouth.
- The most common chlorpheniramine side effects include nausea, dizziness, and drowsiness.
- Codeine, dextromethorphan, diphenhydramine, and chlorpheniramine interact with drugs that cause drowsiness (e.g., narcotics, sedatives, some antihistamines, and alcohol).
- Dextromethorphan and chlorpheniramine also interact with monoamine oxidase inhibitors (e.g., phenelzine, tranylcypromine, and isocarboxazid). Do not take dextromethorphan or chlorpheniramine within 14 days of taking one of these medications.
- Diphenhydramine and chlorpheniramine also interact with drugs that have anticholinergic activity.
- Patients with impaired respiratory reserve (e.g., asthma or chronic obstructive pulmonary disease) should use codeine and diphenhydramine with caution.
- Patients with narrow-angle glaucoma, stenosing peptic ulcer, pyloroduodenal obstruction, symptomatic prostatic hypertrophy, bladder-neck obstruction, elevated intraocular pressure, hyperthyroidism, heart disease, or hypertension should use diphenhydramine with caution.
- Talk with your doctor before using any medication while pregnant.
- Codeine and diphenhydramine are excreted in breast milk and may cause side effects in the child.
- Older adults and children may have paradoxical excitation, restlessness, and irritability with diphenhydramine or chlorpheniramine. Older adults are more likely than the general population to have side effects from diphenhydramine.

#### Expectorants (Protussives)

- Guaifenesin is the only available nonprescription protussive.
- Guaifenesin is generally well tolerated, but side effects may include nausea, vomiting, dizziness, headache, rash, diarrhea, drowsiness, and stomach pain.
- There are no reported drug interactions with guaifenesin.
- Guaifenesin is contraindicated in patients with a known hypersensitivity to the medication.
- Guaifenesin is not indicated for chronic cough associated with chronic lower respiratory tract diseases such as asthma, chronic obstructive pulmonary disease, emphysema, or smoker's cough.

#### Note About Pediatric Dosing

- Manufacturers of cough and cold medications have revised product labeling to state that these products should not be used in children younger than 4 years. Health care providers should stress this information to caregivers of infants and young children.

#### Evaluation of Patient Outcomes for Cough

For most patients, 7 days of nonprescription drug therapy should relieve cough. If the cough persists but has improved at follow-up, the patient should continue the therapy until the cough is resolved. Cough associated with viral URIs usually resolves within 2 weeks; postviral coughs may persist for 3 weeks or longer. Coughs associated with other respiratory infections typically resolve in 3-4 weeks. In all cases, the patient should be referred for further medical evaluation if the cough worsens or if the patient develops other exclusions for self-treatment ([Figure 12-1](#)).

## Key Points for Cough

- Cough is an important respiratory defensive reflex.
- Antitussives (cough suppressants) are the drugs of choice for nonproductive coughs.
- Protussives (expectorants) are the drugs of choice for coughs that expel thick, tenacious secretions from the lungs with difficulty.
- Neither codeine nor dextromethorphan has been shown to be effective for acute coughs associated with viral URIs in either adults or children.
- In 2008, manufacturers voluntarily updated labels for cough and cold products to state “do not use” in children younger than 4 years.
- Combination products are convenient but are generally more expensive per dose and increase the risk of undesirable side effects.
- Refer patients to their primary care provider if they have cough with thick yellow or green sputum or pus-like secretions, or cough accompanied by one or more of the following: high fever (adults,  $\geq 103^{\circ}\text{F}$ ; children,  $>102^{\circ}\text{F}$ ), shortness of breath, chest pain, hemoptysis, chills, night sweats, tight-feeling throat, swollen legs/ankles, cyanosis, unintentional weight loss, rash, or persistent headache.
- Refer patients with cough and a history of or symptoms of chronic underlying disease associated with cough (e.g., asthma, COPD, chronic bronchitis, or heart failure) to their primary care provider.

**Handbook of Nonprescription Drugs > Chapter 13. Heartburn and Dyspepsia****Heartburn and Dyspepsia: Introduction**

Heartburn (pyrosis) is one of the most common gastrointestinal complaints. It is often described as a burning sensation in the stomach or lower chest that rises up toward the neck and occasionally to the back.<sup>1</sup> Patients may also describe it as indigestion, acid regurgitation, sour stomach, or bitter belching. Heartburn is a common symptom of gastroesophageal reflux disease (GERD), but similar symptoms may also occur in patients with peptic ulcer disease (PUD), delayed gastric emptying, gallbladder disease, and numerous other gastrointestinal disorders. Dyspepsia is defined as symptoms originating from the gastroduodenal region and includes bothersome postprandial fullness, early satiation, epigastric pain, and epigastric burning.<sup>2</sup> Patients with dyspepsia may report many of these symptoms, as well as anorexia, belching, nausea and vomiting, and upper abdominal bloating. Heartburn can also occur with dyspepsia. Dyspepsia can be organic, meaning it has an identifiable cause, or functional. Patients with functional dyspepsia have no identifiable organic, systemic, or metabolic disease that is likely to explain the dyspeptic symptoms.

Although rarely a cause of mortality, dyspepsia, heartburn, and GERD are associated with considerable morbidity and cost. Patients with heartburn may limit their activities and restrict their food choices to reduce symptom frequency and severity. Compared with the general population, patients with heartburn have an impaired quality of life, with symptoms affecting activity and work.<sup>3</sup> Nocturnal symptoms of heartburn were reported in 24.9% of the general population and in 74%-79% of patients with heartburn that occurs at least once a week.<sup>4</sup> Nocturnal symptoms are associated with interrupted sleep, decreased health-related quality of life, decreased work productivity, increased daytime sleepiness, and increased complications such as erosive esophagitis and stricture.<sup>4</sup> Patients with dyspepsia report a diminished quality of life similar to patients with mild heart failure or menopause.<sup>5</sup> A retrospective analysis of health insurance claims showed that patients with functional dyspepsia incurred \$5138 more in annual costs than people without dyspepsia.<sup>5</sup> The total direct and indirect costs for GERD were over \$12.6 billion per year; a large percentage of the costs were for prescription medications.<sup>1</sup>

The prevalence of heartburn and acid regurgitation in the past year in a healthy, predominantly white population were 42% and 45%, respectively.<sup>1</sup> Weekly symptoms were reported by 20% of the population, with an equal gender distribution.<sup>1</sup> Most subjects reported their heartburn to be moderately severe. In a cross-sectional study, the prevalence of heartburn was similar among African Americans, Hispanics, Asians, and whites (23%-27%).<sup>1</sup> However, whites had significantly more esophagitis. Although men and women are almost equally affected by GERD, males have a higher rate of esophagitis and Barrett's esophagus (a precancerous condition). Older patients have a higher prevalence of GERD complications, but they may experience fewer symptoms because of decreased sensitivity to refluxed acid. The prevalence of GERD has been increasing in Western countries over the past 30 years, while remaining relatively low among residents of Africa and Asia. The rise in Western countries is speculated to be a result of increasing obesity and decreasing prevalence of *Helicobacter pylori* infection.<sup>1</sup> Heartburn is common during pregnancy, with 30%-80% of women complaining of heartburn, especially in the first trimester.<sup>1</sup>

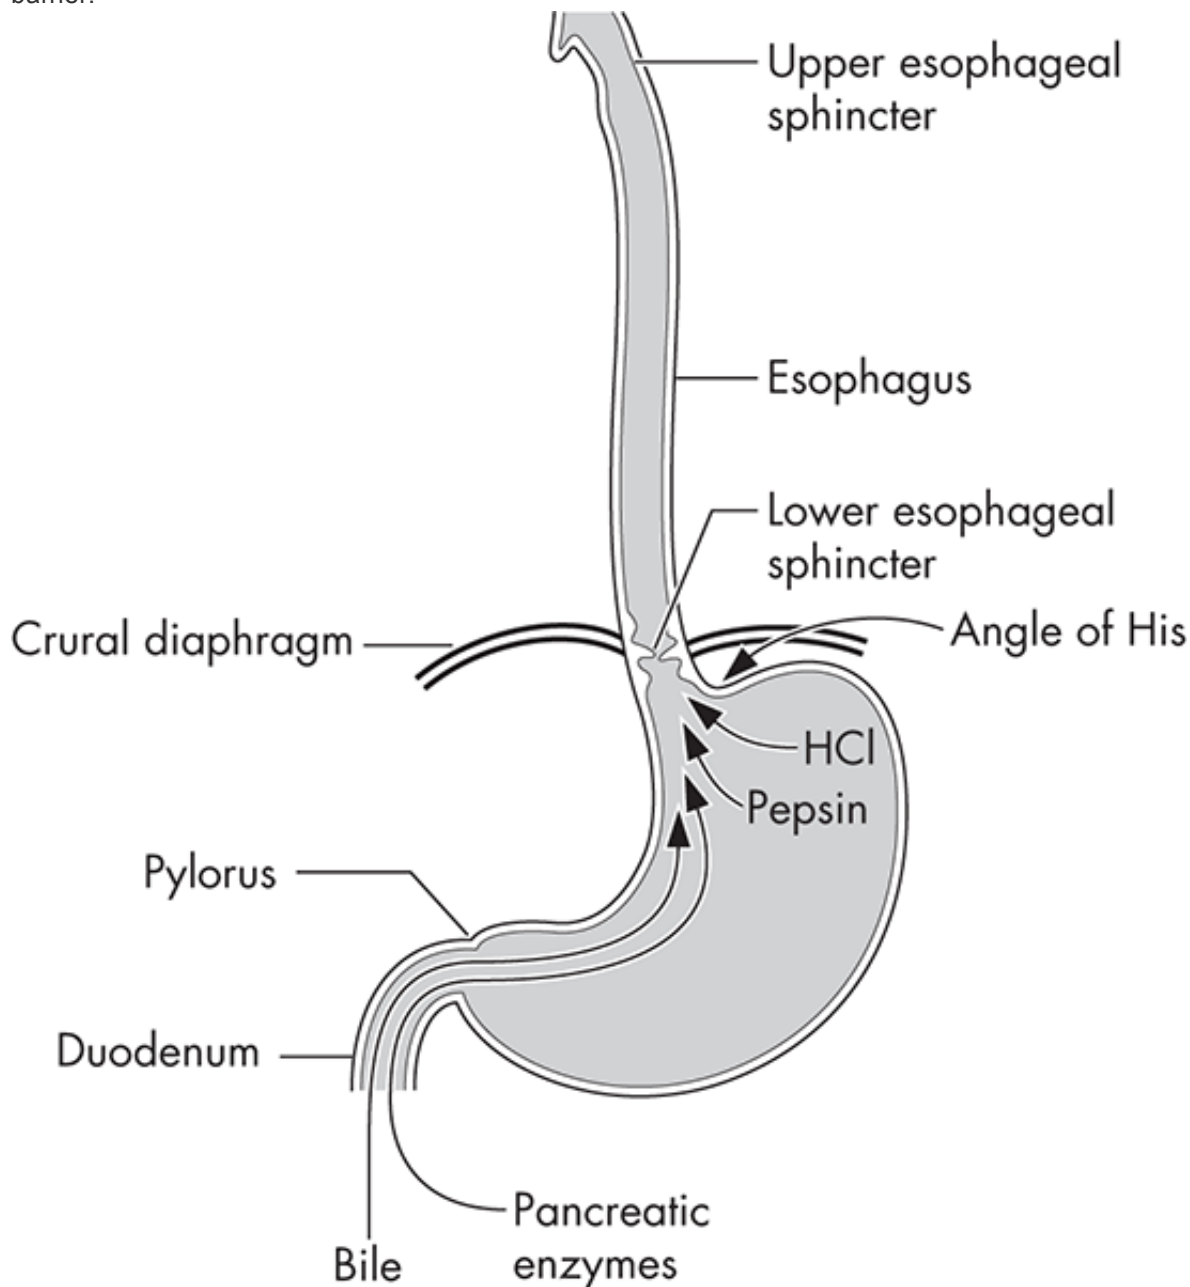

Prevalence of dyspepsia has been estimated to range between 10% and 45%.<sup>2</sup> Much of this variation is influenced by criteria used to define dyspepsia. When heartburn is excluded, the prevalence of uninvestigated dyspepsia is 5%-15%. Women have a slightly higher prevalence compared with men. The incidence of dyspepsia has been estimated to be 2.8% per year.<sup>5</sup> Among patients with dyspepsia, 5%-10% have a peptic ulcer and approximately 20% have erosive esophagitis.

**Pathophysiology**

Esophageal defense mechanisms (antireflux barriers, esophageal acid clearance, and tissue resistance) help protect the esophageal mucosa from acid damage. Antireflux barriers include the intrinsic lower esophageal sphincter (LES), the diaphragmatic crura, the intra-abdominal location of the LES, the phrenoesophageal ligaments, and the acute angle of His (Figure 13-1). These anatomic structures work together to provide a physical barrier against gastric contents being refluxed into the esophagus. The major component is the LES, the distal 3-4 cm of the esophagus that is contracted at rest. The LES relaxes on swallowing to permit the flow of food, liquids, and saliva into the stomach. Transient relaxations occur when there is no swallowing or esophageal peristalsis, allowing retrograde movement of stomach contents into the esophagus. The crural diaphragm provides an extrinsic squeeze to the LES, contributing to resting pressure and augmenting LES pressure during periods of increased abdominal pressure, such as with

coughing, sneezing, or bending over. The angle of His creates a flap valve effect that contributes to the antireflux barrier.

Esophageal defense mechanisms and offensive factors associated with heartburn.

When reflux of acidic gastric material does occur, physiologic mechanisms help protect the esophageal mucosa from damage. Esophageal acid clearance occurs when peristalsis moves refluxed material into the stomach, and saliva and esophageal gland secretions neutralize residual acid. Gravity also helps clear the esophagus. Tight junctions and the matrix of lipid-rich glycoconjugates in the intercellular space reduce epithelial damage from hydrogen ions. Epithelial cells are also capable of buffering and extruding hydrogen ions that do penetrate the cell membrane. Tissue resistance is further aided by the esophageal blood supply that delivers oxygen, nutrients, and bicarbonate and removes hydrogen and carbon dioxide, maintaining normal tissue acid-base balance. Even though gastroesophageal reflux is common, particularly postprandially, symptoms and esophageal damage are uncommon because of these esophageal defense mechanisms.

Heartburn is likely related to stimulation of esophageal mucosal chemoreceptors. Heartburn symptoms can arise from acid reflux, weakly acidic reflux, bile reflux, and mechanical stimulation of the esophagus. It is unclear why some reflux episodes produce symptoms whereas most do not. Possible contributing factors include mucosal disruption, decreased acid clearance, inflammation, reduced salivary bicarbonate concentration, volume of refluxate, frequency of heartburn, and interaction of pepsin with acid. One theory is that the esophagus becomes hypersensitive from repeated acid exposure, causing symptoms to occur from smaller boluses of acid.<sup>6</sup> Any disruption in the esophageal defense mechanisms can lead to increased acid exposure. Distension of the proximal stomach by either food or gas

is a major stimulus for transient LES relaxations. Some patients may have a relatively hypotensive LES that can be overcome by an abrupt increase in intra-abdominal pressure from coughing, straining, or bending over. A hiatal hernia impairs LES function and esophageal acid clearance. A hiatal hernia displaces the LES from the crural diaphragm, reduces LES pressure, and results in more frequent transient relaxations of the LES, all of which contribute to increased reflux. Prolonged exposure of the esophagus to the refluxed material can occur when lying down or sleeping and with decreased salivation or with peristaltic dysfunction. Large refluxate volumes from overeating or delayed gastric emptying can also increase esophageal acid exposure. As a result, damage to the tight intercellular junctions of the esophageal mucosa can lead to increased cellular permeability to hydrogen ions, with subsequent cellular injury. This increased permeability partly explains the development of heartburn in the absence of overt esophagitis.<sup>1</sup> The composition of the refluxate is an important contributor to the degree of esophageal damage. Pepsin and/or bile salts combined with acid produce greater injury than acid alone. *Helicobacter pylori* infection lowers gastric acidity, thereby possibly protecting against heartburn, GERD, and related complications.<sup>1</sup>

A number of risk factors are weakly associated with the development of heartburn (Table 13-1).<sup>1,6,7,8</sup> Foods (e.g., fat, chocolate, peppermint) and drugs (e.g., theophylline, morphine, calcium channel blockers, diazepam) can decrease LES pressure, leading to increased reflux. Foods such as citrus, tomato-based foods, and spicy foods can irritate inflamed esophageal mucosa. Smoking contributes by relaxing LES pressure and decreasing salivation. Anxiety, fear, and worry may lower visceral sensitivity thresholds, leading to increased pain perception. Bending over, straining to defecate, lifting heavy objects, and performing isometric exercises may increase intra-abdominal pressure above the LES pressure, leading to reflux. Obesity increases intra-abdominal pressure, and epidemiologic studies suggest that the prevalence of GERD is considerably higher in obese patients than in those with a normal body mass index.<sup>1</sup>

**TABLE 13-1 Risk Factors That May Contribute to Heartburn**

<b><i>Dietary</i></b>	<b><i>Medications</i></b>
Alcohol (ethanol)	Alpha-adrenergic antagonists
Caffeinated beverages	Anticholinergic agents
Carbonated beverages	Aspirin/NSAIDs
Chocolate	Barbiturates
Citrus fruit or juices	Benzodiazepines
Coffee	Beta <sub>2</sub> -adrenergic agonists
Fatty foods	Bisphosphonates
Garlic or onions	Calcium channel blockers
Mint (e.g., spearmint, peppermint)	Chemotherapy
Salt and salt substitutes	Clindamycin
Spicy foods	Dopamine
Tomatoes/tomato juice	Doxycycline
	Estrogen
<b>Lifestyle</b>	Iron
Exercise (isometric, running)	Narcotic analgesics
Obesity	Nitrates
Smoking (tobacco)	Potassium
Stress	Progesterone
Supine body position	Prostaglandins
Tight-fitting clothing	Quinidine
<b>Diseases</b>	TCAs

Motility disorders (e.g., gastroparesis)	Tetracycline
PUD	Theophylline
Scleroderma	Zidovudine
Zollinger-Ellison syndrome	<b>Other</b>
	Genetics
	Pregnancy

Key: NSAID = Nonsteroidal anti-inflammatory drug; PUD = peptic ulcer disease; TCA = tricyclic antidepressant.

Source: References 1, and 6-8.

Dyspepsia may be caused by PUD, GERD, celiac disease, gastric or esophageal malignancy (rarely), or other gastrointestinal (GI) disorders. Specific foods, such as spicy food, coffee, or alcohol, or excessive food intake have not been established as causing dyspepsia. Medications, including iron, antibiotics, narcotics, digoxin, estrogens, theophylline, and nonsteroidal anti-inflammatory drugs (NSAIDs), commonly cause dyspepsia through direct gastric mucosal injury, changes to GI function, exacerbation of reflux, or some other mechanism.<sup>2</sup> The pathophysiology of functional dyspepsia is unclear but may include delayed gastric emptying, impaired gastric accommodation to a meal, hypersensitivity to gastric distension, altered duodenal sensitivity, abnormal intestinal motility, and central nervous system dysfunction.<sup>2</sup> One or more of these disturbances can occur in individual patients. The cause of symptoms in patients with functional dyspepsia has not been established. Population studies have suggested a genetic predisposition. *H. pylori* may play a role in functional dyspepsia, as evidenced by the small improvement in symptoms following eradication. Patients who have recovered from gastroenteritis may suffer from postinfection functional dyspepsia. Psychosocial factors are an important contributor to symptom severity. Patients with functional dyspepsia may also have anxiety disorders, depression, somatoform disorders, and a recent or remote history of physical or sexual abuse. The exact mechanism is unknown, but some studies have suggested a relationship between psychosocial factors and visceral hypersensitivity.<sup>2</sup>

### Clinical Presentation

Heartburn may occur alone or be associated with other GI disorders such as GERD and PUD (Table 13-2). Heartburn is most frequently noted within 1 hour after eating, especially after a large meal or ingestion of offending foods and/or beverages. Lying down or bending over may exacerbate heartburn. Regurgitation and, less commonly, water brash may also occur. Regurgitation is characterized by a bitter acidic fluid in the back of the throat. It is more common at night or when bending over. It differs from vomiting: nausea, retching, or abdominal contractions do not occur. Water brash is the sudden filling of the mouth with clear, slightly salty fluid secreted from the salivary glands. Severity of any of these symptoms is subjective, and no standard definitions exist for classifying symptoms as mild, moderate, or severe. Symptoms may be considered mild if they bother the patient a little but do not interfere with normal activities. Symptoms that are somewhat bothersome or annoying and/or interfere with normal activities may be considered moderate. Heartburn occurring two or more times a week is suggestive of GERD.<sup>1</sup> GERD can be complicated by erosive esophagitis, hemorrhage, esophageal ulcers, strictures, Barrett's esophagus, and esophageal adenocarcinoma. Heartburn severity is poorly correlated with esophageal damage, especially in older patients who may have no or mild symptoms despite severe erosive esophagitis or other complications on presentation.<sup>1</sup> Upper endoscopy is the standard for determining the presence and extent of esophageal damage.

**TABLE 13-2 Differentiation of Simple Heartburn from Other Acid-Related Disorders**

	<i>Simple Heartburn</i>	<i>GERD</i>	<i>Dyspepsia</i>	<i>PUD</i>
Etiology	See Table 13-1	See Table 13-1	Possible contributing factors: food, alcohol, caffeine, stress, and medications Chronic dyspepsia: associated with PUD, GERD, celiac disease, and gastric cancer; or may lack an identifiable cause (functional dyspepsia)	Gastric or duodenal ulcer caused most commonly by <i>Helicobacter pylori</i> infection and/or NSAIDs
Typical	Burning sensation	Heartburn	Primary: postprandial	Gnawing or burning

Typical symptoms	Burning sensation behind the breastbone that may radiate toward the neck, throat, and occasionally the back	Heartburn, acid regurgitation	Primary, postprandial fullness, early satiation, epigastric pain, epigastric burning Other: belching, bloating, nausea, vomiting	Onset of burning epigastric pain, occurring during day and frequently at night; may be accompanied by heartburn and dyspepsia
------------------	---	-------------------------------	---	---

Key: GERD = Gastroesophageal reflux disease; GI = gastrointestinal; NSAID = nonsteroidal anti-inflammatory drug; PUD = peptic ulcer disease.

Alarm symptoms include dysphagia, odynophagia, upper GI bleeding, and unexplained weight loss, and they can indicate more severe disease and/or complications. Dysphagia (difficulty swallowing) is slowly progressive for solid food and is usually associated with long-standing heartburn. The most common causes are peptic stricture or Schatzki's ring, but severe esophagitis, peristaltic dysfunction, and esophageal cancer are other potential etiologies.<sup>1</sup> Odynophagia (painful swallowing) is less common and may indicate severe ulcerative esophagitis, pill injury (e.g., tetracycline, potassium chloride, vitamin C, NSAIDs, aspirin, or bisphosphonates), or infection. Signs of upper GI bleeding include hematemesis, melena, occult bleeding, and anemia. Patients may also present with atypical or extraesophageal symptoms related to gastroesophageal reflux. These include noncardiac chest pain, asthma, laryngitis, hoarseness, globus sensation (sensation of a lump in the throat), chronic cough, recurrent pneumonitis, and dental erosion.<sup>1,9</sup> Patients presenting with any alarm symptoms or atypical symptoms should be referred to their primary care provider for further evaluation.

Dyspepsia can present with one or more of four main symptoms. Postprandial fullness is an unpleasant sensation perceived as the prolonged persistence of food in the stomach. Early satiation is the feeling of fullness soon after starting to eat that is out of proportion to the amount of food ingested. Early satiety was the term previously used, but satiation is the correct term according to the most recent diagnostic criteria.<sup>2</sup> Epigastric pain is an unpleasant sensation between the umbilicus and lower end of the sternum. Epigastric burning refers to an unpleasant subjective sensation of heat. Less specific symptoms may include bloating, nausea, vomiting, and belching. Symptoms are mostly intermittent and may or may not be related to meals. Weight loss is considered an alarm symptom that should prompt referral for further investigation. Other alarm symptoms include anemia, blood loss, and dysphagia.

## Treatment of Heartburn and Dyspepsia

### Treatment Goals

The goals of self-treatment of heartburn and dyspepsia are to (1) provide complete relief of symptoms, (2) reduce recurrence of symptoms, and (3) prevent and manage unwanted effects of medications.

### General Treatment Approach

The approach to self-treatment of heartburn and dyspepsia requires an initial assessment to determine whether the patient is a candidate for self-care (Figure 13-2). Individuals with exclusions for self-treatment should be referred for further medical evaluation. If the individual is a candidate for self-treatment, specific nondrug measures should be recommended and continued throughout treatment (see Patient Counseling for Heartburn and Dyspepsia). If appropriate, a recommendation should also be made for a nonprescription medication. The selection of the medication should be based on the frequency, duration, and severity of symptoms; the cost of the medication; potential drug-drug interactions and adverse effects; and the patient's preference. Antacids and nonprescription histamine type 2 receptor antagonists (H<sub>2</sub>RAs) should be recommended for individuals with mild, infrequent heartburn and dyspepsia. Antacids are advantageous because they provide rapid relief of symptoms, but relief is brief when taken on an empty stomach (Table 13-3). When used in recommended dosages, the antacids are interchangeable despite differences in antacid salts and potency. Antacid/alginic acid combinations have a comparable onset of action to that of antacids alone and may provide better relief and a slightly longer duration of action.<sup>10,11</sup>

A nonprescription H<sub>2</sub>RA is preferred to an antacid when individuals with mild-moderate episodic heartburn require more prolonged relief of symptoms. H<sub>2</sub>RAs do not relieve heartburn or dyspepsia as rapidly as an antacid (Table 13-3) but may be used with an antacid if quick relief is desired along with a longer duration of action. The H<sub>2</sub>RAs may also be used to prevent heartburn and acid indigestion when given 30 minutes to 1 hour prior to situations in which heartburn is anticipated. Nonprescription H<sub>2</sub>RA products containing the lower doses (e.g., famotidine 10 mg up to twice daily) should be recommended for patients with mild, infrequent heartburn, whereas higher nonprescription dosages (e.g., famotidine 20 mg up to twice daily) should be reserved for moderate symptoms. Patients should not exceed 14 days of self-treatment with an H<sub>2</sub>RA without consulting their primary care provider.

Nonprescription proton pump inhibitors (PPIs) can be used for treating frequent heartburn (2 or more days per week) or when patients do not respond to nonprescription H<sub>2</sub>RAs.<sup>12</sup> The onset of symptomatic relief following a PPI dose is slower than that of an H<sub>2</sub>RA (Table 13-3), and complete relief of symptoms may take several days after initiation of therapy. However, PPIs provide better symptomatic relief and a prolonged duration of action compared with the H<sub>2</sub>RAs. When used to self-treat, the PPI should be limited to a duration of 14 days and retreatment to every 4 months.

### Nonpharmacologic Therapy

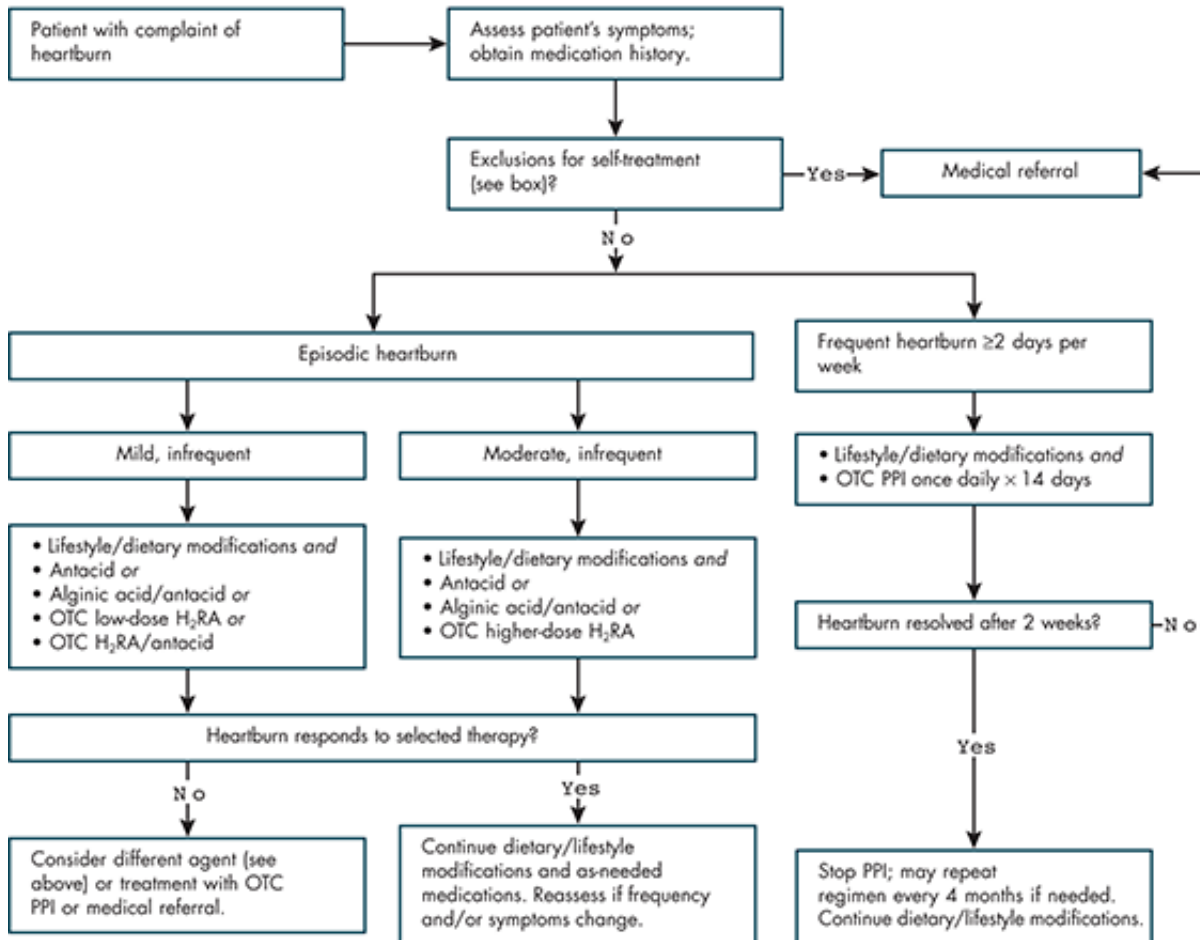

Nonpharmacologic measures may benefit some individuals, but these changes alone are unlikely to completely relieve symptoms in the majority of patients. Dietary and lifestyle modifications recommended for heartburn are aimed at avoiding foods and beverages that precipitate heartburn and adopting behaviors that reduce esophageal acid exposure. Nonpharmacologic measures should be recommended for all patients with heartburn and dyspepsia despite the fact that evidence supporting their effectiveness is either lacking or equivocal.<sup>5,7,8</sup> A complete and accurate history will assist in identifying contributing factors (Table 13-1). Individuals should be asked to keep a diary to track dietary, lifestyle, and medication “triggers.” Recommendations should be tailored to the individual’s specific history. Weight loss should be advised for overweight patients with heartburn. Elevating the head of the bed by placing 6- to 8-inch blocks underneath the legs at the head of the bed or placing a foam wedge (e.g., GERD pillow) beneath the patient’s upper torso and head should be recommended for patients troubled with heartburn when recumbent. Use of traditional pillows may worsen symptoms because they cause the individual to bend at the waist, which contributes to an increase in intragastric pressure.

Individuals should be educated about factors that contribute to heartburn and be advised how to manage them (see the box Patient Education for Heartburn and Dyspepsia). Most important, heartburn sufferers should be counseled to eat smaller meals, to reduce intake of dietary fat, and to refrain from eating within 3 hours of going to bed or lying down. Prescription and nonprescription medications should be evaluated for their potential to cause or exacerbate heartburn and dyspepsia (Table 13-1). When possible, individuals should be advised to switch to less troublesome nonprescription medications or to consult their prescriber about prescription drugs that may be exacerbating their symptoms. Use of tobacco products should be discouraged. If alcohol or caffeine consumption is a contributing factor, individuals should be advised to limit or discontinue use.

## Exclusion for self-treatment

- Frequent heartburn for more than 3 months
- Heartburn while taking recommended dosages of nonprescription H<sub>2</sub>RA or PPI
- Heartburn that continues after 2 weeks of treatment with a nonprescription H<sub>2</sub>RA or PPI
- Heartburn and dyspepsia that occur when taking a prescription H<sub>2</sub>RA or PPI<sup>8</sup>
- Severe heartburn and dyspepsia
- Nocturnal heartburn<sup>9</sup>
- Difficulty or pain on swallowing solid foods<sup>1,8</sup>
- Vomiting up blood or black material or passing black tarry stools<sup>1,8</sup>
- Chronic hoarseness, wheezing, coughing, or choking<sup>8</sup>
- Unexplained weight loss<sup>1,8</sup>
- Continuous nausea, vomiting, or diarrhea
- Chest pain accompanied by sweating, pain radiating to shoulder, arm, neck, or jaw, and shortness of breath<sup>8</sup>
- Children < 2 years (for antacids), 12 years (for H<sub>2</sub>RAs), or 18 years (for PPIs)
- Adults > 45 years with new-onset dyspepsia<sup>2</sup>

Self-care of heartburn. Key: H<sub>2</sub>RA = Histamine type 2 receptor antagonist; OTC = over-the-counter; PPI = proton pump inhibitor.

**TABLE 13-3 Onset and Duration of Symptomatic Relief with Nonprescription Medications in Relieving Heartburn**

Medication	Onset of Relief	Duration of Relief
Antacids	<5 minutes	20-30 minutes <sup>a</sup>
H <sub>2</sub> RAs	30-45 minutes	4-10 hours
H <sub>2</sub> RA + antacid	<5 minutes	8-10 hours
PPIs	2-3 hours	12-24 hours

Key: H<sub>2</sub>RA = Histamine type 2 receptor antagonist; PPI = proton pump inhibitor.

<sup>a</sup> Food prolongs duration of relief.

## Antacids

Antacids relieve heartburn and dyspepsia by neutralizing gastric acid. Nonprescription antacid products contain at least one of the following salts: magnesium (hydroxide, carbonate, or trisilicate); aluminum (hydroxide or phosphate); calcium carbonate; or sodium bicarbonate (Table 13-4). Most antacids are relatively inexpensive, making them affordable products for the temporary relief of mild and infrequent heartburn and dyspepsia.

**TABLE 13-4 Selected Nonprescription Antacid and Bismuth Products and Dosage Regimens**

<i>Trade Name</i>	<i>Primary Ingredients</i>	<i>Dosage (maximum daily dosage)</i>
<b>Adults/Children ≥12 Years</b>		
Alka-Seltzer Heartburn Relief	Sodium bicarbonate 1940 mg; citric acid 1000 mg	Dissolve 2 tablets in 4 ounces of water every 4 hours as needed (8 tablets)
Alka-Seltzer Original	Sodium bicarbonate 1916 mg; citric acid 1000 mg; aspirin 325 mg	Dissolve 2 tablets in 4 ounces of water every 4 hours as needed (8 tablets)
Gaviscon Regular Strength Liquid	Each 15 mL contains <sup>a</sup> aluminum hydroxide 95 mg; magnesium carbonate 358 mg	1-4 tablespoons 4 times a day, after meals and at bedtime (16 tablespoons)
Gelusil Tablets	Aluminum hydroxide 200 mg; magnesium hydroxide 200 mg; simethicone 25 mg	Chew 2-4 tablets; repeat hourly if symptoms return (12 tablets)
Mylanta Ultimate Strength Liquid	Each 5 mL contains aluminum hydroxide 500 mg; magnesium hydroxide 500 mg	2-4 teaspoons between meals and at bedtime (9 teaspoons)
Mylanta Supreme Liquid	Each 5 mL contains calcium carbonate 400 mg; magnesium hydroxide 135 mg	2-4 teaspoons between meals and at bedtime (18 teaspoons)
Pepto-Bismol Maximum Strength Liquid	Each 15 mL contains bismuth subsalicylate 525 mg	2 tablespoons every 1 hour as required (4 doses or 8 tablespoons)
Pepto-Bismol Original Liquid	Each 15 mL contains bismuth subsalicylate 262 mg	2 tablespoons every 30 minutes to 1 hour as required (8 doses or 16 tablespoons)
Rolaids Regular Strength Antacid Tablets	Calcium carbonate 550 mg; magnesium hydroxide 110 mg	Chew 2-4 tablets hourly as needed (12 tablets)
Tums Extra 750 Tablets	Calcium carbonate 750 mg	Chew 2-4 tablets as needed for symptoms (10 tablets)
Tums Regular Strength Tablets	Calcium carbonate 500 mg	Chew 2-4 tablets as needed for symptoms (15 tablets)
<b>Children ≤ 12 Years</b>		
Maalox Children's	Calcium carbonate 400 mg	Age 2-5 years: 1 tablet (3 tablets)
Relief Chewable		Age 6-11 years: 2 tablets (6 tablets)
Children's Pepto	Calcium carbonate 400 mg	Age 2-5 years: 1 tablet (3 tablets)
		Age 6-11 years: 2 tablets (6 tablets)

<sup>a</sup> Sodium alginate (alginic acid) is listed as an inactive ingredient.

Antacids act as buffering agents in the lower esophagus, gastric lumen, and duodenal bulb. The cations react with chloride, but the anionic portion of the molecule reacts with hydrogen ions to form water and other compounds. Sodium bicarbonate rapidly reacts with gastric acid to form sodium chloride, carbon dioxide, and water. Its duration of action is shortened by its quick elimination from the stomach.<sup>13</sup> Of the magnesium salts, magnesium hydroxide is used most often. Magnesium hydroxide rapidly reacts with gastric acid to form magnesium chloride and water. This agent has a shorter duration of action than that of calcium carbonate and aluminum hydroxide. Calcium carbonate is a potent antacid that dissolves slowly in gastric acid to form calcium chloride, carbon dioxide, and water. This agent's

onset of action is slower, but its duration of effect is longer than that of magnesium hydroxide or sodium bicarbonate. Aluminum hydroxide reacts with hydrochloric acid to form aluminum chloride and water. This agent has a slower onset and a longer duration than those of magnesium hydroxide. As a result of these reactions, a small but noticeable increase in intragastric pH occurs. Increasing the intragastric pH above 5 blocks the conversion of pepsin to pepsinogen.<sup>13</sup> Antacids also increase LES pressure.<sup>1</sup>

Liquid antacids usually have a faster onset than tablets because they are already dissolved or suspended and provide a maximal surface area for action. Of the tablet dosage forms, the quick-dissolving antacid tablets may provide the most rapid relief of symptoms. The duration of action for all antacids is transient, lasting only as long as the antacid remains in the stomach. The presence of food affects the duration of action of antacids. When administered within 1 hour after a meal, antacids may remain in the stomach for up to 3 hours.<sup>13</sup>

Differences in antacids are determined primarily by the cation, specific salt, and potency. Antacid potency is based on the number of milliequivalents of acid neutralizing capacity (ANC), which is defined as the amount of acid buffered per dose over a specified period of time. Factors that contribute to the ANC include product formulation, ingredients, and concentration.<sup>13</sup> As a result, the ANC is product specific; the same number of antacid tablets or equal volumes of different liquid antacids are not necessarily equal in potency.

Most antacids are minimally absorbed into the systemic circulation.<sup>13</sup> Approximately 90% of calcium is converted to insoluble calcium salts; the remaining 10% is absorbed systemically. About 15%-30% of magnesium and 17%-30% of aluminum may be absorbed and then excreted renally; therefore, accumulation may occur in patients with renal insufficiency. Sodium bicarbonate is readily absorbed and is eliminated renally.

Antacids are indicated for the treatment of mild, infrequent heartburn, sour stomach, and acid indigestion. Combination products containing aspirin or acetaminophen are FDA approved for overindulgence in food and drink and for hangover, although effectiveness has not been demonstrated. Individuals with mild dyspepsia may experience some relief with antacids, but no studies demonstrate their effectiveness.<sup>2</sup>

Antacids are administered orally. The effective dose of an antacid varies depending on product ingredients, milliequivalents of ANC, formulation, and the frequency and severity of symptoms. Individuals should be instructed to take product-specific recommended doses at the onset of symptoms. Dosing may be repeated in 1-2 hours, if needed, but should not exceed the maximum daily dosage for a particular product (Table 13-4). Individuals should be reevaluated if antacids are used more than twice a week or regularly for more than 2 weeks. Frequent antacid users may need to be switched to a longer-acting product such as an H<sub>2</sub>RA, an H<sub>2</sub>RA plus an antacid, or a PPI.

Antacids are usually well tolerated. Side effects are generally associated with the cation. The most common side effect associated with magnesium-containing antacids is dose-related diarrhea. Diarrhea may be reduced by combining magnesium-containing antacids with aluminum hydroxide. However, when higher dosages are used, the predominating effect is diarrhea. Magnesium excretion is impaired in patients with renal disease and may result in systemic accumulation of magnesium. Magnesium-containing antacids should not be used in patients with a creatinine clearance of less than 30 mL/minute.<sup>13</sup>

Aluminum-containing antacids are associated with dose-related constipation. Aluminum hydroxide binds dietary phosphate in the GI tract, increasing phosphate excretion in the feces. Frequent and prolonged use of aluminum hydroxide may lead to hypophosphatemia.<sup>13</sup> Chronic use of aluminum-containing antacids in patients with renal failure may lead to aluminum toxicity and should be avoided.

Calcium carbonate may cause belching and flatulence as a result of carbon dioxide production. Constipation when taking calcium antacids has been reported, but there is little evidence to support this side effect.<sup>14</sup> Calcium stimulates gastric acid secretion and is hypothesized to cause acid rebound when calcium-containing antacids are used to treat acid-related disorders. The clinical importance of this finding, however, remains uncertain.<sup>13</sup> If renal elimination is impaired, hypercalcemia may occur, and accumulation of calcium may result in the formation of renal calculi.

Because many antacids have been reformulated to contain calcium, there is a risk of hypercalcemia when high and frequent dosages of calcium-containing antacids are taken with other calcium supplements or foods such as milk or orange juice with added calcium. Up to 2500 mg/day of elemental calcium can be ingested safely in individuals with normal renal function.<sup>15</sup> (See Chapter 22 for a discussion of calcium supplementation.)

Sodium bicarbonate frequently causes belching and flatulence that result from the production of carbon dioxide.<sup>13</sup> The high sodium content (274 mg sodium/gram sodium bicarbonate) may cause fluid overload in patients with congestive heart failure, renal failure, cirrhosis, or pregnancy, and in those on sodium-restricted diets. Individuals with normal renal function excrete additional bicarbonate, whereas patients with impaired renal function retain bicarbonate, which may cause systemic alkalosis. A high intake of calcium along with an alkalinizing agent (e.g., sodium bicarbonate or calcium carbonate) may lead to hypercalcemia, alkalosis, irritability, headache, nausea, vomiting, weakness, and malaise (milk-alkali syndrome).<sup>13</sup> Individuals who take calcium supplements should avoid using sodium bicarbonate as an antacid.

When given concomitantly with other oral medications, all antacids may potentially increase or decrease the

absorption of the other medications by adsorbing or chelating the other drugs or by increasing intragastric pH.<sup>16</sup> Medications such as tetracyclines, azithromycin, and fluoroquinolones bind to divalent and trivalent cations, potentially decreasing antibiotic absorption. Absorption of levothyroxine may be decreased in the presence of an antacid; therefore, it is recommended to separate doses by 4 hours. The absorption of medications such as itraconazole, ketoconazole, and iron, which depend on a low intragastric pH for disintegration, dissolution, or ionization, may also be decreased. Specific antacids, such as aluminum hydroxide, may decrease the absorption of isoniazid. Premature breakdown of enteric-coated products may be increased with concurrent administration of antacids. The intraluminal interactions of antacids with other oral medications can usually be avoided when potentially interacting drugs are separated by at least 2 hours. Antacid-induced alkalization of the urine may increase urinary excretion of salicylates and decrease blood concentrations.<sup>16</sup> In contrast, an increase in urine pH may decrease urinary excretion and increase blood concentrations of amphetamines and quinidine.<sup>13</sup> Alginic acid reacts with sodium bicarbonate in saliva to form a viscous layer of sodium alginate that floats on the surface of gastric contents, forming a protective barrier against esophageal irritation. Although alginic acid does not neutralize acid, the combination of alginic acid and antacid may provide better symptomatic relief than the antacid alone.<sup>11</sup> Because there is insufficient evidence supporting its efficacy as a single agent, the Food and Drug Administration (FDA) has not granted alginic acid Category I status. However, alginic acid may be found as an inactive ingredient in several antacid products (Table 13-4). Some antacid products contain simethicone to decrease discomfort related to intestinal gas. (See Chapter 14 for a more detailed description of simethicone.)

### Histamine Type 2 Receptor Antagonists

Cimetidine, ranitidine, famotidine, and nizatidine are approved for nonprescription use (Table 13-5) at one-half of the prescription dose and at the lower prescription dose. Products containing nizatidine are not currently available in the United States. When used in recommended dosages, the H<sub>2</sub>RAs are considered interchangeable despite minor differences in potency, onset, duration of symptomatic relief, and side effects. The H<sub>2</sub>RAs decrease fasting and food-stimulated gastric acid secretion and gastric volume by inhibiting histamine on the histamine type 2 receptor of the parietal cell. Therefore, the H<sub>2</sub>RAs are effective in relieving fasting and nocturnal symptoms.<sup>17</sup> Their bioavailability is not affected by food but may be reduced modestly by antacids. Onset of symptomatic relief is not as rapid as with antacids, but the duration of effect is longer (Table 13-3). Cimetidine is the shortest acting (4-8 hours); ranitidine, famotidine, and nizatidine have a somewhat longer duration. Tolerance to the gastric antisecretory effect may develop when H<sub>2</sub>RAs are taken daily (versus as needed) and may be responsible for diminished efficacy.<sup>18</sup>

Therefore, it is preferable to take an H<sub>2</sub>RA on an as-needed basis rather than regularly every day. All four H<sub>2</sub>RAs are eliminated by a combination of renal and hepatic metabolism, with renal elimination being the most important. A reduced daily H<sub>2</sub>RA dose should be considered in patients with impaired renal function (creatinine clearance of less than 50 mL/minute) and patients of advanced age.<sup>17</sup>

Nonprescription H<sub>2</sub>RAs are indicated for the treatment of mild-moderate, infrequent, or episodic heartburn and for the prevention of heartburn associated with acid indigestion and sour stomach. H<sub>2</sub>RAs are more effective than placebo for relief of mild-moderate heartburn and provide moderate improvement in patients with mild, infrequent uninvestigated dyspepsia.<sup>5</sup> H<sub>2</sub>RAs may be used at the onset of symptoms or 30 minutes to 1 hour prior to an event (e.g., meal or exercise) in which heartburn is anticipated. The combined H<sub>2</sub>RA and antacid product (famotidine plus magnesium hydroxide and calcium carbonate; see Table 13-5) is indicated for individuals with postprandial heartburn who have not premedicated with an H<sub>2</sub>RA. This combined product provides immediate relief and a longer duration of effect. Self-treatment dosing should be limited to no more than 2 times a day. If self-treatment with an H<sub>2</sub>RA is needed for more than 2 weeks, a medical referral is recommended.

H<sub>2</sub>RAs are well tolerated and have a low incidence of side effects. The most common side effects reported with all four H<sub>2</sub>RAs include headache, diarrhea, constipation, dizziness, and drowsiness. Thrombocytopenia is a rare but serious adverse event with all four H<sub>2</sub>RAs, but this effect is reversible upon discontinuation of the drug. Cimetidine is associated with a weak antiandrogenic effect that, when taken in high doses, may result in decreased libido, impotence, or gynecomastia in men.

**TABLE 13-5 Selected Nonprescription H<sub>2</sub>RA and PPI Products and Dosage Regimens**

<i>Trade Name</i>	<i>Primary Ingredients</i>	<i>Dosage (maximum daily dosage)</i>
<b>H<sub>2</sub>RA Products (Adults/Children ≥12 Years)</b>		
Tagamet HB, various	Cimetidine 200 mg	1 tablet with a glass of water (2 tablets)

generic		
Pepcid AC, various generic	Famotidine 10 mg	1 tablet with a glass of water (2 tablets)
Pepcid AC Maximum Strength, various generic	Famotidine 20 mg	1 tablet with a glass of water (2 tablets)
Pepcid Complete	Famotidine 10 mg; calcium carbonate 800 mg; magnesium hydroxide 165 mg	Chew and swallow 1 tablet (2 tablets)
Tums Dual Action	Famotidine 10 mg; calcium carbonate 800 mg; magnesium hydroxide 165 mg	Chew and swallow 1 tablet (2 tablets)
Zantac 75, various generic	Ranitidine 75 mg	1 tablet with a glass of water (2 tablets)
Zantac 150, various generic	Ranitidine 150 mg	1 tablet with a glass of water (2 tablets)
<b>PPI Products (Adults ≥18 Years)</b>		
Prilosec OTC, various generic	Omeprazole magnesium 20.6 mg	1 tablet with a glass of water 30 minutes before morning meal; take daily for 14 days (1 tablet)
Zegerid	Omeprazole 20 mg; sodium bicarbonate 1100 mg	1 capsule with a glass of water 1 hour before morning meal; take daily for 14 days (1 capsule)
Prevacid 24HR, various generic	Lansoprazole 15 mg	1 capsule with a glass of water 30 minutes before morning meal; take daily for 14 days (1 capsule)
Nexium 24HR	Esomeprazole 20 mg	1 capsule with a glass of water 30 minutes before morning meal; take daily for 14 days (1 capsule)

Cimetidine inhibits several hepatic cytochrome P450 (CYP450) isoenzymes (3A4, 2D6, 1A2, and 2C9), resulting in drug interactions with numerous medications (e.g., phenytoin, warfarin, theophylline, tricyclic antidepressants, and amiodarone).<sup>16</sup> Cimetidine also inhibits CYP2C19 and blocks the conversion of clopidogrel to its active form, thus possibly reducing the effectiveness of clopidogrel.<sup>20</sup> CYP450 drug interactions with ranitidine, nizatidine, and famotidine are uncommon at nonprescription doses. Medications such as ketoconazole, itraconazole, indinavir and atazanavir, and iron salts require an acidic environment for absorption.<sup>16,21</sup> When administered with an acid-reducing drug, their absorption may be reduced. Cimetidine may inhibit the renal tubular secretion of drugs such as procainamide, metformin, and dofetilide.

### Proton Pump Inhibitors

PPIs are potent antisecretory drugs that relieve heartburn and dyspepsia by decreasing gastric acid secretion. They inhibit hydrogen potassium ATPase (the proton pump), irreversibly blocking the final step in gastric acid secretion, thus providing a more potent and prolonged antisecretory effect than that of the H<sub>2</sub>RAs (Table 13-3).<sup>17</sup> The relative bioavailability of PPIs increases with continued daily dosing. Onset of symptomatic relief following an oral dose may occur in 2-3 hours, but complete relief may take 1-4 days.<sup>22</sup> The PPIs are almost completely absorbed after oral administration, regardless of the presence of food.<sup>17</sup>

Omeprazole magnesium 20.6 mg (Prilosec OTC), the first PPI to become available for nonprescription use in the United States (Table 13-5), is available as a delayed-release tablet containing enteric-coated pellets (protection against intragastric degradation) and is converted in the body to omeprazole 20 mg.<sup>17</sup> Nonprescription omeprazole is also available as specific pharmacy-branded products. Immediate-release omeprazole (Zegerid) is formulated with omeprazole 20 mg and sodium bicarbonate 1100 mg. The sodium bicarbonate in Zegerid raises intragastric pH, permitting rapid absorption of omeprazole from the duodenum, but there is insufficient evidence to confirm that this results in a quicker onset of symptomatic relief. Esomeprazole magnesium 22.3 mg (Nexium 24HR) is the S-isomer of

omeprazole and is available as a delayed-release capsule. Lansoprazole 15 mg (Prevacid 24HR) is available as a capsule formulation containing enteric-coated granules. Differences in efficacy among the PPIs have not been established. PPI tablets and capsules should not be chewed or crushed because the enteric coating will be compromised, thus decreasing the effectiveness of the drug.<sup>17</sup>

Nonprescription PPIs are indicated for the treatment of frequent heartburn in patients who have symptoms 2 or more days a week. They are not intended for immediate relief of occasional or acute episodes of heartburn and dyspepsia. Because PPIs inhibit only those proton pumps that are actively secreting acid, they are most effective when taken 30-60 minutes before a meal, preferably before breakfast.<sup>23</sup> Self-treatment should be limited to 14 days and no more frequently than every 4 months. If heartburn continues while taking a nonprescription PPI, persists for more than 2 weeks, or recurs within 4 months, a medical evaluation is recommended.

The safety of nonprescription antisecretory medications, when used appropriately, is well established. The most common short-term side effects of PPIs are similar to those reported for the H<sub>2</sub>RAs (i.e., diarrhea, constipation, and headache).<sup>18</sup> Chronic acid suppression has the potential to impair natural defenses and to increase the risk of infection.<sup>24-28</sup> Some studies indicate PPI users may have increased susceptibility to community-acquired pneumonia.<sup>8,25</sup> An association of PPI use with enteric infections, such as *Clostridium difficile* and bacterial gastroenteritis, has been shown to be statistically significant in a number of cohort and case control studies. Patients developing diarrhea or symptoms of gastroenteritis while on a PPI should stop use and contact a health care provider.

An increased risk for hip, spine, and wrist fractures in older patients (>50 years) has been associated with high-dose, long-term (>1 year) PPI therapy.<sup>29</sup> Although reduced gastric acid secretion may decrease calcium absorption, longitudinal studies have not found any evidence of a direct effect of PPIs on bone turnover.<sup>30</sup> FDA released a warning concerning the potential for increased risk of fractures with prescription PPIs but subsequently determined that the risk is low with appropriate nonprescription PPI use.<sup>31</sup>

Rebound acid hypersecretion upon discontinuation of long-term use of PPIs has been reported, but its clinical importance is uncertain.<sup>32</sup> Vitamin B<sub>12</sub> deficiency, hypomagnesemia, and iron malabsorption have also been described in patients taking PPIs long term (usually >1 year) but not in ambulatory patients taking recommended dosages of nonprescription PPIs short term.<sup>24,26,33</sup> Self-treatment with PPIs should be limited to short-term use at nonprescription doses. Nonprescription PPIs should be used to treat only conditions approved by FDA and listed on the product label. Long-term use and ingestion of high doses of acid-suppressing medications should take place only under medical supervision.

Omeprazole, esomeprazole, and lansoprazole may inhibit the metabolism of medications that depend on hepatic CYP2C19 for metabolism.<sup>34</sup> Although clinically important drug interactions are uncommon, given the widespread use of PPIs, patients taking medications such as diazepam, phenytoin, warfarin, theophylline, or tacrolimus should be warned about the potential for a drug interaction. Omeprazole and esomeprazole appear to have the greatest potential of the nonprescription PPIs to reduce the antiplatelet effect of clopidogrel by inhibiting variants of CYP2C19, thus reducing the conversion of clopidogrel to its active form.<sup>34,35</sup> Patients taking clopidogrel should contact their cardiologist or primary care provider before taking a nonprescription PPI (especially omeprazole or esomeprazole). Omeprazole and esomeprazole have been shown to inhibit the metabolism of cilostazol, resulting in increased serum concentrations of cilostazol and its active metabolites.<sup>36</sup> Lansoprazole may be a safer option for self-treatment of frequent heartburn in patients taking cilostazol. Similar to the action of antacids and H<sub>2</sub>RAs, PPIs increase intragastric pH and may decrease the absorption of pH-dependent drugs (see previous discussion of drug-drug interactions for antacids and H<sub>2</sub>RAs). PPIs can interfere with elimination of methotrexate and its metabolite, hydroxymethotrexate, leading to increased risk for toxicity. Patients taking methotrexate should check with their primary care provider before using a PPI.<sup>37,38</sup> In addition, PPIs may increase the bioavailability of digoxin, but the clinical importance of this effect is unknown. Calcium citrate is the preferred calcium supplement form for patients taking acid-reducing medications such as PPIs, given that citrate salts do not require an acid environment for dissolution.

### Bismuth Subsalicylate

Bismuth subsalicylate (BSS) is indicated for heartburn, upset stomach, indigestion, nausea, and diarrhea. FDA has tentatively determined that BSS is safe and effective for the relief of upset stomach associated with belching and for gas associated with overindulgence in food and drink.<sup>39</sup> It is uncertain how BSS relieves heartburn, but for upset stomach, it is believed to have a topical effect on the stomach mucosa. When used to treat acid-related symptoms, the adult dose of BSS is 262-525 mg every 30 minutes to 1 hour as needed (Table 13-4). BSS is generally not recommended for children and should be avoided in patients with renal failure. In the past, some nonprescription antacid product line extensions with common trade names were reformulated to contain BSS in place of an antacid,

or vice versa. Patients and health care providers should examine the ingredients in an antacid product to determine whether it contains BSS because these products are periodically reformulated with different antacids and other ingredients. Individuals taking bismuth salts should know that bismuth may cause the stool and tongue to turn black. Dark-colored stools may be interpreted as an upper GI bleed, prompting needless medical procedures. (For a complete discussion of BSS, see [Chapter 16](#).)

## Product Selection Guidelines

### Special Populations

Careful consideration should be given to the elderly before recommending self-treatment for new-onset heartburn or dyspepsia. Older patients are more likely to take medications that can contribute to heartburn and dyspepsia. In addition, they are at higher risk for developing complications and may have a more severe underlying disorder. If self-treatment is appropriate, an assessment should be performed to determine whether the individual has renal impairment and to identify potentially problematic medications. Patients with decreased renal function should be cautioned about using aluminum- and magnesium-containing antacids, and if an H<sub>2</sub>RA is appropriate, the lower dose should be selected. Omeprazole, esomeprazole, and lansoprazole may be used in patients with renal impairment. Sodium bicarbonate should be avoided in patients taking cardiovascular medications. Antacid selection for eligible patients should be based, in part, on potential side effects. For example, if a patient has a tendency toward constipation, a less-constipating antacid, such as magnesium hydroxide, may be more appropriate, whereas constipating antacids, such as aluminum hydroxide, should be avoided. Children older than 2 years with mild, transient, and infrequent heartburn; acid indigestion; or sour stomach may try children's formulas of calcium carbonate-containing antacids. If symptoms recur or are not resolved quickly, the child should be referred to his or her primary care provider for further evaluation.<sup>40</sup> Nonprescription antacids containing calcium carbonate are labeled for children ages 2 years and older. If antacids are recommended, an assessment of the child's average daily intake of calcium may help guide the recommendation. The recommended daily intake of calcium for children ages 2-3 years is 700 mg, 4-8 years is 1000 mg, and 9-18 years is 1300 mg.<sup>15</sup> Nonprescription H<sub>2</sub>RAs are labeled for patients ages 12 years and older, and nonprescription PPIs are indicated for patients ages 18 years or older.

Infrequent and mild heartburn in pregnant women should be treated initially with dietary and lifestyle modifications.<sup>41</sup> Calcium- and magnesium-containing antacids may be used safely if the recommended daily dosages are not exceeded. Special attention should be given to the recommended intake of calcium during pregnancy (1000-1300 mg/day).<sup>15</sup> If a woman is meeting this recommendation, the addition of a calcium-containing antacid may cause her to exceed the upper limit of 2500 mg of calcium per day. Cimetidine, ranitidine, and nizatidine are listed as compatible with pregnancy. Human data for omeprazole and esomeprazole suggest low risk with pregnancy. Famotidine and esomeprazole have limited or no human data to support use in pregnancy; however, animal data suggest low risk.<sup>32</sup> Pregnant women with frequent and moderate-severe heartburn should be referred for medical evaluation.

Aluminum-, calcium-, or magnesium-containing antacids are considered safe in women who are breast-feeding.<sup>42</sup> The American Academy of Pediatrics considers cimetidine to be compatible with breast-feeding. However, famotidine is less concentrated in the breast milk and may be preferable to cimetidine or ranitidine.<sup>43</sup> There is insufficient information regarding the use of omeprazole, esomeprazole, and lansoprazole in women who are breast-feeding; these medications are best avoided during lactation.<sup>43</sup>

### Patient Preferences

Antacids and antisecretory drugs are available in a wide range of prices, flavors, and dosage forms. Once the most appropriate nonprescription medication is determined, the individual should be involved in selecting a product that is affordable, palatable, and practical to administer. Inactive ingredients such as dyes, sodium, and sugar should be considered for individuals with allergies, sensitivities, certain medical conditions, or dietary restrictions.

## Complementary Therapies

No evidence has shown that any botanical products increase intragastric pH and relieve heartburn. However, peppermint, alone or in combination with other herbs, has been shown in some studies to be useful for dyspepsia. A study of the efficacy of artichoke leaf extract (ALE) for dyspepsia also showed greater improvement of symptoms in the ALE group compared with placebo.<sup>5</sup> (See [Chapter 51](#) for a more thorough discussion of complementary therapies.)

## Assessment of Heartburn and Dyspepsia: A Case-Based Approach

Cases 13-1 and 13-2 illustrate the assessment of patients with heartburn and dyspepsia.

## Patient Counseling for Heartburn and Dyspepsia

Many cases of uncomplicated heartburn and dyspepsia are self-treatable. For optimal outcomes, individuals need to understand how to treat symptoms appropriately and when to seek additional care. This information is provided in the box Patient Education for Heartburn and Dyspepsia. Health care providers should screen patients for use of a prescription H<sub>2</sub>RA or PPI and counsel patients to avoid duplication of therapies.

### Case 13-1

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of recurring substernal burning sensation after eating large meals. It occurs one to two times a week. The discomfort is rated a 4 on a scale of 1-10. It is associated with a feeling of fullness and occasional burping. Symptoms typically last 3-4 hours after eating.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Symptoms occur after eating dinner and are often associated with large meals at restaurants.
c. description of the patient's efforts to relieve the symptoms	Patient has tried Tums (calcium carbonate 500 mg) after meals to help relieve the symptoms. It works initially, but wears off after an hour and the discomfort returns.
d. patient's identity	Steve Lee
e. age, sex, height, and weight	55 years old, male, 5 ft 11 in., 215 lb
f. patient's occupation	Teacher
g. patient's dietary habits	Normal balanced diet; drinks one cup of caffeinated coffee every morning, and 1 ounce of whiskey most evenings with dinner.
h. patient's sleep habits	Sleeps 7-8 hours a night.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Hyperlipidemia: atorvastatin 20 mg every morning; post-myocardial infarction (2 years ago): atenolol 25 mg every morning, clopidogrel 75 mg every morning
j. allergies	Sulfamethoxazole
k. history of other adverse reactions to medications	None
<b>Assessment Triage</b>	

2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Infrequent postprandial substernal burning is consistent with uncomplicated heartburn.
3. Identify exclusions for self-treatment (Figure 13-2).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Steve to his PCP. (2) Recommend lifestyle modifications. (3) Recommend an OTC antacid or acid-reducing product. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	An OTC acid-reducing product should be effective. Patient will consider lifestyle modifications.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Take 20 mg of famotidine 30 minutes prior to meals that may cause heartburn, or when symptoms occur." See directions in Table 13-5.
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Seeing a PCP may not be necessary if adequate relief is experienced and symptoms do not become more severe or frequent. An antacid will not provide long-lasting relief. You should not use a PPI without consulting your primary care provider because of a possible interaction with your clopidogrel."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	See Table 13-5.
b. maximum number of days the therapy should be employed	See the box Patient Education for Heartburn and Dyspepsia
c. product administration procedures	See Table 13-5.
d. expected time to onset of relief	30 minutes to 1 hour if used after symptoms occur.
e. degree of relief that can be reasonably expected	Complete prevention of symptoms if used prior to meals or complete relief of symptoms if used after symptom onset.
f. most common side effects	Side effects are uncommon. Some patients report headache, diarrhea, or constipation.

g. side effects that warrant medical intervention should they occur	Moderate-severe diarrhea or symptoms of gastroenteritis
h. patient options in the event that condition worsens or persists	A PCP should be consulted if symptoms are not resolved satisfactorily, if they increase in frequency or severity, or if alarm symptoms occur (Figure 13-2).
i. product storage requirements	See the box Patient Education for Heartburn and Dyspepsia.
j. specific nondrug measures	Eat smaller meals, reduce alcohol intake, and avoid problematic foods. Consider ways to reduce weight. (See the box Patient Education for Heartburn and Dyspepsia for other measures.)
Solicit follow-up questions from the patient or caregiver.	"May I take an antacid for immediate relief of symptoms?"
Answer the patient's or caregiver's questions.	"Yes. Taking a product that contains calcium carbonate or magnesium hydroxide after symptoms occur will provide quick, short-term relief. These can be taken with famotidine if needed. An alternative would be to take a combination product that contains both an antacid and an acid reducer."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient response.	Ask Steve to call or update you on his response to the famotidine, or call Steve in a week to evaluate his response.

Key: H<sub>2</sub>RA = Histamine type 2 receptor antagonist; OTC = over-the-counter; PCP = primary care provider; PPI = proton pump inhibitor.

### Case 13-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient suffers from ongoing upper abdominal discomfort. Patient describes a gnawing pain that causes nausea and fluctuates throughout the day. Pain rating varies from 4-7 on a scale of 10. Symptoms started 3 days ago. Some difficulty breathing.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Discomfort worsens when she walks, especially up and down stairs. Somewhat better at rest.
c. description of the patient's efforts to relieve the symptoms	Patient has tried Pepcid Complete (famotidine 10 mg, calcium carbonate 800 mg, and magnesium hydroxide 165 mg) as well as Zantac 150 (ranitidine 150 mg) with no relief.

d. patient's identity	Angelica Mousa
e. age, sex, height, and weight	62 years old, female, 5 ft 5 in., 165 lb
f. patient's occupation	Retired
g. patient's dietary habits	Eats small meals throughout the day.
h. patient's sleep habits	Averages 6 hours per night.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Hyperlipidemia: stopped taking atorvastatin 1 year ago because she couldn't afford it. Takes calcium carbonate 1000 mg with vitamin D 400 IU twice daily.
j. allergies	NKDA
k. history of other adverse reactions to medications	None
l. other (describe) _____	Smokes 15-20 cigarettes/day for the past 40 years. Drinks 2-4 cups of caffeinated coffee daily. Stopped drinking alcohol 5 years ago.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Late-onset and ongoing GI symptoms; worsening upon exertion. No response to antacid and H <sub>2</sub> RAs.
3. Identify exclusions for self-treatment ( <a href="#">Figure 13-2</a> ).	May be an indication of cardiac problems, or other non-GI issues. Alarm symptoms indicate medical referral.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Angelica to a PCP immediately for a differential diagnosis. (2) Recommend an OTC product with lifestyle modifications. (3) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Refer the patient to a PCP for a differential diagnosis.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Call your primary care provider immediately or go to urgent care for a medical evaluation."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered	"You need to see your primary care provider because your symptoms indicate a more serious medical condition that needs prompt evaluation. OTC therapy is unlikely to be effective or

therapeutic alternatives.	appropriate.”
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	“I thought heart attacks involved a crushing chest pain, so I am not having a heart attack, right?”
Answer the patient’s or caregiver’s questions.	“In women heart attacks often present with upper abdominal pain, nausea, shortness of breath, and other symptoms such as jaw, arm or shoulder pain. Your symptoms could be from heart disease and should be medically evaluated as soon as possible.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient response.	Contact Angelica in a day or two to ensure that she sought medical care.

Key: H<sub>2</sub>RA = Histamine type 2 receptor antagonist; NKDA = no known drug allergies; OTC = over-the-counter; PCP = primary care provider.

#### Patient Education for Heartburn and Dyspepsia

Heartburn and dyspepsia (indigestion) are often self-treatable conditions. Heartburn is characterized by a burning sensation in the chest, usually occurring after meals. Dyspepsia is characterized by discomfort in the upper abdomen. The goals of self-treatment are to (1) provide complete relief of symptoms, (2) reduce recurrence of symptoms, and (3) prevent and manage unwanted effects of medications.

#### **Nondrug Measures**

- Avoid food, beverages, and activities that may precipitate or increase the frequency and severity of symptoms.
- If possible, avoid the use of medications that may aggravate heartburn or dyspepsia.
- Avoid eating large meals.
- Stop or reduce smoking.
- Lose weight if overweight and not pregnant.
- Wear loose-fitting clothing.
- If nocturnal symptoms are present:
  - Avoid lying down within 3 hours of a meal.
  - Elevate the head of the bed using 6- to 8-inch blocks, or use a foam pillow wedge.

#### **Nonprescription Medications**

- Store all medications at 68°F-77°F (20°C-25°C), and protect them from heat, humidity, and moisture. Discard after expiration date.

#### **Antacids**

- Antacids (sodium bicarbonate, calcium carbonate, magnesium hydroxide, and aluminum hydroxide) are available alone and in combination with each other and other ingredients.
- Antacids work by neutralizing acid in the stomach.
- Antacids may be used for relief of mild, infrequent heartburn or dyspepsia (indigestion).
- Antacids are usually taken at the onset of symptoms. Relief of symptoms typically begins within 5 minutes.
- Because antacids come in a variety of strengths and concentrations, it is essential to consult the label of an individual product for the correct dose and frequency of administration. Generally antacids should not be used more than 4 times a day, or regularly for more than 2 weeks.
- If symptoms are not relieved with recommended dosages, consult a health care provider.
- Diarrhea may occur with magnesium- or magnesium/aluminum-containing antacids; constipation may occur with aluminum- or calcium-containing antacids. Consult a health care provider if these effects are

troublesome or do not resolve in a few days.

- In children older than 2 years, mild transient and infrequent heartburn; acid indigestion; or sour stomach may be treated with children's products containing calcium carbonate if they are used according to package directions.
- Pregnant women with mild and infrequent heartburn may use calcium- and magnesium-containing antacids safely if recommended daily dosages are not exceeded.
- Patients with kidney dysfunction should consult their primary care provider prior to self-treatment with antacids.
- Patients taking tetracyclines, fluoroquinolones, azithromycin, digoxin, ketoconazole, itraconazole, and iron supplements should not take antacids within 2 hours of taking any of these medications.

### ***Histamine Type 2 Receptor Antagonists (H<sub>2</sub>Ras)***

- H<sub>2</sub>RAs (cimetidine, famotidine, and ranitidine) may be used to relieve symptoms of or prevent heartburn and indigestion associated with meals.
- H<sub>2</sub>RAs work by decreasing acid production in the stomach.
- H<sub>2</sub>RAs are usually taken at the onset of symptoms or 30 minutes to 1 hour before symptoms are expected. Relief of symptoms can be expected to begin within 30-45 minutes. A combination product that contains both an antacid and an H<sub>2</sub>RA provides faster relief of symptoms.
- H<sub>2</sub>RAs generally relieve symptoms for 4-10 hours. H<sub>2</sub>RAs can be taken when needed up to twice daily for 2 weeks.
- H<sub>2</sub>RAs should be used for relief of mild-moderate, infrequent, and episodic heartburn and indigestion when a longer effect is needed. Use lower dosages for mild infrequent heartburn and higher dosages for moderate infrequent symptoms.
- If symptoms are not relieved with recommended doses, worsen, or persist after 2 weeks of treatment, consult a primary care provider.
- Side effects are uncommon. Consult a primary care provider if side effects are troublesome or do not resolve within a few days.
- Cimetidine may interact with many medications. Consult your primary care provider if you are also taking other medications, including a blood thinner such as warfarin or clopidogrel, an antifungal such as ketoconazole, an anticonvulsant such as phenytoin, an antianxiety medication such as diazepam, or theophylline and amiodarone.

### ***Proton Pump Inhibitors (Ppis)***

- Nonprescription PPIs are indicated for mild-moderate frequent heartburn that occurs 2 or more days a week. They are not intended for the relief of mild, occasional heartburn.
- PPIs (omeprazole, esomeprazole, and lansoprazole) work by decreasing acid production in the stomach.
- PPIs should be taken with a glass of water every morning 30 minutes before breakfast for 14 days. Make sure that you take the full 14-day course of treatment.
- Do not take more than 1 tablet a day.
- Complete resolution of symptoms should be noted within 4 days of initiating treatment.
- If symptoms persist, worsen, are not adequately relieved after 2 weeks of treatment, or recur before 4 months has elapsed since treatment, consult your primary care provider.
- Do not crush or chew tablets or capsules because this may decrease the effectiveness of the PPI.
- Side effects are uncommon. Consult a health care provider if side effects are troublesome or do not resolve within a few days.
- Consult a health care provider if you are also taking other medications, including a blood thinner such as warfarin or clopidogrel, an antifungal such as ketoconazole, an anticonvulsant such as phenytoin, an antianxiety medication such as diazepam, antiretroviral medications, methotrexate, theophylline, tacrolimus, digoxin, or cilostazol.

### **When to Seek Medical Attention**

Consult your primary care provider if you experience any of the following:

- Heartburn or dyspepsia (indigestion) for more than 3 months
- Heartburn or dyspepsia (indigestion) while taking recommended dosages of nonprescription medications
- Heartburn or dyspepsia (indigestion) after 2 weeks of continuous treatment with a nonprescription medication
- Heartburn that awakens you during the night.

- Difficulty or pain on swallowing foods.
- Light-headedness, sweating, and dizziness accompanied by vomiting of blood or black material or black tarry bowel movements.
- Chest pain or shoulder, arm, or neck pain, with shortness of breath.
- Chronic hoarseness, cough, choking, or wheezing.
- Unexplained weight loss.
- Continuous nausea, vomiting, or diarrhea.
- Severe stomach pain.

### Evaluation of Patient Outcomes for Heartburn and Dyspepsia

Individuals taking antacids or an H<sub>2</sub>RA for infrequent heartburn and dyspepsia should obtain symptomatic relief within 30 minutes to 1 hour. Patients taking PPIs may require up to 4 days for complete relief of symptoms, but most individuals are asymptomatic within 1 or 2 days. Self-treating individuals should be encouraged to contact their primary care provider to report on the effectiveness of therapy and on any problems, such as side effects, that may arise during treatment. In some cases, the provider may make a follow-up contact to assess therapeutic outcomes. Patients should be asked to describe the change in frequency and severity of symptoms following initiation of therapy. Patients should be questioned regarding side effects and any new symptoms that may have developed. If the patient reports an inadequate response to therapy, the individual should be reevaluated to determine whether a different therapy is suitable or whether medical referral is necessary. Side effects may be managed by adjusting the dose or switching to another product. Patients who develop atypical or alarm symptoms ([Figure 13-2](#)) should be referred to their primary care provider.

### Key Points for Heartburn and Dyspepsia

- The self-treatment of heartburn and dyspepsia should be limited to mild or moderate symptoms, including postprandial burning in the upper abdomen or centralized abdominal discomfort.
- Patients with atypical or alarm symptoms ([Figure 13-2](#)) should be referred for further evaluation.
- In children older than 2 years, treatment of mild transient and infrequent heartburn, acid indigestion, or sour stomach symptoms with calcium carbonate-containing antacids should be limited; prompt referral should be made if symptoms recur or persist.
- Pregnant women may self-treat mild and infrequent heartburn with calcium- and magnesium-containing antacids.
- Patients with heartburn should be counseled on nondrug measures such as dietary and lifestyle modifications (see the box Patient Education for Heartburn and Dyspepsia).
- Self-treating individuals should be advised about the advantages and disadvantages of various antacids and acid-reducing products so they can select a product that is best suited to them.
- Antacids provide temporary relief for mild and infrequent heartburn and dyspepsia. Dosages are product specific because of variability in antacid ingredients and concentrations.
- H<sub>2</sub>RAs are indicated for mild and infrequent heartburn or dyspepsia. They may be taken at the onset of symptoms or 1 hour prior to an event (e.g., meal or exercise) that may cause symptoms.
- Combining an antacid with an H<sub>2</sub>RA provides immediate relief of heartburn and a longer duration of action.
- PPIs are indicated for the treatment of frequent heartburn (heartburn that occurs ≥2 days a week). PPIs should be used a maximum of 14 days at a time and no more than every 4 months, and they are not intended for immediate relief of infrequent symptoms.
- Individuals with self-treatable symptoms should be advised to contact their primary care provider if symptoms worsen or recur after 14 days of effective self-treatment.

## Handbook of Nonprescription Drugs &gt; Chapter 14. Intestinal Gas

**Intestinal Gas: Introduction**

Intestinal gas symptoms and conditions that predispose patients to intestinal gas are common, and they may cause considerable discomfort and lifestyle impairment. The most frequent symptoms are eructation (belching of swallowed air), bloating (excessive gas, particularly after eating), and flatulence (excessive passage of air from the stomach or intestines through the anus). Differentiation of healthy individuals with temporary symptoms from those with a chronic gastrointestinal (GI) condition such as irritable bowel syndrome (IBS), lactose intolerance, or celiac disease is important in recommending appropriate nonprescription treatment.

The primary categories of nonprescription pharmacologic therapies for intestinal gas symptoms are antiflatulent medications (simethicone and activated charcoal), digestive enzymes (lactase replacement and alpha-galactosidase products), and probiotic products (*Bifidobacterium*, *Lactobacillus*, *Saccharomyces*, and *Streptococcus* species). Sales of antiflatulent and probiotic products account for a significant portion of the nonprescription drug and dietary supplement markets.<sup>1</sup>

A significant portion of the U.S. population is affected by conditions that may cause intestinal gas symptoms. Intestinal gas can be caused by lactose malabsorption (29% of the population), IBS (7%-10%), and other less common medical conditions, such as celiac disease (1%-3% of the general population and 10% of first-degree relatives of the celiac disease population) and pancreatic insufficiency (<1%).<sup>2-4</sup> In the general population, abdominal distention and bloating are reported by approximately 10% and 20% of individuals in the United States, respectively.<sup>5</sup> More than half of symptomatic respondents rated symptoms as moderate-severe; most indicated that symptoms resulted in some limitation in their ability to conduct usual activities, with 10% reporting that their activities were reduced by half or more.

*Editor's Note:* This chapter is based on the 17th edition chapter of the same title, written by Patrick D. Meek.

**Pathophysiology of Intestinal Gas**

The pathophysiology of gas-related complaints in the GI tract (hereafter referred to as intestinal gas) is poorly understood; however, minor disruptions of normal physiologic processes of the GI tract appear to play a role. Each time food, liquid, or saliva is swallowed, a small amount of air passes into the stomach. Once in the stomach, the swallowed food and air are mixed with gastric acid, pepsin, and other substances; churned into small fragments; and then emptied into the small intestine, where most of the absorption of vitamins, minerals, and digestion products (e.g., food-derived monosaccharides, such as glucose) occurs.<sup>6</sup> The rate at which the stomach empties varies but generally takes about 1-2 hours. Smooth muscle contractions in the small intestine move the liquid food fragments and air downstream toward the large intestine, where the indigestible liquid waste is mixed with the bacterial flora of the colon. In the colon, most of the remaining liquid is absorbed from the mixture of liquid waste, bacteria, and intestinal gas as it is transported toward the rectum and temporarily stored as stool prior to a bowel movement. During a bowel movement, stool is eliminated, and intestinal gas is expelled from the rectum as flatus. Diet, underlying medical conditions, alterations in intestinal flora, and drugs may precipitate or aggravate symptoms attributed to intestinal gas. Although the exact mechanisms are not fully known, the origin of gas retention and symptoms appears to be affected by alterations in visceral sensitivity and intestinal transit that vary at different physiologic locations along the GI tract.<sup>6</sup>

Certain foods can increase intestinal gas production and lead to bothersome symptoms (Tables 14-1 and 14-2).<sup>7-9</sup> Dietary sugars (e.g., lactose in dairy products and prepared foods; fructose in fruits, vegetables, candies, and soft drinks; sucrose from "table sugar"; and glucose from the breakdown of starches) may be incompletely absorbed in the healthy human small intestine.<sup>7</sup> These sugars are the principal substrates for hydrogen gas (H<sub>2</sub>) production in the colon. Similarly, other foods also are malabsorbed, including fatty foods; foods rich in complex carbohydrates (e.g., wheat germ, brown rice, bran, and corn); and indigestible oligosaccharides (e.g., raffinose, found in asparagus, broccoli, Brussels sprouts, and cabbage; and stachyose, found in black-eyed peas, lima beans, and soy beans). These substances remain in the intestinal lumen, are passed into the colon, and provide a substrate for bacterial fermentation and colonic production of H<sub>2</sub> and carbon dioxide (CO<sub>2</sub>).<sup>6</sup> Fermentation in the colon is the primary process for generating intestinal gas and is influenced by the quantity of foods ingested.

Diets high in fiber also may lead to bloating and flatulence. Terminology, recommended intake, and potential benefits associated with fiber are discussed in Chapter 23. Fiber is a valuable component of a balanced diet and may be beneficial in the treatment of constipation (see Chapter 15). Soluble fiber absorbs water and stabilizes intestinal

contractions; however, soluble fiber supplementation does not appear to decrease IBS symptoms.<sup>10</sup> Patients who experience gas-related symptoms (bloating and flatulence) from natural fiber forms (e.g., psyllium) may prefer a soluble semisynthetic fiber supplement (e.g., calcium polycarbophil). However, fiber may increase intestinal gas symptoms in patients with IBS, slow intestinal transit, and/or diverticulosis.<sup>11</sup> Slowly increasing the intake of fiber or using a variety of fiber-containing foods may help reduce symptoms in patients with these conditions.

**TABLE 14-1 Gas-Producing Foods**

<b><i>Foods That Produce Minimal Amounts of Gas</i></b>
• Meats: fowl, fish
• Vegetables: lettuce, peppers, avocado, tomato, asparagus, zucchini, okra, olives
• Fruit: cantaloupe, grapes, berries
• Carbohydrates: white rice, chips, popcorn, graham crackers
• All nuts, eggs, gelatin, fruit juice
<b>Foods That Cause Moderate Amounts of Gas</b>
• Potatoes
• Eggplant
• Citrus fruits, apples
• Carbohydrates: pastries, bread
<b>Foods That Cause Major Amounts of Gas</b>
• Vegetables: onions, celery, carrots, Brussels sprouts, cucumbers, cabbage, cauliflower, radishes
• Beans
• Fruit: raisins, bananas, apricots, prunes, dried fruit
• Carbohydrates: bagels, wheat germ, pretzels
• Peas
• Green salads
• Bran cereal, food high in bran
• Brown rice
• Leeks, parsnips
• Dairy products: milk, ice cream, cheese (in patients who have trouble digesting lactose; check food labels of processed foods for added lactose or milk-derived ingredients)
• Fatty foods: pan-fried or deep-fried foods, fatty meats; rich cream sauces and gravies (although fatty foods are not carbohydrates, these foods also can contribute to intestinal gas)
• Foods with high sugar content or with high fructose corn syrup (e.g., soft drinks)
• Products containing sorbitol and mannitol (e.g., sugar-free candies, sugar-free brownie and cake mixes, diet foods, chewing gum)

*Source:* References 7 and 9.

The odor attributed to flatulence may be worsened by the ingestion of sulfate-containing foods, such as cruciferous vegetables (e.g., broccoli and cabbage); breads and beers containing sulfate additives; and proteins with a high content of the sulfur-containing amino acids methionine and cysteine (e.g., eggs, macadamia nuts, peanuts, pistachio nuts, and red meats). Sulfur-based gases (e.g., hydrogen sulfide [H<sub>2</sub>S]), methanethiol, and dimethyl sulfide are produced through the action of sulfate-reducing bacteria on sulfate.<sup>12</sup> Rating foods by their potential to cause

intestinal gas symptoms is difficult, but clinical experience suggests that certain foods are generally more problematic than others (Table 14-1).

**TABLE 14-2 Oligosaccharide-Containing Foods That Alpha-Galactosidase Might Affect**

<b>Vegetables</b>	<b>Grains</b>	<b>Beans</b>
Beets	Bagels	Black-eyed peas
Broccoli	Barley	Bog beans
Brussels sprouts	Breakfast cereal	Broad beans
Cabbage	Granola	Chickpeas
Cauliflower	Pasta	Lima beans
Corn	Rice bran	Mung beans
Cucumbers	Rye	Peanuts and peanut butter
Leeks	Sorghum, grain	Pinto beans
Lettuce	Wheat bran	Red kidney beans
Onions	Whole wheat flour	Seed flour (sesame, sunflower)
Parsley	Whole-grain breads	Soy products (including lentils, soy milk, and tofu)
Peppers, sweet		

Source: Reference 8.

Gas-related symptoms also may be associated with the amount of air that enters the upper GI tract upon swallowing. Smoking, chewing gum, sucking on hard candies, drinking carbonated beverages, wearing poor-fitting dentures, hyperventilating, or being overly anxious may cause individuals to swallow larger amounts of air than is normal.<sup>12</sup> Poor eating habits (e.g., gulping food or drinking beverages too rapidly) also may cause larger amounts of air to enter the stomach.

A number of medical conditions cause or predispose patients to the formation of intestinal gas. Some conditions (e.g., carbohydrate malabsorption and pancreatic insufficiency) lead to an increased amount of gas produced from bacterial fermentation in the colon. The most common cause of carbohydrate malabsorption is lactase deficiency. Lactase is the enzyme that normally breaks down lactose in the intestinal lumen so that it can be absorbed. Approximately 50 million people in the United States are lactose maldigesters and experience symptoms of lactose intolerance when eating dairy products. The condition is more common in black (90%) and Asian populations (75%) than in eastern Europeans (6%).

In patients with lactase deficiency, the lactase enzyme is not available in sufficient quantities to break down lactose in dairy products before it reaches the colon. Patients who experience symptoms of lactose intolerance with even small amounts of lactose may inquire about the lactose content of their medications. Reviewing the list of excipients in the package insert with the patients and/or contacting the manufacturer can help to determine the lactose content of individual products. Lactose-free formulations of these medications may be available from the manufacturer. If a lactose-free product is unavailable, a compounded product may be considered.

In the colon, the malabsorbed lactose remains in the intestinal lumen, where it is available to colonic bacteria for fermentation to H<sub>2</sub> and other substances. Individuals with lactase deficiency experience GI symptoms (e.g., gas pains, bloating, nausea, and diarrhea) upon exposure to dairy and other products containing milk or milk-derived carbohydrates (e.g., caramel).<sup>13</sup> Milk-derived protein (e.g., whey powder, caseinate, and other lactoproteins) does not cause lactose-associated GI symptoms unless the product is contaminated with a milk-derived carbohydrate (i.e., lactose).

Bacterial fermentation in the small intestine resulting from bacterial overgrowth also may lead to excessive amounts of intestinal gas. The effects of probiotics on bloating symptoms associated with small bowel bacterial overgrowth and lactose intolerance are uncertain (see Chapter 23). Research suggests that probiotics improve bloating associated with lactose intolerance by producing lactic acid, which in turn improves lactose digestion.<sup>13</sup> Patients with lactose intolerance are at risk for the development of low bone density and osteoporosis because of reduced dietary intake; they should be counseled to supplement their diets to achieve the recommended daily intake of 1000-1200 mg of elemental calcium per day.

Other conditions such as IBS may predispose patients to intestinal gas symptoms. Gas pains and bloating are very

common in patients with IBS and may be caused by a number of interrelated factors, including heightened sensation of the GI tract to intestinal stretch (or visceral hypersensitivity), altered intestinal motility, activated intestinal immunity, altered brain-gut interaction, and autonomic dysfunction.<sup>14</sup> Small bowel bacterial overgrowth has been proposed as a unifying theory linking each of these factors, which has stimulated exciting research that aims to further define the relationship between intestinal bacterial overgrowth and the onset of IBS symptoms.<sup>14</sup> Probiotics (e.g., lactobacilli, saccharomyces, and bifidobacteria) are part of the normal “healthy” flora of the intestinal tract. They are thought to maintain intestinal health through a variety of mechanisms, including by shifting the intestinal bacterial content in favor of nonpathogenic organisms; by producing beneficial substances (e.g., short-chain fatty acids); and by acting primarily as carbohydrate-fermenting bacteria, thereby reducing intestinal gas production (see [Chapter 23](#)). Substances such as oligofructose (a “prebiotic”) are used as nutrients by the normal intestinal bacterial flora and by probiotic organisms; however, the normal flora produces greater amounts of CO<sub>2</sub> and H<sub>2</sub>, which may result in increased symptoms of intestinal gas.<sup>5,15</sup>

Intestinal gas symptoms also may result from other less common medical conditions (e.g., celiac disease or diabetic gastroparesis). Patients with celiac disease have an intolerance to gluten (a protein contained in wheat, rye, barley, and oats). Once a diagnosis of celiac disease has been made, and once gluten intolerance has been confirmed with an accurate test, patients should follow a gluten-free diet, preferably under the supervision of an experienced dietitian.<sup>2,15</sup> Intestinal gas symptoms may result from the inflammatory response that occurs in the GI tract after exposure to gluten. The most common sources of gluten are baked goods containing the causative grains (wheat and oat cereals, noodles, and pastas); however, many other food products (especially any processed foods containing thickeners) and some medications contain gluten. Successful adherence to a gluten-free diet requires rigorous label reading and close scrutiny of the gluten content of foods and nonprescription medications. A number of valuable resources exist for individuals seeking information about celiac disease.<sup>16,17</sup> In addition, referral to a registered dietitian may be beneficial because *all* gluten must be removed from the diet to avoid symptoms. A variety of drugs may cause intestinal gas symptoms. These drugs can be categorized broadly by the mechanisms that cause symptoms: drugs that affect intestinal flora (lactulose and antibiotics); drugs that affect metabolism of glucose and other dietary substances (alpha-glucosidase inhibitors, including acarbose and miglitol; and the biguanides, including metformin); and GI lipase inhibitors (orlistat). Drugs that affect GI motility (narcotics, anticholinergics, and calcium channel blockers); drugs that are high in fiber (psyllium) or nonabsorbable polymers (cholestyramine); and drugs that contain or release gas (effervescent solutions such as Alka-Seltzer) also may cause intestinal gas symptoms.

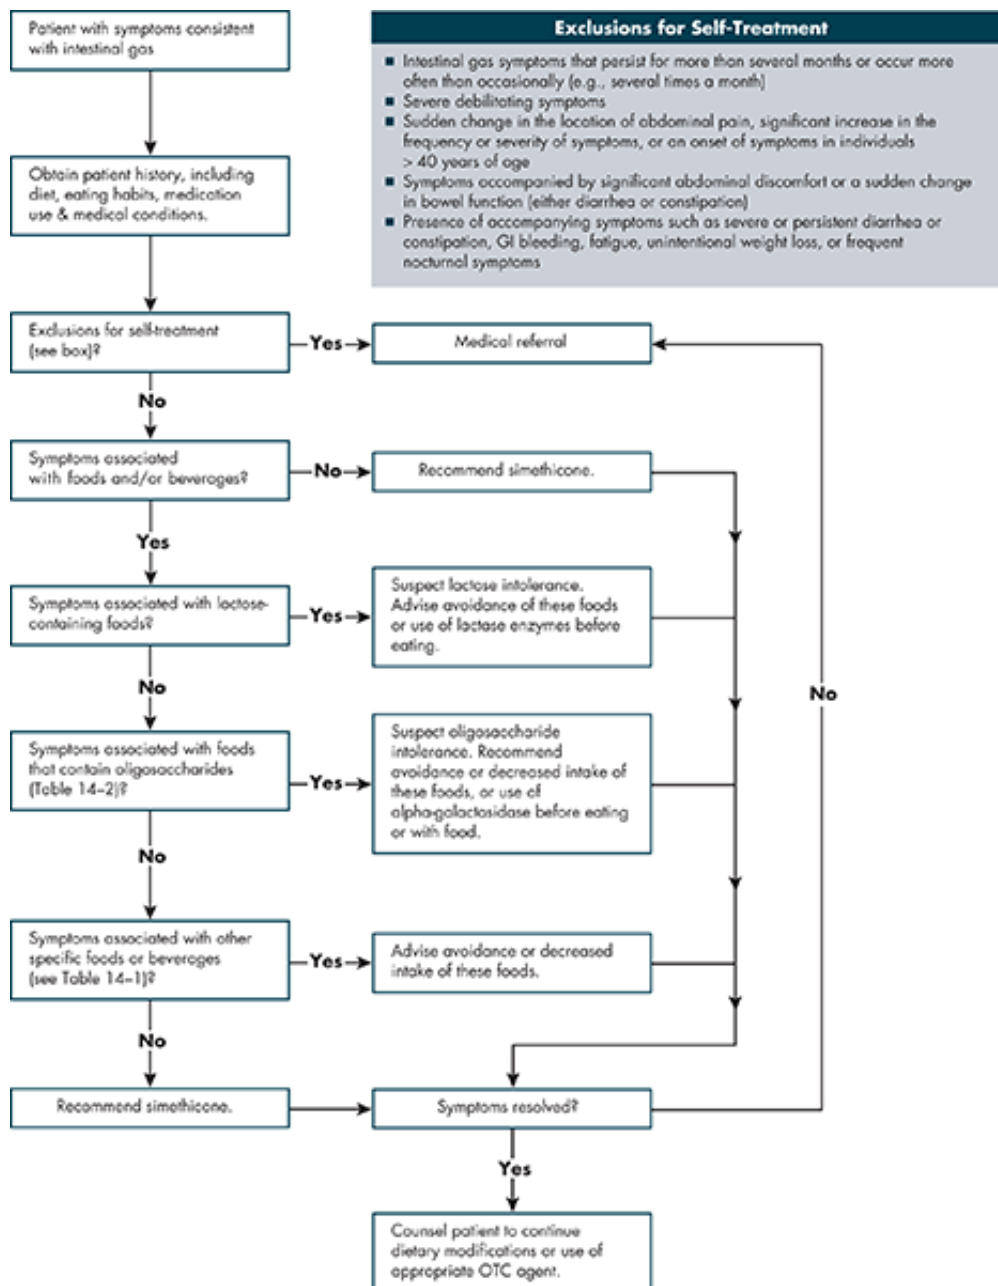

### Clinical Presentation of Intestinal Gas

Patients with symptoms of intestinal gas complain most commonly of excessive belching, abdominal discomfort or cramping, bloating, and flatulence. Complaints of gas pains and belching are more common than are complaints of flatulence. Other less common symptoms associated with “gaseousness” include nausea; audible bowel sounds (called borborygmi); and dyspepsia or indigestion.

Everyone experiences belching, especially after eating and drinking. Belching is the easiest way for air to leave the stomach after it is swallowed. Some people have excessive belching, which may be annoying or embarrassing because of its frequency and/or unexpected occurrence. The more frequently a person swallows, the greater the potential for air to enter the stomach. Drinking carbonated beverages or eating food too quickly is an easy way to increase the amount of air that is swallowed inadvertently, which may then cause excessive belching.

Gas pains often are described as a generalized, crampy discomfort associated with gaseousness. Passing gas or having a bowel movement may relieve gas pains. In some patients, symptoms may be brought on by stress or anxiety. In others, the size of a meal may be associated with the onset and severity of gas pains, with larger meals causing more bothersome symptoms. Patients who complain of recurrent gas pains (occurring at least 3 days per month in the last 3 months) that are associated with either diarrhea or constipation may have IBS. Because gas pains can mimic other conditions (e.g., biliary colic [and other diseases of the gallbladder and biliary tract], diabetic gastroparesis, peptic ulcer disease, intestinal obstruction, neoplastic disease, pancreatic insufficiency, or heart disease), a qualified health care provider (pharmacist, physician, nurse practitioner, etc.) should be consulted prior to initiating self-management. Patients should be referred to a primary care provider if they are experiencing new-onset, persistent, or frequent and/or severe symptoms. These symptoms may be related to an undiagnosed condition and should not be self-managed. In addition, patients should be referred to a primary care provider for medical evaluation if any of the criteria for exclusions for self-management are met ([Figure 14-1](#)).

Self-care of intestinal gas symptoms. Key: GI = Gastrointestinal; OTC = over-the-counter.

Bloating may be characterized as a sensation of tension in the abdominal area after eating or as a subjective sensation that the abdomen is larger than normal. Patients with bloating may observe that clothes fit more tightly or are difficult to fit into comfortably. Eating certain foods (Tables 14-1 and 14-2) (especially foods high in fiber), eating too rapidly, or eating too much may contribute to bloating. Similar to chronic gas pains, chronic bloating accompanied by a change in bowel function is suggestive of IBS. Patients with diabetes who complain that their bloating symptoms are accompanied by a sensation of early satiety or fullness after the ingestion of only a small amount of food may be experiencing diabetic gastroparesis and should be referred to a primary care provider.

Most patients who complain of flatulence are referring to the unpleasant, uncontrollable, or frequent passage of intestinal gas through the rectum. Passing gas is normal and occurs either consciously or unconsciously between 20 and 40 times a day, even while sleeping. Certain foods (Tables 14-1 and 14-2) (especially those that contain fiber, fructose, lactose, or oligosaccharides) are more likely to cause gas and therefore can contribute to flatulence. Sorbitol or mannitol from commonly used sweeteners in low-calorie foods and liquid medications also can contribute to flatulence.

## Treatment of Intestinal Gas

### Treatment Goals

The goals of therapy are to (1) reduce the frequency, intensity, and duration of intestinal gas symptoms and (2)

reduce the impact of intestinal gas symptoms on the patient's lifestyle. Because a certain amount of intestinal gas production is normal and necessary for normal GI function, the complete elimination of intestinal gas is not a realistic or attainable goal.

### General Treatment Approach

Self-treatment of intestinal gas symptoms should begin with an assessment of the patient's history of symptoms, diet, eating habits, medication use, and relevant medical conditions. Most patients will be able to control their symptoms if they understand how the symptoms occur, follow steps to reduce predisposing factors, and make informed decisions regarding the use of nonprescription medications. Identification of the underlying cause of intestinal gas will guide treatment decisions (Figure 14-1). Inquiry into the patient's diet (including a review of the patient's eating habits and rate of food ingestion) often can lead to appropriate suggestions for reducing the problem. Symptoms that are related to eating habits or diet often will subside quickly, once the source of the problem is identified and the necessary changes are made.

Patients who associate symptoms with foods containing lactose or oligosaccharides and who do not meet the criteria for exclusions for self-treatment (Figure 14-1) may use digestive enzymes (e.g., lactase replacement or alpha-galactosidase products). Although several nonprescription antiflatulent products are available (e.g., activated charcoal and simethicone), their use is largely empiric, and evidence supporting their benefit is limited. Probiotics (see Chapter 23) maintain gastrointestinal health by protecting against pathologic GI flora; they may be useful for some individuals with intestinal gas.<sup>18</sup> No consensus exists on whether probiotics or prebiotics are beneficial in patients with lactose intolerance or chronic abdominal bloating; however, increasing evidence suggests that probiotics may be beneficial for treatment of intestinal gas symptoms in patients with IBS because the probiotics have favorable effects on the bacterial content of the small intestine and colon.<sup>14,18,19</sup> The benefit of probiotic products may potentially be linked to specific bacterial strains. More research is needed to identify the true value of individual probiotics.<sup>18,19</sup>

Exclusions for self-treatment (Figure 14-1) should be reviewed with the patient prior to recommending therapy. Referral of the patient to a primary care provider for further evaluation should be considered for patients with exclusions for self-treatment and for patients whose symptoms persist after initiating simple treatment options (e.g., dietary modification and nonprescription medications).

### Nonpharmacologic Therapy

General information for controlling intestinal gas symptoms is provided in Table 14-3.<sup>20</sup> Patients may benefit from changes in eating habits and changes in diet. Reducing the consumption of gas-producing foods (Tables 14-1 and 14-2) may be appropriate, depending on the patient's history. Some people are unable to tolerate gas-producing foods and need to completely avoid these foods in their diet. Patients with lactose intolerance either should avoid milk and dairy products or should use lactase replacement products. Low-lactose milk products (e.g., Lactaid Milk or Dairy Ease Milk), fortified soy milk, almond milk, or rice milk products also may be used as milk substitutes. Low-lactose milk is a prehydrolyzed milk product (i.e., lactose is already hydrolyzed) and contains the same nutrients as regular milk, but the product is not entirely lactose free. Soy milk, almond milk, and rice milk products are palatable lactose-free milk alternatives that are low in fat and may be fortified to include calcium and vitamin D. Similarly, patients who are unable to tolerate foods with high oligosaccharide content should attempt to reduce or remove these foods from their diet.

Understanding the food values of people from different cultures, ethnicities, and socioeconomic backgrounds may lead to improved identification of dietary patterns known to contribute to intestinal gas symptoms. This knowledge may allow health care providers to identify and explain, in a culturally sensitive manner, why problematic gas-forming foods are not appropriate options for all patients. Addressing dietary issues with family members may be a better approach for developing healthy eating habits over time, especially for children experiencing intestinal gas symptoms.

### Pharmacologic Therapy

Simethicone and activated charcoal may relieve symptoms after intestinal gas has formed. Alpha-galactosidase and lactase enzymes are taken with foods to prevent gas from forming. Lactase replacement products may be beneficial for the treatment of intestinal gas and diarrhea associated with lactose intolerance; they also are used as digestive aids, allowing individuals with lactose intolerance to incorporate dairy foods into their diet without producing intolerable symptoms. Most lactose maldigesters can tolerate some milk (up to 1 cup), so use of these products should be individualized according to the patient's report of symptoms.

#### **TABLE 14-3 Useful Information to Help Patients Decrease Symptoms of Intestinal Gas**

<i>Eating Habits</i>
----------------------

• Relax a bit before eating. Follow this simple breathing technique to enhance relaxation and release tension:

- Sit straight in a comfortable position with your arms and legs uncrossed.

- Breathe in comfortably, using your abdomen. Pause briefly before exhaling.

- Each time you exhale, count silently to yourself, "One . . . two . . . three . . . four."

- Repeat this cycle for 5-10 minutes.

- Notice your breathing gradually slowing, your body relaxing, and your mind calming as you practice this breathing technique.

• Avoid the temptation to rush through a meal. Eat and drink slowly in a calm environment.

• Chew food thoroughly.

• Avoid washing down solids with a beverage.

• Avoid gulping and sipping liquids, drinking out of small-mouthed bottles or straws, or drinking from water fountains.

• Eliminate pipe, cigar, and cigarette smoking.

• Avoid chewing gum and sucking hard candy, especially those that contain artificial sweeteners (e.g., sorbitol or mannitol).

• Check dentures for proper fit.

• Attempt to be aware of and avoid deep sighing.

• Do not attempt to induce belching or strain to pass gas.

• Do not overload the stomach at any one meal.

### **Diet**

• Keep a dietary diary for a few days while tracking intestinal gas symptoms.

• Avoid gas-producing foods ([Table 14-1](#)).

• Avoid foods with air whipped into them (e.g., whipped cream, soufflés, sponge cake, milk shakes).

• Avoid carbonated beverages (e.g., sodas, beer).

• Avoid caffeinated beverages (e.g., coffee, energy drinks).

### **Medication Use and Lifestyle Habits**

• Avoid long-term or frequent intermittent use of medications intended for relief of cold and allergy symptoms (e.g., anticholinergic antihistamines such as brompheniramine, carbinoxamine, chlorpheniramine, clemastine, and diphenhydramine).

• Avoid or minimize the use of drugs affecting GI motility (narcotics and calcium channel blockers).

• Avoid or minimize the use of drugs affecting glucose metabolism (orlistat; alpha-glucosidase inhibitors, including acarbose and miglitol; and the biguanides, including metformin).

• Avoid or minimize the use of drugs that affect the intestinal flora (lactulose and antibiotics).

• Avoid drugs high in fiber (psyllium).

• Avoid nonabsorbable polymers (cholestyramine).

• Avoid drugs that contain or release gas (e.g., Alka-Seltzer).

- Avoid tight-fitting garments, girdles, and belts.
- Do not lie down or sit in a slumped position immediately after eating.
- Develop a regular routine of exercise and rest.

### Simethicone

Simethicone (a mixture of inert silicon polymers) is used as a defoaming agent to relieve gas. Simethicone acts in the stomach and intestine to reduce the surface tension of gas bubbles that are embedded in the mucus of the GI tract. As surface tension changes, the gas bubbles are broken or coalesced and then eliminated more easily by belching or passing gas through the rectum.<sup>21</sup>

The Food and Drug Administration (FDA) considers simethicone safe and effective as an antiflatulent agent. In patients with acute, nonspecific diarrhea, the combination of simethicone with loperamide produced quicker relief from gas-related discomfort than either agent alone.<sup>22</sup> However, simethicone's ability to reduce intestinal gas symptoms for all patients with symptoms is questionable.<sup>23</sup> The use of simethicone may be encouraged on a trial basis because some patients report benefit. The usual adult and pediatric dosages for simethicone are provided in [Table 14-4](#).

Many antacid products contain a combination of simethicone and antacids; therefore, patients should follow the label instructions for dosages of these products. However, use of both agents often is unnecessary, and the efficacy of such combination products has not been well-studied. Furthermore, single-ingredient antiflatulent products ([Table 14-5](#)) usually contain a higher concentration of simethicone than the combination products. Because simethicone is not absorbed from the GI tract, it has no known systemic side effects; its safety has been well-documented. Simethicone is contraindicated in patients with a known hypersensitivity to simethicone products or suspected intestinal perforation and obstruction.

### Activated Charcoal

Activated charcoal also is promoted for relief of intestinal gas; however, it is neither approved nor shown to be effective for this indication.<sup>24</sup> The usual adult dosages for this agent are provided in [Table 14-4](#). The proposed antiflatulent properties of activated charcoal are related to the adsorbent effects of the substance and its potential to facilitate the elimination of intestinal gas from the GI tract. Activated charcoal has been purported to be beneficial for the elimination of malodorous, sulfur-based gases.<sup>24</sup> Activated charcoal also has poor palatability. External devices containing activated charcoal also are available to reduce the odor of flatus in patients with ostomies (see [Chapter 21](#)).

### Combination Products

Combination products containing simethicone and activated charcoal also are available; these products aim to provide relief from intestinal gas symptoms by combining the gas-reducing activity of each of the individual components. [Table 14-5](#) lists examples of commercially available products, including products containing activated charcoal and simethicone.

### Alpha-Galactosidase

Another FDA-approved product for use as an antiflatulent is the enzyme alpha-galactosidase. This enzyme, which is derived from the *Aspergillus niger* mold and is classified as a food, hydrolyzes oligosaccharides into their component parts before they can be metabolized by colonic bacteria. The usual adult and pediatric dosages for alpha-galactosidase are provided in [Table 14-4](#).<sup>21</sup>

**TABLE 14-4 Dosage Guideline for Intestinal Gas Products**

Agent	Dosage			
	Adults	Children ≥ 12 Years	Children 2 to < 12 Years	Children < 2 Years
Simethicone	40-360 mg after meals and at bedtime, as needed	40-360 mg 4 times daily	40 mg 4 times daily	20 mg 4 times daily, as needed
Activated	520 mg (2 capsules) orally after meals,	Specific		

charcoal	as needed; may repeat hourly	guidelines not available		
Alpha-galactosidase	300-450 units per serving of food	Not recommended		
Lactase enzyme	3000-9000 units at first bite of food or drink containing lactose	Specific guidelines not available		
Probiotics	Specific guidelines not available	Specific guidelines not available		

Because high-fiber foods contain large amounts of oligosaccharides, alpha-galactosidase is recommended as a prophylactic treatment of intestinal gas symptoms produced by high-fiber diets or foods that contain oligosaccharides (Table 14-2). Two controlled trials of alpha-galactosidase demonstrated that the agent significantly reduced symptoms of intestinal gas in healthy individuals fed oligosaccharide-containing foods.<sup>25,26</sup>

The safety of alpha-galactosidase remains to be determined. Although this enzyme has been used in food processing for years and is regarded as safe by FDA, the amount contained in available pharmacologic products is probably much greater than that in processed foods. Because the enzyme produces galactose, this product should not be used by patients with galactosemia (an inherited metabolic disorder in which galactose accumulates in the blood because of the deficiency of an enzyme that catalyzes galactose's conversion to glucose). Similarly, patients with diabetes should be cautioned about the use of the enzyme, which may produce 2-6 grams of carbohydrates per 100 grams of food.<sup>25</sup> Because alpha-galactosidase is derived from mold, allergic reactions are possible in patients allergic to molds.

#### Lactase Replacement Products

Lactase replacement products are used in patients with lactose intolerance (see Chapter 16). Lactase enzymes break down lactose, a disaccharide, into the monosaccharides glucose and galactose, which are absorbed. Lactase replacement products should be used in patients with lactose intolerance to aid in the digestion of dairy products. There are no adverse effects listed for lactase replacement products. The usual adult dose for lactase enzymes is provided in Table 14-4.

#### Product Selection Guidelines

##### Special Populations

Several pediatric formulations of simethicone are indicated for the relief of intestinal gas. These products, which contain simethicone 40 mg per 0.6 mL suspension, often are promoted and used to relieve gas associated with colic. However, simethicone has not been found to be superior to placebo for intestinal gas and/or infantile colic.<sup>27</sup> Although its efficacy is questionable, simethicone is not absorbed from the GI tract, and it is considered safe for use in infants and children. There are no reports linking simethicone to congenital defects.<sup>27</sup> Simethicone is a Pregnancy Category C drug and is considered to be safe for use by nursing mothers.

For alpha-galactosidase products, safety and efficacy have not been evaluated in infants and children. Therefore, this product should not be used in pediatric patients until data are available to support such use. Manufacturers recommend that pregnant or nursing patients first consult with a primary care provider before using alpha-galactosidase.

No special population considerations are listed for lactase replacement products. Patients should consult a primary care provider if symptoms continue after using a lactase replacement product, or if symptoms are unusual and seem unrelated to eating dairy products.

##### Patient Factors

Alpha-galactosidase and lactase replacement products are used to prevent the onset of symptoms in patients unable to tolerate problematic foods. Patients with gas symptoms who need immediate relief and patients who cannot associate their symptoms with certain foods should use simethicone. Activated charcoal may be an alternative to simethicone for patients with gas symptoms, and also it may be beneficial for patients who experience malodorous gas production. Because alpha-galactosidase produces carbohydrates, patients with galactosemia or diabetes mellitus should avoid this product and use simethicone instead. Patients with lactase maldigestion who experience symptoms of lactose intolerance should consider taking lactase replacement products at the time of exposure to dairy products.

##### Patient Preferences

Most products for intestinal gas are available in a variety of strengths and dosage forms. A liquid formulation of

simethicone is available for infants. Simethicone also is available as chewable tablets, softgels, and an edible filmstrip. Liquid dosage forms and alternative solid dosage forms are generally more expensive than standard solid oral dosage forms (e.g., tablets and capsules) but may be more palatable. Activated charcoal is available in two solid oral dosage forms (tablets and capsules) and in a combination product with simethicone.

**TABLE 14-5 Selected Antiflatulent Products**

<i>Trade Name</i>	<i>Primary Ingredients</i>
<b>Single-Entity Simethicone Products</b>	
Gas-X Regular Strength Chewable Tablets	Simethicone 80 mg
Gas-X Extra Strength Chewable Tablets	Simethicone 125 mg
Mylanta Gas Chewable Tablets	Simethicone 125 mg
Phazyme Chewable Tablets	Simethicone 125 mg
Gas-X Children's Tongue Twisters	Simethicone 40 mg per edible film strip
Gas-X Thin Strips	Simethicone 62.5 mg per edible film strip
Mylicon Infant's Drops	Simethicone 40 mg/0.6 mL
<b>Activated Charcoal Products</b>	
Charcoal Tablets	Activated charcoal 260 mg
CharcoCaps Capsules	Activated charcoal 260 mg
<b>Combination Charcoal Product</b>	
Charcoal Plus Tablets	Activated charcoal 250 mg; simethicone 80 mg
<b>Alpha-Galactosidase Replacement Products</b>	
Beano Chewable Tablets	Alpha-galactosidase 150 units (1 tablet)
Beano Meltaway Tablets	Alpha-galactosidase 300 units (1 tablet)
<b>Lactase Replacement Products</b>	
Lactaid Original Strength Caplets	Lactase enzyme 3000 units
Lactaid Chewable Tablets	Lactase enzyme 4500 units
Lactase Fast Act Chewable Tablets	Lactase enzyme 9000 units
Lac-Dose Tablets	Lactase enzyme 3000 units
Lactrase Capsules	Lactase enzyme 250 mg (3750 lactase enzyme units)
Lacteeze Drops	Lactase enzyme 5 drops (80 lactase enzyme units)
<b>Probiotic Products</b>	
Activia Probiotic Yogurt	<i>Lactobacillus bulgaricus</i> ; <i>Streptococcus thermophilus</i> ; <i>Bifidobacterium animalis</i> DN173010 (1 × 10 <sup>8</sup> live bacteria per gram <sup>a</sup> )
Align Digestive Care Probiotic Supplement Capsules	<i>Bifidobacterium infantis</i> 35624 (4 mg = 1 × 10 <sup>9</sup> live bacteria)

Culturelle Probiotic Digestive Health Capsules	<i>Lactobacillus GG</i> ( $1 \times 10^{10}$ live bacteria per capsule)
DanActive Probiotic Dairy Drink	<i>Lactobacillus bulgaricus</i> ; <i>Streptococcus thermophilus</i> ; <i>Lactobacillus casei</i> DN-114 001
Danimals Yogurt Smoothie Drinks	<i>Lactobacillus bulgaricus</i> ; <i>Streptococcus thermophilus</i> ; <i>Lactobacillus rhamnosus GG</i> ( $1 \times 10^8$ live bacteria per gram <sup>a</sup> )
FloraQ	<i>Lactobacillus acidophilus</i> ; <i>Bifidobacterium</i> ; <i>Lactobacillus paracasei</i> ; <i>Streptococcus thermophilus</i> 230 mg (an aggregate of a minimum of $8 \times 10^9$ freeze-dried bacteria)
Florastor	<i>Saccharomyces boulardi</i> freeze-dried capsules 250 mg

<sup>a</sup> Meets National Yogurt Association criteria for live and active culture yogurt.

Alpha-galactosidase is available as tablets, caplets, and meltaway tablets. There is no difference in onset of symptomatic relief between these dosage forms, so the choice between dosage forms is left entirely to personal preference and convenience.

A variety of products also is available for patients with lactose intolerance. Lactase replacement products can be added to milk or dairy products to reduce the amount of lactose in the product, or they can be ingested along with dairy products in an effort to reduce the amount of lactose in the food. Additionally, patients may elect to use one of the available milk alternatives (e.g., low-lactose milk, fortified soy milk, almond milk, or rice milk).

### Complementary Therapies

A variety of probiotic dietary supplements (see [Chapter 23](#)) is widely used for GI complaints, including intestinal gas and bloating.<sup>18</sup> The most common formulations for intestinal gas ([Table 14-5](#)) are capsules with one bacterium (e.g., *Bifidobacterium infantis*) or multiple bacteria (e.g., *Lactobacillus acidophilus*, *Lactobacillus paracasei*, *Bifidobacterium*, and *Streptococcus thermophilus*). Functional fermented food products with live active cultures of probiotic species (e.g., kombucha tea and kefir products) also are available. In patients with IBS and those with lactose intolerance, increasing but limited evidence suggests that specific probiotics provide temporary relief from GI symptoms.<sup>18,19</sup> Probiotic bacteria leave the intestine soon after therapy is discontinued. When using probiotic therapy, daily administration is required to maintain bacterial populations in the intestinal flora. An adequate trial of 14 days is generally recommended for patients interested in using probiotic therapy. Research shows that probiotics are effective in reducing the incidence of antibiotic-associated diarrhea. More studies are required to identify which probiotic strains are most efficacious for patients receiving specific antibiotics.<sup>27</sup>

Carminatives (e.g., fennel, Japanese mint, peppermint, and spearmint) are other natural products commonly used for intestinal gas.<sup>28</sup> Despite insufficient evidence, these agents are widely used for the management of intestinal gas and IBS.<sup>28,29</sup> Carminatives may reduce the tone of the lower esophageal sphincter and should be minimized or avoided by patients with gastroesophageal reflux disease (see [Chapter 13](#)); however, the effect of carminatives on lower esophageal sphincter tone in healthy individuals with intestinal gas symptoms may be less problematic.<sup>30</sup> Fennel can cause photodermatitis, is contraindicated during pregnancy, and enters breast milk in lactating women. If fennel is used, patients should be advised to avoid excessive sunlight and to avoid use during pregnancy and lactation. In addition, coadministration of fennel with ciprofloxacin may lead to reduced ciprofloxacin levels through a chelation mechanism, so doses should be spaced appropriately in patients using both agents.<sup>31</sup>

### Assessment of Intestinal Gas: A Case-Based Approach

When a patient complains of intestinal gas, it is important to try to discern the causes, duration, and frequency of the symptoms ([Table 14-6](#)). Items that produce relief may provide clues as to the cause. A thorough review of dietary habits, medical problems, and use of prescription and nonprescription medications may provide other clues.

**TABLE 14-6 Differentiation of Intestinal Gas Discomfort and Irritable Bowel Syndrome**

<b>Criterion</b>	<b>Intestinal Gas Discomfort</b>	<b>Irritable Bowel Syndrome</b>
Location	Generalized discomfort in the upper, mid, or lower abdomen	Generalized discomfort, bloating, and/or pain in the lower abdomen or colon
Signs	Eructation (upper abdomen): belching of air; bloating (mid abdomen): increased abdominal girth; flatulence (lower abdomen, colon): excessive air or other gas in	No physical signs of disease; no fever, melena, hematochezia, or signs of other gastrointestinal conditions

	the stomach and intestines	
Symptoms	Sensation of accumulated intestinal gas; may present as minimal physical discomfort but with significant negative psychosocial effects	Vary widely but are commonly described as abdominal pain that is relieved after a bowel movement, is accompanied by either diarrhea or constipation, and usually lasts at least 3 months
Onset	May occur at any age	Begins in early adulthood; rarely occurs after the age of 60
Etiology	Symptoms commonly believed to be caused by an excessive amount of gas in the stomach (eructation) and intestines (bloating, flatulence); other causes include lactase deficiency, overgrowth of intestinal bacteria, and excessive air swallowing (aerophagia)	Unknown May result from altered gastrointestinal motility, heightened visceral sensitivity, and/or overgrowth of intestinal bacteria
Exacerbating factors	Diet; underlying medical conditions; and certain drugs (e.g., lactulose, antibiotics, alpha-glucosidase inhibitors, orlistat, narcotics, anticholinergics, calcium channel blockers, psyllium or cholestyramine, and effervescent solutions)	Stress; overeating; problem foods (e.g., alcohol, chocolate, caffeinated beverages, dairy products, and sugar-free products that contain sorbitol or mannitol); foods high in fat
Modifying factors	Minimization of exacerbating factors	Minimization of exacerbating factors; primary care provider evaluation and treatment

Cases 14-1 and 14-2 are examples of the assessment of patients with intestinal gas.

### Patient Counseling for Intestinal Gas

Patient counseling is important to ensure the appropriate selection and use of nonprescription medications for intestinal gas. Patients should be encouraged to keep a diary of foods in an effort to identify those that are problematic. Avoidance of foods or other substances that cause intestinal gas is the best advice to give patients. The health care provider should explain the proper use of medications for intestinal gas and should warn the patient of possible adverse effects. The box Patient Education for Intestinal Gas contains specific information to provide patients.

#### Case 14-1

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient complains of occasional stomach pain, bloating, and flatulence. She states the symptoms started about 4-5 months ago and have progressively been getting worse. Symptoms now include diarrhea, nausea, and fatigue.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The patient states that the symptoms seem to get worse when she drinks her sugar-free vanilla lattes or eats fast food. There are times when the pain is present in the lower abdomen, and the patient cannot identify a cause. Having a bowel movement tends to relieve some of the pain some of the time.
c. description of the patient's efforts to relieve the symptoms	She has tried several OTC products without much success. The products include simethicone 125 mg 4 times a day and Tums 500

	mg 3 times daily.
d. patient's identity	Ellie Dawn
e. age, sex, height, and weight	28 years old, female, 5 ft 6 in., 145 lb
f. patient's occupation	Social worker
g. patient's dietary habits	Skips breakfast unless she stops at a coffee stand for a latte and whole wheat muffin. Eats sporadically during the day as her schedule allows. Frequently eats at fast food restaurants or consumes prepackaged meals.
h. patient's sleep habits	7-8 hours nightly
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Depression: citalopram 10 mg once daily; hypertension: lisinopril 20 mg once daily
j. allergies	None
k. history of other adverse reactions to medications	None
l. other (describe) _____	Over the past several months, the patient reports losing 10 pounds without changing her diet or increasing exercise.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s) (Table 14-6).	Abdominal symptoms are consistent with intolerance to multiple foods, which suggests the possibility of a lactose intolerance, oligosaccharide intolerance, and glucose sensitivity (celiac disease). Fatigue and weight loss also support a disorder with a nutritional deficiency component, possibly IBS.
3. Identify exclusions for self-treatment (Figure 14-1).	Unintended weight loss; length of time symptoms have been present.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer to a primary care provider or gastroenterologist for a differential diagnosis. (2) Recommend patient keep a food, stress, and symptom diary (3) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Ellie should be referred to a primary care provider or gastroenterologist for a differential diagnosis.
6. Describe the recommended therapeutic	"You should immediately follow up with your primary care provider

approach to the patient or caregiver.	or gastroenterologist.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“Current treatment available OTC will not adequately address the severity of the current symptoms you have. It is important that you follow up with your primary care provider to identify the cause of your complaints and associated weight loss.”
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	“Is there anything that I can do right now to address my symptoms prior to getting in to see the doctor?”
Answer the patient’s or caregiver’s questions.	“Immediately following up with your primary care provider is the best course of action.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact the patient in 1-2 days to ensure she sought medical care and made an appointment.

Key: IBS = Irritable bowel syndrome; OTC = over-the-counter.

#### Case 14-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient’s symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient presents with complaints of bloating with an increased amount of burping and flatulence. The symptoms are mild in nature but uncomfortable and embarrassing.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient’s symptom(s)	Symptoms seem to be worse after eating large meals, especially when ice cream or milk is consumed. The bloating seems to decrease after episodes of burping or flatulence.
c. description of the patient’s efforts to relieve the symptoms	The patient has tried including 1 serving of Activia yogurt into his diet over the past few weeks with no relief.
d. patient’s identity	Francis Welker
e. age, sex, height, and weight	44 years old, male, 6 ft, 240 lb

f. patient's occupation	Publicist
g. patient's dietary habits	Never misses a meal and enjoys eating fried southern comfort food, ice cream, and soda.
h. patient's sleep habits	5-7 hours a night
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Hypertension: losartan 50 mg, 1 tablet every morning GERD: omeprazole 20 mg, 1 capsule every morning with breakfast
j. allergies	Penicillin (rash)
k. history of adverse reactions to medications	None
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Patient is currently experiencing intestinal gas and bloating due to dietary intolerances.
3. Identify exclusions for self-treatment (Figure 14-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer patient to an appropriate health care provider. (2) Recommend self-care with lactose intolerance product (e.g., Lactaid) in addition to simethicone and a reduction in meal size. (3) Recommend self-care until patient can see an appropriate provider. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Francis should take a lactase enzyme whenever he eats more than 4 ounces of dairy. Gas or bloating can be treated with simethicone. He should avoid large meals and carbonated beverages.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should take Lactaid Original Strength Capsules whenever you eat more than 4 ounces of dairy. The Gas-X Extra Strength tablets can be taken with meals or snacks. You should avoid large meals and carbonated beverages."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"The Lactaid will help with the digestion of dairy products—including yogurt, milk, and ice cream—which should decrease the amount of gas produced. If you do experience an increase in belching, flatulence, or bloating, you can use Gas-X, which helps expel gas bubbles formed within your stomach and intestine. By reducing your meal size and avoiding carbonated beverages, you should notice some relief from the bloating you have been experiencing."
<b>Patient Education</b>	

8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. appropriate dose and frequency of administration	See <a href="#">Table 14-4</a> .
b. maximum number of days the therapy should be employed	No maximum, as long as the symptoms are relieved and do not worsen.
c. product administration procedures	Take the product by mouth.
d. expected time to onset of relief	Soon after administration.
e. degree of relief that can be reasonably expected	"If your bloating and gas are being caused by lactose intolerance, then the Lactaid should give you mild to moderate relief."
f. most common side effects	None
g. side effects that warrant medical intervention should they occur	None
h. patient options in the event that condition worsens or persists	See <a href="#">Figure 14-1</a> .
i. product storage requirements	"Store in a cool, dry place out of children's reach."
j. specific nondrug measures	See <a href="#">Table 14-3</a> .
Solicit follow-up questions from the patient or caregiver.	"Can I double the dose of any of the medications for quicker relief?"
Answer the patient's or caregiver's questions.	"No, follow the manufacturer's directions. Additional doses will not provide added benefit."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Ask the patient to call and update you on his response to your recommended treatment; alternatively, you could call him in a week to evaluate his response to the treatment. If the latter, be sure you have the patient's current telephone number.

Key: GERD = Gastroesophageal reflux disease.

Patient Education for Intestinal Gas

The objectives of self-treatment are to (1) reduce the symptoms of intestinal gas and (2) reduce the chance of its recurrence. For most patients, carefully following product instructions and the self-care measures listed below will help ensure optimal therapeutic outcomes.

### **Nondrug Measures**

- If possible, avoid foods known to cause intestinal gas.
- Avoid activities known to introduce gas into the digestive system, such as drinking carbonated beverages.

### **Nonprescription Medications**

- Lactase replacement products and alpha-galactosidase should be taken with foods to prevent intestinal gas from forming.
- Simethicone is used to treat intestinal gas after it has occurred.

### **Alpha-Galactosidase**

- Do not cook with this product. Add to food after it has cooled because food temperatures higher than 130°F may inactivate the enzyme.
- If using drops, add drops to the first bite of problem foods.
- If using tablets, swallow, chew, or crumble tablets with the first bite of problem foods.
- An average meal may contain three servings of a problem food. If needed, use more tablets for larger meals, up to the maximum recommended dose.

### **Lactase Replacement Products**

- Take at first bite of dairy or lactose-containing food.
- Dosing may vary according to the amount of lactase in the product and the level of lactose intolerance.
- Do not take more than the recommended maximum daily dose.
- Low-lactose milk or fortified soy milk products also may be used to supplement dietary intake of calcium.

### **Simethicone**

- For infants, to ease administration, mix the suspension with 1 ounce of cool water, infant formula, or other liquid.
- Discontinue simethicone if adequate relief is not obtained within 24 hours.

### **When to Seek Medical Attention**

- Seek medical attention if symptoms do not improve or they worsen.

### **Evaluation of Patient Outcomes for Intestinal Gas**

Many patients with intestinal gas have mild-moderate distress, and the discomfort is generally self-limiting within 24 hours. Mild-moderate gas and bloating are managed primarily with diet modification, and some relief may occur with symptomatic drug therapy. With effective treatment, the patient can expect reduced intensity and duration of gas-related symptoms such as belching, abdominal pain, bloating, and flatulence. Patients who achieve symptomatic relief should be advised to continue the self-care measures as needed. The provider should ask the patient to return or call after 1 week of self-treatment with dietary measures, nonprescription antiflatulents, or digestive enzymes so outcomes can be assessed. Medical referral is necessary if any of the following occurs before or during treatment:

- Intestinal gas symptoms that persist for more than several days or occur more often than occasionally (e.g., several times a month) and are associated with diarrhea or constipation.
- Sudden change in the location of abdominal pain.
- Significant increase in the severity or frequency of symptoms.
- Sudden change in bowel function.
- Presence of accompanying symptoms such as severe or persistent diarrhea/constipation; greasy or malodorous stools; GI bleeding (e.g., hematemesis, melena, or hematochezia); fatigue; unintentional weight loss; or frequent nocturnal symptoms.

### **Key Points for Intestinal Gas Complaints**

- Limit the self-treatment of intestinal gas symptoms to minor symptoms and to cases in which exclusions for self-treatment (Figure 14-1) do not exist.
- Counsel patients on dietary measures that may reduce the amount of intestinal gas. Certain foods (Tables 14-1 and 14-2) are more likely to cause gas and contribute to symptoms.

- Patients who associate symptoms with lactose- or oligosaccharide-containing foods and who do not meet criteria for exclusions for self-treatment may use digestive enzymes (lactase replacement or alpha-galactosidase products).
- Probiotics may be helpful for patients with lactose intolerance who experience bloating or for patients with bloating associated with irritable bowel syndrome.
- Antiflatulents such as activated charcoal and simethicone also may be used, although there is contradictory evidence supporting the ability of these agents to reduce the amount of intestinal gas formed.
- Referral to a primary care provider for further evaluation should be considered for patients with exclusions for self-treatment and for patients whose symptoms persist after initiating simple treatment options (e.g., dietary modification and nonprescription medications).

## Handbook of Nonprescription Drugs &gt; Chapter 15. Constipation

**Constipation: Introduction**

Constipation is a common gastrointestinal (GI) complaint. Although individual bowel frequency varies, health care providers generally define constipation in adults as having fewer than 3 bowel movements per week that are characterized by straining and the difficult passage of hard, dry stools.<sup>1,2</sup> Patients' perceptions of and definitions of normal bowel frequency and constipation vary widely. Patients may describe constipation as (1) straining to have a bowel movement; (2) passing hard, dry stools; (3) passing small stools; (4) feeling as though bowel evacuation is not complete; or (5) experiencing decreased stool frequency. Constipation usually results from the abnormally slow movement of feces through the colon, resulting in accumulation in the descending colon.<sup>2,3</sup> Constipation is a common symptom that occurs in males and females of all ages. The prevalence in the general population ranges from 2% to 28%.<sup>1,4-6</sup> Constipation leads to 2.5 million physician visits per year in the United States, with direct costs of diagnosis and treatment estimated at billions of dollars annually.<sup>7</sup> It is reported more often in women, nonwhites, children, and older individuals.<sup>1,4,8</sup> Older adults (>65 years) are 5 times more likely to develop constipation than younger adults, and women are more than 3 times as likely to experience constipation than are men.<sup>2</sup> Constipation also is a frequent complaint in late pregnancy and after childbirth.<sup>8</sup> If untreated, constipation can lead to hemorrhoids, anal fissures, rectal prolapse, fecal impaction, or other complications.<sup>9</sup>

**Pathophysiology of Constipation**

All structures shown in [Figure 15-1](#) contribute to the process of digestion. With normal functioning gastric motility, food is retained in the stomach for approximately 3 hours and in the small intestine for the same amount of time. Tonic contractions of the stomach churn and knead food, and large peristaltic waves move food toward the duodenum.<sup>10</sup>

Once ingestible matter has passed through the stomach, it enters the small intestine and passes through the large intestine before defecation. After ingestion of food, contractions occur in the small intestine to promote movement of nondigestible materials into the large intestines. Fecal matter is stored in the sigmoid colon until defecation occurs.<sup>10</sup>

The process of defecation begins with a peristaltic movement that propels fecal matter into the rectum. This movement results in a desire to defecate, relaxation of the internal anal sphincter, and tightening of the abdominal wall muscles. A Valsalva maneuver forces the stool down. Defecation is either voluntarily inhibited (by keeping the external anal sphincter contracted) or facilitated (by relaxing the sphincter and contracting the abdominal muscles).<sup>10</sup> Causes of constipation include various medical conditions and medications; psychological and physiologic conditions (e.g., menopause and dehydration); and lifestyle characteristics. Constipation can stem from either primary or secondary causes. Primary constipation is often characterized by slower-than-normal movement of fecal matter through the GI tract (slow transit time) or by defecatory disorders (e.g., pelvic floor dysfunction, anal sphincter abnormalities, rectal prolapse, etc.).<sup>2,6,8</sup> Secondary causes of constipation include systemic, neurological, or psychological disorders, as well as structural abnormalities that result in obstruction ([Table 15-1](#)).<sup>1-3,5,6</sup>

Dietary fiber dissolves or swells in the intestinal fluid, which increases the bulk of fecal mass and, in turn, aids in stimulating peristalsis and eliminating stools. A diet that is low in calories, carbohydrates, or fiber may contribute to diet-related constipation. Inadequate intake of fluids may also promote constipation in patients who are dehydrated. Intestinal fluids are essential for eliminating stools and therefore must be replenished.<sup>1</sup> Gravity and good abdominal muscle tone also aid in proper bowel function. Exercise increases muscle tone and promotes bowel motility.

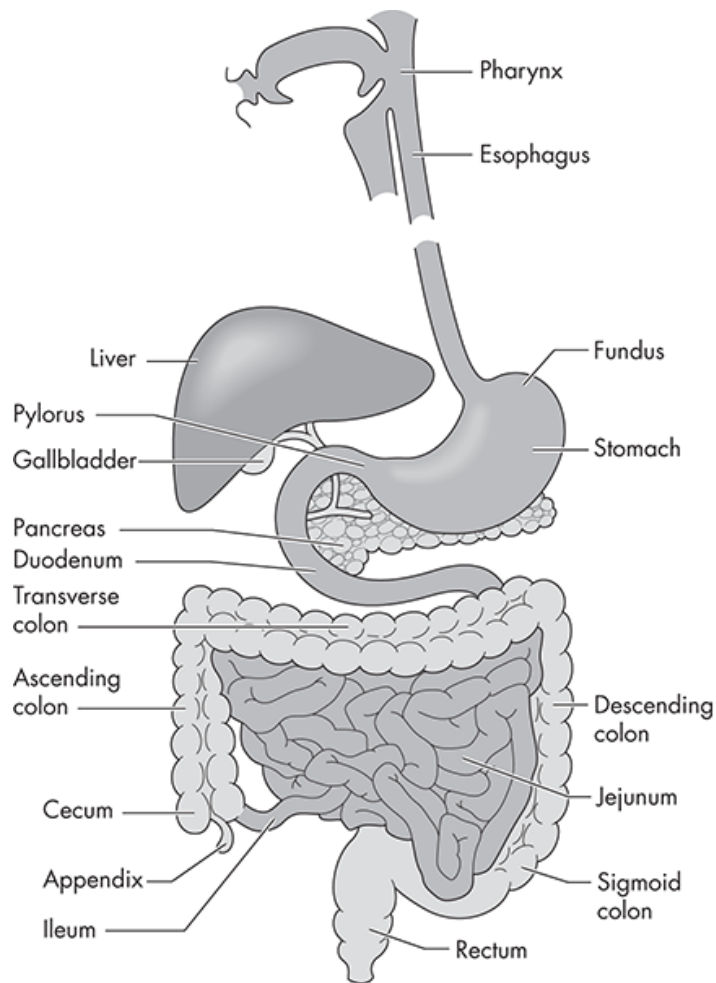

Avoiding the urge to empty the bowel can eventually lead to constipation. When the urge is ignored or suppressed, rectal muscles can lose tonicity and become less effective in eliminating stool. Nerve pathways may degenerate and stop sending the signal to defecate. In these cases, bowel retraining often is necessary to establish a pattern of regular bowel movements.

Medications can also contribute to constipation ([Table 15-2](#)).<sup>2,3,11,12</sup> Constipation is of particular concern in patients taking multiple medications and in those who also have conditions that can induce constipation. Opioid-induced constipation is a common reason for self-care laxative use.

**Clinical Presentation of Constipation**

Patients will often present with a complaint of constipation. In addition to the patient's report of decreased frequency or difficulty passing stools, other presenting symptoms may include anorexia, dull headache, lassitude, low back pain, abdominal discomfort, bloating, flatulence, and psychosocial distress.<sup>1</sup> Occasional bouts of temporary constipation usually are treatable with self-care measures. Constipation continuing over several weeks to months is considered to be chronic and may require more sustained and aggressive therapy directed by a health care provider.<sup>13,14</sup> The Rome criteria are a set of guidelines developed primarily to aid researchers in classifying chronic constipation.<sup>1</sup> These criteria are used to some extent in routine practice, but providers generally rely on patient history and clinical presentation to characterize constipation and assist in treatment decisions.

Anatomy of the digestive system.

Longstanding or untreated constipation can lead to complications. Acutely, straining to pass hard stool can lead to hemorrhoids, anal fissures with rectal bleeding, or rectal prolapse. If hard stool is packed very tightly in the rectum or intestine, fecal impaction or rectal ulcers may occur. Because defecation has been found to alter hemodynamics, straining to defecate may result in blood pressure surges or cardiac rhythm disturbances.<sup>9</sup>

### Treatment of Constipation

#### Treatment Goals

The primary goals of treatment are to (1) relieve constipation and reestablish normal bowel function, (2) establish dietary and exercise habits that aid in preventing recurrences, and (3) promote the safe and effective use of laxative products.

**TABLE 15-1 Selected Conditions Associated with Constipation**

<b>Structural</b>
Colorectal or anorectal injury, inflammation, or damage (e.g., anal fissure)
Pelvic floor disorders
Structural abnormalities (e.g., tumors, hernias, strictures) leading to bowel obstruction
<b>Systemic</b>
Electrolyte imbalances
Thyroid disorders
Diabetes mellitus
Irritable bowel syndrome
Uremia
Pituitary disorders
<b>Neurological</b>
Autonomic neuropathy
Multiple sclerosis
Parkinsonism
Cerebrovascular accidents

Dementia
<b>Psychological</b>
Depression
Eating disorders
Situational stress

Source: References 1-3, 5, and 6.

#### General Treatment Approach

Initial management of constipation involves adjusting the diet to include foods high in fiber, increasing fluid intake, and engaging in some form of exercise. Pharmacologic intervention can be used in conjunction with lifestyle modifications if more immediate relief is desired. Laxatives should be selected according to the age and health status of the patient, as well as the mechanism of action of the individual product. Food and Drug Administration (FDA) labeling for nonprescription products limits patients to short-term (<7 days) treatment duration without medical referral, which is consistent with the need for medical supervision of chronic constipation treatment.<sup>13,14</sup> Accordingly, patients should not use any nonprescription laxative product for more than 7 days unless the therapy is directed by a health care provider. If rectal bleeding occurs at any time during the use of a laxative, or if constipation persists in spite of laxative therapy, patients should stop use of the laxative and receive medical referral.<sup>1,15</sup>

Self-care is inappropriate and medical referral is also necessary in other instances, including the presence of marked or severe abdominal pain, significant abdominal distention or cramping, marked or unexplained flatulence, fever, nausea and/or vomiting with constipation, or a sudden change in bowel habits that persists for 2 weeks.<sup>1-3</sup> Abdominal pain, nausea, vomiting, or marked cramping or distention may indicate the presence of fecal impaction or bowel obstruction.<sup>15</sup> A sudden change in bowel habits that persists for 2 weeks may indicate an underlying disease process such as inflammatory bowel disease or colorectal cancer.<sup>1</sup> Similarly, patients with underlying disorders (e.g., inflammatory bowel disease) or constipation presenting with symptoms of a potential underlying disorder (e.g., dark or tarry stool) should also be referred for medical care.<sup>8</sup> A treatment algorithm (Figure 15-2) provides a systematic approach to the self-care of constipation and lists exclusions for self-treatment.<sup>1-3,8</sup>

#### TABLE 15-2 Selected Drugs That May Induce Constipation

Analgesics (including nonsteroidal anti-inflammatory drugs)
Antacids (e.g., calcium and aluminum compounds, bismuth)
Anticholinergics (e.g., benztropine, glycopyrrolate)
Anticonvulsants (e.g., carbamazepine, divalproate)
Antidepressants (specifically tricyclics such as amitriptyline)
Antihistamines (e.g., diphenhydramine, loratadine)
Antimotility (e.g., diphenoxylate, loperamide)
Antimuscarinics (e.g., oxybutynin, tolterodine)
Barium sulfate
Benzodiazepines (especially alprazolam and estazolam)
Calcium channel blockers (e.g., verapamil, diltiazem)
Calcium supplements (e.g., calcium carbonate)
Clonidine
Diuretics (e.g., hydrochlorothiazide, furosemide)
Gastrointestinal antispasmodics (e.g., dicyclomine, hyoscyamine)
Hematinics (especially iron)
Hyperlipidemia agents (e.g., cholestyramine, pravastatin, simvastatin)
Hypotensives (e.g., angiotensin-converting enzyme inhibitors, beta-blockers)
Memantine
Muscle relaxants (e.g., cyclobenzaprine, metaxalone)
Opiates (e.g., morphine, codeine)
Parasympatholytics (e.g., atropine)
Parkinsonism agents (e.g., bromocriptine)
Polystyrene sodium sulfonate
Psychotherapeutic drugs (e.g., phenothiazines, butyrophenones)
Sedative hypnotics (e.g., zolpidem, benzodiazepines, phenobarbital)
Sucralfate

Source: References 2, 3, 11, and 12.

#### Nonpharmacologic Therapy

To prevent constipation, patients should adhere to a balanced diet that incorporates recommendations from the Dietary Guidelines for Americans, 2010, including increasing fruit and vegetable intake and consuming at least half of all grains as whole grain. The American Dietetic Association recommends an adult daily dietary fiber intake of 14 grams per 1000 kcal, or 25 grams for adult women and 38 grams for adult men.<sup>16,17</sup> (See Chapter 23 for information on dietary fiber types, sources, intake, and benefits.)

Added fiber increases stool weight and also tends to normalize frequency of bowel movements to 1 movement per day and GI transit time to 2-4 days. This normalization of bowel movement frequency is important; the longer stool is retained in the bowel, the more water is absorbed out of the bowel and into the intestinal cells, leading to hard stools and difficulty in passing stool.<sup>17</sup> Patients complaining of constipation should gradually increase their intake of insoluble fiber (e.g., whole grains, wheat bran, and vegetables), which is associated with laxation.<sup>8,17</sup> Patients should also limit intake of foods with little or no fiber (e.g., cheese, meat, and processed foods) to promote normal bowel function.

If dietary modifications are not effective, patients may choose to supplement their diet with a commercially available fiber supplement. Many newer flavorless and texture-free fiber supplements (e.g., inulin) are classified as dietary supplements (Table 15-3).<sup>8</sup> Others (e.g., psyllium and methylcellulose) are bulk-forming laxatives approved as FDA drug products. The pharmacologic effects of FDA-approved fiber supplements have been studied more extensively than dietary supplement products (see Pharmacologic Therapy). The onset of laxation from a high-fiber diet or fiber supplement usually is not immediate. Individual benefits will vary and may take 3-5 days or longer. Patients should be encouraged to find the fiber supplement that provides the best balance of tolerability, desirable dosage form, effectiveness at promoting laxation, and cost (see Chapter 23 and [www.nationalfiberCouncil.org](http://www.nationalfiberCouncil.org) for more information). Significantly increasing dietary fiber from any source may lead to erratic bowel habits, flatulence, and abdominal discomfort during the first few weeks. Some fiber-supplemented foods contain approximately 10 grams of fiber per serving and can cause significant side effects if added to the diet too quickly.

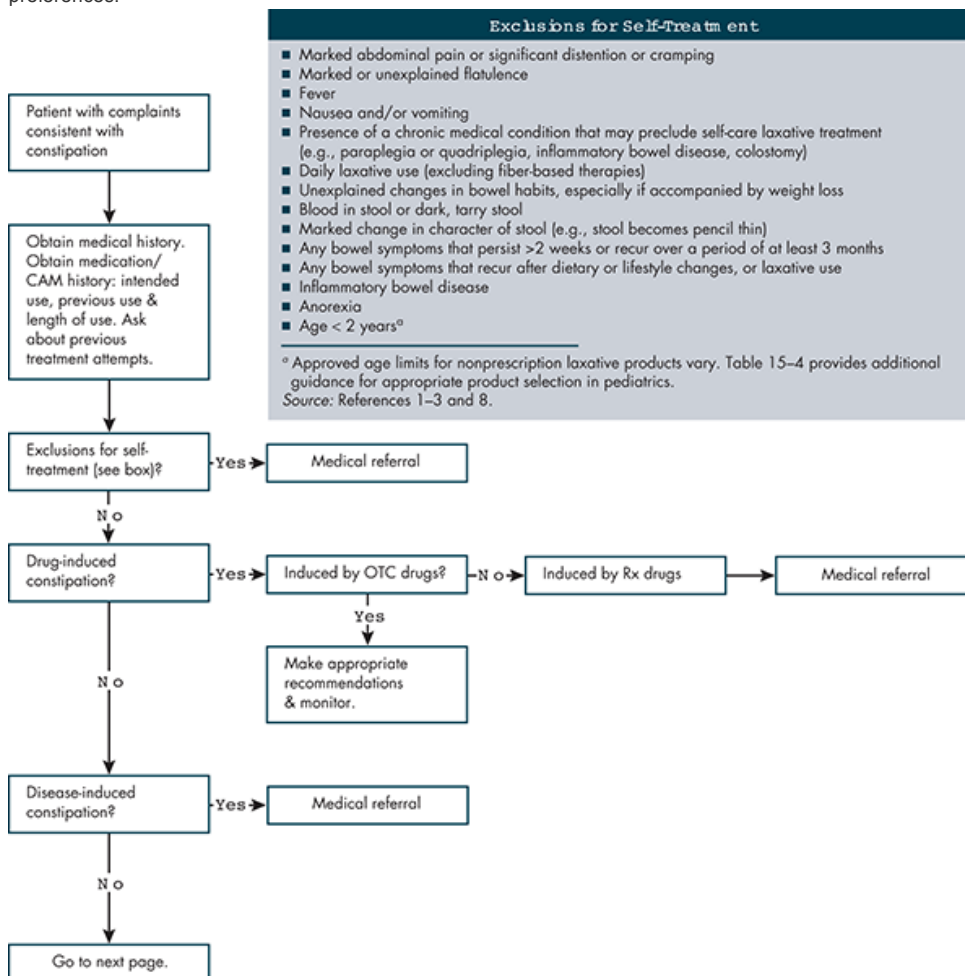

Recommend that patients gradually increase fiber intake over a period of 1-2 weeks to improve tolerance.<sup>1,8,17</sup> Advise patients to increase their fluid intake when increasing dietary fiber. In general, 2 liters of fluid per day is recommended. Fluid requirements increase for pregnant and lactating women; an additional 300 mL and 750-1000 mL of fluid, respectively, should be added to daily requirements.<sup>17</sup>

Behavior modifications (or "bowel training") can also be beneficial for promoting regular bowel movements. Promptly heeding the urge to pass the stool and allowing sufficient time for toileting are important. Gastrocolic reflexes are greatest first thing in the morning and 30 minutes after a meal, so attempting a bowel movement at these times can help promote defecation consistent with the body's normal physiologic response.<sup>1,18</sup>

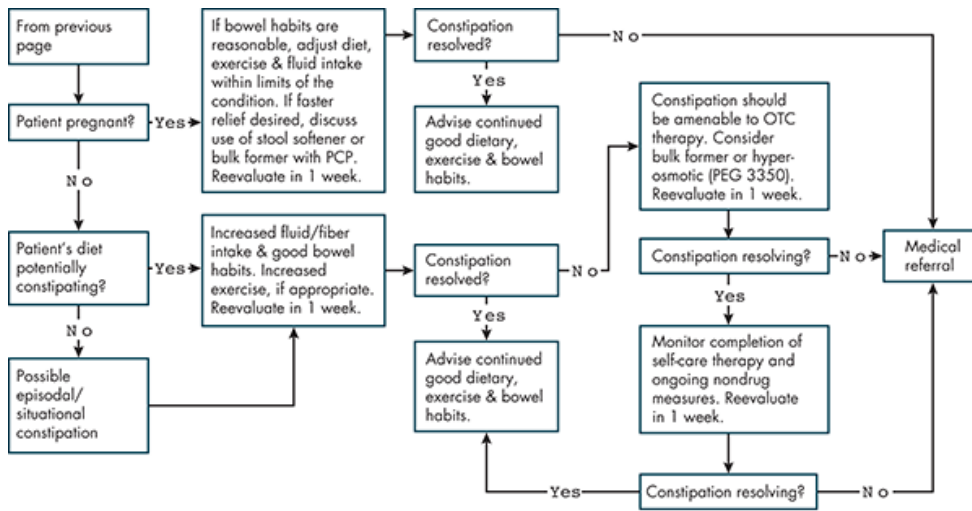

Although there is no consistent evidence that exercise relieves constipation, low levels of physical activity have been associated with an increased risk of constipation.<sup>1,18</sup> Encourage regular physical activity consistent with a healthy lifestyle to decrease the risk of constipation.

### Pharmacologic Therapy

The ideal laxative (1) would be nonirritating and nontoxic, (2) would act only on the descending and sigmoid colons, and (3) would produce a normally formed stool within a few hours, after which time the laxative's action would cease and normal bowel activity would resume. Because no currently available laxative precisely meets these criteria, proper selection of a laxative depends on the etiology of the constipation and individual patient factors and preferences.

Self-care of constipation. Key: CAM = Complementary and alternative medicine; OTC = over-the-counter; PCP = primary care provider; PEG = polyethylene glycol; Rx = prescription.

Agents used to treat constipation are classified by mechanism of action and include bulk-forming, hyperosmotic, emollient, lubricant, saline, and stimulant agents (Table 15-4).

**Bulk-Forming Agents**

Products classified as bulk-forming laxatives include those containing methylcellulose, polycarbophil, and psyllium. Bulk-forming products are the recommended choice for the treatment of most instances of constipation because they most closely approximate the physiologic mechanism in promoting evacuation.<sup>1,5,8</sup> These agents dissolve or swell in the intestinal fluid of the small and large intestines, forming emollient gels that stimulate peristalsis and facilitate passage of the intestinal contents. Available dosage forms include tablets or capsules; powders to be mixed with water or other liquids; and fiber chews, wafers, or gummies.

Bulk-forming agents are not absorbed systemically; the usual onset of action is from 12 to 24 hours, but onset may be delayed as long as 72 hours. They are indicated as short-term therapy to relieve constipation and may be useful for (1) patients on low-fiber diets; (2) postpartum women; (3) older adults; and (4) patients with colostomies, irritable bowel syndrome, or diverticular disease. They are also indicated prophylactically in patients who should refrain from straining during a bowel movement. Dosages vary according to the type of product (Table 15-4). Exceeding the recommended doses for a bulk-forming agent could lead to increased flatulence or obstruction if appropriate fluid intake is not maintained.

**TABLE 15-3 Types of Fiber Supplements**

Type of Fiber	Examples of Common Brands
<b>Products Classified as Bulk-Forming Laxatives<sup>a</sup></b>	
Methylcellulose	Citrucel
Calcium polycarbophil	FiberCon
Psyllium	Metamucil, Konsyl
<b>Products Classified as Dietary Supplements</b>	
Inulin	FiberChoice, Metamucil Clear & Natural
Partially hydrolyzed guar gum	Sunfiber
Powdered cellulose	Unifiber
Wheat dextrin	Benefiber

<sup>a</sup> Products classified as bulk-forming laxatives are FDA-labeled to treat constipation.

Source: Adapted with permission from reference 8.

When taken as directed, bulk-forming agents have few systemic side effects. The most common adverse effects include abdominal cramping and flatulence. If not taken with adequate fluid, bulk-forming laxatives may swell in the throat or esophagus and cause choking. Bulk-forming products should be avoided in patients who have swallowing difficulties or esophageal strictures; additionally, bulk-forming agents may be inappropriate for patients who must restrict fluid intake (e.g., those with heart failure). Obstruction is a particular risk for palliative care patients and those patients suffering from opiate-induced constipation who have inadequate fluid intake.<sup>19</sup> Patients experiencing chest pain, vomiting, difficulty swallowing, or difficulty breathing after use should seek immediate medical attention. Granular psyllium products have been taken off the market because of reports of esophageal obstruction.<sup>20</sup> Acute bronchospasm has been associated with inhalation of dry hydrophilic mucilloid, as well as hypersensitivity reactions to psyllium characterized by anaphylaxis.<sup>21</sup> Individuals who are sensitive to inhaled or ingested psyllium should avoid these products. Bulk-forming laxatives are not systemically absorbed, but they may interfere with the absorption of oral medications because of physical binding in the GI tract or other mechanisms. Additionally, calcium polycarbophil may decrease the absorption of oral tetracyclines and quinolones secondary to calcium chelation. Patients should separate doses of bulk-forming laxatives from other medications by at least 2 hours to avoid potential drug interactions.

**TABLE 15-4 Dosage Guidelines for Nonprescription Laxative Products<sup>a</sup>**

Agent	Dosage Form/Strength	Adults/Children ≥ 12 Years	Children 6 to < 12 Years <sup>b</sup>	Children 2 to < 6 Years <sup>b,c</sup>

<b>Bulk-Forming Agents</b>							
Methylcellulose		Caplet: 500 mg	2 caplets up to 6 times daily	1 caplet up to 6 times daily	Not recommended for children < 6 years, except under advice of a PCP		
Powder: 2 grams per heaping tablespoon	Starting dose: 1 rounded tablespoon; increase as needed, 1 rounded tablespoon at a time, up to 3 times daily	Starting dose: 2 level teaspoons; increase as needed, 2 level teaspoons at a time, up to 3 times daily	Not recommended for children < 6 years except under advice of a PCP				
Calcium polycarbophil		Caplet: 625 mg	2 caplets 1-4 times daily	1 caplet 1-4 times daily	Not recommended for children < 6 years, except under advice of a PCP		
Psyllium (plantago seeds, ispaghula)		Capsule: psyllium husk, 0.52 gram	5 capsules with 8 ounces of liquid (swallow 1 capsule at a time), up to 3 times daily	Not recommended for children < 12 years except under advice of a PCP		Not recommended for children < 6 years except under advice of a PCP	
Powder: 3.4 grams psyllium husk per scoop or per packet of "fiber singles" product	1 rounded tablespoon in 8 ounces of liquid, up to 3 times daily	1/2 of adult dose in 8 ounces of liquid, up to 3 times daily	Not recommended for children < 6 years except under advice of a PCP				
<b>Hyperosmotic Agents</b>							
Polyethylene glycol 3350		Powder: 17 grams per capful	17 grams in 4-8 ounces of beverage once daily in adults and children ≥ 17 years	Not recommended for children < 17 years, except under advice of a PCP			
Glycerin				Rectal solid suppository: 2 grams	1 suppository, or as directed by a PCP	1 suppository, or as directed by a PCP	Not recommended for children < 6 years except under advice of a PCP
Rectal solid suppository: 1 gram (pediatric formulation)	—	—	1 suppository, or as directed by a PCP				
Rectal liquid suppository: 5.6 grams glycerin per 5.5 mL	1 suppository, or as directed by a PCP	1 suppository, or as directed by a PCP	Not recommended for children < 6 years, except under advice of a PCP				
Rectal liquid suppository: 2.8 grams glycerin per 2.7 mL (pediatric formulation)	—	—	1 suppository, or as directed by a PCP				
<b>Emollient Agents</b>							
Docusate sodium			Capsules: 50 mg and 100 mg	50-300 mg daily in single or divided	50-150 mg daily in single or divided	50-150 mg daily in single or divided	

				doses	doses	doses	
Syrup: 60 mg per 15 mL	1-6 tablespoons daily, or as directed by a PCP, in single or divided doses (doses must be given in 6-8 ounces of milk or juice to prevent throat irritation)	1-2 1/2 tablespoons daily, or as directed by a PCP, in single or divided doses (doses must be given in 6-8 ounces of milk or juice to prevent throat irritation)	1-2 1/2 tablespoons daily, or as directed by a PCP, in single or divided doses (doses must be given in 6-8 ounces of milk or juice to prevent throat irritation)				
Syrup: 50 mg/15 mL (pediatric formulation)	—	1-3 tablespoons daily, in single or divided doses (doses must be given in 6-8 ounces of milk or juice to prevent throat irritation)	1-3 tablespoons daily, in single or divided doses (doses must be given in 6-8 ounces of milk or juice to prevent throat irritation)				
Docusate calcium	Capsule: 240 mg	1 capsule daily for several days, or until bowel movements are normal	Not recommended for children < 12 years, except under advice of a PCP	Not recommended for children < 6 years, except under advice of a PCP			
<b>Lubricant Agent</b>							
Mineral oil <sup>d</sup> Oral liquid			1-3 tablespoons (15-45 mL); maximum 3 tablespoons (45 mL) in 24 hours	1-3 teaspoons (5-15 mL); maximum 3 teaspoons (15 mL) in 24 hours	Not recommended for children < 6 years except under advice of a PCP		
Oral liquid emulsion: 2.5 mL mineral oil/5 mL	6-15 teaspoons (30-75 mL) per day, or as directed by a PCP	2-5 teaspoons (10-25 mL) per day, or as directed by a PCP	Not recommended for children < 6 years except under advice of a PCP				
Rectal liquid enema: 118 mL	1 bottle as directed	1/2 bottle as directed	1/2 bottle as directed				
<b>Saline Laxative Agents</b>							
Magnesium citrate	Liquid: 10 fluid ounces; 300 mL	1/2-1 bottle (150-300 mL)	1/3-1/2 bottle (100-150 mL)	Not recommended for children < 6 years except under advice of a PCP			
Magnesium hydroxide				Liquid: 400 mg/5 mL	2-4 tablespoons daily as single or divided doses	1-2 tablespoons daily as single or divided doses	Not recommended for children < 6 years except under advice of a PCP
Concentrated liquid: 2400 mg/15 mL	1-2 tablespoons daily as single or divided doses	1/2-1 tablespoon daily as single or divided doses	Not recommended for children < 6 years except under advice of a PCP				
Chewable tablet: 311 mg per tablet	8 tablets once in a 24-hour period, preferably at	4 tablets once in a 24-hour period, preferably at	Children 3-5 years: chew 2 tablets once in a 24-hour				

	bedtime, in divided doses or as directed by a PCP	bedtime, in divided doses or as directed by a PCP	period, preferably at bedtime, in divided doses or as directed by a PCP Not recommended for children < 3 years except under advice of a PCP					
Chewable tablet: 400 mg per tablet (pediatric formulation)	—	3-6 tablets daily in single or divided doses	1-3 tablets daily in single or divided doses					
Monobasic sodium phosphate/dibasic sodium phosphate			Rectal liquid enema: 118 mL	1 bottle, as directed	Not recommended for children < 12 years, except under advice of a PCP	Not recommended for children < 6 years, except under advice of a PCP		
Rectal liquid enema: 197 mL	1 bottle, as directed	Not recommended for children < 12 years, except under advice of a PCP	Not recommended for children < 6 years, except under advice of a PCP					
Rectal liquid enema: 59 mL (pediatric formulation)	—	Children 5-11 years: 1 bottle or as directed by a PCP	Children 2-5 years: 1/2 bottle					
Magnesium sulfate (Epsom salt) <sup>d</sup>	Solid: magnesium sulfate USP	2-6 level teaspoons (10-30 grams) daily <sup>d</sup>	1-2 level teaspoons (5-10 grams) daily <sup>d</sup>	Not recommended for children < 6 years except under advice of a PCP				
<b>Stimulant Agents</b>								
Senna					Tablets: 8.6 mg sennosides	Starting dose: 2 tablets once daily Maximum dose: 4 tablets twice daily	Starting dose: 1 tablet once daily Maximum dose: 2 tablets twice daily	Starting dose: 1/2 tablet once daily Maximum dose: 1 tablet twice daily
Tablets or chocolate pieces: 15 mg sennosides	2 tablets or chocolate pieces 1-2 times daily	1 tablet or chocolate piece 1-2 times daily	Not recommended for children < 6 years, except under advice of a PCP					
Tablets: 17.2 mg sennosides	Starting dose: 1 tablet once daily Maximum dose: 2 tablets twice daily	Starting dose: 1/2 tablet once daily Maximum dose: 1 tablet twice daily	Not recommended for children < 6 years, except under advice of a PCP					
Pills: 25 mg sennosides	2 pills 1-2 times daily	1 pill 1-2 times daily	Not recommended for children < 6 years, except under advice of a PCP					

Liquid <sup>e</sup> : senna concentrate 33.3 mg senna pod concentrate/mL (pediatric formulation [i.e., Fletcher's Laxative for Kids])	—	Age 6-15 years: 2-3 teaspoons 1-2 times daily	1-2 teaspoons 1-2 times daily		
Liquid <sup>e</sup> : sennosides 1.8 mg sennosides/mL	2-3 teaspoons once a day	1-1 1/2 teaspoons once a day	1/2-3/4 teaspoon once a day		
Bisacodyl		Tablets: 5 mg	1-3 tablets (usually 2) once daily	1 tablet daily	Not recommended for children < 6 years except under advice of a PCP
Rectal solid suppository: 10 mg	1 suppository in a single daily dose	1/2 suppository in a single daily dose	Not recommended for children < 6 years except under advice of a PCP		
Castor oil <sup>d</sup>	Liquid	1 to a maximum of 4 tablespoons (15-60 mL) in a single daily dose <sup>d</sup>	1 to a maximum of 3 teaspoons (5-15 mL) in a single daily dose <sup>d</sup>		Not recommended for children < 6 years except under advice of a PCP

Key: FDA = Food and Drug Administration; OTC = over-the-counter; PCP = primary care provider.

<sup>a</sup> All doses are based on FDA-labeled instructions and are for oral products, unless indicated otherwise.

<sup>b</sup> All doses for children are listed as those for ages 2 to < 6 years or ages 6 to < 12 years, unless otherwise indicated in FDA-labeled dosing instructions. In these cases, FDA-labeled age ranges are provided within the table.

<sup>c</sup> No recommended dosages exist for children < 2 years of age, except under the advice and supervision of a PCP.

<sup>d</sup> Although magnesium sulfate (Epsom salt) and castor oil are approved as nonprescription laxatives, they are not recommended because safer, better tolerated, and well-studied alternatives are available. Self-care use of mineral oil is also discouraged in most cases. See Pharmacologic Therapy for specific recommendations on appropriate use of each agent.

<sup>e</sup> Liquid senna products vary in product concentration and dosing, depending on the form of senna. Take care to ensure that patients are following FDA-labeled dosing instructions with use of these products, especially in pediatric patients.

Because of the danger of fecal impaction or intestinal obstruction, individuals with intestinal ulcerations, stenosis, or disabling adhesions should not take bulk-forming products. Diarrhea, abdominal discomfort, flatulence, and excessive loss of fluid can also occur.

The maximum calcium content of calcium polycarbophil is approximately 150 mg (7.6 mEq) per tablet. Certain patients (e.g., older adults; individuals with malignancy, renal disease, or AIDS) may be at risk for hypercalcemia with recommended doses of calcium polycarbophil.

The sugar content of bulk-forming agents should be evaluated before use by patients with diabetes or those with restricted caloric intake. Sugar-free agents that contain aspartame should be avoided by patients with phenylketonuria.

#### Hyperosmotic Agents

Hyperosmotic agents include polyethylene glycol 3350 (PEG 3350) and glycerin (Table 15-4). These products contain large, poorly absorbed ions or molecules that draw water into the colon or rectum through osmosis to stimulate a bowel movement.<sup>22</sup> Other commonly used agents in this class are prescription-only products, including lactulose, sorbitol, and PEG solutions with electrolytes (e.g., Colyte and GoLYTELY). PEG 3350 is available for self-care use in individuals ages 17 years or older; it comes in a powder for oral administration and is usually taken as 17 grams of powder (approximately 1 capful or 1 packet) per day mixed into 4-8 ounces of water. After oral administration, the PEG 3350 dose remains almost entirely within the GI tract and is not subject to degradation by intestinal enzymes or bacterial metabolism. The very small amount that is systemically absorbed (0.2%) is rapidly excreted in the urine. PEG 3350 usually produces a bowel movement in 12-72 hours, but onset may take as long as 96 hours in some patients.

PEG 3350 is safe and effective for the short-term treatment of occasional constipation, with few side effects.<sup>23</sup> PEG 3350 is generally well-tolerated because very little drug is absorbed systemically. Adverse effects may include bloating, abdominal discomfort, cramping, and flatulence. Higher doses (e.g., 34 g/day) might lead to diarrhea and excessive stool frequency. FDA-approved labeling indicates that patients who have renal disease or irritable bowel syndrome should be cautioned to consult with their primary care provider before using PEG 3350. No clinically significant drug-drug interactions have been reported with PEG 3350.

Glycerin has been available for many years in suppository form for lower bowel evacuation (Table 15-4). It works primarily in the colon and is poorly absorbed after rectal administration. Glycerin suppositories usually produce a bowel movement within 15-30 minutes of administration. They are considered to be safe for occasional use in all approved age groups but may cause rectal irritation with overdosage. Use of liquid glycerin as an enema is not recommended because of rectal irritation.

Other than potential rectal irritation, adverse reactions with glycerin suppositories are minimal. Interactions between glycerin and other drugs are not clinically important. Use of glycerin may be inappropriate in patients who have an existing condition that involves rectal irritation. Chronic use or overuse may lead to reduced serum potassium concentrations.

#### Emollient Agents

Emollients (stool softeners) are anionic surfactants that act in the small and large intestines to increase the wetting efficiency of intestinal fluid, facilitating a mixture of aqueous and fatty substances to soften the fecal mass (Table 15-4). They are used primarily to prevent straining and painful defecation with anorectal disorders or in patients who should avoid straining (e.g., those with severe hypertension or cardiovascular disease, recent abdominal or rectal surgery, or recent myocardial infarction; or women who are immediately postpartum). Although emollients can be used to treat occasional constipation, they are more often used in combination with a stimulant (e.g., senna or bisacodyl) as a long-term treatment for opioid-induced constipation.<sup>19,24</sup> (See the box A Word about Opioid-Induced Constipation.)

Docusate, available as a sodium and calcium salt, has an onset of action of 12-72 hours. Effectiveness is usually achieved within 48 hours, but some patients may require as long as 3-5 days. Docusate sodium is supplied in capsule or syrup form in multiple strengths; docusate calcium is available as a 240 mg capsule. Although no therapeutic differences exist between these salt forms, docusate sodium's availability in multiple strengths and dosage forms results in more frequent use.

Docusate is generally well tolerated but can potentially cause diarrhea and mild abdominal cramping. Emollients can increase systemic absorption of mineral oil and should not be used in combination with products containing mineral oil. Doses above those recommended by the manufacturer may result in weakness, sweating, muscle cramps, and an irregular heartbeat in some patients. These agents are not believed to be appreciably absorbed from the GI tract and do not hamper absorption of nutrients from the intestinal tract.

#### Lubricant Agent

Mineral oil (liquid petrolatum) is the only nonprescription lubricant. Mineral oil acts in the colon to soften fecal contents by coating the stool and preventing colonic absorption of fecal water. It is available in liquid forms for oral or rectal administration (Table 15-4). Mineral oil's onset of action is about 6-8 hours after oral administration and 5-15 minutes after rectal administration.

Mineral oil can help maintain a soft stool, and its uses are similar to those of emollient laxatives for preventing straining or painful defecation. However, because of safety concerns with mineral oil, docusate forms are preferred if a stool softener is needed.<sup>8</sup> Although patients may use mineral oil for an occasional bout of constipation, its use in self-care is strongly discouraged because of the availability of safer agents.

The most significant acute safety concern with mineral oil is lipid pneumonia resulting from aspiration into the lungs after an oral dose. Patients most at risk for aspiration include young children, older patients, debilitated or bedridden patients, and those with swallowing difficulties or dysphagia. Mineral oil should not be used in these patients or given to any patients before they lie down. FDA-approved labeling for mineral oil products includes a warning against its use in patients younger than 6 years, pregnant women, bedridden or older adults, and those with difficulty swallowing.

#### A Word About Opioid-Induced Constipation

Opioid use is common in the treatment of non-cancer and cancer pain. Constipation is experienced by approximately 40% of patients and is the most common adverse effect with opioid use. Opioid-induced constipation may prevent patients from receiving appropriate pain-relieving dosages or may cause discontinuation of therapy despite the need for pain relief. Opioids cause constipation by binding to bowel and central nervous system receptors to decrease GI motility and intestinal secretions, leading to longer retention time of fecal matter in the intestines and drying of the stool. Unlike other opioid-induced side effects, patients generally do not develop tolerance to constipation over time. Constipating effects of opioids are dependent on the opioid dose and duration of use.<sup>19,24</sup>

Some forms of opioids are more likely to cause constipation. Oral opioids generally are more constipating than parenteral agents. Transdermal fentanyl patches have fewer constipating effects than oral opioids and may be an option for outpatients requiring chronic opioid therapy.<sup>11,24</sup>

Patients on chronic opioids will require a long-term laxative regimen to prevent and/or treat constipation. Stimulant laxatives (e.g., senna or bisacodyl, with or without docusate) are most commonly recommended.<sup>24</sup> The stimulant helps to propel the stool through the colon, whereas the emollient (docusate) increases wetting of the stool and softens the fecal mass. Typically, a stool softener alone is not effective. Polyethylene glycol preparations or other osmotic agents may also be used for prevention and treatment of opioid-induced constipation. Saline laxatives or rectal preparations may be needed intermittently for acute evacuation. Bulk-forming laxatives are unlikely to be adequately effective if used alone and may not be tolerated because of fluid restrictions or immobility in some chronic opioid patients (e.g., palliative care).<sup>19,24</sup>

Identify patients at risk for opioid-induced constipation to help prevent problems, including patients with cancer- and non-cancer-related pain. Educate patients on the role of nondrug measures to help prevent constipation (e.g., increasing fluid intake, fiber intake, and physical activity as tolerated). For patients on chronic opioid therapy, emphasize the importance of bowel regimen adherence, and explain the need for long-term use of laxatives with chronic opioids. If appropriate, suggest alternative opioids (e.g., transdermal fentanyl) that may be less constipating than oral agents. Inform patients on short-term opioid therapy about constipating effects of opioids, and help individuals take steps to prevent constipation. This is especially true in patients who have other risk factors for constipation, such as those taking opioids immediately after abdominal surgery or childbirth.

Patients can also experience adverse effects related to high doses or long-term use. Taking larger than recommended doses can cause leakage of oil through the anal sphincter, resulting in anal pruritus (pruritus ani), cryptitis, or other perianal conditions. Patients can avoid this by reducing or dividing the dose, or by using a stable emulsion of mineral oil. FDA-approved labeling for mineral oil products directs patients to stop its use and consult their primary care provider if leakage of oil occurs. With repeated and prolonged use of mineral oil, the droplets may reach the mesenteric lymph nodes and may also be present in the intestinal mucosa, liver, and spleen, where they elicit a typical foreign-body reaction.

Mineral oil may impair the absorption of the fat-soluble vitamins A, D, E, and K, as well as many oral medications (including oral contraceptives and digitalis glycosides). Mineral oil's effects on vitamin K may increase blood-thinning properties of some oral anticoagulants. To minimize any interactions, patients should not take mineral oil with food. Concomitant use of mineral oil with docusate emollients should be avoided because of potential increased absorption of mineral oil.

#### Saline Laxative Agents

Saline laxative agents include magnesium citrate, magnesium hydroxide, dibasic sodium phosphate, monobasic sodium phosphate, and magnesium sulfate. They are available in liquid or solid form for oral administration and in liquid form for rectal administration (Table 15-4). Saline laxatives act primarily by osmosis in the small and large intestines (oral products) or in the colon (rectal forms). After administration, ions are retained in the intestinal wall and draw water in by osmosis, thereby increasing intraluminal pressure and intestinal motility. Saline laxatives are used for occasional relief of constipation or for acute bowel evacuation that is required before a procedure (e.g., colonoscopy preparation).

Oral magnesium hydroxide is appropriate for treatment of occasional constipation in otherwise healthy patients. When administered at standard doses, magnesium hydroxide produces a bowel movement within 30 minutes to 6 hours of administration.<sup>8</sup>

Other saline agents (magnesium citrate and sodium phosphate preparations) are more commonly used orally or rectally for acute catharsis (e.g., prior to a colonoscopy; only the prescription version of the oral formulation should be used for this indication). When used for these purposes, the onset of action is generally 30 minutes to 3 hours for oral doses and 2-15 minutes for rectal doses. Magnesium sulfate (Epsom salt) is labeled for nonprescription use, but it is not recommended because safer and better-studied laxatives are available.

Adverse effects related to saline laxatives most often include abdominal cramping, nausea, vomiting, or dehydration. Patients who cannot tolerate fluid loss should not use saline laxatives. In patients who are not fluid restricted, oral doses of magnesium salts should be followed by at least 1 full glass of water to prevent dehydration. When used for treatment of occasional constipation, doses should be administered at bedtime, if possible.

Saline laxatives can cause serious electrolyte imbalances if used long term or at higher-than-recommended doses. As much as 20% of the administered magnesium ion may be absorbed from magnesium salts, potentially leading to hypermagnesemia.<sup>8</sup> FDA-approved labeling for these products recommends against their use in patients on sodium-, phosphate-, or magnesium-restricted diets. Although some health care providers continue to recommend regular use of oral magnesium hydroxide to promote regularity, alternative treatment options with more favorable adverse effect profiles exist. Toxicity risk is increased in newborns, older adults, and patients with renal impairment; therefore, magnesium-containing laxatives should be avoided in those populations. Symptoms of magnesium toxicity include hypotension, muscle weakness, and fatigue.

Products containing sodium phosphate can cause hyperphosphatemia, hypocalcemia, and hypernatremia; therefore, they should be used cautiously in patients with renal impairment, in cardiac patients on sodium-restricted diets, and in those taking medications that may affect serum electrolyte levels (e.g., diuretics).<sup>8</sup> Sodium phosphate products are contraindicated in patients with congestive heart failure. Additionally, rectally administered sodium phosphate should be avoided in patients with megacolon, gastrointestinal obstruction, imperforate anus, or colostomy.

Acute phosphate nephropathy leading to renal function impairment has also been reported with the use of oral sodium phosphate products for bowel cleansing prior to colonoscopy or other procedures. A 2008 FDA warning restricted nonprescription oral sodium phosphate solutions to treatment of constipation only (i.e., not for use as bowel preparations) and required prescription products to carry a boxed warning and MedGuide. In 2014, FDA noted continued reports of acute phosphate nephropathy occurring with these agents and provided further guidance to ensure their safe use for bowel preparation, including the development of a risk evaluation and mitigation strategy (REMS) for prescription products. Although nonprescription oral sodium phosphate products are indicated only for treatment of constipation, FDA also announced at that time that additional labeling changes would be made for these agents to support their appropriate and safe use as self-care laxatives.<sup>25</sup> Of note, at the time of this writing (July 2014), no nonprescription oral sodium phosphate solution products were available.

Saline laxatives can interact with oral anticoagulants, digitalis glycosides, and some phenothiazines (especially chlorpromazine). Magnesium-containing laxatives may interfere with the absorption of oral tetracycline products. If used concurrently with a magnesium salt, sodium polystyrene sulfonate may bind with magnesium and lead to systemic alkalosis.

### Stimulant Agents

Stimulant laxatives are classified according to their chemical structure and pharmacologic activity as anthraquinones (e.g., senna) or diphenylmethanes (e.g., bisacodyl). FDA has deemed formerly available products containing cascara sagrada, casanthranol, and phenolphthalein as “not safe and effective.”<sup>26,27</sup> Because some of these unapproved agents are marketed as dietary supplements, they may be available in some pharmacies and health food stores; however, unapproved supplement products should not be recommended (see Complementary Therapies). Although rhubarb and aloe were not included in FDA rulings, providers should not recommend the use of those very irritating substances.

Stimulant laxatives (Table 15-4) work primarily in the colon to increase intestinal motility either by local irritation of the mucosa or by a more selective action on the intramural nerve plexus of intestinal smooth muscle. They also increase secretion of water and electrolytes in the intestine.<sup>5</sup>

The onset of senna and bisacodyl is usually 6–10 hours after oral use but may require up to 24 hours. Bisacodyl suppositories usually take effect 15–60 minutes after administration.

Bisacodyl, administered orally or rectally, is also a component of bowel preparation regimens before colonoscopy or other bowel procedures. Stimulant laxatives are often used in combination with docusate to prevent or treat constipation in patients taking chronic opioids.<sup>19,24</sup> (See the box A Word about Opioid-Induced Constipation.) Overdoses of stimulants may lead to sudden vomiting, nausea, diarrhea, or severe abdominal cramping and require prompt medical attention.

Major hazards of stimulant laxative use are severe cramping, electrolyte and fluid deficiencies, enteric loss of protein, malabsorption caused by excessive hypermotility and catharsis, and hypokalemia. All stimulants may produce cramping, colic, increased mucus secretion, and (in some people) excessive evacuation of fluid at excess doses. Stimulants can be effective but should be recommended cautiously. Nevertheless, these laxatives are frequently used for constipation by those who self-medicate or by patients who perceive a benefit to frequent or thorough “cleansing” of the colon. Consequently, stimulant laxatives may be subject to overuse.<sup>28-31</sup> (See the box A Word about Laxative Overuse.)

Prolonged use of senna can also cause a harmless, reversible melanotic pigmentation of the colonic mucosa (melanosis coli), which may be seen on sigmoidoscopy, colonoscopy, or rectal biopsy. Senna may color urine pink to red, red to violet, or red to brown, and its presence may affect interpretation of the phenolsulfonphthalein test.

Enteric-coated bisacodyl tablets prevent irritation of the gastric mucosa. These should not be broken, crushed, chewed, or given with agents that increase gastric pH. The administration of bisacodyl tablets within 1 hour of antacids, histamine<sub>2</sub>-receptor antagonists, proton pump inhibitors, or milk results in rapid erosion of the bisacodyl’s enteric coating, which may lead to gastric or duodenal irritation.

Although castor oil historically has been viewed as a stimulant laxative, its exact mechanism is unknown.<sup>31</sup> Castor oil acts quickly and has significant laxative effects with accompanying abdominal cramping. Prolonged use of castor oil may result in excessive loss of fluid, electrolytes, and nutrients. Its use in the self-care setting is discouraged because safer and better-tolerated alternatives are available.<sup>8,19</sup>

### Combination Products

Combination laxative products are also available (Table 15-5). Companies attempt to take advantage of multiple mechanisms of action to create a product that better meets the criteria for an ideal laxative. For example, several combination products contain both a stimulant and an emollient (e.g., senna with docusate sodium). Emollients do not stimulate bowel movements when used alone, but they support bowel movements when combined with stimulant laxatives.

In cases of fecal impaction, a solution of docusate is often added to the enema fluid. Some products incorporate senna with psyllium. The desired effect is for the senna to act quickly, whereas the bulk-forming agent aids in producing easier stools after the initial movement. Other available combination oral products include psyllium, bisacodyl, docusate, or another agent as the principal ingredient, with glycerin as an adjunctive agent; glycerin’s contributing effect likely is insignificant to the overall laxative action of these products.

Patients should be counseled that combining laxatives can have the potential for greater adverse effects because a common ingredient in most combination products is a stimulant. If a stimulant and a stool softener are combined, the potential for adversity depends largely on the stimulant. However, if a stimulant and a saline are combined, the potential for adverse effects is enhanced, given that both agents have significant effects on the intestine.

#### A Word About Laxative Overuse

Health care providers should stay alert for patients who may be at risk for laxative overuse. Some patients perceive that a daily bowel movement is normal and routinely take stimulant or other laxatives to achieve this bowel pattern. Older adults may perceive that natural changes in bowel habits as a result of declining physical mobility or dietary changes are actually “constipation.” Other patients are looking to “cleanse” their system of toxins through the use of colon-cleansing regimens marketed for this purpose; such regimens often contain high doses of laxatives.<sup>28</sup> Individuals may also have comorbid conditions that contribute to laxative overuse. For example, patients with anorexia or bulimia nervosa may abuse laxatives to “purge” unwanted food, or as a form of self-harm.<sup>29</sup> Factors that contribute to laxative overuse include older age, misconceptions about normal bowel movement frequency, fear of constipation, and widespread availability of laxatives.<sup>30</sup>

Excessive use of laxatives can acutely cause diarrhea and vomiting, fluid and electrolyte losses (especially hypokalemia), and dehydration. Concerns about long-term consequences of chronic stimulant laxative use have been disproved in the literature. Although previous cases of potential adverse effects of chronic use of stimulant laxatives have been reported, well-designed recent clinical trials do not support an increased risk of colonic muscle or nerve damage or colorectal cancer with the use of these laxatives.<sup>30,31</sup>

Acute adverse effects are concerning in patients who take large doses of laxatives for purging, colon-cleansing, or detoxification effects. Colon-cleansing

preparations are available in many pharmacies and are promoted for a wide range of potential benefits, including removing toxins, losing weight, or preventing disease. These products often contain a combination of stimulant laxatives, probiotics, herbals, or other ingredients. No literature supports a medical benefit of colon cleansing for "detoxification." In fact, acute overuse of laxatives or colon-cleansing regimens can cause serious dehydration, electrolyte imbalances, or other adverse effects and should be avoided. Also inform patients that enemas, colonic irrigation, and "colon hydrotherapy" carry additional risks (e.g., bowel perforation or infection) and are not recommended.<sup>28</sup> If laxative overuse for purging related to anorexia or bulimia is suspected, medical referral for appropriate care is needed.

Educate patients whose misperceptions about the need for a daily bowel movement contribute to unnecessary laxative use. Older adults may be especially susceptible to this pattern of behavior. Discuss laxative use with patients if concerns arise about unnecessary use or overuse. Explain that normal bowel patterns vary and that daily bowel movements are not a physical necessity. Encourage lifestyle changes that can promote regularity, such as increased fluid intake, fiber intake, and physical activity.<sup>30</sup>

Note that chronic laxative use may be appropriate in some patients (e.g., patients who require chronic opioid therapy or who have certain medical conditions). A thorough medical history can help determine if laxative use and choice are appropriate for individual patients and if medical referral for further evaluation is necessary.

#### Pharmacotherapeutic Comparison

Head-to-head comparison studies of solely nonprescription laxatives are largely unavailable because most nonprescription laxative ingredients became available prior to the current emphasis on comparative evidence. With many products, much of what is practiced has been learned through observation and a common-sense approach. For example, a bulk-forming product should soften the stool by its normal action. Because both a stool softener and a bulk-forming agent take about the same length of time to work, a bulk-forming agent may be the correct choice for some patients who require stool softening. Although stimulants and saline-type laxatives have been used widely for self-care, health care providers should recommend a product with the lowest likelihood of untoward effects.

PEG 3350 was approved as a nonprescription product relatively recently and therefore has been the subject of more clinical trials. In a 2012 Cochrane review of osmotic and stimulant laxatives, PEG 3350 was found to be likely superior to placebo, lactulose, and milk of magnesia, although the overall quality of evidence was poor.<sup>32</sup> PEG 3350 has also been compared with psyllium (ispaghula husk) and has been demonstrated to be superior in terms of efficacy, with similar rates of adverse effects.<sup>33</sup> Of the available nonprescription agents, many professional groups and practitioners consider PEG 3350 to have the strongest support for efficacy and safety; this conclusion is based on the relatively large body of clinical evidence supporting its effectiveness.<sup>34</sup>

#### Product Selection Guidelines

When considering the use of any laxative to treat simple constipation, the provider should remember that normal defecation empties only the rectum and the descending and sigmoid branches of the colon. A bulk-forming laxative most closely duplicates this normal physiologic process and is often recommended as the initial treatment choice for patients needing self-care for acute constipation. However, bulk-forming laxatives may take up to 72 hours or longer for effectiveness. If faster onset is desired, or if a bulk-forming agent is ineffective or inappropriate, the hyperosmotic PEG 3350 is also considered a first-line agent, given its effectiveness and favorable adverse effect profile. If PEG 3350 is unable to produce a satisfactory response, a stimulant (e.g., bisacodyl) should be considered.<sup>6,8,9</sup> In each case, the lowest effective dose should be used, and the dose should be reduced once symptoms improve. Patients not achieving a therapeutic response after 7 days of self-treatment warrant medical referral.

#### Special Populations

**Children.** Constipation in children is generally defined as a delay or difficulty in bowel movements for 2 weeks or longer.<sup>35,36</sup> Constipation affects 16%-37% of children and is the most common cause of abdominal pain in children.<sup>15,37</sup> A number of factors can alter a child's bowel habits, including unavailable toilet facilities; emotional distress; febrile illness; chronic medical conditions (e.g., cystic fibrosis and hypothyroidism); family conflict; dietary changes (e.g., switching from human to cow milk); fear of defecation; or a change in daily routine or environment.<sup>35</sup> Although parents often focus on regular bowel movements as a sign of good health in their child, constipation associated with underlying disease is uncommon in children.<sup>15,35</sup> Bowel movement patterns vary widely among children and at different ages; therefore, constipation can be a complex problem that is often difficult to detect and manage. Children typically describe constipation as difficulty in passing stools; parents or caregivers are usually concerned that a child's stool is too large, too hard, too infrequent, or painful.<sup>35</sup> If a child experiences pain from straining to pass large or hard stools, the child may then avoid or withhold bowel movements, resulting in worsening symptoms and a fear of toileting.

**TABLE 15-5 Selected Nonprescription Laxative Products**

<i>Trade Name</i>	<i>Primary Ingredients</i>
<b>Bulk-Forming Laxatives</b>	
Citrucel Powder	Methylcellulose 2 g/heaping tablespoon
Citrucel Sugar Free Powder	Methylcellulose 2 g/heaping tablespoon
FiberCon Caplets	Calcium polycarbophil 625 mg/caplet
Metamucil Smooth Texture, Sugar Free Orange Flavor Powder/Individual Packets	Psyllium fiber 3 g/packet
<b>Emollient Laxatives</b>	
Colace Capsules	Docusate sodium 100 mg/capsule
<b>Lubricant Laxatives</b>	
Fleet Mineral Oil Enema	Mineral oil 100%
Kondremul Emulsion	Mineral oil 55%
<b>Saline Laxatives</b>	
Magnesium Citrate Oral Solution	Magnesium citrate 1.745 g/30 mL
Fleet Enema	Monobasic sodium phosphate 19 g/118 mL; dibasic sodium phosphate 7 g/118 mL
Pedia-Lax Enema	Monobasic sodium phosphate 9.5 g/59 mL; dibasic sodium phosphate 3.5 g/59 mL
Phillips' Milk of Magnesia Suspension	Magnesium hydroxide 400 mg/5 mL

Hyperosmotic Laxatives	
Fleet Glycerin Suppository (adult size)	Glycerin 2 g/suppository
MiraLAX	Polyethylene glycol 3350 17 g/capful
Stimulant Laxatives	
Dulcolax Tablets	Bisacodyl 5 mg/tablet
Senokot Tablets	Sennosides 8.6 mg/tablet
Fletcher's Laxative for Kids	Senna concentrate 33.3 mg/mL
Combination Laxatives	
Senokot-S Tablets	Sennosides 8.6 mg/tablet; docusate sodium 50 mg/tablet

Before a laxative product is recommended, the possible causes for constipation should be assessed thoroughly, with consideration of the child's age and any previous laxative use. The route of administration and the taste of oral products are especially significant in children. Laxative use can often be avoided in older children by encouraging them to adhere to suggested dietary guidelines to improve stool regularity.

Evaluation of constipation in children should begin with determination of exclusions for nonprescription therapy (Figure 15-2). Constipation in children often presents with fecal impaction.<sup>15</sup> Children with suspected symptoms of impaction (abdominal cramping; rectal bleeding; small, semi-formed stools; fecal soiling; and/or constipation symptoms alternating with or accompanied by watery diarrhea) should be referred for further evaluation and/or disimpaction.<sup>15,35</sup>

Mild constipation in children can often be relieved with dietary or behavioral modifications, such as increasing intake of fluids and fruit juices containing sorbitol (e.g., prune, apple, or grape), or adding small amounts of barley malt extract or corn syrup to juice or milk.<sup>15,35</sup> Once solid foods are introduced, adding or increasing the amount of high-fiber cereals or grains, vegetables, and fruits to the diet may relieve symptoms of constipation. The recommended dietary fiber intake (in grams) for children older than 2 years should equal or exceed their age plus 5 g/day.<sup>17</sup> Parents should also be encouraged to establish a regular stooling time for toilet-trained children (usually after a morning meal) and to develop a supportive system (e.g., charts or stickers) for positively reinforcing bowel movements. Children should be encouraged to promptly heed the urge to pass a bowel movement to avoid negative consequences of retaining stool in the rectum (e.g., increased hardening, pain, and abdominal distention).<sup>35,36</sup>

If dietary or behavior modifications are insufficient or inappropriate, pharmacologic therapy is indicated (Table 15-4). Nonprescription laxative therapy should be administered to children younger than 2 years only under the direction of a medical provider.

Nonprescription laxatives approved for self-care in children ages 2 to younger than 6 years include oral docusate sodium, magnesium hydroxide, or senna. Rectal use of glycerin, mineral oil, or sodium phosphate products is also approved in this age group. Oral products approved for children ages 6 to younger than 12 years include methylcellulose, calcium polycarbophil, psyllium powder, docusate sodium, mineral oil, magnesium citrate, magnesium hydroxide, magnesium sulfate, senna, bisacodyl, and castor oil (see Pharmacologic Therapy for recommendations about use of individual agents). Oral use of PEG 3350 is FDA approved in patients ages 17 years or older, but its use in children is increasing. Health care providers may be called on to assist parents and caregivers in appropriate use of PEG 3350 in cooperation with prescribers.<sup>15,34-38</sup> Rectal products approved for children ages 6 to younger than 12 years include glycerin suppositories, mineral oil, sodium phosphate, and bisacodyl.

If medication is needed for the occasional relief of temporary constipation in children ages 2 to younger than 6 years, oral docusate sodium or magnesium hydroxide can be recommended first.<sup>15,35</sup> Docusate sodium may be especially helpful if the primary complaint is difficulty passing dry, hard stools. If faster relief is needed, providers can recommend pediatric glycerin suppositories, taking care to ensure that caregivers select the pediatric size suppositories for this age group (1 gram) and understand proper administration technique. Oral senna or magnesium citrate and rectal mineral oil or sodium phosphate enemas should be reserved for use when other treatments fail or should be used under the supervision of a health care provider.<sup>15,35-38</sup>

In children ages 6 to younger than 12 years, bulk-forming agents, docusate sodium, or magnesium hydroxide can be recommended for the occasional relief of temporary constipation, with oral stimulants reserved for when other treatments fail.<sup>15,33-36</sup> If faster relief is needed, glycerin or bisacodyl suppositories can be recommended, with mineral oil or sodium phosphate enemas reserved for when other treatments fail, or at the direction of a health care provider.<sup>15</sup> Magnesium sulfate (Epsom salt) and castor oil are not recommended because safer, better-tolerated, and well-studied laxatives are available.

**Patients of Advanced Age.** Compared with the general adult population, the prevalence of constipation in older adults is higher, with 15%-20% of community-dwelling older patients and up to 50% of nursing home residents reporting constipation.<sup>5</sup> Older adults report passing fewer stools per week and often describe constipation as straining to move bowels. Although aging itself does not cause constipation, older adults are at greater risk for constipation because of dietary changes (e.g., reduced caloric, fiber, and/or fluid intake); decreased physical activity; presence of comorbid conditions (e.g., parkinsonism, diabetes, or depression); and increased use of medications that can cause constipation (e.g., opioids and anticholinergics).<sup>5,18</sup> Laxative recommendations should be patient specific. Older individuals can have complicating pathology and multiple medical complaints, and they are vulnerable to medication effects. With older patients, one of the first interventions should be a complete medication review to identify agents that may contribute to constipation and where necessary, discussion of suggestions for appropriate alternatives.<sup>5</sup> As with other age groups, lifestyle modifications are an important initial step, including increased fiber and fluid intake, physical activity as tolerated, and bowel training.<sup>5,19</sup> Notably, recent data support the use of prunes or prune juice as an effective dietary alternative to medications in some patients.<sup>5</sup> Consideration should be given to fluid or other restrictions that may be associated with comorbid conditions (e.g., congestive heart failure or renal failure). Often, constipation is an indication of dehydration in older individuals; therefore, fluid status should be monitored closely. Frail, older patients may also have activity restrictions or limitations secondary to arthritis, cardiovascular, or other chronic conditions.<sup>5</sup>

If medication adjustments and lifestyle changes do not provide adequate relief, laxative therapy is needed. Similar to other populations, treatment of constipation in older adults is often based on experience rather than scientific evidence. Bulk-forming laxatives can be considered a first step. Sugar-free products are recommended for patients with diabetes. Patients who are dehydrated, very frail, bedridden, or unable to drink adequate fluid to prevent mechanical obstruction or fecal impaction should not use bulk-forming laxatives. If these laxatives cannot be used or do not provide sufficient relief, or if faster onset is desired, PEG 3350 is also used as a first-line option because of its efficacy and tolerability.<sup>5,39</sup> Stool softeners (e.g., docusate) may be helpful in older adults with anal fissures or with hemorrhoids that cause painful defecation.<sup>18</sup>

A number of nonprescription laxatives should be avoided or used very cautiously in this population. Mineral oil is not recommended because of the increased risk of aspiration and depletion of fat-soluble vitamins. Saline laxatives such as magnesium hydroxide should be avoided in older individuals, given the potential for magnesium toxicity in those with reduced renal function and given the potential for drug interactions with medications such as digoxin.<sup>5</sup> Older patients are particularly sensitive to shifts in fluid and electrolytes. Use of any laxative that alters the fluid and electrolyte balance (particularly saline and stimulant laxatives) may be inappropriate in certain patients of advanced age. These laxatives can place older patients at risk for adverse effects (particularly those who are on diuretics or who have decreased fluid intake).<sup>5,18</sup> Although regular use of stimulant laxatives is sometimes recommended, these products have limited evidence in older adults.<sup>40</sup>

Older adults may also require rectal therapy with a suppository or enema, especially if fecal impaction is suspected. Rectal preparations are generally

considered to be safe in older adults, although there is limited comparative evidence of safety and effectiveness among individual preparations.<sup>5,40</sup> Sodium phosphate enemas are effective, but they can result in hyperphosphatemia in patients with renal disease.<sup>5</sup> Additionally, older adults may be more susceptible to water and electrolyte imbalances with sodium phosphate enemas.<sup>40</sup>

Chronic laxative use is common among older adults, but it may not always be indicated. Health care providers should counsel older adults about appropriate use of medications with lifestyle and dietary changes. Laxative overuse may predispose patients to dehydration, electrolyte imbalances, and pharmacokinetic drug interactions. Laxatives can also increase GI motility and decrease absorption and effectiveness of concurrent medications.

**Pregnancy and Lactation.** Constipation is common during pregnancy and after childbirth. It affects up to one-third of women throughout pregnancy and the postpartum period.<sup>41</sup> The increasing size of the growing uterus compresses the colon, affecting the emptying of fecal material. Other contributing factors during pregnancy include increasing progesterone levels, low fluid and fiber intake, and iron and calcium in prenatal vitamin and mineral supplements.<sup>41</sup> Constipation in pregnancy can lead to backaches, hemorrhoids, and fecal impaction.

The main goal of treatment in pregnancy is to achieve soft stools without the use of laxatives. Dietary measures (e.g., increasing fiber and fluid intake or adding prunes or prune juice to the diet) should be attempted as an initial measure.<sup>41</sup> If dietary measures are insufficient, a laxative may be indicated. Bulk-forming laxatives are recommended initially (taken with plenty of fluid to prevent worsening constipation).<sup>41-44</sup> Docusate may also be used for patients who have primarily dry, hard stools, and it is a component of some prenatal vitamins.<sup>44</sup> If needed, short-term use of senna or bisacodyl is considered low-risk in pregnancy.<sup>42-44</sup> Some experts also consider PEG 3350 to be a first-line choice in pregnancy because very little is absorbed systemically.<sup>44</sup> However, short-term use of senna or bisacodyl is preferred by some practitioners because more data are available for use of these agents in pregnancy than for use of PEG 3350.<sup>41,42</sup> In more severe cases, or when the safety of a laxative product is questionable, consultation with a woman's health care provider is recommended prior to laxative use.

Some laxatives should be used very cautiously or avoided altogether in pregnancy. Castor oil is associated with uterine contraction and rupture, and it should be avoided. Mineral oil may impair maternal fat-soluble vitamin absorption and should not be recommended. Saline laxatives (e.g., magnesium hydroxide, etc.) used long-term or at high doses may cause dehydration or electrolyte imbalances and generally should be avoided, given that better options exist.<sup>42-44</sup>

Laxatives may also be necessary postpartum to reestablish normal bowel function. Senna, bisacodyl, PEG 3350, and docusate are considered compatible or low risk with breast-feeding.<sup>43,45,46</sup> Research has shown that, at usual doses, these agents are minimally absorbed or are not present in significant concentrations in breast milk; no data are available to suggest that infants may experience any potential toxicity.<sup>42,45,46</sup> Castor oil and mineral oil should not be used during breast-feeding.<sup>42</sup>

#### Patient Factors

Laxative products are available in a wide array of oral dosage forms. This variety yields the most benefits for pediatric and geriatric patients. Many of the dosage forms (e.g., thin film strip formulations for children) enhance patient acceptability. However, laxatives available as chewing gum, wafers, effervescent granules, gummy candy, or chocolate tablets may be more likely to be misused or abused. Additionally, the glucose and calorie contents of these dosage forms should be considered for patients with diabetes or calorie restrictions.

Patient factors may also limit the use of some laxatives. For example, patients with fluid restrictions should avoid bulk-forming laxatives that require significant fluid intake. Patients on sodium-restricted diets should examine the sodium content of laxative products (especially saline laxatives). FDA requires manufacturers of laxative products to list sodium content on the product labeling.<sup>47</sup> Patients with severely limited mobility (e.g., postoperative patients or older adults) are at increased risk for constipation and may require regular use of stool softeners or laxative products to promote laxation.

Enemas and suppositories may be required for some patients with constipation. Enemas are routinely used in preparing patients for surgery, child delivery, and GI radiologic or endoscopic examinations. The enema fluid determines the mechanism by which evacuation is produced. Vegetable oils lubricate, soften, and facilitate the passage of hardened fecal matter, whereas tap water, normal saline, and sodium phosphate enemas create bulk through an osmotic volume effect. Sodium phosphate enemas are more efficient and effective than tap water, soapsuds, saline, or vegetable oil enemas. However, chronic use is not recommended because sodium phosphate enemas can significantly alter fluid and electrolyte balance.

A properly administered enema cleans only the distal colon, most nearly approximating a normal bowel movement. However, improper use or administration may result in adverse effects (e.g., fluid and electrolyte imbalances, mucosal changes or spasm of the intestinal wall, abrasion of the anal canal, or colonic perforation). Advise patients to follow all directions carefully when using these products (Table 15-6).

Suppositories containing bisacodyl are used for postoperative, antepartum, and postpartum care and are adequate in preparing for proctosigmoidoscopy. Although bisacodyl suppositories are prescribed and used more often than other suppositories, some providers still prefer enemas as agents for cleaning the lower bowel. Glycerin suppositories are useful in initiating the defecation reflex in children and in promoting rectal emptying in adults.

**TABLE 15-6 Administration of Enemas and Rectal Suppositories**

<i>Enemas</i>	<i>Suppositories</i>
<ol style="list-style-type: none"> <li>1. If someone else is administering the enema, lie on your left side with knees bent or in the knee-to-chest position (see drawings A and B). Position A is preferred for children younger than 2 years. If self-administering the enema, lie on your back with your knees bent and buttocks raised (see drawing C). A pillow may be placed under the buttocks.</li> <li>2. If using a concentrated enema solution, dilute solution according to the product instructions. Prepare 1 pint (500 mL) for adults and ½ pint (250 mL) for children.</li> <li>3. Lubricate the enema tip with petroleum jelly or other nonmedicated ointment/cream. Apply the lubricant to the anal area, as well.</li> <li>4. Gently insert the enema tip 2 inches (recommended depth for children) to 3 inches into the rectum.</li> <li>5. Allow the solution to flow into the rectum slowly. If you experience discomfort, the flow is probably too fast.</li> <li>6. Retain the enema solution until definite lower abdominal cramping is felt. (The parent/caregiver may have to gently hold a child's buttocks closed to prevent the solution from being expelled too soon.)</li> </ol>	<ol style="list-style-type: none"> <li>1. Gently squeeze the suppository to determine if it is firm enough to insert. Chill a soft suppository by placing it in the refrigerator for a few minutes, or by holding it under cool running water.</li> <li>2. Remove the suppository from its wrapping.</li> <li>3. Dip the suppository in lukewarm water for a few seconds to soften the exterior.</li> <li>4. Lie on your left side with knees bent or in the knee-to-chest position (see drawings A and B). Position A is best for self-administration of a suppository. Small children can be held in a crawling position.</li> <li>5. To ease insertion, relax the buttocks just before inserting the suppository. Gently insert the tapered end of the suppository high into the rectum. If the suppository slips out, it was not inserted past the anal sphincter (the muscle that keeps the rectum closed). In this case, reinsert the suppository correctly.</li> <li>6. Continue to lie down for a few minutes, and hold the buttocks together to allow the suppository to dissolve in the rectum. (The parent/caregiver may have to gently hold a child's buttocks closed.)</li> <li>7. Remember that the medication is most effective when the bowel is empty. Try to avoid a bowel movement for up to 1 hour after insertion of the suppository so that the intended action can occur.</li> </ol>

### Patient Preferences

Palatability and convenience are important considerations with laxative products, especially for patients needing products on a regular basis. Liquid formulations of emollients may be made more palatable if mixed with juices or milk. Mixing gritty, bulk-forming laxative powders (e.g., psyllium) with orange juice instead of water may increase their taste and texture palatability. Patients may also prefer wafer or single-use packets of bulk-forming laxative powders for convenience and ease of use. Patients should be reminded that many fiber products marketed as grit-free, flavor-free, or taste-free may contain ingredients that have not been studied as bulk-forming laxatives and are approved only as dietary supplements (e.g., inulin).

Cost is also an important consideration in patient preference. Most laxative ingredients are available in some form as a generic. However, patients with a specific dosage form or other preference may need to choose a brand-name product. It is important to help patients choose the laxative product with the optimal balance of cost, effectiveness, tolerability, and palatability, depending on their individual needs.

### Complementary Therapies

Dietary supplements commonly used to treat constipation include flaxseed, aloe, cascara, and probiotics.<sup>48</sup> Evidence supporting the safety and efficacy of these products varies. A single double-blind trial demonstrated the superiority of flaxseed over psyllium in decreasing constipation, bloating, and abdominal pain over a 3-month period in patients with irritable bowel syndrome. However, a much larger body of evidence supports psyllium's effectiveness, and practitioners should not recommend flaxseed on the basis of limited efficacy and safety data.<sup>48</sup>

Although many commercially available stimulant laxatives are derived from plants, patients should be advised to choose FDA-approved products if a stimulant laxative is indicated. FDA has banned the use of aloe and cascara in nonprescription stimulant laxatives, and both agents are classified as generally unsafe and not effective. Senna is available in dietary supplement form, but use of standardized, FDA-approved senna drug products is preferred.

Probiotics are thought to work in constipation through alteration of GI flora, stimulation of motility and peristalsis, and/or acceleration of gut transit.<sup>5,49</sup> However, from a mechanistic or clinical efficacy standpoint, little available evidence consistently supports these agents. A systematic review conducted by Chmielewska and colleagues<sup>50</sup> identified five randomized controlled trials (n = 377) of probiotic supplementation for constipation management. Study results suggested there may be a potential benefit, but authors questioned the overall efficacy and clinical relevance of specific study outcomes. Probiotics should be considered investigational for constipation until more efficacy and safety evidence are available.<sup>5,49,50</sup>

### Assessment of Constipation: A Case-Based Approach

The health care provider should obtain as much lifestyle and medical information as possible before making any recommendations for preventing or treating constipation. Appropriate information allows the provider to make rational recommendations that are based on knowledge of the patient, the problem, and available products, as well as on the provider's own judgment and experience. A patient who presents with constipation should initially be evaluated for any signs of significant GI problems that may warrant medical evaluation or in which laxative use is inappropriate (Figure 15-2). Health care providers should initially ask questions related to diet, fluid intake, physical activity, and any underlying pathology that may produce constipation as a symptom. Patients should then be questioned regarding the characteristics of bowel movements, including the caliber, color, and texture of stools, as well as the frequency of elimination. Additional assessment should include questions about use of medications (both prescription and nonprescription), natural products, and previous laxative use. For patients without a history of constipation, a thorough investigation should be conducted to determine whether acute cases of constipation have resulted from new or old diseases or from the use of medications. When information is insufficient to assess the cause of the symptoms, or if any doubt exists regarding the patient's disease status, medical referral is appropriate. Cases 15-1 and 15-2 provide sample assessments for patients presenting with constipation.

**Case 15-1**

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient indicates he has not had a bowel movement over the past week because he has been studying for exams, eating fast food, and not exercising or playing sports. It is really bothersome because he has exams looming and wants fast relief.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient does not recall having problems with constipation in the past.
c. description of the patient's efforts to relieve the symptoms	Patient has been taking docusate sodium capsules daily for the past 3 days.
d. patient's identity	Jake Richardson
e. age, sex, height, and weight	19 years old, male, 6 ft, 190 lbs
f. patient's occupation	Freshman in college
g. patient's dietary habits	Diet usually consists of no breakfast, sandwiches for lunch, and a meat or pasta dish with vegetables or salad for dinner.
h. patient's sleep habits	Sleeps 4-5 hours a night.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Perennial allergies: loratadine 10 mg daily
j. allergies	Pollen and dust mites
k. history of other adverse reactions to medications	None
l. other (describe) _____	He typically has 1 bowel movement every day. Patient is active in intramural sports and exercises regularly.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	The patient is experiencing constipation most likely precipitated by his change in routine, eating fast food, and not exercising. Constipation during periods of change in routine and stress is common.
3. Identify exclusions for self-treatment (Figure 15-2).	None
4. Formulate a	Options include:

<p>4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.</p>	<p>Options include:</p> <ol style="list-style-type: none"> <li>(1) Refer patient to an appropriate health care provider.</li> <li>(2) Recommend nondrug measures:             <ol style="list-style-type: none"> <li>a. Resume a balanced diet with adequate fiber, fruits, and vegetables.</li> <li>b. Drink at least 2 liters of fluid daily.</li> <li>c. Resume a regular exercise routine, and get more sleep to decrease the effect of stress.</li> </ol> </li> <li>d. Recommend strategies to prevent future recurrences.</li> <li>(3) Recommend continuing docusate sodium and adding a bulk-forming laxative to help facilitate resolution of symptoms.</li> <li>(4) Recommend a hyperosmotic (e.g., an adult glycerin suppository or PEG 3350). The glycerin suppository will offer the fastest resolution, if the patient is willing to use that dosage form.</li> <li>(5) Recommend a stimulant laxative once daily for resolution of symptoms. A stimulant laxative will also offer fast relief from symptoms.</li> <li>(6) Recommend self-care until patient can see an appropriate health care provider.</li> <li>(7) Refer patient to an appropriate health care provider if therapeutic option and lifestyle changes do not alleviate symptoms within a week.</li> <li>(8) Take no action.</li> </ol>
<b>Plan</b>	
<p>5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.</p>	<p>Patient would like some help resolving his symptoms quickly given that final exams are coming soon. Because he has tried docusate sodium for the past 3 days, and because a bulk-forming laxative has a similar onset of action, it may be helpful to consider an alternative. If the patient is willing, a glycerin suppository could be used for a quick resolution. If the patient prefers an oral medication, PEG 3350 is also an option, but it will take longer to work. To prevent similar recurrences in the future, the patient should be encouraged to increase fiber and fluid intake while studying. If he is unable to modify his diet during study periods, discuss a fiber supplement to eat during this time, (e.g., a fiber-enriched granola bar, psyllium wafer, or fiber packet added to beverage).</p>
<p>6. Describe the recommended therapeutic approach to the patient or caregiver.</p>	<p>"You should resume a proper diet that includes more fiber, fruits, and vegetables, and increase your fluid intake. You should restart your regular exercise routine. A stronger laxative medication can be tried for quick relief of symptoms, including a glycerin suppository or oral polyethylene glycol 3350, also called PEG 3350."</p>
<p>7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.</p>	<p>"Because you have been experiencing constipation for 1 week and have been taking docusate sodium for 3 days, perhaps you should try another agent with a quicker onset of action. If you are willing to use a suppository, a glycerin suppository will provide quick relief. If you prefer taking a medication by mouth, PEG 3350 will take longer to work than the suppository, but it usually works very well to relieve constipation. If the glycerin suppository or oral PEG 3350, along with changes in your diet and exercise routine, do not successfully relieve your constipation, or if your symptoms get worse, you should make an appointment with your primary care provider to discuss other treatment options and ways to prevent constipation."</p>
<b>Patient Education</b>	
<p>8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.</p>	
<p>a. appropriate dose and frequency of administration</p>	<p>See the box Patient Education for Constipation.</p>
<p>b. maximum number of days the therapy should be employed</p>	<p>See the box Patient Education for Constipation.</p>
<p>c. product administration procedures</p>	<p>See <a href="#">Table 15-6</a> for patient education for administering a suppository.          "If you opt for PEG 3350, measure a 17 gram dose of PEG 3350 powder (1 capful or packet of the OTC product), stir and dissolve powder in 4-8 ounces of any beverage, and then drink."</p>
<p>d. expected time to onset of relief</p>	<p>"The glycerin suppository will work in about 15-30 minutes. PEG 3350 usually produces a bowel movement in 12-72 hours, but the onset of action may take as long as 96 hours in some patients."</p>
<p>e. degree of relief that can be reasonably expected</p>	<p>"Your constipation symptoms should be relieved with the use of either of these drugs."</p>
<p>f. most common side effects</p>	<p>"You may experience cramping or stomach pain, diarrhea or loose stools, or rectal irritation from the glycerin suppository."</p>
<p>g. side effects that warrant medical intervention should they occur</p>	<p>"Contact your primary care provider if you experience rectal bleeding; nausea, bloating, cramping, or abdominal pain persist or worsen; a bowel movement does not occur; diarrhea occurs; or symptoms are not relieved within a week."</p>
<p>h. patient options in the event</p>	<p>"Contact your primary care provider."</p>

that the condition worsens or persists	
i. product storage requirements	"Store glycerin suppositories in the tightly closed container in a cool, dry location. Protect from heat."
j. specific nondrug measures	See the box Patient Education for Constipation.
Solicit follow-up questions from the patient or caregiver.	"I'd prefer not to use the suppository; I will try the PEG 3350 instead. Is there any difference between the brand-name and generic PEG 3350 products? What type of beverage can be used to dissolve the powder?"
Answer the patient's or caregiver's questions.	"There's no difference in the brand-name versus the generic product except for the cost. Whichever product you prefer is fine, and the generic will save a little bit of money. It doesn't matter what beverage you dissolve the powder in, and the beverage can be hot, cold, or at room temperature."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Ask the patient to call to update you on his response to your recommendations; alternatively, you could call him in a few days to evaluate his response.

Key: OTC = Over-the-counter; PEG = polyethylene glycol.

### Case 15-2

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient says that she is having a very difficult time passing her stools. She admits to straining to pass "normal looking" but hard stools, and she is experiencing severe abdominal pain. She has only about one bowel movement per week. She has been experiencing these symptoms over the past 3 months.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient notes that her problems really started when her primary care provider added an additional medication to help control her chronic back pain.
c. description of the patient's efforts to relieve the symptoms	The patient has occasionally used a stool softener.
d. patient's identity	Ann Holcomb
e. age, sex, height, and weight	45 years old, female, 5 ft 5 in., 150 lb
f. patient's occupation	Teacher
g. patient's dietary habits	Usual diet consists of some vegetables, occasional fruit, pastas, occasional whole-grain breads, meat and fish, caffeinated coffee, diet sodas, and desserts.
h. patient's sleep habits	Sleeps about 4 hours per night.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Chronic back pain: Celebrex 200 mg daily, Lortab every 4-6 hours as needed for pain; Osteoporosis prevention: calcium 600 mg plus vitamin D 600 IU twice daily
j. allergies	Penicillin
k. history of other adverse reactions to medications	None
l. other (describe) _____	She typically has 3-4 bowel movements every week. She takes about 3-4 Lortab tablets per day.
<b>Assessment and Triage</b>	

2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	The patient recently started an opioid medication, Lortab, which can cause constipation. The patient's constipation appears to be correlated with the start of this medication. The patient takes calcium plus vitamin D, which can also contribute to constipation.
3. Identify exclusions for self-treatment (Figure 15-2).	Presence of marked abdominal pain, unexplained changes in bowel habits, bowel symptoms that persist for more than 2 weeks.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer patient to an appropriate health care provider. (2) Recommend self-care with a nonprescription laxative and nondrug measures. (3) Recommend self-care until patient can see an appropriate health care provider. (4) Refer patient to an appropriate health care provider if therapeutic option and lifestyle changes do not alleviate symptoms within a week. (5) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Patient has experienced constipation secondary to the initiation of an opioid medication. She has been experiencing these symptoms for 3 months with abdominal pain. She should consult a health care provider. However, she should also implement nondrug measures to help prevent constipation and promote a healthy lifestyle.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should consult a health care provider. You should also modify your diet to include more fiber, fruits, and vegetables. You should add a fiber supplement to your diet, and you should increase your fluid intake. Also, you should establish a regular exercise routine."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"This option is best because your constipation began after you started your new pain medication, and it has been occurring for 3 months. Additionally, you have been experiencing marked abdominal pain. Under these conditions, nonprescription laxative therapy may not be the best choice right now. You should be evaluated by your health care provider."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	"Even though you need to see your health care provider, you can still implement nondrug measures that promote a healthy lifestyle, such as eating more fiber, fruits, and vegetables, and beginning a regular exercise routine. You should consult your health care provider about these measures as well."
Solicit follow-up questions from the patient or caregiver.	"Can you suggest some high-fiber foods that I could add to my diet?"
Answer the patient's or caregiver's questions.	"I would start by adding more fruits and vegetables to your diet, as well as eating a high-fiber cereal like Bran Buds, All Bran, or Kashi GoLean for breakfast each morning. Be sure to increase your dietary fiber gradually to avoid side effects such as gas, bloating, or diarrhea during the first few weeks following these dietary changes."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact the patient in a day or two to ensure that she made an appointment and sought medical care.

### Patient Counseling for Constipation

Patient education about laxative products is important for all patients (particularly for children, their caregivers, and older adults). Before recommending a laxative product, the health care provider should first inform the patient of the nondrug measures available for treating constipation. Pregnant women and children, especially, should be counseled on proper diet, adequate fluid intake, and reasonable exercise. If a laxative is needed, explain why a particular type of laxative is appropriate for the present situation, how to use the laxative, when to expect to see results, what adverse effects could occur, and what precautions to take. The box Patient Education for Constipation lists specific information to provide patients.

### Evaluation of Patient Outcomes for Constipation

Constipation often presents with a great degree of variability among individuals. Although a decrease in frequency of bowel movements is typically associated with constipation, difficulty passing stools and a decrease in the amount passed are also common complaints. The type, severity, and chronicity of symptoms are important determinants in selecting the most appropriate treatment modality. Once therapy has been selected, effectiveness is determined by how rapidly constipation is relieved and to what degree normal bowel habits have been restored. For acute constipation, dietary changes, exercise, or the use of bulk-forming laxatives may take several days to weeks to provide relief. Most hyperosmotic, saline, or stimulant laxatives will provide relief within 3-72 hours. Enemas can produce evacuation within minutes. If initial treatment of constipation is ineffective, therapy should be repeated according to product-specific directions.

If an adequate response is not achieved after a short period of laxative use (usually within 7 days) follow-up should assess whether the patient needs medical referral. If a laxative must be continued for an extended period of time, the patient should be referred for further evaluation, as frequent use may be a sign of (1) a more severe form of constipation, (2) a medication side effect, or (3) an underlying medical problem. Adhering to a high fiber diet and drinking plenty of fluids can aid in preventing constipation and should be continued even during periods when bowel habits are normal.

#### Patient Education for Constipation

The goals of self-treatment are to relieve constipation and restore "normal" bowel functions through (1) dietary and lifestyle measures and/or (2) the safe use of laxative products. For most patients, carefully following the product instructions and the self-care measures listed here will help achieve this.

#### Nondrug Measures

- To promote regular bowel movements, use nondrug strategies such as a high-fiber diet (slowly increase intake to 25-35 grams per day), plenty of fluid intake, and regular exercise.
- Increase dietary fiber by eating foods with whole grains, oats, fruits, and vegetables.
- Avoid constipating foods, such as processed cheeses and concentrated sweets.
- Drink plenty of fluids (six to eight 8-ounce glasses a day) to help soften your stool and move food through your gastrointestinal tract.
- Develop and maintain a routine exercise program. Walking can be helpful if your heart is healthy and if you have no other apparent health risks.
- Establish a regular pattern for bathroom visits. Do not delay in responding to the urge to use the bathroom; allow adequate time for elimination in a relaxed, unhurried atmosphere.
- Maintain general emotional well-being and avoid stressful situations.

#### Nonprescription Medications

- Bulk-forming laxatives (e.g., methylcellulose, psyllium)
- Hyperosmotic laxatives (e.g., polyethylene glycol [PEG] 3350, glycerin)
- Emollient laxatives, or "stool softeners" (e.g., docusate sodium)
- Lubricant laxative (mineral oil)
- Saline laxatives (e.g., magnesium citrate, magnesium hydroxide)
- Stimulant laxatives (e.g., bisacodyl, senna)

#### Complementary Therapies

- Not routinely recommended for self-treatment of constipation.

#### Disease Information

- Constipation is usually defined as having fewer than 3 bowel movements per week that involve straining and the difficult passage of dry, hard stools. In most cases, constipation is temporary. Self-treatment of constipation is safe for short-term symptoms in patients without other underlying disorders or conditions.
- You do not need to take laxatives routinely because your bowel habits are interrupted for 1 or 2 days, nor do you need to routinely "clean your system."

#### Drug Information

##### **Bulk-Forming Laxatives**

- Unless a rapid effect is needed (e.g., to clean out the bowel for a diagnostic procedure or x-ray), take a bulk-forming laxative. Be sure to drink at least 8 ounces of fluid with each dose to prevent an intestinal blockage. If you have swallowing difficulties, alert your health care provider before taking a bulk-forming laxative.
- If you have diabetes or are on a carbohydrate- or calorie-restricted diet, choose sugar-free bulk-forming agents, if possible. Many bulk-forming agents contain sugar and have a high caloric content per dose.
- Do not give sugar-free bulk-forming products to patients with phenylketonuria.

##### **Hyperosmotic Laxatives**

- If you have irritable bowel syndrome, do not take PEG 3350 without the supervision of your primary care provider.
- When using PEG 3350, use the provided cap to measure the dose, or use 1 packet of powder. Mix the powder with 4-8 ounces of a hot, cold, or room temperature beverage (e.g., water, juice, soda, coffee, or tea).
- Consult a primary care provider before using glycerin suppositories if you have previously had a condition that caused rectal irritation.

##### **Emollient Laxatives**

- Do not take docusate if you are taking mineral oil unless told to do so by a primary care provider. Taking these together can increase the amount of mineral oil that gets into your body.

##### **Lubricant Laxative**

- Although some patients use mineral oil for occasional bouts of constipation, its use in self-care is strongly discouraged because safer agents that work just as well are available.
- Do not give mineral oil to children younger than 6 years, pregnant women, older adults, or bedridden patients without the supervision of a primary care provider. These patients are at a higher risk for adverse effects from mineral oil.
- Do not take mineral oil with emollient laxatives (e.g., docusate). Taking these together can increase the amount of mineral oil that gets into your body.
- To avoid delaying the absorption of foods, nutrients, and vitamins, do not take mineral oil within 2 hours of eating.
- Stop use and consult your health care provider if anal leakage of oil occurs. This may indicate your dose is too high.

##### **Saline Laxatives**

- Take doses with an 8-ounce glass of water, if possible, to prevent dehydration.
- Consult your health care provider before using a saline laxative if you are taking a diuretic ("water pill") for high blood pressure (e.g., hydrochlorothiazide or furosemide); if you are taking other drugs that can cause electrolyte changes; or if you are on a sodium-, phosphate-, or magnesium-restricted diet.
- If you are an older adult, you may be at increased risk for dehydration or electrolyte imbalances with saline laxatives. Consult a health care provider before using these agents.
- Do not use magnesium sulfate (Epsom salt) to treat constipation except under the advice of a primary care provider.

##### **Stimulant Laxatives**

- Do not use castor oil to treat constipation except under the advice of a health care provider.
- Do not chew or crush bisacodyl tablets, which may cause stomach discomfort, faintness, and cramps. Do not use bisacodyl within 1 hour after taking an antacid or milk. Doing so can cause the tablet's coating to break down too quickly.

#### Administration of Medication/Safe Usage

- Read and carefully follow labeled dosage and administration instructions for all laxative products.
- Oral laxatives are available as tablets, capsules, thin-film strips, chewing gum, wafers, effervescent granules, gummy candy, chocolate tablets, and other forms. Choose the best form for you, and consider glucose and caloric content if you have diabetes or calorie restrictions.

- Rectal laxatives (enemas, suppositories) should be used according to administration instructions (Table 15-6).
- If constipation symptoms continue after 7 days of laxative treatment, contact your health care provider.
- Do not give laxatives to children younger than 2 years unless the use is recommended by a primary care provider.
- Take most laxatives at bedtime, especially if more than 6-8 hours will be needed to produce results.
- Do not take any laxatives at doses higher than the recommended amounts.

#### Warning Signs/Symptoms

- Do not take laxatives if you have marked abdominal pain, nausea, vomiting, significant abdominal distention, cramping, or fever. These may be symptoms of a more serious condition (e.g., appendicitis).
- Do not take laxatives if you have a sudden change in bowel habits that persists more than 2 weeks because that can be a sign of a more serious condition. See your primary care provider for treatment recommendations.
- If rectal bleeding, blood in your stool, or black, tarry stools occur, see your health care provider. These may be symptoms of an underlying medical condition.
- If you have kidney or liver disease, heart failure, hypertension, or other conditions requiring sodium, potassium, magnesium, or calcium restriction, do not use laxative products with a maximum daily dose of more than 345 mg (15 mEq) sodium, 975 mg (25 mEq) potassium, 600 mg (50 mEq) magnesium, or 1800 mg (90 mEq) calcium.
- Consult your health care provider before using laxatives if you currently have or have a history of any condition that may affect self-treatment of constipation (e.g., paraplegia or quadriplegia, inflammatory bowel disease, colostomy, megacolon, or ileostomy).
- Some laxatives require you to drink a lot of water with each dose. Patients with fluid restrictions should avoid bulk-forming or other laxatives that require fluid intake.

#### Adverse Effects

- The most common adverse effects of laxatives are abdominal cramping, gas, bloating, or diarrhea.

#### Interactions

- Avoid taking laxatives within 2 hours of other medications.
- To make sure you avoid any potential drug-drug interactions, alert your health care provider if you are taking anticoagulants (blood thinners), digoxin (a heart medicine), sodium polystyrene sulfonate (a treatment for high potassium levels), or other drugs that need to be maintained at precise levels.

#### Storage of Medications/Expiration Date/ Signs of Instability

- Discard any medications that are outdated, that appear to have been tampered with, or that have an unusual appearance.

#### Key Points for Constipation

- Nonprescription laxative treatment should not be recommended if exclusion criteria for self-treatment are met (Figure 15-2). Patients meeting these criteria should receive medical referral.
- Special circumstances and patient characteristics (e.g., pregnancy or age) should be considered when assessing the need for self-medication.
- For most cases of simple constipation, a balanced diet, exercise, and adequate fluid intake are helpful.
- Bulk-forming laxatives and PEG 3350 as directed are first-line laxative choices in most adults, but they may take up to 72 hours to work. Glycerin suppositories or stimulant laxatives provide faster relief, if needed.
- Therapy with any laxative product should be limited to 7 days, unless supervised by a health care provider.
- If rectal bleeding occurs at any time during use of a laxative, or if constipation persists in spite of therapy, patients should stop using the laxative and consult their health care provider.<sup>15</sup>
- To reduce the potential for drug interactions, patients should avoid taking most laxatives within 2 hours of other medications.

## Handbook of Nonprescription Drugs > Chapter 16. Diarrhea

### Diarrhea: Introduction

Diarrhea is a symptom characterized by an abnormal increase in stool frequency, liquidity, or weight. Although the normal frequency of bowel movements varies with each individual, having more than 3 bowel movements per day is considered abnormal.

Diarrhea may be acute, persistent, or chronic. Acute diarrhea, defined as symptoms lasting less than 14 days, can generally be managed with fluid and electrolyte replacement, dietary interventions, and nonprescription drug treatment. In persistent diarrhea, symptoms last 14 days to 4 weeks. Chronic diarrhea, by definition, lasts more than 4 weeks. Chronic and persistent diarrheal illnesses are often secondary to other chronic medical conditions or treatments and need medical care; therefore, these illnesses are outside the scope of this chapter.

Diarrhea is a common cause of morbidity. Worldwide, approximately 2.5 billion episodes of acute diarrhea occur each year, causing significant morbidity and mortality among all age groups, especially children under 5 years of age, in whom it causes 1.9 million deaths annually.<sup>1</sup> Approximately 179 million cases of acute gastroenteritis (irritation of the gastrointestinal tract commonly caused by viruses or bacteria) occur in the United States each year.<sup>2</sup> The overall prevalence of acute diarrhea is estimated to be 5.1%; the incidence rate is 0.6 episodes per person per year.<sup>3</sup> The prevalence of diarrheal disease is highest in children younger than 5 years and lowest in older adults (ages 65 years and older); prevalence rates are estimated to be 7%-10% for children younger than 5 and 2%-3% for older adults.<sup>3</sup> Most patients experience illness without seeking medical attention; however, in the United States more than 500,000 patients are hospitalized each year and approximately 5000 deaths result from acute gastroenteritis and its complications.<sup>2</sup>

### Pathophysiology of Diarrhea

**Table 16-1** highlights some of the common viral, bacterial, and protozoal diarrheas and their treatment. Epidemiologic factors that increase the risk for particular infectious diarrheal diseases or their spread include attendance or employment at day care centers, occupation as a food handler or caregiver, congregate living conditions (e.g., nursing homes, prisons, and multifamily dwellings), consumption of unsafe foods (e.g., raw or undercooked meat, eggs, and shellfish), and presence of medical conditions, such as acquired immunodeficiency syndrome (AIDS) or diverticulitis. Acute diarrhea may also be caused by poisoning, medications, intolerance of certain foods, or various non-gastrointestinal (GI) acute or chronic illnesses.

#### Viral Gastroenteritis

Noroviruses are the most common cause of diarrhea in adults and the second most common cause in children. They cause more than 90% of epidemic viral gastroenteritis and approximately 50% of all-cause epidemic gastroenteritis worldwide.<sup>4</sup> In addition, noroviruses play a major role in sporadic acute gastroenteritis, accounting for up to 36% of cases.<sup>5</sup> The symptoms, clinical course and treatment are described in **Table 16-1**. Although the virus is most often transmitted by contaminated water or food, it can also be transmitted from person to person and through contact with contaminated environmental surfaces. Outbreaks of norovirus gastroenteritis frequently occur in certain populations, such as restaurant patrons, cruise ship passengers, students on college campuses, residents of long-term care facilities and hospitals, military personnel, and immunocompromised patients.

Rotavirus is the most common cause of severe gastroenteritis in infants and young children worldwide. In the United States, prior to widespread rotavirus vaccine administration, approximately 80% of children developed rotavirus gastroenteritis before reaching 5 years of age.<sup>6</sup> Rotavirus accounted for 30%-50% of all hospitalizations for gastroenteritis in those patients.<sup>6</sup> Two oral vaccines are available to prevent rotavirus gastroenteritis and are recommended for routine use in healthy infants. These vaccines prevent 75%-85% of all rotavirus gastroenteritis and 95%-98% of severe infections, and they have substantially reduced the health care burden of rotavirus disease.<sup>6-8</sup>

Rotavirus also causes diarrheal disease in adults, although specific epidemiological data are lacking.<sup>9</sup> The virus has been found in 18% of stool specimens of adults presenting to emergency departments with acute gastroenteritis and may account for 3%-5% of adult hospitalizations due to diarrheal disease.<sup>10,11</sup>

Rotavirus tends to be a seasonal infection, with peaks of gastroenteritis occurring between November and February. It is spread by the fecal-oral route, can cause severe dehydration and electrolyte disturbances, and may result in death. Clinical features are presented in **Table 16-1**. Other, less frequent viral causes of gastroenteritis include

adenoviruses, astroviruses, and hepatitis A virus.

**TABLE 16-1 Common Infectious Diarrheas and Their Treatment**

<i>Type</i>	<i>Epidemiologic/Etiologic Factors</i>	<i>Symptoms</i>	<i>Treatment</i>	<i>Usual Prognosis</i>
<b>Viral</b>				
Rotavirus	Infects infants; oral-fecal spread	Onset of 24-48 hours; vomiting, fever, nausea, acute watery diarrhea	Vigorous fluid and electrolyte replacement	Self-limiting, usually lasts 5-8 days
Norovirus	Infects all ages; frequently spread person to person by the fecal-oral route; causes "24-hour stomach flu"	Onset of 24-48 hours; sudden-onset vomiting, nausea, headache, myalgia, fever, watery diarrhea	Fluid and electrolytes	Self-limiting, usually lasts 12-60 hours
<b>Bacterial</b>				
<i>Campylobacter jejuni</i>	Ingestion of contaminated food or water; oral-fecal spread; immunocompromised host	Onset of 24-72 hours; nausea, vomiting, headache, malaise, fever, watery diarrhea	Fluid and electrolytes; in severe or persistent diarrhea, antibiotics may be required <sup>a</sup>	Self-limiting, usually lasts <7 days
<i>Salmonella</i>	Ingestion of improperly cooked or refrigerated poultry and dairy products; immunocompromised host	Onset of 12-24 hours; diarrhea, fever, chills, malaise, myalgia, epigastric pain, anorexia	Fluid and electrolytes for mild cases; antibiotics reserved for complicated cases <sup>b</sup>	Self-limiting
<i>Shigella</i>	Ingestion of contaminated vegetables or water; frequently spread person to person; immunocompromised host	Onset of 24-48 hours; nausea, vomiting, diarrhea	Fluid and electrolytes; antibiotics	Self-limiting
<i>Escherichia coli</i> (enterotoxigenic <i>E. coli</i> [ETEC], enteroaggregative <i>E. coli</i> [EAEC])	Ingestion of contaminated food or water; recent travel outside the United States or to a U.S. border area	Onset of 8-72 hours; watery diarrhea, fever, abdominal cramps, bloating, malaise, occasional vomiting	Fluid and electrolytes; antibiotics <sup>c</sup>	Self-limiting, usually within 3-5 days
Shiga toxin-producing <i>E. coli</i> (STEC), including <i>E. coli</i> O157:H7 and non-O157 strains	Ingestion of contaminated food or water; direct person-to-person spread	Onset of 8-72 hours; watery and often bloody diarrhea, abdominal cramps, hemolytic uremic syndrome	Fluid and electrolytes	Self-limiting, usually within 5-10 days
<i>Clostridium difficile</i>	Antibiotic-associated diarrhea leading to pseudomembranous colitis	Onset during or up to several weeks after antibiotic therapy; watery or mucoid diarrhea, high fever, cramping	Fluid and electrolytes; discontinuation of offending agent;	Self-limiting

			antibiotics	
<i>Clostridium perfringens</i>	Ingestion of contaminated food, especially meat and poultry	Onset of 8-14 hours; watery diarrhea without vomiting, cramping, mid-epigastric pain	Fluid and electrolytes	Self-limiting; usually resolves within 24 hours
<i>Staphylococcus aureus</i>	Ingestion of improperly cooked or stored food	Onset of 1-6 hours; nausea, vomiting, watery diarrhea	Fluid and electrolytes	Self-limiting
<i>Yersinia enterocolitica</i>	Ingestion of contaminated food	Onset within 16-48 hours; fever, abdominal pain, diarrhea, vomiting	Fluid and electrolytes; antibiotics may be needed in severe cases	Self-limiting, although diarrhea may persist for up to 3 weeks
<i>Vibrio cholerae</i>	Ingestion of contaminated food, including undercooked or raw seafood; recent travel outside the United States	Onset within 24-48 hours; painless, watery, and often voluminous diarrhea, vomiting	Fluid and electrolytes; antibiotics needed in moderate-severe cases	Self-limiting, although severe, fatal illness may occur
<i>Bacillus cereus</i>	Ingestion of contaminated food	Onset within 10-12 hours; abdominal pain, watery diarrhea, tenesmus, nausea, vomiting	Fluid and electrolytes	Self-limiting
<b>Protozoal</b>				
<i>Giardia lamblia</i>	Ingestion of water contaminated with human or animal feces; frequently spread person to person; immunocompromised host	Onset of 1-3 weeks; acute or chronic watery diarrhea, nausea, vomiting, anorexia, flatulence, abdominal bloating, epigastric pain	Fluids and electrolytes; antimicrobial therapy <sup>d</sup>	Resolves with treatment
<i>Cryptosporidium</i> spp.	Frequently spread person to person; travel outside the United States; AIDS, immunocompromised host	Onset of 2-14 days; acute or chronic watery diarrhea, abdominal pain, flatulence, malaise	Fluid and electrolytes; antimicrobial therapy <sup>e</sup>	Self-limiting, lasting up to 3 weeks, except in patients with AIDS or other immunosuppressive diseases
<i>Entamoeba histolytica</i>	Travel outside the United States; fecal-soiled food or water; immunocompromised host	Chronic watery diarrhea, abdominal pain, cramps	Fluid and electrolytes; antibiotics <sup>f</sup>	Good, except for immunocompromised host
<i>Isospora belli</i>	Ingestion of contaminated food or water; immunocompromised host	Onset of approximately 1 week; profuse watery diarrhea, malaise, anorexia, weight loss, abdominal cramps	Fluid and electrolytes; antibiotics	Self-limited, remitting in 2-3 weeks

Key: AIDS = Acquired immunodeficiency syndrome.

<sup>a</sup> Empirical therapy with prescription antibiotics (e.g., azithromycin or erythromycin) should be considered for patients with febrile diarrheal illness, especially if moderate-severe invasive disease is suspected, and for patients in whom supportive therapy fails to manage symptoms. Ciprofloxacin has been recommended, but it is no longer considered a

first-line agent because many *Campylobacter* strains are resistant to fluoroquinolones.

<sup>b</sup> Antibiotics are not indicated routinely for *Salmonella* gastroenteritis; antibiotic therapy is used in infants and young children who fail to respond to supportive treatment, who do not spontaneously remit, or who are at increased risk of disseminated disease. Antibiotic therapy is also indicated for suspected bacteremia in patients at high risk for this complication. These include patients who appear to be toxic with high fever ( $\geq 102.2^{\circ}\text{F}$  [ $39^{\circ}\text{C}$ ]); infants (<3 months); older adult patients ( $\geq 65$  years); patients with cancer, immunodeficiency (e.g., AIDS), or hemoglobinopathy (e.g., sickle cell disease); patients receiving corticosteroids or who are on hemodialysis; and patients with vascular grafts or prosthetic joints. Fluoroquinolones are used for adults; ceftriaxone is used for children. Duration of antimicrobial therapy is usually 7-10 days.

<sup>c</sup> Antibiotic treatment with fluoroquinolones, azithromycin, or rifaximin (prescription antibiotics) is given for travelers' diarrhea caused by *E. coli*. Trimethoprim/sulfamethoxazole is no longer an optimal choice because of increasing worldwide resistance. Antibiotic treatment is not recommended for gastroenteritis caused by *E. coli* O157:H7 because the treatment is likely to enhance toxin release and may increase risk for hemolytic uremic syndrome.

<sup>d</sup> Self-treatment of giardiasis is not appropriate; metronidazole, nitazoxanide, and tinidazole are effective prescription alternatives for treating giardiasis.<sup>42,43</sup>

<sup>e</sup> Self-treatment of cryptosporidiosis is not appropriate. Symptomatic relief of cryptosporidiosis may be achieved in patients with AIDS by adding paromomycin and azithromycin (both prescription antimicrobial agents) to patients' antiretroviral therapy.<sup>42</sup>

<sup>f</sup> Self-treatment of amebiasis is not appropriate; prescription therapy with metronidazole followed by either paromomycin or iodoquinol is preferred.<sup>42</sup>

Accessed at <http://aapredbook.aappublications.org/>, March 11, 2013.

## Bacterial Gastroenteritis

Bacterial pathogens cause approximately 10% of acute diarrheal illnesses each year; most cases result from food-borne transmission. Pathogens most commonly responsible, in order of decreasing causality, are *Campylobacter* spp.; *Salmonella* spp.; *Shigella* spp.; *Escherichia coli* (including O157:H7, non-O157:H7 Shiga toxin-producing *E. coli* [STEC], enterotoxigenic *E. coli* [ETEC], diffusely adherent *E. coli* [DAEC], and other diarrheagenic strains); *Staphylococcus* spp.; *Clostridium* spp.; *Yersinia enterocolitica*; and *Bacillus cereus*. In addition, *Aeromonas* spp., *Arcobacter* spp., enterotoxigenic *Bacteroides fragilis*, *Klebsiella oxytoca*, *Laribacter hongkongensis*, and *Plesiomonas shigelloides* cause acute diarrhea.<sup>12,13</sup>

Bacteria cause diarrhea through elaboration of enterotoxin (e.g., ETEC and *Staphylococcus aureus*), by attachment and production of localized inflammatory changes in the gut (e.g., enteroaggregative *E. coli* [EAEC], enteropathogenic *E. coli*, STEC, and *Clostridium difficile*), or by directly invading the mucosal epithelial cells (e.g., *Shigella*, *Salmonella*, *Yersinia*, *Campylobacter jejuni*, and invasive *E. coli*).<sup>14,15</sup> Patients with diarrhea caused by toxin-producing pathogens have a watery diarrhea, which primarily involves the small intestine. If the large intestine is the primary site of infection, invasive organisms produce a dysentery-like (bloody diarrhea) syndrome characterized by fever, abdominal cramps, tenesmus (straining), and the frequent passage of small-volume stools that may contain blood and mucus. Clinical features of common bacterial diarrheas are presented in [Table 16-1](#). Enteric infection, most notably bacterial infection caused by *Campylobacter*, *Shigella*, *Salmonella*, and diarrheagenic *E. coli*, can cause prolonged bowel dysfunction, including irritable bowel syndrome (IBS), a functional bowel disorder characterized by abdominal pain and discomfort following resolution of the infection. Norovirus may also cause postinfectious IBS. IBS develops in 2%-30% of patients following enteric infection, depending on the causative agent, and is usually diagnosed 1-2 years after an episode of acute bacterial gastroenteritis.<sup>16</sup> The prognosis is favorable for most patients, and symptoms of IBS resolve 4-8 years after diagnosis. Acute gastroenteritis may also unmask or exacerbate underlying chronic gastrointestinal diseases, such as celiac disease, Crohn's disease, or ulcerative colitis.

## Protozoal Diarrhea

Diarrhea may also be caused by protozoa, including *Giardia lamblia*, *Entamoeba histolytica*, *Isospora belli*, and *Cryptosporidium* spp. No nonprescription therapies are available to manage diarrhea caused by these pathogens, and self-management is inappropriate.

### Food-Borne Gastroenteritis

Food-borne transmission of pathogens causes 47.8 million episodes of acute gastroenteritis that lead to 135,000 hospitalizations and approximately 3000 deaths in the United States each year.<sup>2,17</sup> When pathogens are identified, 59% of those infections are caused by viruses (predominantly noroviruses), 39% by bacteria, and 2% by protozoa.<sup>17</sup> Recent surveillance statistics on the incidence of food-borne illnesses confirm that *Salmonella* and *Campylobacter*, which caused 16.47 and 14.31 cases of illness per 100,000 population in 2011, respectively, are the most frequently diagnosed bacterial pathogens. These are followed by *Shigella* (3.21 cases per 100,000 population), STEC O157:H7 (0.98 cases per 100,000 population), *Listeria* (0.34 cases per 100,000 population), *Vibrio* (0.33 cases per 100,000 population), and *Yersinia* (0.32 cases per 100,000 population).<sup>18</sup>

Outbreaks of food-borne bacterial infection have been traced to poor sanitation and manufacturing practices in food production facilities, including meat-processing plants, and contamination of foods in various retail locations such as grocery stores and restaurants. Outbreaks of infection have also been associated with specific foods (Table 16-2).<sup>18</sup> Therefore, taking a thorough history regarding the patient's food intake 48-72 hours before the onset of diarrhea is essential in identifying a possible cause.

Outbreaks of acute food-borne illness caused by *E. coli* O157:H7 and other STECs are a major public health issue. Toxins produced by these organisms cause an acute bloody diarrhea and may also be associated with serious, potentially fatal systemic complications such as hemolytic uremic syndrome or thrombotic thrombocytopenic purpura. Other causes of food-borne gastroenteritis include *Listeria monocytogenes*, *Cyclospora cayetanensis*, and rotovirus.

**TABLE 16-2 Specific Foods Associated with Food-Borne Gastroenteritis**

Organism	Associated Foods		
Shiga toxin-producing <i>E. coli</i> (STEC), including <i>E. coli</i> O157:H7 and non-O157 strains		Apple cider, unpasteurized	Lettuce
Bologna	Milk, raw		
Clover sprouts, raw	Cookie dough, raw, refrigerated prepackaged		
Eggs	Spinach		
Gouda cheese			
Ground beef (undercooked)			
<i>Salmonella</i>		Chicken	Papayas
Dry dog food <sup>a</sup>	Peanut butter		
Eggs	Pine nuts		
Ground beef	Pistachio nuts		
Ground turkey	Red and black pepper spice		
Jalapeno peppers	Yellowfin tuna, raw, scraped, ground		
Mangoes			
Melons (e.g., cantaloupe)			
<i>Campylobacter</i>		Milk	
Chicken			

<i>Listeria</i>		Hummus
Melons		
Ricotta cheese		
<i>Cyclospora</i>	Raspberries	

<sup>a</sup> *Salmonella* infection is a zoonotic disease, i.e., the infection can be transmitted from animals to people, and people have developed *Salmonella* infections after contact with contaminated dry pet food or with an animal that has eaten contaminated dry pet food. Spread is by the fecal-oral route.

Source: Adapted from reference 17.

### Travelers' Diarrhea

Travelers' diarrhea is an acute, secretory diarrhea acquired mainly through ingestion of contaminated food or water. It is usually caused by bacterial enteropathogens; however, a cause may not be identifiable in as many as 40% of cases. Enterotoxigenic *E. coli* (ETEC), enteroaggregative *E. coli* (EAEC), and diffusely adherent *E. coli* (DAEC) are responsible for most cases of travelers' diarrhea.<sup>19-21</sup> ETEC is found in 50%-76% of travelers with diarrhea in various areas around the world.<sup>21</sup> Other important pathogens that cause travelers' diarrhea include *Shigella* spp., *Salmonella* spp., *C. jejuni*, *Aeromonas* spp., *Plesiomonas* spp., and noncholera *Vibrio*; noroviruses cause 12%-17% of cases.<sup>21</sup> The causative organisms are found most often on foods such as fruits, vegetables, raw meat, seafood, and even hot sauces. Less commonly, pathogens are found in the local water, including ice cubes. After ingestion, ETEC produces two plasmid-mediated enterotoxins that cause symptoms; one of these enterotoxins is closely related structurally, functionally, and immunologically to cholera toxin. The pathogenic mechanisms underlying diarrhea caused by EAEC are not well understood. These organisms may produce disease through elaboration of an enterotoxin or a cytotoxin, or by some other means. The diarrheal disorder caused by these organisms is characterized in [Table 16-1](#). Patients may experience between three and eight (or more) watery stools per day, with symptoms usually subsiding over 3-5 days.

### Food-Induced Diarrhea

Food intolerance can provoke diarrhea and may result from a food allergy or ingestion of foods that are excessively fatty or spicy or contain a high amount of dietary fiber or many seeds. Dietary carbohydrates (e.g., lactose and sucrose) are normally hydrolyzed to monosaccharides by the enzyme lactase. If not hydrolyzed, these carbohydrates pool in the lumen of the intestine and produce an osmotic imbalance. The resulting hyperosmolarity draws fluid into the intestinal lumen, causing diarrhea. Lactase activity may be reduced by infectious diarrhea; thus, acute viral diarrhea may cause temporary milk intolerance in patients of all ages. Lactase deficiency resulting from viral gastroenteritis is short-lived, but it is particularly problematic during the first few days of the disease. Infants born with lactase deficiency and adults who develop lactase deficiency are intolerant of cow milk and milk-based products. Lactase enzyme products are effective treatments for some patients (see Treatment of Diarrhea).

### Clinical Presentation of Diarrhea

The most common signs and symptoms of acute infectious diarrheal illnesses are shown in [Table 16-1](#). Variability in the causes of diarrhea makes identification of the pathophysiologic mechanisms difficult. The etiology, and subsequently the pathophysiology, can be determined by conducting a thorough medical history in most cases. However, a complete medical assessment, including clinical laboratory evaluation, may be required to identify the cause in a subset of patients with severe or persistent diarrhea.

Diarrhea can be classified as osmotic, secretory, inflammatory, or motor, depending on the underlying pathophysiologic mechanisms that disrupt normal intestinal function. The common mechanisms of acute diarrhea are osmotic and secretory, whereas motor and inflammatory mechanisms commonly underlie chronic diarrheal illnesses. [Table 16-3](#) correlates the clinical groups and mechanisms with their most common causes.

**TABLE 16-3 Clinical Classification of Diarrhea**

Type	Mechanism	Common Causes
Osmotic		<ul style="list-style-type: none"> <li>Unabsorbed solutes in intestines increase luminal osmotic load,</li> </ul> Noroviruses, rotaviruses, <i>Escherichia coli</i> ,

		retarding fluid absorption.	<i>Campylobacter jejuni</i> , lactase deficiency, excess magnesium antacid intake
<ul style="list-style-type: none"> <li>• Decreased absorption of solutes and fluid can be secondary to brush border damage caused by lactase deficiency or infection.</li> </ul>			
<ul style="list-style-type: none"> <li>• Viral-induced damage to epithelial cells accelerates migration of immature crypt cells to the tip of the villus; altered epithelial turnover also decreases absorption.</li> </ul>			
Secretory	<ul style="list-style-type: none"> <li>• Stimulation of crypt cells produces net flow of electrolytes and fluids into intestinal lumen.</li> </ul>	<i>C. jejuni</i> , <i>Clostridium difficile</i> , <i>E. coli</i> , <i>Salmonella</i> , <i>Shigella</i> , <i>Vibrio</i> , rotaviruses, <i>Giardia lamblia</i> , <i>Cryptosporidium</i> spp., <i>Isospora</i> , ileal resection, thyroid cancer	
<ul style="list-style-type: none"> <li>• Tumors can secrete GI hormones and peptides that act as secretagogues.</li> </ul>			
Inflammatory	<ul style="list-style-type: none"> <li>• Impaired fluid absorption and leaking of mucus, blood, and pus into lumen caused by inflammation of intestinal mucosa (e.g., IBD) or bacterial infection (i.e., dysentery).</li> </ul>	<i>C. jejuni</i> , <i>E. coli</i> , <i>Salmonella</i> , <i>Shigella</i> , <i>Yersinia</i> , <i>Entamoeba histolytica</i> , ulcerative colitis, Crohn's disease	
Motor	<ul style="list-style-type: none"> <li>• Abnormally rapid intestinal transit time reduces contact time between luminal contents and absorptive areas of intestinal wall.</li> </ul>	IBS, diabetic neuropathy	

Key: GI = Gastrointestinal; IBD = inflammatory bowel disease; IBS = irritable bowel syndrome.

Bacterial enterotoxins play a role in the pathophysiology of secretory diarrheas. Enterotoxins elaborated by *E. coli* and *Vibrio cholerae* evoke the release of endogenous secretagogues that mediate secretory reflexes, including serotonin, substance P, and vasoactive intestinal peptide. Some enterotoxins, such as cholera toxin, can directly stimulate GI secretomotor neurons to increase intestinal secretion. *Clostridium difficile* enterotoxin A also injures enterocytes and evokes a necroinflammatory response that causes a secretory diarrhea. Although viruses such as rotavirus also produce enterotoxins, the role of viral enterotoxins in the disease pathophysiology is uncertain. In

addition, inflammatory mediators (e.g., interleukins 1 and 6, prostaglandins, substance P, tissue necrosis factor- $\alpha$ , and platelet-activating factor) evoked by enteric infection stimulate a characteristic GI motility pattern that leads to the urgent defecation associated with diarrhea. This altered motility also causes abdominal cramps.

Stool characteristics give valuable information about the diarrhea's pathophysiology. For example, undigested food particles in the stool suggest disease of the small intestine. Black, tarry stools may indicate upper GI bleeding, and red stools suggest possible lower bowel or hemorrhoidal bleeding or simply recent ingestion of red food (e.g., beets) or drug products (e.g., rifampin). In secretory diarrhea of the small bowel, chloride secretion and inhibition of sodium absorption appear to be the major events; thus, stools will be high in sodium.<sup>14</sup> Passage of many small-volume stools suggests a colonic disorder. Yellowish stools may suggest the presence of bilirubin and a potentially serious pathology of the liver. A whitish tint to the stool suggests a fat malabsorption disease.

Fluid and electrolyte imbalance is the major complication of diarrheal illness. Therefore, assessment of the patient's risk for dehydration and the degree of dehydration present is a key factor in determining the appropriateness of self-care and the need for medical referral. The specific signs and symptoms of dehydration are associated with the severity of the diarrhea, as well as the etiology and degree of fluid and electrolyte losses (Table 16-4).<sup>22</sup>

**TABLE 16-4 Assessment of Dehydration and Severity of Acute Diarrhea**

	<i>Self-Treatable</i>		<i>Not Self-Treatable</i>
	<i>Minimal or No Dehydration</i>	<i>Mild-Moderate Dehydration/Diarrhea</i>	<i>Severe Dehydration/Diarrhea</i>
Degree of dehydration (% loss of body weight)	$\leq 3\%$	3%-9%	$\geq 9\%$
Signs of dehydration <sup>a</sup>			
Mental status	Good, alert	Normal, fatigued or restless, irritable	Apathetic, lethargic, unconscious
Thirst	Drinks normally, might refuse liquids	Thirsty, eager to drink	Drinks poorly, unable to drink
Heart rate	Normal	Normal to increased	Tachycardia, bradycardia in most severe cases
Quality of pulses	Normal	Normal to decreased	Weak, thready, impalpable
Breathing	Normal	Normal, fast	Deep
Eyes	Normal	Slightly sunken <sup>b</sup>	Deeply sunken <sup>b</sup>
Tears	Present	Decreased <sup>b</sup>	Absent
Mouth and tongue	Moist	Dry	Parched
Skin fold	Instant recoil	Recoil in <2 seconds	Recoil in $\geq 2$ seconds
Capillary refill	Normal	Prolonged	Prolonged, minimal
Extremities	Warm	Cool	Cold, mottled, cyanotic

Urine output	Normal to decreased	Decreased <sup>b</sup>	Minimal <sup>b</sup>
Number of unformed stools/day	<3	3-5	6-9
Other signs/symptoms	Afebrile, normal blood pressure, no orthostatic changes in blood pressure/pulse	May be afebrile or may develop fever $\geq 102.2^{\circ}\text{F}$ ( $39^{\circ}\text{C}$ ); normal blood pressure; possible mild orthostatic blood pressure/pulse changes with or without mild orthostatic-related symptoms <sup>c</sup> ; sunken fontanelle <sup>d</sup>	Fever $\geq 102.2^{\circ}\text{F}$ ( $39^{\circ}\text{C}$ ), low blood pressure, dizziness, severe abdominal pain

<sup>a</sup>If signs of dehydration are absent, rehydration therapy is not required. Maintenance therapy and replacement of stool losses should be undertaken.

<sup>b</sup>Signs and symptoms experienced especially by young children.

<sup>c</sup>Postural (orthostatic) hypotension is defined as a drop in the systolic and/or diastolic pressure of greater than 15-20 mm Hg on movement from a supine to an upright position and may cause lightheadedness, dizziness, or fainting. On rising, the diastolic pressure normally remains the same or increases slightly, and the systolic pressure drops slightly. If the blood pressure drops, the pulse should be checked simultaneously; the pulse rate should increase as blood pressure drops. Failure of the pulse to rise suggests the problem is neurogenic (e.g., diabetic patients with peripheral neuropathy) or that the patient may be taking a beta-blocker. The presence of orthostatic hypotension suggests that the patient has lost  $\geq 1$  liter of vascular volume, and referral for medical care is necessary.

<sup>d</sup>Signs and symptoms of concern for young infants.

Source: Adapted from reference 22.

Children younger than 5 years and adults older than 65 years are at greater risk for complications than other age groups. In the United States, most children recover completely from diarrhea; however, approximately 300-450 children (mostly infants) die annually from complications of acute gastroenteritis.<sup>3,22</sup> Children 2 years of age and younger are more likely to suffer complications that require hospitalization. In newborns, water may make up 75% of total body weight; severe diarrhea may cause water loss equal to 10% or more of body weight. After 8-10 bowel movements within a 24-hour period, a 2-month-old infant could lose enough fluid to cause circulatory collapse and renal failure.

In recent years, deaths from viral and bacterial GI infection have increased most sharply among people 65 years of age and older. Diarrhea in this population is likely to be more severe than in other adults; older adults experience the highest rate of death from enteric infections.

## Treatment of Diarrhea

### Treatment Goals

The goals of self-treatment of diarrhea are to (1) prevent or correct fluid and electrolyte loss and acid-base disturbance, (2) control symptoms, (3) identify and treat the cause, and (4) prevent acute morbidity and mortality.

### General Treatment Approach

Infectious diarrhea is often self-limiting. Initial self-management for adults and children with mild-moderate, uncomplicated diarrhea should focus on fluid and electrolyte replacement by administering commercially available oral rehydration solutions (ORS) in adequate doses (Table 16-5). Simultaneous implementation of oral rehydration and specific dietary measures is appropriate for treating mild-moderate diarrheal illness. Symptomatic control can also be achieved by using nonprescription antidiarrheal drugs, such as loperamide, in carefully selected patients. Normal function of the alimentary tract is often restored in 24-72 hours without additional treatment.

**TABLE 16-5 Selected Oral Rehydration Products**

Trade Name	Osmolarity	Calories	Carbohydrate	Electrolytes
CeraLyte 50	<200	160	Rice starch polymers 40	Sodium 50 mEq/L; chloride 40 mEq/L;

Powder Packets	mOsm/L	cal/L	g/L; sucrose 10 g/L	citrate 30 mEq/L; potassium 20 mEq/L
CeraLyte 70 Powder Packets	<260 mOsm/L	160 cal/L	Rice starch polymers 40 g/L	Sodium 70 mEq/L; chloride 60 mEq/L; citrate 30 mEq/L; potassium 20 mEq/L
CeraLyte 75 Powder Packets	<250 mOsm/L	160 cal/L	Rice starch polymers 40 g/L	Sodium 75 mEq/L; chloride 80 mEq/L; citrate 30 mEq/L; potassium 20 mEq/L
CeraLyte 90 Powder Packets	<260 mOsm/L	160 cal/L	Rice starch polymers 40 g/L	Sodium 90 mEq/L; chloride 80 mEq/L; citrate 30 mEq/L; potassium 20 mEq/L
Enfamil Enfalyte Solution	160 mOsm/L	126 cal/L	Corn syrup solids 30 g/L	Sodium 50 mEq/L; chloride 45 mEq/L; citrate 33 mEq/L; potassium 25 mEq/L
Pedialyte <sup>a</sup>	249 mOsm/L	100 cal/L	Dextrose 20 g/L; fructose 5 g/L	Sodium 45 mEq/L; chloride 35 mEq/L; citrate 30 mEq/L; potassium 20 mEq/L
Pedialyte Freezer Pops <sup>b</sup>	270 mOsm/L	6.25 cal/L	Dextrose 25 g/L	Sodium 45 mEq/L; chloride 35 mEq/L; citrate 30 mEq/L; potassium 20 mEq/L

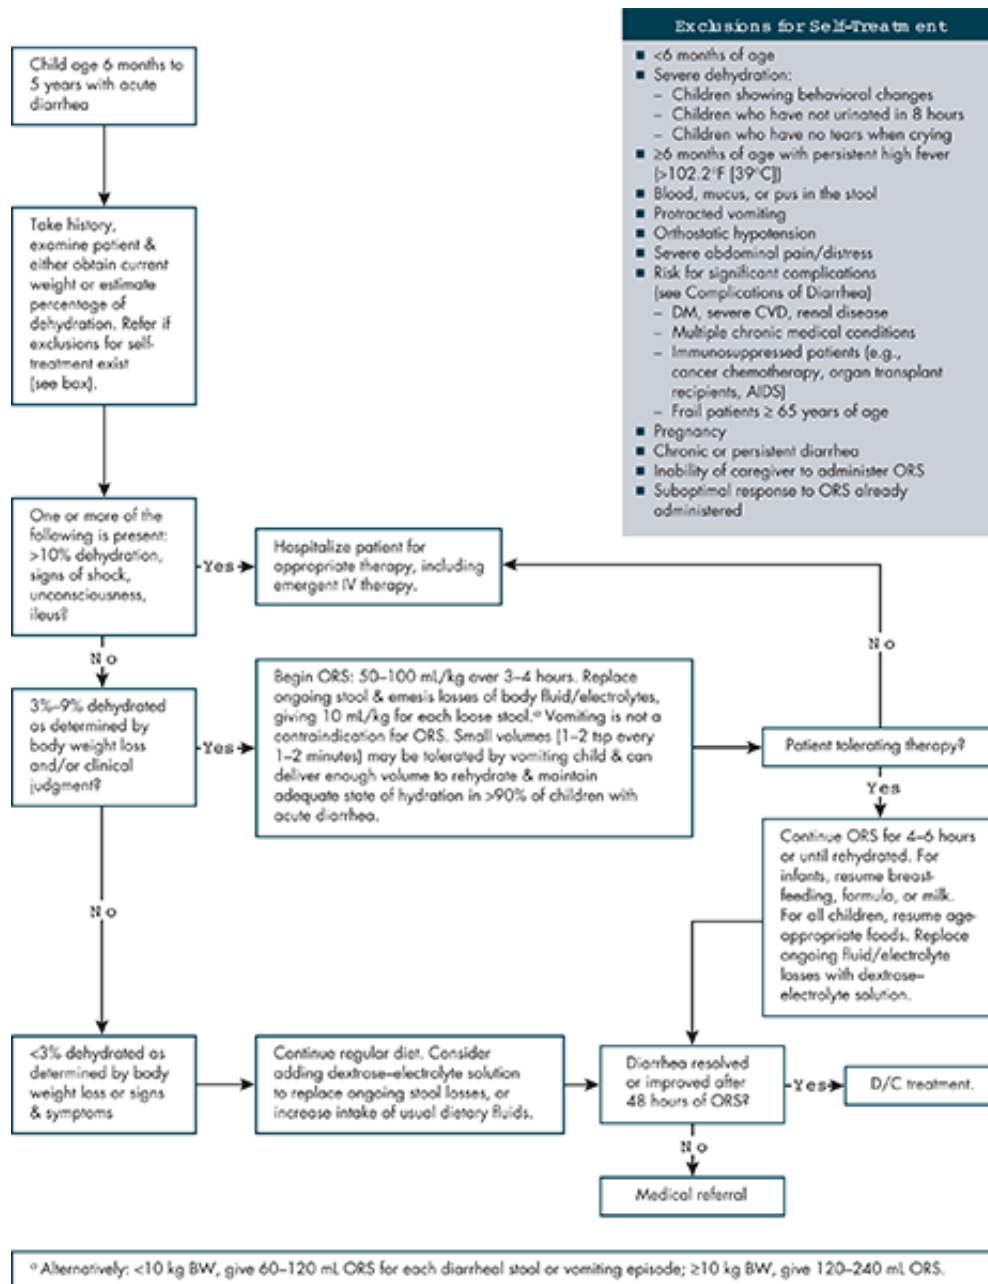

Key: ORS = Oral rehydration solution; WHO = World Health Organization.

<sup>a</sup>Many generic products (e.g., store brands) are available.

<sup>b</sup>Product to be used with appropriate maintenance ORS.

Diarrhea of any severity in infants younger than 6 months of age and moderate diarrhea in children 2 years of age and younger who have unusually high fluid output or mental status changes require evaluation by a primary care provider, a pediatrician, or a health care provider in an emergency department. Severe diarrhea constitutes a medical emergency, especially in young children, and requires immediate referral for medical evaluation and treatment with intravenous (IV) fluid therapy. Specific exclusions for self-treatment that require referral for medical evaluation are listed in [Figure 16-1](#).

Patients with uncomplicated acute diarrhea who are otherwise healthy usually improve clinically within 24-48 hours. If the condition remains the same or worsens after 48 hours of onset, medical referral is necessary to prevent complications. Patients who have stool that contains blood or mucus need medical evaluation. Certain medical conditions can increase the risk for dehydration. Referral for medical care should be considered for patients with diabetes mellitus, severe cardiovascular or renal diseases, or multiple unstable chronic medical conditions. Patients with severe abdominal pain (particularly those >50 years of age) may have a complicating illness such as ischemic bowel disease and should be referred for medical evaluation. Immunocompromised patients, such as those receiving cancer treatment, organ transplant recipients, and patients with AIDS, also need medical evaluation because their diarrhea will often be complicated and difficult to manage. Self-care during pregnancy is not appropriate; pregnant women who develop diarrhea should consult with a primary care provider or an obstetrician.

Self-care of acute diarrhea in children 6 months to 5 years. Key: AIDS = Acquired immunodeficiency syndrome; BW = body weight; CVD = cardiovascular disease; D/C = discontinue; DM = diabetes mellitus; IV = intravenous; ORS = oral rehydration solution.

## Nonpharmacologic Therapy

### Fluid and Electrolyte Management

Rehydration using ORS is the preferred treatment for mild-moderate diarrhea. This approach is as effective as IV therapy in managing fluid and electrolytes in children with mild-moderate dehydration secondary to diarrhea. Water absorption in the small intestine is passive and depends on the absorption of electrolytes and selected solutes such as sodium, chloride, glucose, small peptides, and amino acids. As these substances are absorbed, water accompanies their movement to maintain an isotonic state. Sodium ion transport is the primary mechanism controlling water movement. An active sodium-potassium adenosine triphosphatase pump present in enterocytes moves sodium into the cell in exchange for potassium ions. Other transport mechanisms include the sodium-glucose and sodium-amino acid co-transport processes (each of which transports these substances into the enterocytes) and the sodium luminal exchange mechanism. The sodium-glucose co-transport mechanism, in which glucose absorption is coupled with active transport of sodium, is important in the management of diarrhea. Unlike other sodium transport systems, the sodium-glucose co-transport mechanism is not adversely affected by most diarrheal diseases, and hypotonic ORS containing low concentrations of glucose or dextrose (2%-2.5%) can be useful in managing fluid and electrolyte balance. The sugar molecules provide little caloric support but facilitate intestinal

sodium and water absorption. Maximal sodium absorption occurs at a molar glucose-to-sodium ratio close to 1. Health care providers can safely recommend an ORS for mild-moderate diarrhea.

Depending on the patient's fluid and electrolyte status, oral treatment may be carried out in two phases: rehydration therapy and maintenance therapy. Rehydration over 3-4 hours quickly replaces water and electrolyte deficits to restore normal body composition. In the maintenance phase, electrolyte solutions are given to maintain normal body composition until adequate dietary intake is reestablished. [Figures 16-1](#) and [16-2](#) outline rehydration and maintenance therapies, including fluid and electrolyte recommendations for children and adults. Although ORS is generally recommended for adults with diarrhea, little evidence supports this use, and ORS may not provide any real benefit to otherwise healthy adults with mild diarrhea who can maintain an adequate fluid intake during the episode of diarrhea. For these patients, fluid and electrolyte status can be maintained by increasing intake of fluids such as clear juices, soups, or sports drinks.

A variety of oral rehydration products are available ([Table 16-5](#)). Most products are premixed solutions; a few are available as dry powders of glucose and electrolytes that require the addition of water. The premixed products are preferred for use in children because they are safe and convenient, and improper mixing of dry powders by caregivers has led to fluid and electrolyte complications and injury. All available premixed solutions are equally safe and effective; there is no evidence that one product is clinically superior to another for rehydration. The World Health Organization (WHO) and United Nations Children's Fund (UNICEF) recommend use of an ORS containing 75 mEq/L of sodium.<sup>23</sup> Compared with the standard WHO ORS (which contains 90 mEq/L of sodium), this ORS significantly reduces the need for unscheduled IV therapy, the duration of diarrhea, stool output, and the incidence of vomiting in children with noncholera diarrhea. This ORS is also effective in children and adults with cholera, although transient, asymptomatic hyponatremia may develop in adults. Rehydration solutions available in the United States contain 70-90 mEq/L of sodium; maintenance ORSs contain 45-50 mEq/L of sodium.

Some cereal-based products use complex carbohydrates (e.g., rice syrup solids) instead of glucose. Complex carbohydrates are converted into glucose at the intestinal brush border and provide more co-transport molecules while reducing the osmotic load of the ORS. Cereal-based ORS therapy potentially reduces stool volume by 20%-30% in children with cholera, but this therapy may not significantly alter stool volume in children with noncholera acute diarrhea.

A variety of common household oral solutions have also been used for oral rehydration and maintenance ([Table 16-6](#)). These solutions may be sufficient to manage mild, self-limiting diarrhea in some patients, but they should be avoided if dehydration or moderate-severe diarrhea is present. Unlike commercial ORS, these remedies are not formulated on the basis of the physiology of acute diarrhea. The inappropriately high carbohydrate content and osmolality of these solutions can worsen diarrhea, and their low sodium content can contribute to the development of hyponatremia. Sports drinks may be used in children older than 5 years and adults if additional sources of sodium, such as crackers or pretzels, are used concomitantly. Colas, ginger ale, apple juice, sports drinks, and similar products are not recommended for infants and young children (6 months to 5 years of age) with diarrhea. Tea, another popular household remedy, is also inappropriate for children because of its low sodium content. Chicken broth is not recommended because of its inappropriately high sodium content.

## Dietary Management

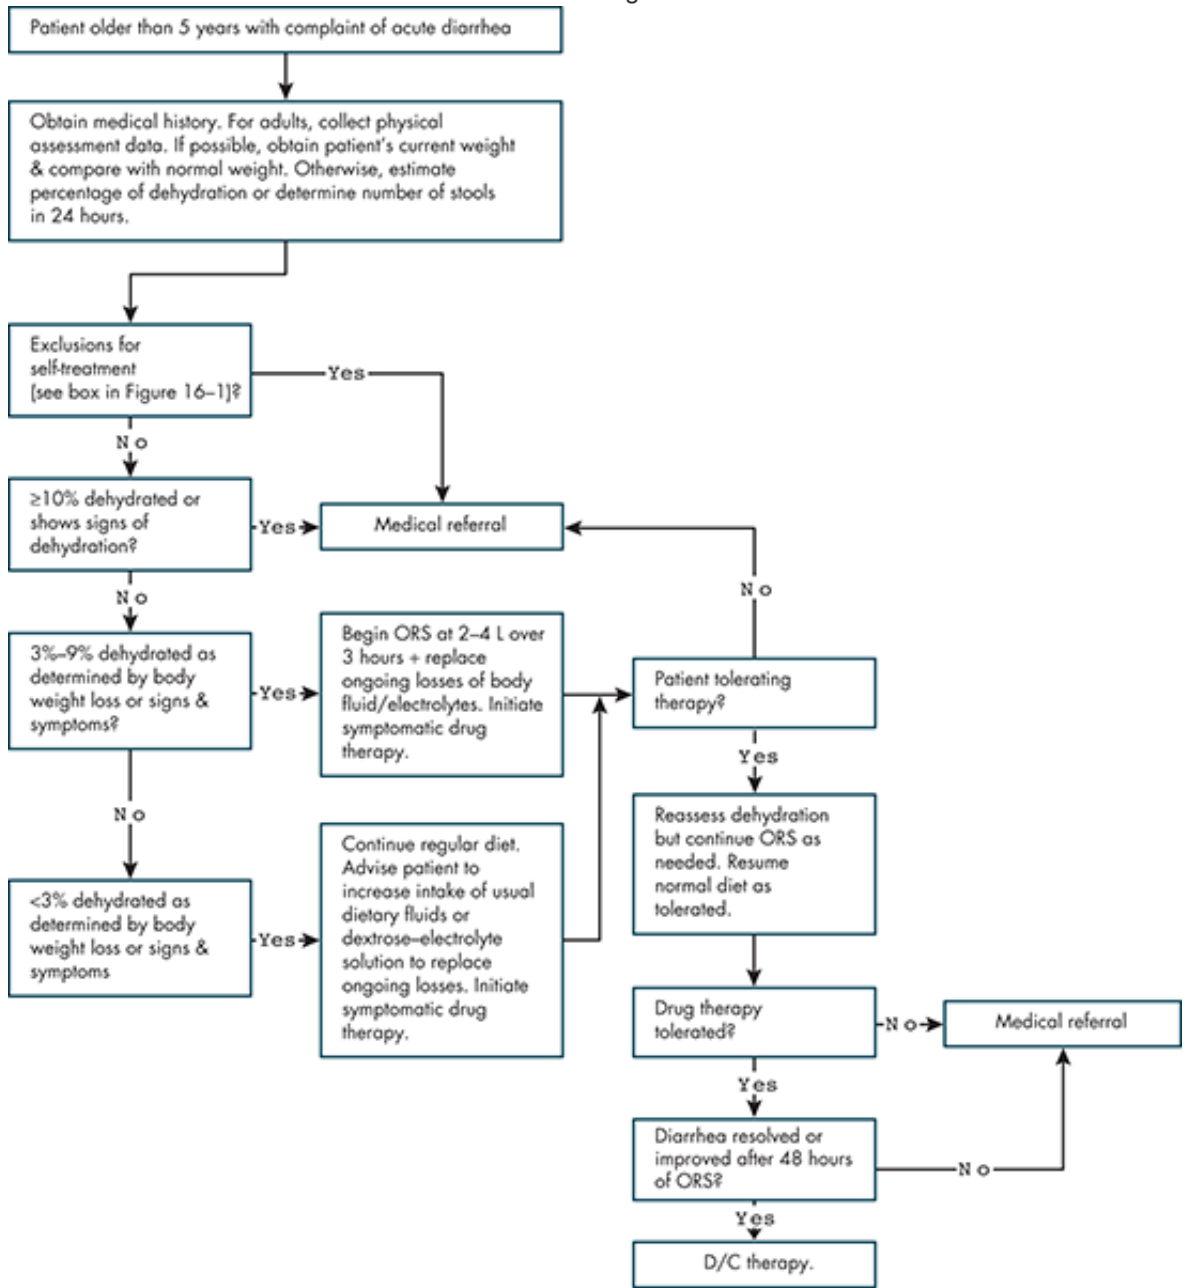

Oral intake does not worsen diarrhea, and clinically significant nutrient malabsorption is uncommon in acute diarrhea. In fact, during acute diarrhea, patients are able to absorb 80%-95% of dietary carbohydrates, 70% of fat, and 75% of the nitrogen from protein. Furthermore, early refeeding, in combination with maintenance oral rehydration, improves outcomes in children by reducing the duration of the diarrhea, reducing stool output, and improving weight gain. Current guidelines recommend withholding food no longer than 24 hours and encourage the reintroduction of a normal, age-appropriate diet once the patient has been rehydrated, which should take no longer than 3-4 hours to accomplish.<sup>22</sup> Most infants and children with acute diarrhea can tolerate full-strength breast milk and cow milk. The BRAT diet (bananas, rice, applesauce, and toast) is not recommended; it provides insufficient calories, protein, and fat, especially in situations of strict or prolonged use.<sup>22</sup> Patients (or their parents) should be advised to avoid fatty foods, foods rich in simple sugars (e.g., carbonated soft drinks, juice, gelatin desserts) that can cause osmotic diarrhea, spicy foods that may cause GI upset, and caffeine-containing beverages, which can promote fluid secretion and may worsen diarrhea.

There is no evidence that fasting or dietary modification influence outcomes of acute diarrhea in adults; however, the previous recommendations about foods to avoid can be applied if a normal diet is not tolerated.<sup>22</sup>

## Preventive Measures

Infectious diarrhea, especially acute viral gastroenteritis, often occurs in congregate living conditions such as day care centers and nursing homes through person-to-person transmission. Isolating the individual with diarrhea, washing hands, and using sterile techniques are basic preventive measures that reduce the risk of transmission among such populations and their caregivers. Strict food handling, sanitation, and other hygienic practices help

control transmission of bacteria and other infectious agents.

Self-care of acute diarrhea in children older than 5 years, adolescents, and adults. Key: D/C = Discontinue; ORS = oral rehydration solution.

Short-term bismuth subsalicylate (BSS) prophylaxis is frequently recommended to provide protection against travelers' diarrhea; however, the Food and Drug Administration (FDA) has deemed that available data are insufficient to support prophylactic use of BSS.<sup>24</sup> Antibiotics with reliable activity against endemic enteropathogens (e.g., fluoroquinolones, rifaximin) provide effective prophylaxis. However, prophylactic antimicrobial agents are not currently recommended for most travelers.<sup>24</sup> Prophylactic antibiotics may be considered for short-term travelers who are high-risk hosts (e.g., immunosuppressed patients) or travelers with underlying conditions that may be complicated by diarrheal illness, or for critical trips during which even a short bout of diarrhea could adversely affect the purpose of the trip.<sup>25</sup>

**TABLE 16-6 Comparison of Electrolyte and Dextrose Concentrations of Household Fluids**

Clear Liquids	Sodium (mEq/L)	Potassium (mEq/L)	Bicarbonate (mEq/L)	Dextrose (g/L)	Osmolarity (mOsm/L)
Cola	2	0.1	13	50-150 dextrose and fructose	550

Seven Up	7.5	0.2	0	80 dextrose and fructose	564

## Pharmacologic Therapy

Although most acute, nonspecific diarrhea in the United States is self-limiting, nonprescription antidiarrheal products may provide symptom control and will usually do no harm when used according to label instructions. [Table 16-7](#) lists dosage and administration guidelines for these agents. However, evidence is lacking to show that pharmacologic agents other than loperamide and BSS reduce stool frequency or duration of disease in adults. [Table 16-8](#) lists available trade-name products that contain loperamide and BSS. No antidiarrheal drugs have been shown to significantly improve clinical outcomes of acute, nonspecific diarrhea in infants and children ages 5 years and younger.

### Loperamide

Loperamide is a popular, effective, and safe nonprescription antidiarrheal agent. It is a synthetic opioid agonist that lacks central nervous system (CNS) effects because it is a substrate for P-glycoprotein. P-glycoprotein is an efflux transporter found in many tissues, including the blood-brain barrier. Loperamide is so efficiently removed from the CNS by this efflux transporter that pharmacologically effective concentrations in the CNS are not normally achieved and the risk of CNS adverse effects is minimized.<sup>26</sup> Loperamide produces antidiarrheal effects by stimulating peripheral micro-opioid receptors on the intestinal circular muscles to slow intestinal motility and allow absorption of electrolytes and water. Disruption of cholinergic and noncholinergic mechanisms involved in the regulation of peristalsis may also contribute to this effect. Loperamide also has antisecretory effects that may be mediated through stimulation of GI micro-opioid receptors, inhibition of calmodulin function, and inhibition of voltage-dependent calcium channels.

Loperamide provides symptomatic relief of acute, nonspecific diarrhea. Its therapeutic effects include reduced daily fecal volume, increased viscosity and bulk volume, and reduced fluid and electrolyte loss. It may be used when the patient is afebrile or has a low-grade fever and does not have bloody stools. Nonprescription loperamide is labeled for use in children 6 years of age and older; the product information for prescription loperamide provides directions for use in children as young as 2 years of age. However, use of loperamide in children younger than 6 years is not recommended because it produces only modest, clinically insignificant effects on stool volume and duration of illness, with an unacceptably high risk of side effects, including life-threatening ileus and toxic megacolon.<sup>23</sup>

Loperamide is also indicated for treatment of travelers' diarrhea (in combination with antibiotics) and chronic diarrhea associated with IBS and inflammatory bowel disease, as well as to reduce the volume of discharge from high-output ileostomies. Off-label uses include control of chronic diarrhea secondary to diabetic neuropathy and other conditions, and control of toddler diarrhea (defined as diarrhea of at least 1 month in duration in an otherwise healthy, active, well-nourished child in whom stool examination has revealed no bacterial, viral, or protozoal pathogens). Off-label uses require medical supervision.

At usual doses ([Table 16-7](#)), loperamide has few side effects other than occasional dizziness and constipation. Infrequently occurring adverse effects include abdominal pain, abdominal distension, nausea, vomiting, dry mouth, fatigue, and hypersensitivity reactions. Loperamide is generally not recommended for use in patients with invasive bacterial diarrhea (enteroinvasive *E. coli*, *Salmonella*, *Shigella*, or *C. jejuni*) or antibiotic-associated diarrhea (*C. difficile*) because it may worsen diarrhea or cause toxic megacolon or paralytic ileus. However, there is no evidence that these complications occur in actual practice when loperamide is used with appropriate antimicrobial therapy. Patients with symptoms suggestive of infection with invasive organisms or antibiotic-associated diarrhea (i.e., fecal leukocytes, high fever, or blood or mucus in the stool) require medical evaluation for proper management. If abdominal distension, constipation, or ileus occurs, loperamide should be discontinued.

Very few clinically significant drug-drug interactions are reported for loperamide. Although loperamide is a substrate for P-glycoprotein, interactions with P-glycoprotein inhibitors (e.g., quinidine, ketoconazole, and ritonavir) do not appear to result in clinically significant CNS depression or opioid toxicity when loperamide is used in the

recommended doses.<sup>26</sup> Loperamide is metabolized primarily by CYP3A4 and CYP2C8. Concurrent administration of loperamide with other substrates for these enzymes (e.g., protease inhibitors, cyclosporine, erythromycin, or clarithromycin) may elevate loperamide concentrations, but the effect on loperamide disposition does not appear to be associated with clinically relevant outcomes when taken in the recommended doses.<sup>26,27</sup> However, loperamide may significantly decrease saquinavir concentrations, and patients receiving saquinavir should be advised not to use loperamide, especially for long periods of time.<sup>28</sup>

**TABLE 16-7 Recommended Dosages of Nonprescription Antidiarrheal Agents for Acute Diarrhea**

<i>Medication</i>	<i>Dosage Forms</i>	<i>Adult Dosages (maximum daily dosage)</i>	<i>Pediatric Dosages</i>	<i>Duration of Use</i>			
Loperamide				Caplets (2 mg), liquid (1 mg/7.5 mL)	4 mg initially, then 2 mg after each loose stool (not to exceed 8 mg/day)	Consult product instructions; not recommended for children <6 years except under medical supervision	48 hours
	6-8 years (48-59 lb):						
	Caplets: 2 mg initially, then 1 mg after each loose stool (not to exceed 4 mg/day)						
	Liquid: 1.3 mg (2 teaspoonfuls) initially, followed by 1 mg (1.5 teaspoonfuls) after each loose stool. Do not give more than 2.7 mg (4 teaspoonfuls) in 24 hours.						
	9-11 years (60-95 lb):						
	Caplets: 2 mg initially, then 1 mg after each loose stool (not to						

exceed 6 mg/day)				
Liquid: 1.3 mg (2 teaspoonfuls) initially followed by 1 mg (1.5 teaspoonfuls) after each loose stool. Do not give more than 4 mg (6 teaspoonfuls) in 24 hours.				
Bismuth subsalicylate	Tablets (262 mg), caplets (262 mg), liquids (262 mg/15 mL, 525 mg/15 mL)	525 mg every 30-60 minutes up to 4200 mg/day (8 doses/day)	Not recommended for children <12 years except under medical supervision	48 hours
Digestive enzymes (lactase)	Chewable tablets, caplets, liquids	5-15 drops placed in or taken with dairy product; 1-3 tablets or 1-2 capsules with first bite of dairy product	Same as adult dosage	Taken with each consumption of dairy product

### Bismuth Subsalsicylate

BSS is effective in the treatment of acute diarrhea. BSS reacts with hydrochloric acid in the stomach to form bismuth oxychloride and salicylic acid. Bismuth oxychloride is insoluble and poorly absorbed from the GI tract; less than 1% of the administered dose is absorbed systemically. The salicylate is readily and efficiently absorbed. Both moieties are pharmacologically active. The bismuth moiety exerts direct antimicrobial effects against ETEC and EAEC, *C. jejuni*, and other diarrheal pathogens, whereas the salicylate moiety exerts antisecretory effects that reduce fluid and electrolyte losses. These effects reduce the frequency of unformed stools, increase stool consistency, relieve abdominal cramping, and decrease nausea and vomiting. In travelers' diarrhea, the salicylate appears to be the active moiety. Its antisecretory effects may be mediated by several mechanisms, including inhibition of prostaglandin synthesis, inhibition of intestinal secretion through stimulation of sodium and chloride reabsorption, or disruption of calcium-mediated processes that regulate intestinal ion transport. The antimicrobial effects of the bismuth moiety have not been shown to be important in the treatment of travelers' diarrhea, although they may play a role in the prophylactic use of this drug. BSS also directly binds to enterotoxins produced by *E. coli* and other diarrheal pathogens; however, the clinical significance of this effect in the treatment of diarrhea is not clear.

BSS is FDA approved for management of acute diarrhea, including travelers' diarrhea, in adults and children 12 years of age and older; it is not recommended for use in young children. BSS is also indicated for indigestion and as an adjuvant to antibiotics for treating *Helicobacter pylori*—associated peptic ulcer disease. [Table 16-7](#) provides dosing information for BSS.

### TABLE 16-8 Selected Antidiarrheal Products

<b>Loperamide Products</b>	<b>Primary Ingredients</b>
Imodium A-D Caplets	Loperamide HCl 2 mg
Imodium EZ Chews (Tablets)	Loperamide HCl 2 mg
Imodium Advanced Caplets	Loperamide HCl 2 mg; simethicone 125 mg
Imodium Advanced Chewable Tablets	Loperamide HCl 2 mg; simethicone 125 mg
Imodium A-D Liquid	Loperamide HCl 1 mg/7.5 mL
<b>Bismuth Subsalicylate Products</b>	
Kaopectate Vanilla Flavor Liquid	Bismuth subsalicylate 262 mg/15 mL (contains 130 mg of salicylate)
Kaopectate Extra Strength Peppermint Flavor Liquid	Bismuth subsalicylate 525 mg/15 mL (contains 236 mg of salicylate)
Kaopectate Peppermint Flavor Liquid	Bismuth subsalicylate 262 mg/15 mL (contains 130 mg of salicylate)
Kaopectate Cherry Flavor Liquid	Bismuth subsalicylate 262 mg/15 mL (contains 130 mg of salicylate)
Kaopectate Antidiarrheal Caplets	Bismuth subsalicylate 262 mg (contains 99 mg of salicylate)
Maalox Total Relief Peppermint Flavor Liquid	Bismuth subsalicylate 525 mg/15 mL (contains 232 mg of salicylate)
Maalox Total Relief Strawberry Flavor Liquid	Bismuth subsalicylate 525 mg/15 mL (contains 232 mg of salicylate)
Pepto-Bismol Caplets	Bismuth subsalicylate 262 mg (contains 99 mg of salicylate)
Pepto-Bismol Cherry Liquid	Bismuth subsalicylate 262 mg/15 mL (contains 130 mg of salicylate)
Pepto-Bismol Cherry Chewable Tablets	Bismuth subsalicylate 262 mg (contains 99 mg of salicylate)
Pepto-Bismol Chewable Tablets	Bismuth subsalicylate 262 mg (contains 102 mg of salicylate)
Pepto-Bismol Original Liquid	Bismuth subsalicylate 262 mg/15 mL (contains 130 mg of salicylate)
Pepto-Bismol Maximum Strength Liquid	Bismuth subsalicylate 525 mg/15 mL (contains 236 mg of salicylate)
Pepto-Bismol With Instacool Peppermint Chewable Tablets	Bismuth subsalicylate 262 mg (contains 102 mg of salicylate)

*Note:* Pepto-Bismol adult formulations contain bismuth subsalicylate, but the products for children that contain calcium carbonate as the active ingredient are not listed.

BSS is available in several dosage forms; each contains various amounts of salicylate ([Table 16-8](#)). If a patient is taking aspirin or other salicylate-containing drugs, toxic levels of salicylate may be reached even if the patient follows dosing directions on the label for each medication.

Mild tinnitus, a dose-related side effect, may be associated with moderate-severe salicylate toxicity. If tinnitus occurs, the product should be discontinued and the patient referred for medical evaluation. Salicylates may cause adverse effects that are independent of the dose. Children and adolescents who have or are recovering from chicken pox or influenza are at risk of Reye's syndrome, a rare but serious illness associated with salicylates. These patients should not use BSS. However, Children's Pepto has been reformulated to contain calcium carbonate as the active ingredient. Unlike other forms of Pepto-Bismol, Children's Pepto Antacid is not associated with Reye's syndrome, but it is not labeled for treatment of diarrhea. In susceptible patients, salicylate-induced gout attacks have occurred. Patients who are sensitive to aspirin (i.e., experience asthmatic bronchospasm) should not use BSS.

Although the oral bioavailability of bismuth from BSS is poor (<1%), BSS has rarely been associated with bismuth-related neurotoxicity. Encephalopathy characterized by slow onset of tremors, postural instability, ataxia, myoclonus, poor concentration, confusion, memory impairment, seizures, visual and auditory hallucinations, psychosis, delirium, depression, and death can occur when bismuth concentrations in the blood exceed 50 mcg/L. Use of BSS in the recommended doses, even for several weeks, such as in prophylaxis for travelers' diarrhea, produces mean blood concentrations well below 50 mcg/L and does not result in bismuth-related neurotoxicity. However, AIDS patients with acute diarrhea may be at particular risk for bismuth encephalopathy, perhaps resulting from altered GI absorption; BSS should not be used in patients with AIDS.

Harmless black staining of stool (which should not be confused with melena) and darkening of the tongue occur in more than 10% of patients treated with BSS. Bismuth salts react with hydrogen sulfide produced by bacteria in the mouth and colon. The resulting compound, bismuth sulfide, imparts the black discoloration. It is easily removed from the surface of the tongue by brushing the tongue with a soft-bristled brush. It may also be treated by discontinuing the bismuth product.

Bismuth is radiopaque and may interfere with radiographic intestinal studies. BSS may interact adversely with a number of other drugs, particularly those that potentially interact with aspirin. The salicylate moiety can increase the risk of toxicity with warfarin, valproic acid, and methotrexate by significantly decreasing plasma protein binding of these drugs in vivo. Salicylate can also increase the plasma concentration of methotrexate by decreasing its renal clearance. The uricosuric effects of probenecid may be inhibited by the salicylate moiety. The bismuth moiety is a trivalent cation and may decrease absorption of other medications, such as tetracycline and quinolone antibiotics, by forming complexes with them in the GI tract. Solid dosage forms of BSS contain calcium carbonate, which may enhance this interaction. When fluoroquinolones are used to treat travelers' diarrhea, the patient should be instructed to discontinue BSS.

### Digestive Enzymes

For patients with lactase deficiency who are intolerant of milk products, lactase enzyme preparations ([Table 16-9](#)) may be taken with milk or other dairy products to prevent osmotic diarrhea.

### Product Selection Guidelines

[Table 16-7](#) provides a quick reference for recommended dosages and durations of therapy for selected antidiarrheal agents. [Tables 16-8](#) and [16-9](#) list dosage forms and primary ingredients of selected trade-name products.

In May 2011, FDA released final guidance on nonprescription liquid products that include any type of measuring device, such as the dropper packaged with lactase drops.<sup>29</sup> Other devices mentioned include cups, syringes, and spoons. The key points of the guidance are the recommendations that:

- A dosing device be included with all oral liquid nonprescription products
- The device be calibrated to the dose recommended in the product directions
- The device be used only with the product in which it is packaged
- The markings remain visible even when the liquid is in the device

### Special Populations

For young children (5 years and younger), self-treatment is limited to treating dehydration with ORS; antidiarrheal medications are not recommended. If diarrhea persists despite oral rehydration therapy, a primary care provider or pediatrician must be consulted.

**TABLE 16-9 Selected Lactase Enzyme Products**

<i>Trade Name</i>	<i>Primary Ingredient</i>
Lactaid Caplets	Lactase enzyme 3000 FCC units <sup>a</sup> /caplet
Lactaid Fast Act Caplets	Lactase enzyme 9000 FCC units <sup>a</sup> /caplet
Lactaid Fast Act Chewable Tablets	Lactase enzyme 9000 FCC units <sup>a</sup> /tablet
Lacteez Drops	Lactase enzyme 80 FCCLU <sup>b</sup> /5 drops
Lactrase Capsules	Lactase enzyme 250 mg/capsule

<sup>a</sup>FCC units are standardized units established by the Food Chemicals Codex (FCC), a compendium of internationally recognized standards for purity and identity of food ingredients published by the United States Pharmacopeia.

<sup>b</sup>FCCLU = FCC lactase units.

Elderly patients (65 years and older) should be strongly cautioned against self-treatment with antidiarrheal medications. Diarrhea in these patients is more likely to be severe or possibly fatal; therefore, these patients should be referred for medical evaluation.

Use of nonprescription antidiarrheals may be inappropriate during pregnancy; therefore, pregnant women should also be referred for medical evaluation before self-treating. Both loperamide and BSS are classified as Pregnancy Category C drugs. BSS-containing products are contraindicated during pregnancy because of concerns that the salicylate component may inhibit platelet function and, in the third trimester, cause premature closure of the fetal ductus arteriosus. Nursing women should generally avoid BSS.

### Patient Factors and Preferences

Selection of antidiarrheal products for older children and adults should be based on factors such as the etiology of the diarrhea (if known), prominent symptoms, potential interactions with prescribed medications, and applicable contraindications. For example, BSS is suggested to be the preferred agent when vomiting is the predominant clinical symptom of acute gastroenteritis. BSS should not be used to treat diarrhea in immunocompromised patients (e.g., AIDS and transplant recipients) because they are at increased risk for bismuth encephalopathy. A patient's preference for a particular dosage form and products requiring fewer doses should also be considered.

### Complementary Therapies

Convincing evidence suggests that probiotics, including several *Lactobacillus* species, *Bifidobacterium lactis*, and *Saccharomyces boulardii*, are effective in preventing and treating mild acute, uncomplicated diarrhea, especially rotavirus diarrhea in children.<sup>30-32</sup> (See [Chapter 23](#) for discussion of probiotics.) Although the exact mechanisms underlying their effects are not clear, probiotics produce acids (e.g., lactic acid) that lower intestinal pH and suppress growth of pathogenic bacteria, enhance immune responses, produce antimicrobial substances, and compete with pathogenic bacteria for intestinal mucosal binding sites. Their role in moderate-severe diarrhea is not supported conclusively by available evidence.

Probiotics appear to be safe for most patients. Major side effects, such as *Lactobacillus* or *Saccharomyces* sepsis, occur only rarely. Elderly, critically ill, and immunocompromised patients and patients with severe bowel diseases are at risk for systemic infection from probiotic use. The Food and Agriculture Organization of the United Nations and WHO have recognized the benefits of probiotics in the prevention and treatment of acute diarrhea, and recent European evidence-based guidelines for management of acute gastroenteritis in children support the use of selected probiotics.<sup>33,34</sup> However, probiotics are not recognized as medications by FDA. Their classification as dietary supplements or components of functional foods limits the health claims that can be made, and they cannot be recommended for treatment or prevention of acute, uncomplicated diarrhea.

Compelling evidence also demonstrates that daily zinc supplementation reduces the duration, severity, and persistence of acute diarrhea in children younger than 5 years of age.<sup>35-41</sup> Most of the studies showing a benefit were conducted in malnourished children in developing countries where zinc deficiency is prevalent. Few studies have been conducted in developed countries; thus, the role of zinc supplementation in young children with diarrhea in developed countries is not yet defined. Zinc produces antidiarrheal effects by stimulating intestinal water and electrolyte absorption, preventing villous atrophy, and enhancing overall immunity, perhaps in part, through upregulation of T helper (Th1) immune responses, including macrophage activation and cell-mediated immunity. WHO and UNICEF recommend that children with acute diarrhea receive zinc (10 mg of elemental zinc/day for infants younger than 6 months; 20 mg of elemental zinc/day for older infants and children) for 10-14 days in addition to ORS.<sup>23</sup> Zinc supplementation in children with diarrhea is associated with an increased risk for vomiting.<sup>37-40</sup> There is no evidence to substantiate the safety and effectiveness of herbal products and homeopathic remedies in the management of acute diarrheal diseases. Therefore, their use cannot be recommended.

### Assessment of Diarrhea: A Case-Based Approach

To evaluate a patient with diarrhea, the health care provider differentiates symptoms and makes clinical judgments. This triage function is based on the patient's responses to questions designed to help determine the cause of the specific signs and symptoms, their characteristics, and their severity ([Tables 16-1](#) and [16-3](#)). The provider should therefore ask the patient about vomiting, high and/or prolonged fever, and other symptoms to determine the patient's susceptibility to complications. Persistent or chronic diarrhea precludes self-treatment and requires immediate medical referral, as does the presence of high fever (greater than 102.2°F [39°C]), protracted vomiting, abdominal pain in patients older than 50 years, or blood or mucus in the stool. If none of these significant findings is present, the degree of dehydration should be assessed ([Table 16-3](#)); the provider should ask about the nature and amount of fluid intake. Severity of dehydration can be accurately assessed by evaluating changes in body weight. For example, in children, mild dehydration is associated with a 3%-5% loss of body weight, whereas severe dehydration is associated with a loss of more than 9%. However, the patient (or the parent) seldom knows the exact premorbid weight for comparison, and distinguishing between mild and moderate dehydration may be difficult.

The initial assessment of a pediatric patient should also seek to determine plausible causes of the symptoms. The common symptoms of acute gastroenteritis (e.g., vomiting, loose stools, and fever) are nonspecific findings associated with many other childhood diseases (e.g., acute otitis media, bacterial sepsis, meningitis, pneumonia, and urinary tract infections). This information is a key factor in recommending a proper course of action, which may include self-treatment or referral for medical evaluation. A complete medication history must be assessed before a product is selected.

Physical assessment of a patient with complaints of diarrhea can provide information useful in assessing the severity of the diarrhea (Table 16-3). Checking skin turgor and moistness of oral mucous membranes will help determine the degree of dehydration. Vital signs (e.g., pulse, temperature, respiration, and blood pressure) are important indicators of illness severity and should be routinely measured. Symptoms of moderate-severe dehydration may include postural (orthostatic) hypotension, defined as a drop in the systolic and/or diastolic pressure of greater than 15-20 mm Hg when a patient moves from a supine to an upright position. Normally, the diastolic pressure remains the same or increases slightly and the systolic pressure drops slightly on rising. If the blood pressure drops, the pulse should be checked simultaneously; the pulse rate should increase as blood pressure drops. Failure of the pulse to rise suggests that the problem is neurogenic (e.g., diabetic patients with peripheral neuropathy) or that the patient may be taking a beta blocker. The presence of orthostatic hypotension suggests that the patient has lost 1 liter or more of vascular volume, and referral for medical care is necessary.

Cases 16-1 and 16-2 provide examples of assessment of patients with diarrhea.

### Patient Counseling for Diarrhea

Patients with diarrhea may focus on the need for a nonprescription medication to stop the frequent bowel movements. The health care provider should remind them that most episodes of acute diarrhea stop after 48 hours and that preventing dehydration is the most important component of treatment. Counseling on the two-step treatment of dehydration and the need for dietary management should follow. For infants and children, educating parents and caregivers on the appropriate use of an ORS (including appropriate volumes to administer, rates of administration, and use in vomiting) and of dietary management is very important. For patient safety reasons, premixed solutions are preferred. If dry powder ORS is selected, however, the provider should give parents (or caregivers) explicit directions for mixing and verify that they understand the directions. For families with infants, the Centers for Disease Control and Prevention recommends a home supply of ORS because its early administration at home is vital if hospitalization is to be avoided. If travelers are using ORS dry powder in developing countries, potable water should be used to reconstitute the powder.

If an antidiarrheal product is recommended:

- Review label instructions with the patient or caregiver.
- Calculate an appropriate dosage on the basis of the patient's age and weight, and emphasize the maximum number of doses that can be taken in 24 hours.
- Explain potential drug interactions, side effects, contraindications, and the maximum duration of treatment before the patient should seek medical help.

The box Patient Education for Diarrhea contains specific information to provide patients.

### Evaluation of Patient Outcomes for Diarrhea

Many patients have mild-moderate diarrhea that is generally self-limiting within 48 hours. Mild-moderate diarrhea is managed with oral rehydration therapy, symptomatic drug therapy, and dietary measures. The patient should be monitored for dehydration by measuring body weight, vital signs, and mental alertness. With effective symptomatic treatment, the patient can expect reduced stool frequency and normal consistency of stools, as well as a reduction in generalized symptoms such as lethargy and abdominal pain. As the diarrhea resolves, the patient's appetite will return to normal and the patient can return to a regular diet.

Medical referral is necessary if any of the following signs and symptoms occur before or during treatment: high fever, worsening illness, bloody or mucoid stools, diarrhea continuing beyond 48 hours, or signs of worsening dehydration (e.g., low blood pressure, rapid pulse, or mental confusion). Also, medical referral is advised for infants, young children, frail patients of advanced age, pregnant patients, and patients with chronic illness at risk from secondary complications (e.g., diabetes mellitus).

### Case 16-1

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<i>Information Gathering</i>	

1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient describes acute onset diarrhea that started about 36 hours ago. Since it started, she has had 3-4 loose stools per day. She complains of mild-moderate abdominal cramping and 1 episode of vomiting, but has no other relevant signs or symptoms. She remarks, "This diarrhea is exhausting. I feel like it's taken a lot out of me."
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	None noted.
c. description of the patient's efforts to relieve the symptoms	None. She tells you, "I thought it would get better by itself, but it hasn't."
d. patient's identity	Marjorie Lewis
e. age, sex, height, and weight	36 years old, female, 5 ft 2 in., 180 lb
f. patient's occupation	Social worker
g. patient's dietary habits	She eats a well-balanced diet, although she likes dessert; drinks wine and beer several times weekly.
h. patient's sleep habits	Sleeps 5-6 hours nightly.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Migraine headaches: sumatriptan 25 mg as needed; back pain: ibuprofen 400 mg as needed
j. allergies	NKA
k. history of other adverse reactions to medications	None
l. other (describe) _____	
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s) (Table 16-1).	Patient appears to have acute diarrhea, most likely of viral etiology.
3. Identify exclusions for self-treatment (Figure 16-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health	Options include: (1) Refer Marjorie to an appropriate health care provider. (2) Recommend self-care with a nonprescription antidiarrheal product,

care provider is required, and share this information with the patient or caregiver.	such as loperamide, and nondrug measures, such as ORS. (3) Recommend self-care with a nonprescription antidiarrheal product, such as loperamide, and nondrug measures, like ORS, until patient can see an appropriate health care provider. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Patient has minimal to no dehydration and no exclusions for self-care. It is appropriate to recommend self-care with a nonprescription antidiarrheal product.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Loperamide is the preferred treatment for symptomatic relief of your diarrhea. You may continue your regular diet during treatment, but you should increase your intake of your usual fluids to prevent dehydration."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Nonprescription antidiarrheal products are safe and effective in managing symptoms of acute diarrhea when no fever or signs of serious infection are present."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. appropriate dose and frequency of administration	See the box Patient Education for Diarrhea.
b. maximum number of days the therapy should be employed	See the box Patient Education for Diarrhea.
c. product administration procedures	See the box Patient Education for Diarrhea.
d. expected time to onset of relief	Onset of effect is 1-3 hours.
e. degree of relief that can be reasonably expected	No unformed stools within 48-72 hours of starting loperamide
f. most common side effects	See the box Patient Education for Diarrhea.
g. side effects that warrant medical intervention should they occur	See the box Patient Education for Diarrhea.
h. patient options in the event that condition worsens or persists	See the box Patient Education for Diarrhea.
i. product storage requirements	Store in a cool, dry place out of children's reach.

j. specific nondrug measures	See the box Patient Education for Diarrhea.
Solicit follow-up questions from the patient or caregiver.	"May I use a sports drink to keep from getting dehydrated?"
Answer the patient's or caregiver's questions.	"Yes, sports drinks can be used to help prevent dehydration in mild diarrhea, as long as you also eat something salty, like pretzels, along with them to help maintain your sodium levels, too. You could also use Pedialyte or a similar product."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact the patient in a day or two to evaluate the response to your recommendations.

**Case 16-2**

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient describes sudden onset of diarrhea with severe abdominal cramps that awakened him from sleep at about 3 am this morning. Since then, he has experienced 3 episodes of loose, watery stools in the last 6 hours and notes that his last stool looked as if it contained some blood. He also complains of lightheadedness and becomes somewhat dizzy on standing. He denies fever, but says that at times, he feels his heart beating faster.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	None noted.
c. description of the patient's efforts to relieve the symptoms	The patient has not tried anything to relieve his symptoms.
d. patient's identity	Andrew Mitchell
e. age, sex, height, and weight	37 years old, male, 5 ft 11 in., 195 lb
f. patient's occupation	Businessman/sales executive
g. patient's dietary habits	Eats a well-balanced diet.
h. patient's sleep habits	Sleeps 6-7 hours nightly.
i. concurrent medical conditions,	Hypertension: atenolol 50 mg daily, amlodipine 10 mg daily,

prescription and nonprescription medications, and dietary supplements	hydrochlorothiazide 25 mg daily. Hyperlipidemia: simvastatin 20 mg daily. Cardiac prophylaxis: aspirin 81 mg daily.
j. allergies	Penicillin: anaphylaxis
k. history of other adverse reactions to medications	None
l. other (describe) _____	Not applicable
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s) (Table 16-1).	Patient is experiencing acute infectious diarrhea, most likely of bacterial etiology.
3. Identify exclusions for self-treatment (see Figure 16-1).	Severe abdominal cramps, blood in the stool
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer patient to an appropriate health care provider. (2) Recommend self-care with a nonprescription antidiarrheal product, such as bismuth subsalicylate, and nondrug measures, like ORS. (3) Recommend self-care with a nonprescription antidiarrheal product, such as bismuth subsalicylate, and nondrug measures, such as ORS, until patient can see an appropriate health care provider. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Refer patient to an appropriate health care provider, urgent care center, or emergency department for evaluation and treatment.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You need to seek urgent medical care from your primary care provider, urgent care center, or emergency department right away."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Your symptoms suggest that your condition is serious. You probably have a bacterial infection that requires prescription antibiotics. No nonprescription remedies are available to treat bloody diarrhea."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient	Criterion does not apply in this case.

or caregiver.	
Solicit follow-up questions from the patient or caregiver.	"Can I take some Pepto-Bismol before I go to the emergency department?"
Answer the patient's or caregiver's questions.	"No. If you have a bacterial infection, Pepto-Bismol may actually make your condition worse. You should not take any nonprescription medicine while seeking medical attention."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Ask patient to call after seeking medical attention to update you on his condition, or obtain his phone number and call him in a few days.

Key: ORS = Oral rehydration solution.

### Patient Education for Diarrhea

The primary objective of self-treatment is to prevent excessive fluid and electrolyte losses. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal outcomes.

#### **Nondrug Measures**

##### ***Infants and Children 6 Months to 5 Years***

- For mild-moderate diarrhea, indicated by three to five unformed bowel movements per day, give the child or infant an oral rehydration solution (ORS) at a volume of 50-100 mL/kg of body weight over 2-4 hours to replace the fluid deficit. Give additional ORS to replace ongoing losses. Continue to give the solution for the next 4-6 hours or until the child is rehydrated.
- If the child is vomiting, give 1 teaspoon of ORS every few minutes.
- If the child is not dehydrated, give 10 mL/kg or ½-1 cup of the ORS for each bowel movement, or 2 mL/kg for each episode of vomiting. As an alternative, to replace ongoing fluid losses, children weighing less than 10 kg should be given 60-120 mL of ORS for each episode of vomiting or diarrheal stool, and children weighing more than 10 kg should be given 120-240 mL for each episode of vomiting or diarrheal stool.
- After the child is rehydrated, reintroduce food appropriate for the child's age, while also administering an ORS as maintenance therapy.
- If breast-feeding an infant with diarrhea, continue the breast-feeding. If the infant is bottle-fed, consult your primary care provider or pediatrician about replacing a milk-based formula with a lactose-free formula.
- Give children complex carbohydrate-rich foods, yogurt, lean meats, fruits, and vegetables. Do not give them fatty foods or sugary foods. Sugary foods can cause osmotic diarrhea.
- Do not withhold food for more than 24 hours.

##### ***Adults and Children Older Than 5 Years***

- For mild-moderate dehydration, indicated by a 3%-9% drop in body weight or three to five unformed stools per day, drink 2-4 liters of an ORS over 4 hours.
- If not dehydrated, drink ½-1 cup of ORS or fluids after each unformed bowel movement.
- If no medical conditions exist, sports drinks (with salty crackers, etc.), diluted juices, soups, and broths may be consumed until the diarrhea stops.
- Do not withhold food for more than 24 hours.

#### **Nonprescription Medications**

- See [Table 16-7](#) for dosages of loperamide and bismuth subsalicylate.

##### ***Loperamide***

- Note that loperamide can cause dizziness and constipation.
- Do not give this agent to children 2 years of age and younger. Loperamide is not recommended for children younger than 6 years, except under the supervision of a primary care provider or pediatrician.
- If loperamide is not effective in treating your diarrhea (if no clinical improvement is observed in 48 hours), check with your primary care provider or pharmacist about using a different nonprescription medication. You may have a bacterial diarrhea or pseudomembranous colitis; these conditions require specific antibiotic therapy that loperamide cannot treat.

## Bismuth Subsalicylate

- Note that bismuth subsalicylate can cause a dark discoloration of the tongue and stool.
- Do not take this medication if you are taking tetracyclines, quinolones, or medicines for gout (uricosurics).
- Do not give this medication to children younger than 12 years.
- Do not give this medication to children or adolescents who have or are recovering from influenza or chicken pox. Reye's syndrome, a rare but serious condition, could occur.
- Do not give this medication to patients with AIDS.
- Do not take this medication if you are sensitive to aspirin, have a history of gastrointestinal bleeding, or have a history of problems with blood coagulation.

### When to Seek Medical Attention

- If the diarrhea has not resolved after 72 hours of initial treatment, see your primary care provider.
- Monitor for excessive number of bowel movements, signs of dehydration, high fever, or blood in the stool. If any of these complications are present, discontinue bismuth subsalicylate and consult your primary care provider.

### Key Points for Diarrhea

- Self-treatment of diarrhea should be limited to patients with mild-moderate acute diarrhea who have minimal, mild, or moderate dehydration. Patients who appear volume depleted, weak, dizzy, febrile (temperature > 102.2°F), or hypotensive should be referred for evaluation.
- ORS is the mainstay of therapy and should be used to rehydrate patients with minimal or mild-moderate dehydration.
- Rehydration should be performed rapidly (i.e., within 3-4 hours). Additional ORS should be given to maintain hydration and replace ongoing fluid losses resulting from diarrheal stools and/or vomiting (Figures 16-1 and 16-2).
- Patients or their caregivers should be instructed how to prepare and administer an ORS.
- Older children and adults may use sports drinks instead of an ORS if additional sources of sodium (e.g., crackers and pretzels) are used concomitantly.
- An age-appropriate, unrestricted diet should be initiated as soon as the patient is rehydrated. Food should be withheld for no more than 24 hours.
- Loperamide and BSS may be used to help control acute diarrhea in carefully selected patients.
- Antibiotic therapy is generally not indicated for patients with acute diarrhea unless it is travelers' diarrhea.

## Handbook of Nonprescription Drugs &gt; Chapter 17. Anorectal Disorders

**Anorectal Disorders: Introduction**

Anorectal disorders involve the perianal area, anal canal, and lower rectum. Many signs and symptoms associated with hemorrhoids may be related to nonhemorrhoidal anorectal disorders.<sup>1</sup> Hemorrhoids often are self-treated, whereas other anorectal disorders may require immediate medical attention. A number of products are available for the symptomatic treatment of anorectal disorders. Hemorrhoidal complaints are a medical burden for the health care system, with an estimated 1 million ambulatory care visits and nearly 2 million prescriptions filled for anorectal products.<sup>2-4</sup> Despite a significant decrease in hospitalizations over the past several decades, anorectal disorders ranked as the 13th most common digestive disease for ambulatory care visits.<sup>4</sup> More than 10 million people in the United States are estimated to have hemorrhoids, and 75% of those individuals are estimated to be older than 45 years.<sup>2,5</sup> However, the true prevalence of hemorrhoids is unknown because people often do not seek medical attention.<sup>2,4</sup> The diagnosis of hemorrhoids is equal in men and women and increases with advancing age.<sup>2</sup> In the United States, age-adjusted hospitalization rates are higher in blacks when compared to whites.<sup>2</sup> Although epidemiologic data are lacking, approximately 25%-35% of the general population (and up to 85% of women of childbearing age) have some degree of pain and discomfort that is associated with hemorrhoids.<sup>6</sup>

**Pathophysiology of Anorectal Area**

Anorectal disorders occur in the perianal area (the portion of the skin immediately surrounding the anus), the anal canal, and the lower portion of the rectum (Figure 17-1). The anal canal is about 2.5-5 cm long and connects the rectum with the outside of the body.<sup>7</sup> Two different types of epithelium line the anal canal; their junction is defined by the dentate line (also known as the pectinate line). The dentate line divides squamous epithelium from columnar epithelium, thus delineating where sensory pain fibers are located in the anal canal. Anorectal disorders occurring below the dentate line may be associated with pain, whereas disorders above the line rarely cause any discomfort.<sup>7</sup> The area proximal to the dentate line contains several longitudinal folds known as the columns of Morgagni. In between and next to these columns are small pockets or crypts containing ducts and glands that may become obstructed and cause infections (e.g., abscesses and fistulas).<sup>8</sup>

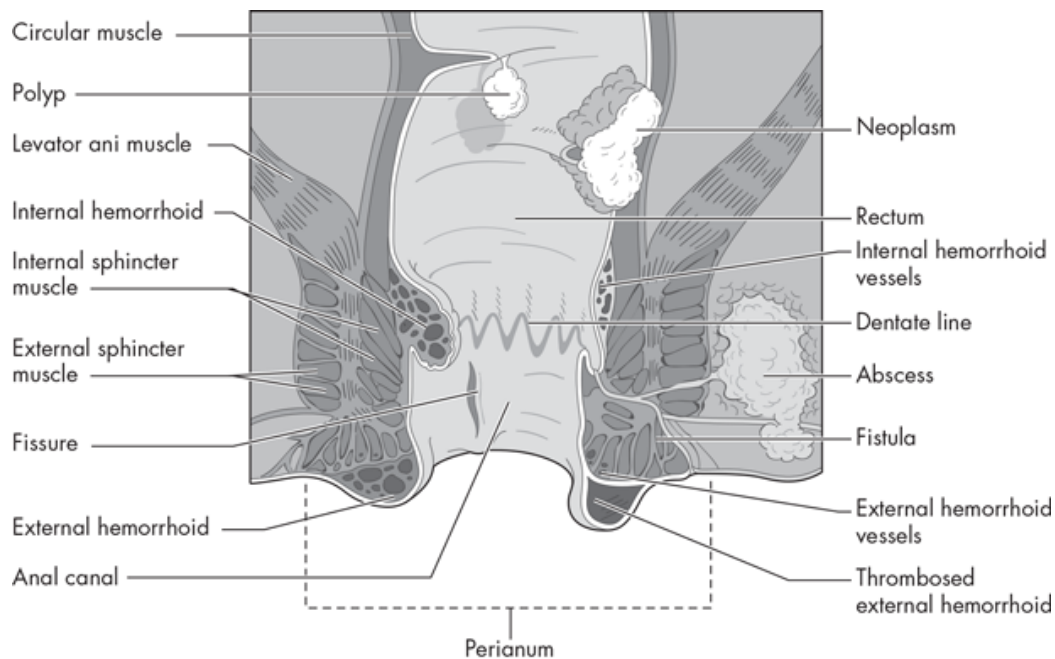

The external anal sphincter is a voluntary muscle located at the bottom of the anal canal that remains closed under normal conditions to prevent involuntary passage of feces. The internal sphincter is an involuntary muscle innervated by the autonomic nervous system. When the sphincters are relaxed, defecation occurs. In healthy individuals, skin covering the anal canal serves as a barrier against absorption of substances into the body. If that protective barrier breaks, then the absorptive character of the anal skin may be altered, diminishing the skin's protective capabilities.

The rectum, which lies above the anal canal, is about 12-18 cm long and is the terminal portion of the large intestine.<sup>7</sup> The highly vascular rectal mucosa is lined with a semipermeable membrane to protect the body from fecal bacteria. Three hemorrhoidal arteries and their accompanying veins are the most prominent parts of the vasculature. The arteries and veins lying above the dentate line are referred to as internal and those below as external. Blood returns to the heart through the hemorrhoidal veins; therefore, rectal medications may be absorbed and enter the systemic circulation without passing through the liver.<sup>7</sup>

Hemorrhoids are large, bulging, symptomatic conglomerates of hemorrhoidal vessels, supporting tissues, and overlying mucous membranes in the anorectal region.<sup>9</sup> Hemorrhoids are believed to develop as a result of inflammation of vascular cushions. The cushions (located circumferentially around the anal canal, above the dentate line) contain blood vessels, smooth muscle, and supportive connective tissue that project into the lumen and cause a downward pressure during defecation. With increasing age or poor bowel habits (e.g., prolonged sitting and straining at defecation), muscle fibers may weaken and cause vascular cushions to slide, become congested, bleed, and eventually protrude.<sup>9,10</sup> Downward pressure during defecation and a high resting anal pressure are common in the development of hemorrhoids.

Internal hemorrhoids originate from the superior hemorrhoidal vein and are located above the dentate line, an area that is covered with columnar epithelium and lacks sensory fibers (Figure 17-1).<sup>9,10</sup> Hemorrhoids are graded by severity of prolapse into the anal canal using a degree system<sup>10</sup>:

- First-degree hemorrhoids are enlarged but do not prolapse into the anal canal.
- Second-degree hemorrhoids protrude into the anal canal and return spontaneously on defecation.
- Third-degree hemorrhoids protrude into the anal canal on defecation but can be returned to their original position manually.
- Fourth-degree hemorrhoids are permanently prolapsed and cannot be reintroduced into the anus.

Disorders of the anorectal canal.

External hemorrhoids develop from the inferior hemorrhoidal vein and originate below the dentate line, which is covered with squamous epithelium (Figure 17-1).<sup>9,10</sup> These hemorrhoids are visible as bluish lumps at the external or distal boundary of the anal canal (known as the anal verge). The blue color may be caused by thrombosed blood vessels, which cause symptoms ranging from minimal discomfort to severe pain.<sup>10</sup>

#### Nonhemorrhoidal Anorectal Disorders

Potentially serious nonhemorrhoidal anorectal disorders (e.g., abscesses, fistulas, fissures, neoplasms, polyps, and pruritus ani) may present as hemorrhoid-like symptoms; these disorders should not be self-treated but referred for immediate medical evaluation (Table 17-1).<sup>8,11</sup>

#### Clinical Presentation of Anorectal Disorders

The Food and Drug Administration (FDA) Advisory Review Panel identified signs and symptoms for which a nonprescription anorectal product is indicated.<sup>12</sup> These symptoms include itching, discomfort, irritation, burning, soreness, inflammation, pain, dry anal tissue, and swelling in the perianal area.<sup>12</sup> In contrast, abdominal pain, bleeding, seepage, change in bowel patterns, prolapse, and thrombosis may indicate a more serious condition requiring immediate medical attention (Table 17-2).<sup>9,11,13</sup>

#### Treatment of Anorectal Disorders

##### Treatment Goals

The primary goal of treatment is to maintain soft stools to prevent straining while having a bowel movement.<sup>9,14</sup> Additional goals for patients with symptoms associated with anorectal disorders are to (1) alleviate and maintain remission of anorectal symptoms and (2) prevent complications.

##### General Treatment Approach

Figure 17-2 presents an algorithm for treating minor anorectal symptoms and lists exclusions for self-treatment. If the complaint is self-treatable, the clinician may recommend nonpharmacologic measures and an OTC agent to treat the symptoms. Patients should be advised to maintain adequate fluid intake and a well-balanced high-fiber diet. Practicing good perianal hygiene and avoiding prolonged sitting on the toilet may also minimize anorectal symptoms. Table 17-3 outlines guidelines for applying anorectal products.<sup>8,9,15</sup>

##### Nonpharmacologic Therapy

Nondrug measures for treating anorectal disorders include dietary modifications, surgical interventions, and nonoperative methods.<sup>3,9</sup> Patients diagnosed with or suspected of having hemorrhoids should avoid lifting heavy objects, discontinue foods that aggravate symptoms (e.g., alcohol, caffeinated beverages, citrus, and spicy foods), and increase dietary fiber.<sup>14</sup> Nonsteroidal anti-inflammatory drugs or aspirin may promote bleeding and therefore should be avoided.

Dietary fiber softens stool and may prevent further irritation of symptomatic hemorrhoids and anorectal complaints. A meta-analysis confirmed that initiating fiber therapy in subjects with first- or second-degree hemorrhoids improves bleeding and overall symptomatic relief.<sup>14,16</sup> Increasing fiber intake to at least 20-30 grams daily may permit the passage of softer stools, thus reducing or preventing irritation and straining at defecation.<sup>8,17</sup> Increased fiber intake should be introduced slowly and accompanied by increased fluid intake. If the amount of dietary fiber intake cannot be increased, fiber supplements such as psyllium or methylcellulose may be added (see Chapter 15).

**TABLE 17-1 Nonhemorrhoidal Anorectal Disorders**

Disorder	Definition	Common Signs and Symptoms	Comments
Anal abscess	Collection of pus causing an obstruction of the anal glands, resulting in a bacterial infection	Pain, perirectal swelling, discharge, fever, or chills; pain worsens with sitting and defecation	Possible life-threatening sepsis if not identified and treated promptly

Anal fistula (or groove)	Abnormal internal opening that connects with an external opening (i.e., tube-like appearance between the rectum and anus)	Chronic, persistent drainage; pain; possible bleeding on defecation; perianal itching; stool seeping through external opening	Surgical repair required
Anal fissure	Slit-like ulcer in anal canal resulting from a traumatic tear during passage of stool or explosive diarrhea	Severe or burning pain during and after defecation, lasting several minutes to hours; anal spasms; blood may be seen on toilet tissue	Young, middle-aged individuals; equal in women and men
Anal neoplasms	Include a variety of histologic types classified as epidermoid carcinomas	Rare and usually asymptomatic in 25% of patients; bleeding; changes in bowel habits; anal discharge; anal mass; pain; pruritus; rash	Relatively uncommon, accounting for 1%-2% of all GI malignancies; most are curable, but poor prognosis with anorectal melanomas
Pruritus ani	Itching sensation localized in anorectal area	Persistent itching, scratching in perianal region; more bothersome at bedtime or when patient is not preoccupied	More common in men

Source: References 7, 8, 11, and 17.

Proper bowel habits should be encouraged, and avoiding urges to defecate should be discouraged because doing so may lead to constipation resulting in anorectal discomfort. Avoidance of sitting on the toilet for long periods of time reduces strain and decreases pressure on the hemorrhoidal vessels.<sup>3,10,17</sup> Proper hygiene of the anal area (e.g., cleaning the area regularly and after each bowel movement using mild, unscented soap and water, or using commercially available hygienic and lubricated wipes or pads) may relieve anorectal symptoms. Excessive scrubbing should be discouraged to minimize aggravation.<sup>1</sup> A measure often recommended to promote good anal hygiene is sitting in warm water ( $\leq 120^{\circ}\text{F}$  [ $48.89^{\circ}\text{C}$ ]) in a bath tub or sitz bath (a small bath tub that fits over the toilet rim, available at pharmacies and medical supply vendors) for 10-20 minutes 2-4 times a day<sup>3,8,9,18</sup>; however, the exact therapeutic usefulness of this measure is still in question. A systematic review of randomized controlled trials found no evidence to support the use of sitz baths to relieve pain or assist in wound healing associated with anorectal disease.<sup>18</sup> Additionally, in a systematic review of four randomized controlled trials, evidence to support the use of sitz baths to relieve pain or assist in wound healing associated with anorectal disease was lacking.<sup>19</sup>

Large and prolapsed hemorrhoids often are treated surgically. The surgical procedure that involves excising one or more of the three hemorrhoidal masses is called a hemorrhoidectomy. Nonsurgical procedures treating hemorrhoids include injection of sclerosing agents, rubber band ligation, cryosurgery, electrocoagulation, infrared photocoagulation, and local anal hypothermia.<sup>3,9,17</sup>

#### Pharmacologic Therapy

Local anesthetics, vasoconstrictors, protectants, astringents, keratolytics, analgesics, anesthetics, antipruritics, and corticosteroids are commonly used to relieve anorectal symptoms.<sup>12,15</sup> Certain astringents, protectants, and vasoconstrictors may be used only intrarectally and should be administered with an applicator (i.e., "pile pipe") so that the product may reach the affected area.<sup>12</sup> Suppositories may be considered another way of administering drug to the anal area; however, their effectiveness is in question, as suppositories may not "stay in place" after insertion.<sup>20</sup> The remaining agents are for external use only and are not indicated for the relief of anorectal pain, bleeding, seepage, prolapse, or thrombosis.<sup>12</sup> Table 17-4 provides FDA-approved dosages for anorectal drug products.<sup>12</sup>

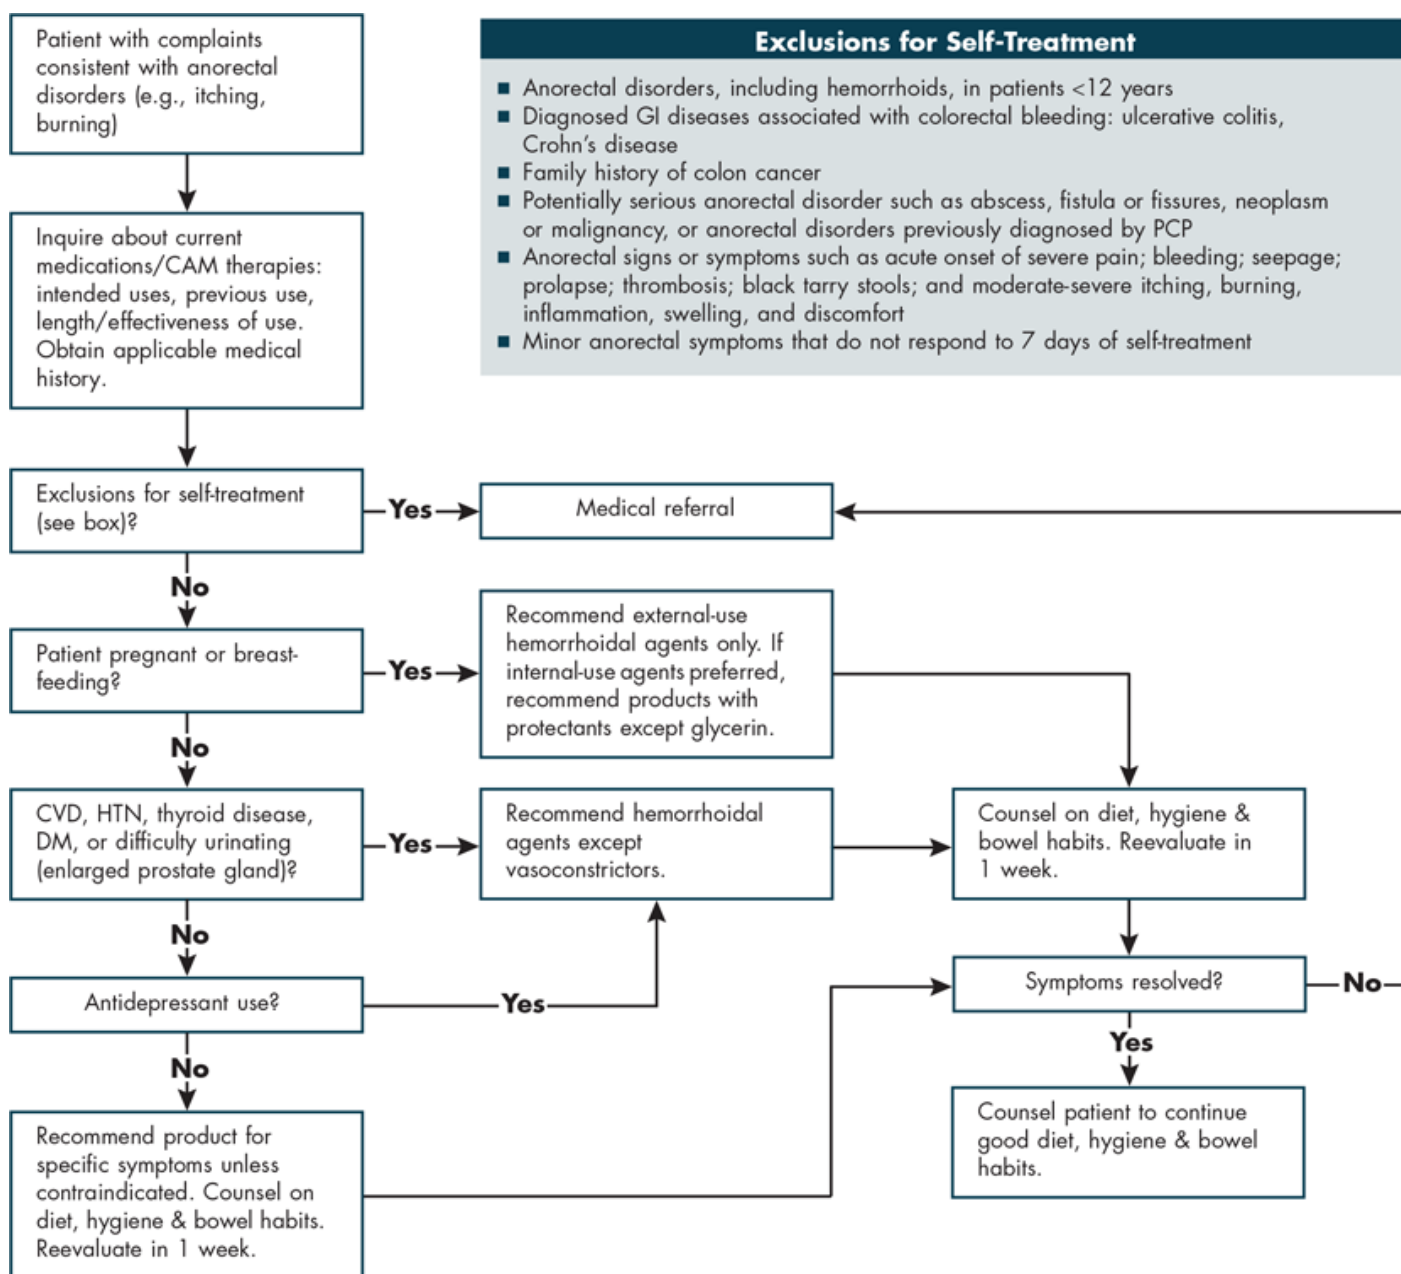

**TABLE 17-2 Signs and Symptoms of Anorectal Disorders**

<i>Sign/Symptom</i>	<i>Definition/Etiology</i>
<b>Usually Self-Treatable</b>	
Itching (pruritus)	Mild stimulation of sensory nerve fibers; associated with many anorectal disorders, including hemorrhoids (typically with a mucoid discharge from prolapsing internal hemorrhoids). Common causes include poor hygiene (e.g., incomplete wiping/cleaning after defecation); diarrhea; parasitic or fungal infections; allergies (e.g., sensitivity to fabrics, soaps, laundry detergents, dyes, perfumes in toilet tissue); anorectal lesions; moisture in anal area. May be secondary to swelling; diet (e.g., caffeinated beverages, chocolate, citrus fruits); oral broad-spectrum antibiotics. Rare cause includes psychogenic origins.
Discomfort	May result from burning, itching, pain, irritation, inflammation, and swelling.
Irritation	Uncomfortable feeling associated with stimulation of sensory nerve fibers.
Burning	Greater degree of irritation of sensory nerve fibers than seen in anal itching; often associated with hemorrhoids; sensation of warmth or intense heat. May be constant or occur only at defecation.
Inflammation	Tissue reaction characterized by heat, redness or discoloration, pain, and swelling; often associated with trauma, allergy, or infection.
Swelling	Temporary enlargement of cells and/or tissue resulting from excess fluid; may be accompanied by pain, burning, and itching.
<b>Requires Medical Referral</b>	
Pain	Intense stimulation of sensory nerve fibers caused by inflammation or irritation. Internal hemorrhoids usually are painless; external hemorrhoids often cause mild pain; acute, severe perianal pain may be from a thrombosed external hemorrhoid. Pain from anal fissure during bowel movement often described as "being cut with sharp glass." Other possible causes of pain include abscess, fistula, or anorectal neoplasm.
Bleeding	Hemorrhoids are most common cause of minor anorectal disorders (e.g., from straining or passage of hard stool, or ulceration of perianal skin overlying thrombosed external hemorrhoid). Often appears as bright red spots or streaks on toilet tissue, or bright red blood around stool or in toilet.

	Black or tarry stools (melena) may indicate a possible upper GI bleed (e.g., PUD, erosive esophagitis, or gastric varices). Large amounts of red blood (hematochezia) in toilet bowl indicative of lower GI bleeding (e.g., fissure, IBD, polyps, malignant disease of the colon or rectum). Possible indications of large-volume blood loss include shortness of breath, dizziness, fatigue, or light-headedness, especially upon standing (orthostatic hypotension).
Seepage	Involuntary passage of fecal material or mucus caused by an incompletely closed anal sphincter; may include discharge of pus or feces from a fistula connecting the rectum to the anal canal.
Change in bowel pattern	Unexplained change in bowel frequency or in stool form; may signal serious underlying GI disorder (e.g., IBD) or colorectal cancer.
Prolapse (protrusion)	Protrusion of hemorrhoidal or rectal tissue of variable size into anal canal; usually appears after defecation, prolonged standing, unusual physical exertion, or swelling of hemorrhoidal tissue with loss of muscular support; painless except when accompanied by thrombosis, infection, or ulceration.
Thrombosis	Strangulation of protruded (external) hemorrhoid by anal sphincter, possibly leading to thrombosis; pain is most acute during first 48-72 hours but usually resolves after 7-10 days. Minimal pain with thrombosed internal hemorrhoids; patient likely to be unaware of condition unless sudden change in bowel habits occurs. If a thrombosed hemorrhoid persists, ulcers or gangrene may develop and cause bleeding, especially during defecation.

Key: GI = Gastrointestinal; IBD = inflammatory bowel disease; PUD = peptic ulcer disease.

TABLE 17-3 Guidelines for Applying or Inserting Anorectal Products

• Clean affected anorectal area after bowel movement with mild, nonmedicated, unscented soap and warm water; rinse thoroughly.
• Clean anorectal area prior to applying products containing aluminum hydroxide gel or kaolin. Be sure to remove any previously used petrolatum-containing or greasy ointment. <sup>a</sup>
• Dry anorectal area gently by patting or blotting with unscented and uncolored toilet tissue or a soft cloth prior to applying product.
• Apply a thin layer to the perianal area and anal canal when using an external anorectal product.
• Insert anorectal products indicated for intrarectal use by using an intrarectal applicator or a finger. Intrarectal applicators are preferred to digital application because an applicator enables the drug product to be applied to the rectal mucosa (which cannot be reached with a finger).
• Ensure intrarectal applicators have lateral openings and holes in the tip to facilitate anorectal application and coverage of the rectal mucosa.
• Lubricate intrarectal applicator by spreading product around the applicator tip prior to inserting into the anorectal area.
• Avoid using the intrarectal applicator in the anorectal area if it causes additional pain.
• Do not exceed the recommended daily dosage unless directed by a primary care provider.

<sup>a</sup> *Ointment* refers to all semisolid preparations.

**TABLE 17-4 Dosage Guidelines for Anorectal Products**

<i>Ingredient</i>	<i>Concentration per Dosage Unit (%)</i>	<i>Frequency of Use (maximum daily dosage)</i>
<b>Local Anesthetics</b>		
Benzocaine	5-20	Up to 6 times/day (2.4 g)
Benzyl alcohol	1-4	Up to 6 times/day (480 mg)
Dibucaine, dibucaine hydrochloride	0.25-1	Up to 3-4 times/day (80 mg)
Dyclonine hydrochloride	0.5-1	Up to 6 times/day (100 mg)
Lidocaine	2-5	Up to 6 times/day (500 mg)
Pramoxine hydrochloride <sup>a</sup>	1	Up to 5 times/day (100 mg)
Tetracaine, tetracaine hydrochloride	0.5-1	Up to 6 times/day (100 mg)
<b>Vasoconstrictors</b>		
Ephedrine sulfate	0.1-1.25	Up to 4 times/day (100 mg)
Epinephrine hydrochloride/epinephrine	0.005-0.01	Up to 4 times/day (800 mg)
Phenylephrine hydrochloride	0.25	Up to 4 times/day (2 mg)
<b>Protectants</b>		
Aluminum hydroxide gel, cocoa butter, glycerin, hard fat, kaolin, lanolin, mineral oil, white petrolatum, calamine, <sup>c</sup> petrolatum, shark liver oil, <sup>d</sup> zinc oxide, <sup>e</sup> topical starch, cod liver oil <sup>d</sup>	See footnote <sup>b</sup> .	Petrolatum/white petrolatum as often as needed; other protectants up to 6 times/day or after each bowel movement
<b>Astringents</b>		
Calamine <sup>c</sup>	5-25	Up to 6 times/day or after each bowel movement
Zinc oxide	5-25	Up to 6 times/day or after each bowel movement
Witch hazel	10-50	Up to 6 times/day or after each bowel movement
<b>Keratolytics</b>		
Alcloxa	0.2-2	Up to 6 times/day
Resorcinol	1-3	Up to 6 times/day
<b>Analgesics, Anesthetics, Antipruritics</b>		
Menthol	0.1-1	Up to 6 times/day
Juniper tar	1-5	Up to 6 times/day
Camphor	0.1-3	Up to 6 times/day
<b>Corticosteroids</b>		
Hydrocortisone	0.25-1	Up to 3-4 times/day

<sup>a</sup> External dosage forms may include aerosol foams, ointments, creams, and jellies (water-miscible base).

<sup>b</sup> Any two, three, or four protectants may be combined, provided that the combined percentage by weight of all protectants in the combination is at least 50% of the final product (e.g., 1 gram of a 2-gram dosage unit). Any protectant ingredient included in the combination must be present at a level that contributes at least 12.5% by weight (e.g., 0.25 gram of a 2-gram dosage unit), except cod liver oil and shark liver oil. If cocoa butter is included in the combination, it must not exceed the concentration limit for calamine,<sup>c</sup> cod liver oil,<sup>d</sup> or shark liver oil.<sup>d</sup>

<sup>c</sup> Calamine not to exceed 25% by weight per dosage unit (based on the zinc oxide content of calamine).

<sup>d</sup> Provided that the product is labeled so that the amount of the product that is used in a 24-hour period represents a quantity that provides 10,000 USP units of vitamin A and 400 USP units of cholecalciferol.

<sup>e</sup> Any product containing calamine or zinc oxide for use as a protectant and/or as an astringent may not have a total weight of zinc oxide exceeding 25% by weight per dosage unit.

Key: USP = United States Pharmacopeia.

Source: Reference 12.

### Local Anesthetics

Local anesthetics are approved for the temporary relief of external anal symptoms (e.g., itching, irritation, burning, discomfort, and pain); they provide relief by reversibly blocking transmission of nerve impulses (Table 17-4).<sup>12</sup> These products should be used with caution, as they may mask the pain of more severe anorectal disorders.<sup>7,15</sup>

Local anesthetics may produce allergic reactions (e.g., burning and itching) that are indistinguishable from the anorectal symptoms. Several cases of contact dermatitis have been reported with hemorrhoidal anesthetics, including benzocaine, dibucaine, and lidocaine.<sup>21-23</sup> Patients who have an allergic reaction to a local anesthetic should use agents with different chemical structures (e.g., pramoxine) or avoid use of these agents completely. Local anesthetic preparations must carry a warning stating that allergic reactions may occur.<sup>12</sup> These agents should be avoided on open sores because they are rapidly absorbed through abraded skin and may cause cardiovascular and central nervous systemic effects. Accidental oral ingestion of dibucaine-containing anorectal products has been reported in children, resulting in lethargy, seizures, and cardiorespiratory arrest.<sup>15</sup> All anorectal products containing any local anesthetic should be kept out of children's reach.<sup>12,24</sup>

### Vasoconstrictors

Vasoconstrictors are structurally related to the endogenous catecholamines epinephrine and norepinephrine. When ephedrine or epinephrine is applied to the anorectal area, stimulation of alpha-adrenergic receptors in the vascular beds constricts arterioles, producing a modest and transient reduction of swelling. These agents are indicated (Table 17-4) for relief of itching, discomfort, and irritation and to shrink and decrease swelling of the hemorrhoidal tissues.<sup>14</sup> Ephedrine sulfate and phenylephrine hydrochloride are safe and effective for external and intrarectal use, and epinephrine hydrochloride is approved for external use.<sup>12</sup>

Adverse effects of ephedrine and epinephrine include increased cardiac rate and contractility, as well as bronchodilation if absorbed systemically. In contrast, because phenylephrine HCl is structurally related to norepinephrine, effects on the central nervous system and cardiac rhythm are minimal. When used in recommended dosages, vasoconstrictors may cause nervousness, tremors, sleeplessness, nausea, and loss of appetite.<sup>15</sup> Serious adverse effects (e.g., elevation of blood pressure, aggravation of hyperthyroidism, cardiac arrhythmias, and irregular heart rate) are less likely to occur with topical than with oral administration.<sup>15</sup> Prolonged use may lead to rebound vasodilatation, anxiety, and (rarely) paranoia. Contact dermatitis may also occur.

Rectally administered vasoconstrictors may attenuate the effects of oral antihypertensive agents and increase blood pressure. Alternatively, the hypertensive effects of vasoconstrictors may be potentiated by monoamine oxidase inhibitors and tricyclic antidepressants. Concomitant use may lead to serious and even lethal outcomes, including cerebral hemorrhage or stroke.<sup>12,15</sup> Patients with diabetes, thyroid disease, heart disease, hypertension, or enlarged prostate, as well as those taking antidepressants, antihypertensive agents, or cardiac medications, should not use hemorrhoidal agents with vasoconstrictors without first consulting their primary care provider.<sup>12,25,26</sup>

### Protectants

Protectants are ingredients that provide a physical protective barrier and soften the anal canal by preventing fecal matter from irritating the perianal mucosa.<sup>12,15</sup> This drug class includes absorbents, adsorbents, demulcents, and emollients. Approved indications for most protectants include the temporary relief of discomfort, irritation, and burning with external and internal hemorrhoids (one exception is glycerin, which is for external use only) (Table 17-4).<sup>12</sup> Kaolin or aluminum hydroxide gel is indicated for the temporary relief of itching associated with moist anorectal conditions.<sup>12</sup> Systemic absorption of protectants is minimal; therefore, adverse reactions as a class are uncommon. Lanolin is a natural product obtained from the fleece of sheep, and it may cause allergic reactions.<sup>17</sup> Chemically modified lanolin is available and may be less sensitizing. A warning statement for anorectal products says that, because of their greasy properties, petrolatum or greasy ointments should be removed prior to applying products containing aluminum hydroxide gel or kaolin.<sup>12</sup>

### Astringents

Astringents are products that promote coagulation of surface protein in the anorectal skin cells to protect the underlying tissue. Astringents also act to decrease cell volume, making the affected environment drier. To prevent further irritation, astringents form a thin protective layer over the injured mucosal membrane.<sup>12,15</sup> Astringents listed in Table 17-4 are approved for the temporary relief of itching, irritation, and burning symptoms associated with anorectal disorders.<sup>15</sup> Witch hazel (known as hamamelis water prior to January, 1, 1995) is indicated for external use, whereas calamine and zinc oxide may be used for external and internal anorectal disorders.<sup>12</sup>

Adverse effects with the topical use of astringents are uncommon. Upon application, witch hazel may cause a slight stinging sensation from the alcohol used to prepare the compound. Contact dermatitis may occur with witch hazel because it contains a small amount of volatile oil.<sup>27</sup> If calamine or zinc oxide is used for prolonged periods of time (especially for internal anorectal disorders), systemic zinc toxicity (nausea, vomiting, lethargy,

and/or severe pain) may develop.<sup>15</sup>

#### Keratolytics

Keratolytics are agents that cause desquamation and debridement (or sloughing) of epidermal surface cells. By fostering cell turnover and loosening surface cells, low concentrations of keratolytics may expose the underlying tissue. When other anorectal ingredients are used in combination with keratolytics, they reduce itching and inflammation (Table 17-4).<sup>12,15</sup> Because mucous membranes do not contain a keratin layer, intrarectal use is not justified and may be harmful.<sup>15</sup>

With repeated dosing, the absorption of the keratolytic resorcinol has led to methemoglobinemia, exfoliative dermatitis, death in infants, and myxedema in adults.<sup>15</sup> Other adverse effects range from tinnitus, increased pulse rate, diaphoresis, and shortness of breath to circulatory collapse, unconsciousness, and convulsions. Products containing resorcinol must list the following warnings to minimize absorption through abraded mucosal lining and to decrease the potential for systemic toxicity: (1) "Certain persons can develop allergic reactions to ingredients in this product. If the symptoms being treated do not subside, or if redness, irritation, swelling, pain, or other symptoms develop or increase, discontinue use and consult a doctor." (2) "Do not use on open wounds near the anus."<sup>15</sup> Although keratolytics are available in selected anorectal preparations, their use must be weighed against their potentially serious adverse effects.

#### Analgesics, Anesthetics, and Antipruritics

Formerly classified as "counterirritants," menthol, juniper tar, and camphor are safe and effective when used for external perianal disorders. These agents (Table 17-4) are approved for the temporary relief of itching and inflammation by producing a cool, warm, or tingling sensation.<sup>12,15</sup> The agents should not be used internally because the rectum has no identifiable nerve fibers. Menthol-containing products must have the following warning: "Certain persons can develop allergic reactions to ingredients in this product. If the symptoms being treated do not subside, or if redness, irritation, swelling, pain, or other symptoms develop or increase, discontinue use and consult a doctor."<sup>12</sup> Extensive application of menthol to the trunk of the body has caused laryngospasm, dyspnea, and cyanosis; therefore, menthol should be used only sparingly.<sup>15</sup> Juniper tar, which contains phenol, also should be used only sparingly; it should not be ingested orally because organ failure and cardiac rhythm abnormalities may result.<sup>28</sup> Camphor is readily absorbed through mucous membranes, and it stimulates the central nervous system, which may cause convulsions or death. The latter is seen mostly with accidental oral ingestion, especially in children.<sup>29</sup>

#### Corticosteroids

Approximately 60% of the topical anorectal agents contain corticosteroids, which act as a vasoconstrictor and antipruritic by producing lysosomal membrane stabilization and antimitotic activity.<sup>30</sup> The onset of action may take up to 12 hours, but the effect has a longer duration than that of most other agents (e.g., local anesthetics). Hydrocortisone, in concentrations of no more than 1%, is the only corticosteroid approved for nonprescription use in anorectal preparations for the temporary relief of minor external anal itching caused by minor irritation or rash.<sup>31</sup> Local adverse effects include rare skin reactions and skin atrophy with prolonged use. Hydrocortisone may mask the symptoms of bacterial and fungal infections.

#### Combination Products

Federal regulations state that a nonprescription anorectal product may combine two or more active ingredients; combination products generally are recognized as safe and effective when (1) each active ingredient contributes to the claimed effect; (2) the combination of active ingredients does not decrease the safety or effectiveness of any individual active ingredient; and (3) the combination, when listing adequate directions for use and warning against unsafe use, provides rational, concurrent therapy for a significant proportion of the target population.<sup>12,15</sup> FDA restrictions on combination anorectal products can be found by accessing the *Federal Register*.<sup>15</sup> Use of combination products is reasonable, given that some self-treatable anorectal disorders may have concurrent symptoms. However, a combination of active ingredients has not been shown to be any more effective than a preparation containing a therapeutic amount of a single agent.<sup>15,30</sup> Theoretically, restricting the number of ingredients should decrease the risk of interactions and adverse drug reactions, while also lessening the likelihood of altering the product's effectiveness.<sup>30</sup>

**TABLE 17-5 Selected Nonprescription Products for Hemorrhoids**

<i>Trade Name</i>	<i>Primary Ingredients</i>
<b>Local Anesthetics</b>	
Americaine Ointment <sup>a</sup>	Benzocaine 20%
Tronolane Anesthetic Hemorrhoid Cream <sup>b</sup>	Pramoxine HCl 1%; zinc oxide 5%
TUCKS Hemorrhoidal Ointment <sup>c</sup>	Pramoxine HCl 1%; zinc oxide 12.5%; mineral oil 46.6%
TUCKS Fast Relief Spray <sup>c</sup>	Pramoxine HCl 1%
<b>Vasoconstrictors</b>	
Preparation H Cooling Gel <sup>d</sup>	Witch hazel 50%; phenylephrine HCl 0.25%
Preparation H Suppositories <sup>d</sup>	Phenylephrine HCl 0.25%; cocoa butter 88.4%
<b>Skin Protectants</b>	
Preparation H Ointment <sup>d</sup>	Mineral oil 14%; petrolatum 74.9%; phenylephrine HCl 0.25%
TUCKS Internal Soothers Suppositories <sup>c</sup>	Topical starch 51%
<b>Hydrocortisone Products</b>	
Preparation H Anti-Itch Cream Hydrocortisone 1% <sup>d</sup>	Hydrocortisone 1%
<b>Miscellaneous Combination Products</b>	

Preparation H Maximum Strength Pain Relief Cream <sup>d</sup>	Glycerin 14.4%; phenylephrine HCl 0.25%; pramoxine HCl 1%; white petrolatum 15%
Preparation H Medicated Wipes <sup>d</sup>	Witch hazel 50%
TUCKS Medicated Cooling Pads <sup>c</sup>	Witch hazel 50%

#### Product Selection Guidelines

Table 17-5 contains examples of products that can be recommended for hemorrhoids.

Knowledge of a patient's medical history, medication profile, and relevant socioeconomic factors is necessary to determine how an individual may respond to self-treatment. Selection of a product should be based on (1) the type, location, and severity of the anorectal disorder; (2) diseases or significant past medical history; (3) medications; (4) allergies; (5) ability to apply or insert the medication (considering physical, mental, and emotional limitations); and (6) any other factors that may affect treatment (e.g., diet, daily activities, and the cost of the product).

#### Special Populations

Pregnant and breast-feeding women should use products recommended for external use; exceptions include the recommended protectants, which may be used internally. Recommending nonpharmacologic interventions, including increasing dietary fiber and fluid intake to minimize constipation, may be of benefit throughout the trimesters.<sup>32</sup> Children younger than 12 years who have hemorrhoids or any other anorectal disorder should be referred for further medical evaluation.<sup>15</sup> Because constipation is more common in the older population, these patients may be more prone to hemorrhoids and anal fissures.<sup>32</sup> Treatment for this population is similar to treatment of young patients. Patients who have a positive family history of colon cancer should be referred for further medical evaluation.<sup>32,33</sup>

#### Patient Factors

FDA does not require comparison trials between combination and individual products; therefore, therapeutic differences are unknown. However, when used to treat indicated anorectal symptoms, combination products containing approved ingredients in appropriate dosages are most likely therapeutically similar to individual drug products.<sup>12,15</sup> Any perceived differences most likely are related to personal preference for a specific product or dosage form. Using more than one product or products containing multiple ingredients is reasonable because patients may have multiple different symptoms that may not be completely treated by one product alone.<sup>10,12,15,30</sup>

Medications used to treat anorectal disorders are available in many dosage forms, including ointments, creams, suppositories, and gels. Applicators, intrarectal applicators, or the patient's fingers are used to facilitate applying and instilling the anorectal preparations. Creams, gels, ointments, pastes, liquids, and foams are used externally. Although considerable pharmaceutical differences exist among these dosage forms, therapeutic differences do not appear to be clinically different.<sup>15</sup> This discussion uses the term *ointment* to refer to all semisolid preparations designed for intrarectal or external use in the anorectal area. The primary function of an ointment is to provide a vehicle for the safe and efficient delivery of the active ingredients, yet some ointments also possess inherent protectant and emollient properties.

Suppositories are solid dosage forms that deliver drugs into body orifices, typically in the anorectal area.<sup>34</sup> Suppositories should not be recommended as an initial dosage form because they may leave the affected anal region and ascend into the rectum and lower colon when the patient is in an upright position.<sup>15,34</sup> If the patient remains in an upright position after inserting a suppository or ointment, the active ingredients may not distribute evenly over the anal mucosa. Therefore, when inserting the suppository, patients should lie on their left side with knees bent so that the drug remains in the affected area for at least 15-20 minutes.<sup>20</sup> Suppositories have a relatively slower onset of action than other formulations because the solid dosage form must dissolve to release the active ingredients (see Chapter 15). To prolong retention rates in the anorectal area, some health care providers recommend introducing the base of the suppository first, rather than the tapered end.<sup>34</sup> Also, a suppository that is too soft to administer can be hardened in the refrigerator for at least 30 minutes before use.<sup>34</sup>

Foam products theoretically should provide more rapid release of active ingredients compared with ointments.<sup>15</sup> However, foams are more expensive than ointments and do not offer any advantage. Also, foams may not remain in the affected area, and differences in the size of the foam bubbles may result in different concentrations of the active ingredient.<sup>15</sup>

#### Complementary Therapies

Dietary supplements used to treat hemorrhoids have been researched poorly, although several have evidence of efficacy to support their use.<sup>35</sup> The combination of diosmin and hesperidin (a micronized purified flavonoid fraction) has been used to stop acute bleeding and decrease symptoms associated with hemorrhoids.<sup>36</sup> The mechanism of action is still in question, but animal models suggest this product inhibits prostaglandin and thromboxane mediators, thereby decreasing the inflammatory processes. The combination appears safe when both are taken orally for less than 6 months, with the most common adverse effects being abdominal pain, diarrhea, and gastritis.<sup>36,37</sup> Purified diosmin without hesperidin administered orally or topically has been shown as effective in reducing pain, bleeding, and swelling with hemorrhoids.<sup>38</sup> Butcher's broom combined with other dietary supplements (e.g., flavonoids) may be effective in reducing pain associated with hemorrhoids.<sup>36,37</sup> Horse chestnut seed extract (HCSE) has been used to reduce bleeding and decrease swelling associated with hemorrhoids.<sup>37</sup> When the herbal agent is processed properly, it is considered relatively safe; the most commonly reported side effects include itching, nausea, and vomiting.<sup>39</sup> Improperly prepared HCSE preparations may be poisonous and may lead to death. (See Chapter 51 for further discussion of HCSE.)

#### Assessment of Anorectal Disorders: A Case-Based Approach

To accurately assess whether the anorectal disorder is self-treatable, a health care provider should obtain a thorough description of the patient's signs and symptoms. For self-treatable disorders, the provider should ask questions about the presence of specific diseases (e.g., hypertension, diabetes mellitus, benign prostatic hyperplasia, and psychiatric illness); prescription and nonprescription medications; complementary and alternative medicines; and diet, lifestyle, and exercise before recommending self-treatment. Cases 17-1 and 17-2 illustrate assessment of patients with anorectal disorders.

**Patient Counseling for Anorectal Disorders**

The most appropriate drug and nondrug measures for treating patient-specific anorectal signs and symptoms should be explained to each patient. Counseling should include dosage and frequency of administration, administration technique, possible adverse effects, precautions or warnings, and product storage. Patients should understand when self-care should be discontinued and when to consult a primary care provider. If the topical nonprescription agents do not resolve the anorectal symptoms within 7 days, medical referral is appropriate.<sup>12</sup> The box Patient Education for Anorectal Disorders lists specific information to provide patients.

**Case 17-1**

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Pregnant patient complains of heartburn for 2 weeks. Over the past 5 days, she has experienced symptoms of burning discomfort in the anal area and occasional pain with bowel movements. Blood was seen in the stools and on the toilet paper.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Straining during defecation causes discomfort. Bowel movement causes anal pain. Stool has become harder over the past few months, more so as she goes through her pregnancy. Drinking water seems to help her symptoms.
c. description of the patient's efforts to relieve the symptoms	When able to, scratching the anal area seems to relieve symptoms. She notices that her symptoms are less problematic on days she drinks more water.
d. patient's identity	Victoria Mills
e. age, sex, height, and weight	35 years old, female, 5 ft 4 in., 144 lb
f. patient's occupation	Stay-at-home mom
g. patient's dietary habits	Eats meat, ice cream, sweets, and pickles. Used to eat vegetables but now avoids them. Will occasionally eat some fruits, mostly pineapple.
h. patient's sleep habits	5-8 hours nightly
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Pregnant, early third trimester; MVI daily, folate daily, iron twice daily; docusate sodium as needed (few times weekly)
j. allergies	NKA
k. history of other adverse reactions to medications	None
l. other (describe) _____	Patient does water exercises every other day, but she admits exercising is becoming difficult as she approaches giving birth.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s) (Tables 17-1 and 17-2).	Patient is suffering from constipation, which may be causing the patient to have anorectal symptoms.
3. Identify exclusions for self-treatment (Figure 17-2).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if	Options include: (1) Recommend self-care with an appropriate OTC anorectal product, and advise on nondrug measures. (2) Recommend self-care with an appropriate OTC anorectal product, and advise on nondrug measures until

trriage to a health care provider is required, and share this information with the patient or caregiver.	patient contacts her primary care provider. (3) Refer patient to her primary care provider for medical evaluation of her symptoms. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The best option is #2: self-care and nondrug measures until patient can contact PCP. Recommend an external-hemorrhoidal agent only. If internal-use agents preferred, recommend products with protectants (except glycerin). Recommend patient increase fluid intake (water), dietary fibers (fruits, vegetables), and, if possible, exercise. Sitz baths used 3 times a day may resolve anorectal symptoms.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Your symptoms, including blood in the stools, may be related to hemorrhoids. The hemorrhoids may have developed because you are in your third trimester and have a baby growing in your uterus. These changes in your body cause you to have a lot of pressure, especially when you are having a bowel movement, which may produce hemorrhoids. Although your symptoms are infrequent, I'm concerned about the blood in your stools. Even though I'm recommending you use a self-care product, you should contact your PCP for further evaluation in a few days, if your symptoms do not improve."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Although your symptoms, including blood in the stools, may be related to hemorrhoids, you should contact your PCP for further evaluation because other conditions may also cause similar symptoms, including rectal bleeding."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. appropriate dose and frequency of administration	See <a href="#">Table 17-4</a> .
b. maximum number of days the therapy should be employed	"Contact your PCP as soon as possible, even if your symptoms resolve with treatment. Be sure to let your primary care provider know what self-care measures you have taken. Ask your PCP whether you should continue with your self-treatment if your symptoms do not resolve after 7 days."
c. product administration procedures	See <a href="#">Table 17-3</a> .
d. expected time to onset of relief	"The irritation, burning, and discomfort may be relieved within a few days of applying the topical agent as directed. Straining may be relieved with adequate fluids and a healthy diet that is high in dietary fibers. If required, keep using the stool softener, or add a fiber supplement, as needed. Although the rectal bleeding may stop with treatment, still contact your PCP."
e. degree of relief that can be reasonably expected	"Complete relief of your anorectal symptoms may be possible, but you should expect to continue to have these symptoms until the birth of your child."
f. most common side effects	"Most products applied to the anal area are usually well-tolerated."
g. side effects that warrant medical intervention should they occur	"If you develop an allergic reaction to the product (redness, swelling, increased irritation, or pain), discontinue use, and contact your PCP as soon as possible."
h. patient options in the event that condition worsens or persists	"If your symptoms worsen, contact your PCP as soon as possible."
i. product storage requirements	"Store medication out of the reach of children and at a controlled room temperature."
j. specific nondrug measures	"Practice good anal hygiene, take sitz baths, and consider modifying your diet to increase fluids and fiber to soften stools and decrease straining."
Solicit follow-up questions from the patient or caregiver.	"Will this affect my newborn baby?"

Answer the patient's or caregiver's questions.	"Probably not. The anorectal complaints usually affect the mother. The newborn should not have anorectal problems at such a young age. Anorectal problems usually are not hereditary."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Ask the patient to call to update you on her response to your recommendations; alternatively, you could call her in a week to evaluate her response and make sure that she touched base with her PCP.

Key: MVI = Multiple vitamin; NKA = no known allergies; OTC = over-the-counter; PCP: primary care provider.

### Case 17-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of bleeding in the anal area for the past 3 days. Patient experiences burning, pain, and blood on the toilet paper with each wiping. He has had these symptoms before but says there is more blood this time than he has seen in the past. He describes his stool as being more "pencil-like" over the past few months.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Symptoms are worst at night, especially after eating and before going to bed. This time is also when he has his bowel movements. He has not changed his soaps or detergents, and he has not changed his diet or exercise.
c. description of the patient's efforts to relieve the symptoms	The patient has tried topical hydrocortisone cream in the anorectal area without relief for the last 2 days.
d. patient's identity	Simon Jabor
e. age, sex, height, and weight	42 years old, male, 5 ft 11 in., 193 lb
f. patient's occupation	Attorney
g. patient's dietary habits	Eats healthy meals, including meat, fruits, and vegetables. Occasionally eats sweets. Drinks alcohol at social events, which is about once every few months.
h. patient's sleep habits	8-9 hours nightly
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Hypertension diagnosed at age 38: felodipine 5 mg daily
j. allergies	Sulfa (anaphylactic reaction)
k. history of other adverse reactions to medications	None
l. other (describe) _____	Simon's dad died 20 years ago secondary to colon cancer at the age of 45. His mom is alive and diagnosed with diabetes. He has no siblings. He is happily married and has two children.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s) (Tables 17-1 and 17-2).	Patient noticed burning, pain, and blood on the toilet paper with each wiping. He states that this is not uncommon but that lately there is a lot more blood than he has seen in the past. He states that his diet, fluid, and exercise regimens have not changed. He is 42. Considering that Simon is in his 40s and has a family history of colon cancer, there may be a genetic relationship; therefore, there is a probability that he has an oncologic condition.
3. Identify exclusions for self-treatment (Figure 17-2).	Bleeding in the anal area; change in stool consistency to "pencil-like." Strong family history of colon cancer.

4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Recommend self-care with an appropriate OTC anorectal product, and advise on nondrug measures. (2) Recommend self-care with an appropriate OTC anorectal product, and advise on nondrug measures until patient contacts his PCP. (3) Refer patient to his PCP for medical evaluation of his symptoms immediately. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Patient should consult a health care provider immediately for medical evaluation to rule out bleeding from a source other than a hemorrhoid. He is young and has had a change in stool consistency over the past few months. Patient may have colon cancer because there is a strong family history of cancer (Figure 17-2).
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should consult a health care provider for immediate medical evaluation. I'm concerned about a few things, including your symptoms and your family history."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Because you tried using the hydrocortisone cream for 2 days with no relief, the best option is for you to see your primary care provider immediately. You have a strong family history of colon cancer. The signs and symptoms you are complaining about may be symptoms of colon cancer. Please see your primary care provider to have your symptoms evaluated and testing done as soon as possible."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"Is my wife at risk of acquiring colon cancer?"
Answer the patient's or caregiver's questions.	"No. Colon cancer is not transmitted via blood. Your wife may have other colon cancer risk factors (e.g., a low-fiber diet), but she cannot contract it from you."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact the patient in a day or two to ensure he made an appointment and sought immediate and appropriate medical care.

Key: NKA = No known allergies; OTC = over-the-counter; PCP = primary care provider.

### Evaluation of Patient Outcomes for Anorectal Disorders

Self-treatment of anorectal disorders should be limited to minor symptoms. If serious or severe symptoms are present, or if symptoms become progressively worse, advise the patient to contact his or her primary care provider. In addition, if alarm signs or symptoms are present, including blood in the stool or severe anal pain, or if symptoms persist beyond 7 days of self-treatment, the patient should be counseled to seek immediate medical attention.<sup>12</sup> If symptoms resolve, the patient should be encouraged to maintain a well-balanced diet, good personal hygiene, and good bowel habits.<sup>20</sup>

### Key Points for Anorectal Disorders

- Limit self-treatment to burning, itching, discomfort, swelling, and irritation.
- Refer patients to their primary care provider when symptoms include anorectal seepage, bleeding, thrombosis, severe pain, fevers, or a change in bowel patterns.
- Advise patients with self-treatable symptoms to contact their primary care provider if symptoms worsen or do not improve after 7 days.
- Advise pregnant and breast-feeding women to use only products for external use (except for protectants that do not contain glycerin, which can be used internally).
- Refer parents and caregivers of children younger than 12 years to seek medical attention from a primary care provider.
- To minimize undesirable effects, advise patients to select an anorectal product containing the fewest number of ingredients necessary to treat specific symptoms.
- Instruct patients on the proper use or application of specific anorectal products (Table 17-3).
- Counsel patients on nondrug measures (e.g., dietary measures and perianal hygiene) (see the box Patient Education for Anorectal Disorders).
- Do not use vasoconstrictors in patients with conditions such as diabetes, hypertension, and cardiac disease because of the possibility of systemic adverse effects.
- Advise patients on the advantages and disadvantages of various anorectal dosage forms so the best product can be selected for their needs.

### Patient Education for Anorectal Disorders

The objectives of self-treatment are to (1) relieve specific signs and symptoms and (2) prevent complications leading to serious problems. For most patients, carefully following product instructions and the self-care measures listed here will help ensure relief of symptoms.

### Nondrug Measures

- Maintain hydration and a healthy diet. If experiencing hard stools, straining, or constipation, increase amount of fiber and fluids in the diet to reduce or prevent straining during bowel movements (see [Chapter 15](#)).
- Avoid medications that cause constipation, if possible (see [Chapter 15](#)).
- Clean anorectal area after each bowel movement with a moistened, unscented, white toilet tissue or wipe.
- Use a sitz bath, or soak in a bathtub two to four times a day, which may help mild anal itching, burning, irritation, and discomfort. Avoid use of soaps, salts, and oils.

### Nonprescription Medications

- Select products containing only the ingredients needed to relieve specific anorectal symptoms.
- See [Table 17-3](#) for guidelines for applying anorectal products.
- See [Table 17-4](#) for recommended dosages of these products.
- Use only selected vasoconstrictors (ephedrine and phenylephrine), protectants (not glycerin), and astringents (calamine and zinc oxide) intrarectally.
- (If patient is pregnant) Use only products approved for external use. If internal use is required, protectants, with the exception of glycerin, may be used.
- (If patient has a history of cardiovascular disease, diabetes, hyperthyroidism, hypertension, depression, or difficulty urinating because of prostate problems) Avoid topical products that contain vasoconstrictors.
- (If taking medications for hypertension or depression) Avoid using any anorectal product containing vasoconstrictors without first consulting your primary care provider.
- Monitor for nervousness, tremor, sleeplessness, nausea, and possible loss of appetite when using an anorectal product containing ephedrine sulfate or phenylephrine.
- Explain that a reduction or relief of symptoms should occur within a few days of self-treatment.
- Review patient's preferences, especially when the patient may choose from an ointment, cream, or suppository, and when generic products are available.

### When to Seek Medical Attention

- Stop using the anorectal product and contact a primary care provider as soon as possible if insertion of a product into the anorectal area causes pain.
- Contact a primary care provider if symptoms worsen, if new symptoms (e.g., bleeding) develop, or if symptoms do not improve after 7 days of self-treatment.
- Discontinue using product and contact a primary care provider at the first occurrence of side effects (e.g., a rash; increased itching, redness, burning, or swelling in the anorectal area).
- Discontinue product and contact a primary care provider immediately if allergic or hypersensitivity reactions to the anorectal product develop.

## Handbook of Nonprescription Drugs > Chapter 18. Pinworm Infection

### Pinworm Infection: Introduction

*Enterobius vermicularis*, commonly referred to as “pinworm,” “seatworm,” “threadworm,” or oxyuriasis, is an intestinal nematode and the primary agent that causes human enterobiasis. This chapter will focus on the detection and management of pinworm infection because it is the most common worm infestation in the United States, and it is the only helminthic infection for which a nonprescription medication has been approved for treatment. This infection is most common in temperate regions of the world; in the United States, pinworms are found with a high prevalence in day care settings and urban areas.<sup>1,2</sup> Although pinworms are a nuisance, the pinworm infection presents little risk to the infected individual or the public.

Pinworm infection may be the most common helminth infection in the United States, with the greatest infection rate in children ages 5-14 years.<sup>3</sup> Enterobiasis is associated with all socioeconomic levels and, in contrast to other helminthic infections, does not affect any particular race or culture. Nearly 50% of all *E. vermicularis* cases occur among individuals who are institutionalized (e.g., in child care facilities or hospitals) and among family members.<sup>3,4,6</sup>

### Pathophysiology of Pinworm Infection

Humans are the only hosts of *E. vermicularis*. Unlike most other worm infections, pinworms do not live in the soil or water and are not transmitted through animal feces. However, animal fur of household dogs and cats may be a carrier of infective eggs.<sup>4</sup> The most common pinworm transmission route is through ingestion of infective eggs by direct anus-to-mouth transfer by fingers or fomites. Reinfection may occur readily, because eggs often are found under fingernails of infected children who have scratched the anal area. Finger sucking may be considered a source of infection, particularly in children with recurring symptoms.<sup>4</sup> Nail biting and nose picking have not been associated with the initial infection; however, they certainly can contribute to reinfection.<sup>5</sup> Embryonated eggs also can be transferred from the perianal region to clothes, bedding, or bathroom fixtures; because of their small size, pinworm eggs sometimes can become airborne in dust and reach the intestinal tract through the nose during breathing.<sup>1,6</sup> The eggs can remain viable outside the intestinal tract for 20 days (especially under humid conditions) and can spread within a microcommunity (e.g., a household or school).<sup>7</sup>

After 1-2 months of molting, the adult pinworm emerges as small, white, thread-like worm with a pin-shaped, pointed tail (from which the name is derived; see Color Plates, photograph 1A); its lifespan is about 2 months.<sup>3,7</sup> Adult male and female worms inhabit the first portion of the large intestine, or ileocecum, and seldom cause damage to the intestinal wall. The mature female, approximately 8-13 mm in length, usually stores approximately 11,000 eggs in her body (see Color Plates, photograph 1B). After her nocturnal migration down the colon and out the anus, she deposits her sticky eggs in the perianal region and dies shortly afterward. Males are smaller (2.5 mm), live approximately 2 weeks, and do not migrate. If eggs are not washed off, they hatch within a few hours, and larvae may return to the large intestine through the anus (retroinfection). Within 2-6 weeks of egg ingestion, larvae are released and mature into gravid females, thus continuing the cycle indefinitely unless appropriate behavioral and pharmacotherapeutic interventions are instituted.

Rarely, extraintestinal infestations, typically involving the genitourinary tract, may occur. As many as 36% of young girls with urinary tract infections may be infected with pinworms because the pinworms have mistakenly crawled into the urogenital tract.<sup>1</sup> Genitourinary pinworm infections are harder to treat because of the low systemic absorption of antiparasitic agents.<sup>7</sup>

### Clinical Presentation of Pinworm Infection

Patients with minor pinworm infections often are asymptomatic. Nocturnal pruritus ani, a perianal or perineal itch, is the most common symptom of enterobiasis.<sup>1</sup> Perianal itching occurs predominantly at night and is caused by an inflammatory reaction to the presence of adult worms and eggs on the perianal skin.<sup>2</sup> Major infestations may produce symptoms ranging from abdominal pain, insomnia, and restlessness, to anorexia, diarrhea, and intractable localized itching.<sup>4,5</sup> Patients with severe symptoms of major infestations and extraintestinal disease should be referred to a primary care provider (PCP) for further evaluation. Before recommending treatment or referral, the pharmacist should ask appropriate assessment questions to rule out diaper dermatitis in children, as well as constipation and hemorrhoids in older patients because these conditions also can cause inflammation in the rectal region, leading to

itching and discomfort.

In addition to physical signs and symptoms, psychological trauma (i.e., pinworm neurosis) to patients and parents also can occur when worms are found near a child's anus. Patients and parents need to be assured that pinworms are common and curable and that no social stigma is attached to their occurrence.<sup>5</sup>

Scratching to relieve itching from pinworm infection may lead to secondary bacterial infection of the perianal and perineal regions.<sup>7</sup> Helminthic infections in the genital tract may lead to endometritis, salpingitis, tubo-ovarian abscess, pelvic inflammatory disease, vulvovaginitis, and possibly infertility.<sup>7-9</sup> Pinworms also may migrate into the peritoneal cavity and form granulomas. Rarely, they may cause appendicitis in children.<sup>10</sup>

## Treatment of Pinworm Infection

### Treatment Goals

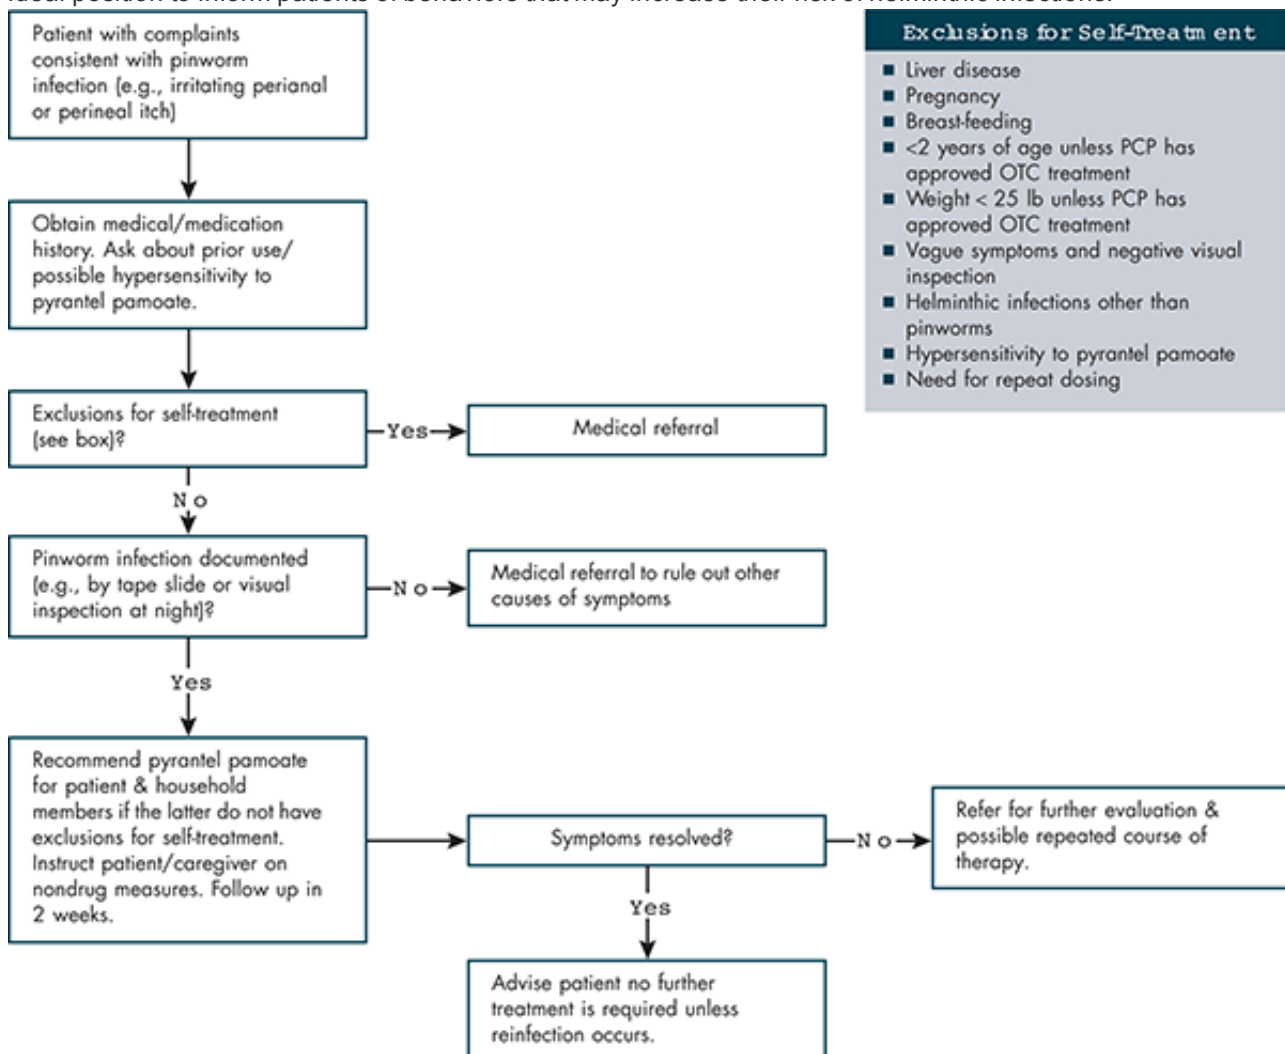

The goals of self-treatment are to relieve symptoms of pinworm infection and to eradicate pinworms from the patient and the household, thereby preventing reinfection.

### General Treatment Approach

The management of pinworm infection and prevention of reinfection includes drug treatment with pyrantel pamoate for the patient and for every household member. Strict hygiene (e.g., washing linens and disinfecting toilet seats) is an integral part of the treatment. [Figure 18-1](#) outlines self-care of this infection and lists exclusions for self-treatment.

### Nonpharmacologic Therapy

Once pinworm infection is suspected, the patient or caregiver should follow the nondrug measures in [Table 18-1](#) to minimize family and household infections and reinfections. Children can usually return to school after the first dose of an appropriate anthelmintic agent and after their fingernails are cut and cleaned. Health care providers are in an ideal position to inform patients of behaviors that may increase their risk of helminthic infections.

Self-care of pinworm infection. Key: OTC = Over-the-counter; PCP = primary care provider.

**TABLE 18-1 Nondrug and Preventive Measures for Treating Pinworm Infection**

<ul style="list-style-type: none"> <li>• Educate the public in personal hygiene, particularly the need to wash hands before eating or preparing food and after using the toilet. Encourage keeping fingernails short to prevent harboring of eggs and autoinoculation (hand-to-mouth reinfection); discourage biting nails and scratching anal area.</li> </ul>
<ul style="list-style-type: none"> <li>• Eggs are destroyed by sunlight and ultraviolet rays, so ensure blinds or curtains are open in the affected room to enhance cleaning of the environment.</li> </ul>
<ul style="list-style-type: none"> <li>• Wash bed linens, underwear, bedclothes, and towels of the infected individual and the entire family in hot water daily during treatment. Pinworm eggs are killed by exposure to temperatures of 131°F (55°C) for a few seconds; therefore, the “hot” cycle should be used while washing and drying.</li> </ul>
<ul style="list-style-type: none"> <li>• Bathe daily in the morning; showers (stand-up baths) are preferred over tub baths.</li> </ul>
<ul style="list-style-type: none"> <li>• Change underwear, nightclothes, and bed sheets daily for several days after treatment.</li> </ul>
<ul style="list-style-type: none"> <li>• Clean and vacuum (do not sweep) house daily for several days after treatment of cases. Wet mopping before or instead of vacuuming may limit spread of pinworm eggs into the air.</li> </ul>
<ul style="list-style-type: none"> <li>• Reduce overcrowding in living accommodations.</li> </ul>

Source: Heymann D. *Control of Communicable Diseases Manual*. 19th ed. Washington, DC: American Public Health Association; 2008.

## Pharmacologic Therapy

### Pyrantel Pamoate

Pyrantel pamoate is the only nonprescription medication approved for treatment of pinworm infection. Pyrantel pamoate was first used in veterinary practice as a broad-spectrum drug for pinworms, roundworms, and hookworms. It has become an important drug for treating certain helminthic infections in humans. Pyrantel pamoate has a cure rate of 90%-100% when used for treatment of enterobiasis.<sup>11</sup> This variable cure rate may be a result of the medication's lack of effect on eggs and larvae as well as the eggs' viability for up to 20 days, which may lead to reinfection.

Although this product is readily available in a nonprescription form, helminthic infections other than those caused by pinworms require a medical referral and should be diagnosed and treated by a PCP.

Pyrantel pamoate is a depolarizing neuromuscular agent that paralyzes adult worms, causing them to loosen their hold on the intestinal wall and subsequently be passed out in the stool before they can lay eggs. The drug is poorly absorbed, with 50% excreted unchanged in the feces and about 7% excreted in the urine as unchanged drug and metabolites.<sup>11</sup>

A single oral dose of pyrantel pamoate (liquid, caplet, or chewable tablet) is based on the adult or child patient's body weight (11 mg/kg of the pyrantel base). The maximum single dose is 1 gram. The recommended dosage is the same for children younger than 2 years or weighing less than 25 pounds; however, they should not be treated without first consulting a PCP. The product includes a schedule of recommended dosages that is based on a range of body weights. The dose can be repeated in 2 weeks if symptoms do not resolve because reinfection can occur; however, the repeat dose should be administered only after consultation with a PCP. Pyrantel pamoate may be taken at any time of the day without regard to meals, and it may be taken or mixed with milk or fruit juice.<sup>11</sup> A special diet or fasting before or after administration is not necessary. The liquid formulation (containing 50 mg/mL of the pyrantel base) should be shaken well before the dose is measured.

Side effects usually are mild, infrequent, and transient. The most common adverse effects involve the gastrointestinal (GI) tract and include nausea, vomiting, tenesmus, anorexia, diarrhea, and abdominal cramps.<sup>12</sup> These adverse effects are typically related to expulsion of the helminths from the GI tract. However, a patient who experiences severe or persistent abdominal symptoms or other side effects after taking the first or second dose of this medication should be referred to a PCP for further evaluation. Less common side effects such as headache, dizziness, drowsiness, insomnia, rash, fever, and weakness may occur. In very rare circumstances, transient increases in aspartate aminotransferase, ototoxicity, optic neuritis, and hallucinations with confusion and paresthesia have been reported.<sup>11</sup>

Patients who do not respond to the recommended doses of pyrantel pamoate should be evaluated further, and the

use of prescription products should be considered. Mebendazole (Vermox) once was considered by experts to be the drug of choice to treat pinworm infection,<sup>13,14</sup> but it has since been discontinued by the manufacturer. The currently available prescription agent for treatment of pinworm infection is albendazole. Albendazole is approved to treat other helminthic infections, but FDA considers its use off label when used to treat pinworms. Albendazole is given as a single oral dose (400 mg for patients ages 2 years and older; 200 mg for patients younger than 2 years).

#### Product Selection Guidelines

Pyrantel pamoate is a safe and effective treatment for pinworms. The brands listed in [Table 18-2](#) are comparatively priced and generally less expensive than prescription treatment (e.g., albendazole). Pyrantel pamoate is contraindicated in patients with hypersensitivity to the drug. Patients with preexisting liver dysfunction or severe malnutrition should not self-medicate without first consulting a PCP. Pyrantel pamoate is Pregnancy Category C and has not been studied in pregnant women; therefore, it should be used during pregnancy only when the benefits clearly outweigh the risks, and only under the direction of a PCP.<sup>15</sup> The World Health Organization does not recommend the use of pyrantel pamoate during the second and third trimesters for high-risk patients.<sup>6</sup> Pyrantel pamoate also should not be used in patients younger than 2 years or those weighing less than 25 pounds, unless under the direction of a PCP.

**TABLE 18-2 Selected Nonprescription Pyrantel Pamoate Products**

<i>Trade Name</i>	<i>Primary Ingredient</i>
Pin-X Liquid/Chewable Tablet	Pyrantel 50 mg/mL (base) and 250 mg/tablet (base)
Pyrantel Suspension	Pyrantel 50 mg/mL (base)
Reese's Pinworm Caplet	Pyrantel 180 mg (equals 62.5 mg base)
Reese's Pinworm Medicine Liquid	Pyrantel 144 mg/mL (equals 50 mg/mL base)
Reese's Pinworm Medicine Family Pack	Pyrantel 144 mg/mL (equals 50 mg/mL base); contains two 1-fl oz bottles to treat the entire family

#### Complementary Therapies

Various home remedies (e.g., applying a combination of garlic paste and Vaseline to the anus, or ingesting coconut oil and castor oil) and complementary therapies (e.g., white willow bark, green tea, or turmeric) have been used to treat pinworm infection. These remedies should not be recommended because insufficient efficacy and safety evidence exists to support their use for the treatment of pinworm infections. Because of the high risk of transmission of this infection, patients instead should take nonprescription medications such as pyrantel pamoate or prescription medications that are approved by the Food and Drug Administration (FDA) for pinworm infection.

#### Assessment of Pinworm Infection: A Case-Based Approach

Before recommending treatment, the provider should explain how to confirm a pinworm infection by any of the following methods: (1) nighttime perianal or perineal itching in a child, (2) visual inspection of the perianal or perineal area for the adult worm, or (3) a cellophane tape or an adhesive paddle test. Adult pinworms and eggs are seldom found in the feces; therefore, looking for worms in the stool is not a reliable way to diagnose enterobiasis.<sup>16</sup> When symptoms of pinworms (e.g., nocturnal perianal or perineal itching) are present in children, nonprescription therapy may be initiated. Other more vague symptoms (e.g., sleep disturbances and GI complaints) should be evaluated medically before initiating nonprescription therapy. However, asymptomatic disease is common in enterobiasis, and visual inspection may be necessary. To conduct a visual inspection, the parent should inspect the anal area during the night with a flashlight while the child is sleeping or in the very early morning before the child arises. White, thread-like, wriggling worms between 3 and 7 mm in length (about the size of a staple) may be seen. If pinworms are present, treatment should be initiated. Finally, if pinworms are suspected but symptoms are vague and/or visual inspection is negative, a PCP may instruct the patient to obtain a cellophane tape sample. The parent should apply the sticky side of the tape to the perianal area (usually with a tongue depressor) and affix it sticky side down on a glass slide. Commercially available kits, such as the Falcon SWUBE paddles, use a sticky paddle instead of tape to affix to a slide (see Color Plates, photograph 1C). These pinworm paddles usually are supplied by laboratories to conduct the test. Samples should be taken over 3 consecutive days upon the child's awakening, which may increase the likelihood of detection to around 90%.<sup>5</sup> The samples should then be taken to a PCP for microscopic examination. If the test is positive, treatment of the pinworm infection should be initiated.

Cases 18-1 and 18-2 illustrate the assessment of patients with pinworm infections.

### Patient Counseling for Pinworm Infection

Once the decision to treat the pinworm infection with pyrantel pamoate is made, the package insert material should be reviewed with the patient or caregiver. The insert explains the pinworm life cycle, symptoms of pinworm infection, and methods of transmitting the infection. Doses should be calculated for the patient and all family members, and the need to treat the whole family should be emphasized. The patient or caregiver should be advised to implement strict hygienic measures to prevent reinfection or transmission of the infection to other family members (Table 18-1). In addition, it should be explained that the side effects of pyrantel pamoate usually are mild and infrequent, but that medical referral may be necessary if more severe effects occur. Patients who experience severe or persistent symptoms after taking this medication should be referred for medical evaluation. Finally, patients should be advised that pinworm infection symptoms (e.g., nocturnal perianal itching) should improve within 2 weeks of treatment and that if symptoms persist or worsen to include systemic complaints (e.g., abdominal discomfort, insomnia, and/or nervousness), medical referral may be necessary. The box Patient Education for Pinworm Infection lists specific information to provide patients.

### Evaluation of Patient Outcomes for Pinworm Infection

The patient or caregiver should be instructed to contact a PCP if anal itching persists beyond 2 weeks, if the itching recurs, or if new symptoms develop. Because of pyrantel pamoate's variable cure rate, a second dose may be required. It should be given 2 weeks after the first dose and only under the care of a PCP. In addition, the patient or caregiver should be asked about the implementation of hygienic measures. If these measures are not being followed, their importance for preventing reinfection should be stressed again.

### Key Points for Pinworm Infection

- Pinworms are common in the United States and rarely cause significant morbidity.
- Health care providers should be familiar with common helminthic infections, their symptoms, and their treatment.
- A medical referral may be necessary when helminths other than pinworms are suspected.
- Although pyrantel pamoate is used in treating other helminthic infections, only pinworm infection should be evaluated for self-treatment with this nonprescription agent.
- Health care providers can aid patients and caregivers in the self-diagnosis, counseling, and self-treatment with nonprescription pinworm medication.

### Case 18-1

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patients' symptoms, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	A man presents to the pharmacy requesting assistance in selecting an OTC product for his family. He reports that his daughter was diagnosed with pinworms by the pediatrician, who recommended an OTC medication to treat the daughter as well as mom and dad. The father says his daughter has been complaining about perianal itching that is most intense at night. He and his wife have no current symptoms. He needs a liquid formulation because his daughter cannot swallow tablets or capsules.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patients'	No precipitating factors

symptom(s)	
c. description of the patients' efforts to relieve the symptoms	The parents applied hydrocortisone cream to the child's perianal region for itching, with no relief.
d. patients' identity	Daughter: Bella Turner; mother: Karen Turner; Father: Ray Turner
e. age, sex, height, and weight	Daughter: 5 years old, female, 3 ft 6 in., 39 lb; mother: 32 years old, female, 5 ft. 6 in., 143 lb; father: 36 years old, male, 5 ft 11 in., 190 lb
f. patients' occupation	The father is an attorney, and his wife is a real estate agent.
g. patients' dietary habits	Normal diet
h. patients' sleep habits	Daughter: frequent awakenings at night caused by perianal itching; parents: normal sleep habits
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Daughter: daily children's chewable multivitamin; mother: oral contraceptive pills, daily multivitamin; father: fish oil capsules daily
j. allergies	Daughter: NKDA, mother: NKDA, father: penicillin allergy
k. history of other adverse reactions to medications	None
l. other (describe) _____	The father does cardio and weight training at the gym 3 days a week.
<b>Assessment and Triage</b>	
2. Differentiate patients' signs/symptoms and correctly identify the patient's primary problem(s).	Bella is experiencing perianal itching because of a pinworm infection, which results in restless sleep at nights.
3. Identify exclusions for self-treatment (Figure 18-1).	Patients should be excluded for self-treatment if they (1) are allergic to the OTC product, (2) are younger than 2 years (unless treatment is approved by PCP), (3) weigh less than 25 lb (unless treatment is approved by PCP), or (4) have liver disease. The patients do not have exclusions for self-treatment.
4. Formulate a	Options include:

comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patients or caregiver.	(1) Recommend an appropriate OTC product (e.g., pyrantel pamoate) at appropriate doses for each member of the family, along with nondrug therapies. (2) Recommend that mother and father see their PCP for a prescription medication. (3) Counsel only on environmental control measures. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patients' problem, taking into account patient preferences.	OTC treatment with pyrantel pamoate is appropriate for all three patients. The child is not comfortable swallowing tablets or caplets, but she can take chewable tablets or liquid formulations; therefore, pyrantel pamoate is a good choice.
6. Describe the recommended therapeutic approach to the patients or caregiver.	"Both albendazole and pyrantel pamoate are effective in the treatment of pinworms. However, pyrantel pamoate is available without a prescription, and albendazole requires a prescription. Because one of your family members was recently diagnosed with pinworm infection and the medical provider instructed that other family members be treated, pyrantel pamoate is a reasonable option."
7. Explain to the patients or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Pinworms are not life threatening and may resolve on their own. However, if the infection is untreated, the infected person (in this case, your daughter) may reinfect herself or infect other family members. She also may experience some complications of infection if she is not treated. Therefore, treatment is recommended. Pyrantel pamoate is a reasonable option because it is available without a prescription; therefore, the other family members do not need to visit a primary care provider, which could have increased the cost of treatment and delay its initiation. Pyrantel pamoate also is available as a chewable tablet or an oral suspension, which offers flexible dosing that is based on weight for multiple family members. Other formulations (e.g., tablets and caplets) are available, if preferred."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patients or caregiver:	
a. appropriate dose and frequency of administration	Bella (daughter) weighs 17.7 kg (39 lb); the dose of pyrantel is 11 mg/kg, so she should receive about 195 mg. She can take 4 mL of the liquid formulation (144 mg/mL equivalent to 50 mg/mL pyrantel base). Karen (mom) weighs 65.0 kg, so she should receive at least 715 mg of pyrantel pamoate (which would be approximately 3 chewable tablets or 15 mL of the liquid formulation). Ray (dad) weighs 86.4 kg, so he should receive 950 mg of pyrantel pamoate (4 chewable tablets or about 25 mL of the liquid formulation).

b. maximum number of days the therapy should be employed	"A single dose usually is required. If symptoms persist after 2 weeks, contact your primary care provider for evaluation and, if needed, recommendation for a second dose."
c. product administration procedures	"Pyrantel pamoate may be taken at any time of day without regard to meals. It may be mixed with milk or fruit juice. If using the oral suspension, shake well before administering." [Note: Prior to administering medication, the practitioner should verify that other family members who need to be treated do not meet criteria for exclusion for self-treatment. Doses will need to be calculated for the other family members.]
d. expected time to onset of relief	"Relief of symptoms may take several days. The repeat dose should not be administered until 2 weeks have elapsed and should be administered only if recommended by your primary care provider."
e. degree of relief that can be reasonably expected	"Perianal itching should decrease after several days, with complete pinworm eradication after at least 2 weeks."
f. most common side effects	"Adverse effects are usually mild and may consist of nausea, vomiting, loss of appetite, diarrhea, or abdominal cramps."
g. side effects that warrant medical intervention should they occur	"Severe or persistent abdominal symptoms require medical attention."
h. patient options in the event that condition worsens or persists	"Contact the appropriate health care provider if any family member's condition worsens, or if any family member experiences any severe adverse effects, such as severe or persistent abdominal symptoms, after taking the medication." [Note: The practitioner should reinforce to the parents that pinworms are very common and rarely cause serious problems, but that the condition will continue and potentially spread to others if not treated.]
i. product storage requirements	"Store at room temperature away from direct light with container sealed tightly."
j. specific nondrug measures	See <a href="#">Table 18-1</a> .
Solicit follow-up questions from the patient or caregiver.	"Should my daughter receive a prescription medication instead because she has an active infection?"
Answer the patient's or caregiver's questions.	"Both the prescription and nonprescription medications are equally effective in treating pinworms. You can use either the prescription medication or the nonprescription pyrantel pamoate, depending on your preferences (such as cost)."
<b>Evaluation of Patient Outcomes</b>	
9. Assess patient outcome	You can call the parents in 1-2 weeks to assess the child's response to the medication. If symptoms have resolved, reinforce the importance of hygienic measures. If symptoms persist, another single dose of pyrantel pamoate can be administered but only after

reevaluation by the child's pediatrician.

Key: NA = NKDA = No known drug allergies; OTC = over-the-counter; PCP = primary care provider.

**Case 18-2**

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	A woman presents to the pharmacy requesting assistance choosing a product to help "tie up her stomach" and a product to help her with intense itching. She says she's had loose stool and generalized abdominal pain for about 2 weeks. She mentions that her stool has been watery most of the time and that she's noticed little white squiggly things on the tissue after wiping. The itching, which began approximately 10 days before the diarrhea started, is mostly in her perineal and vaginal area and is worse at night.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	No precipitating factors
c. description of the patient's efforts to relieve the symptoms	She tried bismuth subsalicylate for 3 days without much relief. She took 3 doses of loperamide, which helped the diarrhea temporarily but did not help the itching. She's tried applying hemorrhoidal ointment and hydrocortisone ointment to the region to help with the itching.
d. patient's identity	Letty Whitaker
e. age, sex, height, and weight	46 years old, female, 5 ft 2 in., 140 lb
f. patient's occupation	Dance instructor
g. patient's dietary habits	Normal diet, high in fruits and vegetables
h. patient's sleep habits	Frequent awakenings at night caused by perineal itching
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Daily multivitamin; occasional ibuprofen or acetaminophen for pain
j. allergies	NKDA
k. history of other adverse	None

reactions to medications	
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Patient's symptoms, such as perianal itching at night, are consistent with pinworms, but prolonged diarrhea and abdominal pain are unusual symptoms and should be evaluated medically. The appearance of "white squiggly things" on the tissue may indicate the presence of pinworms, but a tape test or a slide test must be done to confirm infection.
3. Identify exclusions for self-treatment (Figure 18-1).	Consider the patient to be excluded from self-treatment if she (1) is allergic to the OTC product, (2) is younger than 2 years (unless treatment approved by PCP), (3) weighs less than 25 lb (unless treatment approved by PCP), (4) has liver disease, (5) is pregnant, (6) is breast-feeding, or (7) has vague symptoms and negative visual inspection.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Recommend an appropriate OTC product at appropriate doses for the patient, along with nondrug therapies. (2) Refer the patient to a PCP for further evaluation, diagnosis, and recommended treatment. (3) Counsel on only environmental control measures. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Medical evaluation by a PCP is warranted for the perineal, gastrointestinal, and vaginal symptoms and subsequent treatment.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should see your primary care provider for further evaluation of your symptoms, appropriate diagnosis, and recommended treatment."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Because you have no documented pinworm infection, either by visual inspection or by tape slide, and because you have other symptoms that may be complications of a pinworm infection, self-treatment is not appropriate. Your symptoms may be consistent with pinworm infection, but other possibilities need to be ruled out."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Self-treatment is not appropriate, but you should institute environmental control measures shown in Table 18-1 and seek medical care.
Solicit follow-up questions from the patient or caregiver.	(1) "What are some of the complications associated with pinworms?" (2) "How are pinworms normally treated?"

Answer the patient's or caregiver's questions.	(1) "If untreated, pinworms may possibly lead to secondary bacterial infections in the perianal and perineal regions. Pinworms also can lead to pelvic inflammatory disease, endometritis, and urinary tract infections. In addition, other possible symptoms associated with pinworm infection include insomnia, restlessness, and anorexia." (2) "Patients may be treated with a single dose of various nonprescription (pyrantel pamoate) or prescription (albendazole) medications. Along with medications, patients also must follow specific nondrug measures to prevent reinfection."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome	Ask the patient to call you in 1 week, or initiate a follow-up call to the patient to assess whether she was evaluated by a physician and whether her symptoms are improving.

Key: OTC = Over-the-counter; PCP = primary care provider.

#### Patient Education for Pinworm Infection

The objectives of self-treatment are to (1) eradicate pinworms in the infected patient, (2) prevent reinfection, and (3) prevent transmission of the infection to others. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Nondrug Measures

- See [Table 18-1](#) for nondrug/preventive measures.

#### Nonprescription Medications

- Read package insert for pyrantel pamoate information carefully; this information will help prevent reinfection or transmission of the infection.
- Consult a primary care provider before giving the medication to a person with liver disease or severe malnutrition, a child who is younger than 2 years and/or weighs less than 25 pounds, or a woman who is pregnant or breast-feeding.
- Treat all household members to ensure elimination of the infection. Medical referral may be necessary if household members meet criteria for exclusion for self-treatment (e.g., malnutrition, pregnancy, liver disease, anemia, or age younger than 2 years).
- Take only one dose as shown on the dosing schedule included with the product. For adults and children older than 2 years, dosing is the same: 11 mg/kg taken orally. The maximum dose is 1 gram.
- Shake the liquid formulation well, and use a measuring spoon to ensure an accurate dose.
- If desired, pyrantel pamoate may be taken with food, milk, or fruit juices on an empty stomach any time during the day. The liquid formulation may be mixed with milk or fruit juice.
- Note that fasting, laxatives, and special diets are not necessary to aid treatment.

#### When to Seek Medical Attention

- Seek medical attention if you experience any of the following:
  - Abdominal cramps, nausea, vomiting, anorexia, rash, diarrhea, headache, drowsiness, or dizziness occurs and persists after taking the medication.
  - Symptoms of the pinworm infection persist beyond 2 weeks after the initial dose of pyrantel pamoate. A second dose of pyrantel pamoate can be given if symptoms are present beyond 2 weeks, but only if directed to do so by a primary care provider.
  - Rare symptoms such as vaginal itching or bleeding, pain upon urination, urinary tract infection, and hives are present.

**Handbook of Nonprescription Drugs > Chapter 19. Nausea and Vomiting****Nausea and Vomiting: Introduction**

Nausea and vomiting (N/V) symptoms can occur in both adults and children from a variety of circumstances associated with several medical disorders. Common self-care disorders that involve N/V are motion sickness, pregnancy (NVP), acute viral gastroenteritis, and “upset stomach” (overeating or indigestion). Nonprescription antiemetics can be used to prevent or treat the symptoms of N/V for these disorders. Vomiting accounts for 2.3% of all emergency department visits in the United States.<sup>1</sup> Accurate data on the epidemiology of N/V are not available because these symptoms occur in many medical disorders and many individuals do not report these disturbances to a health care provider.

The severity of N/V related to motion sickness is difficult to quantify because of interindividual variability and susceptibility to the condition. Motion sickness rarely occurs in children younger than 2 years. Women are more susceptible than men to motion sickness (1.7:1), and symptoms of nausea occur more often during menstruation and pregnancy.<sup>2</sup>

The incidence of N/V in early pregnancy is quoted as between 50% and 80%. Typically these symptoms subside by the 20th week of pregnancy, but they may persist throughout the pregnancy in 20% of women.<sup>3</sup> Half of all pregnant women have both nausea and vomiting, one-fourth have nausea only, and it is rare for only vomiting to occur.<sup>4</sup> A very severe form of pregnancy-related vomiting, hyperemesis gravidarum, occurs in less than 1% of women and may require rehydration and hospitalization.<sup>5</sup>

The third typically self-treatable cause of N/V is acute viral gastroenteritis. Viral gastroenteritis is an inflammation of the stomach and small intestines that commonly presents with acute vomiting and diarrhea.<sup>6</sup> This illness may affect any age group and is usually self-limiting, but pediatric patients may experience serious consequences from dehydration.<sup>7</sup> Gastroenteritis is most commonly caused by rotavirus and norovirus and occurs most often in autumn and winter<sup>8</sup> (see [Chapter 16](#)). The Centers for Disease Control and Prevention (CDC) reports that in children, rotavirus infections result in approximately 400,000 physician visits, up to 272,000 emergency room visits, and 55,000-70,000 annual hospitalizations, with total costs approximating \$1 billion.<sup>9</sup> The rotavirus vaccine is included in the childhood immunization schedule.<sup>10</sup> CDC estimates that 19-21 million cases of acute gastroenteritis each year are due to norovirus infection, and that norovirus is the most common cause of foodborne disease outbreaks.<sup>11</sup>

The last self-care disorder that involves N/V is indigestion or distension associated with overeating. Limited treatment options for this disorder are discussed in this chapter. A more comprehensive discussion occurs in [Chapter 13](#).

**Pathophysiology of Nausea and Vomiting**

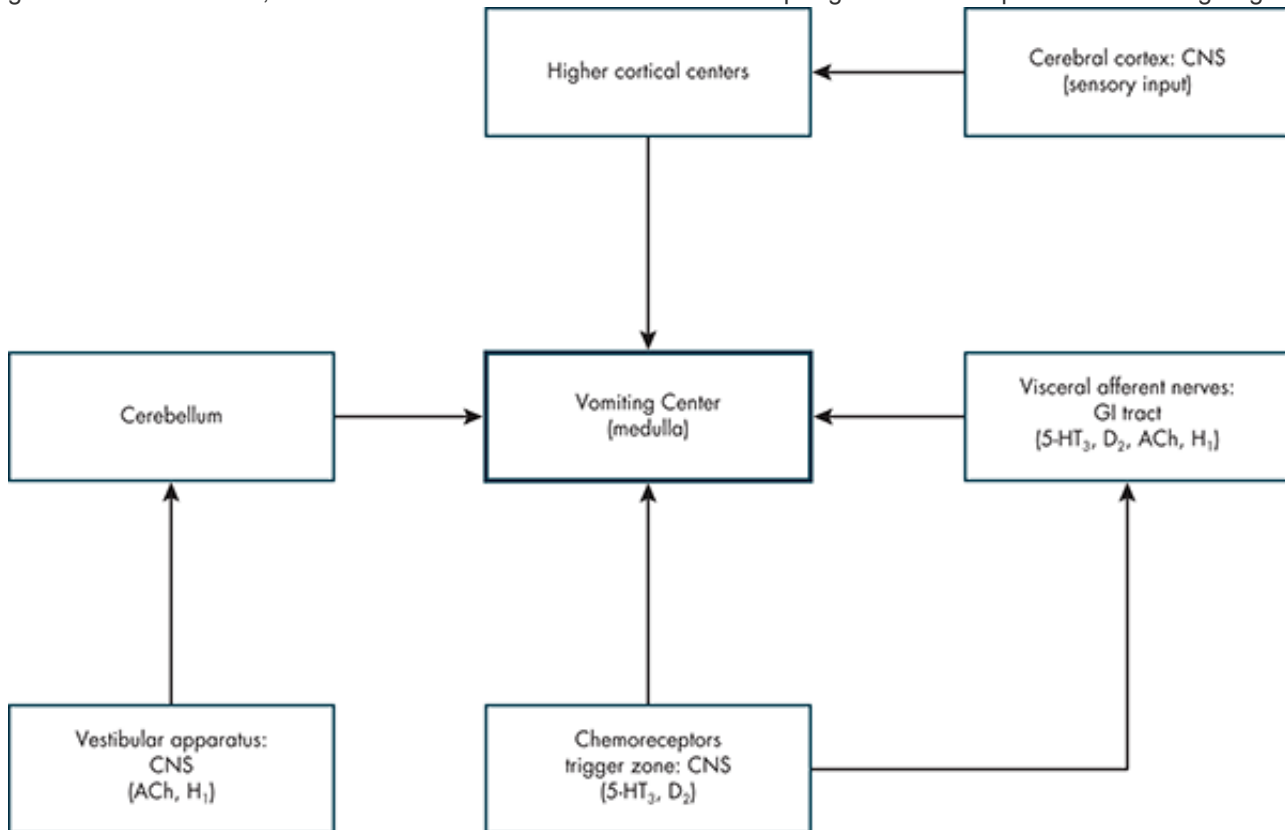

The pathophysiology of N/V involves both the central nervous system (CNS) and the gastrointestinal (GI) tract. Figure 19-1 shows four different areas of the body that provide input to a complex system of neurons in the medulla oblongata in the brain stem, known as the vomiting center (VC): the chemoreceptor trigger zone (CTZ), vestibular apparatus, cerebral cortex, and visceral GI tract afferent nerves.<sup>12-14</sup>

The neurons in the CTZ are outside the blood-brain barrier, therefore the CTZ responds to stimuli from either the bloodstream or the cerebral spinal fluid.<sup>13,14</sup> The vestibular apparatus is located in the bony labyrinth of the temporal lobe. It detects motion and body position, including changes in equilibrium; direct input to the VC is through cholinergic pathways. The cerebral cortex system provides input to the VC through higher cortical centers; this pathway for initiating emesis is the least understood. Sensory input, including sight, smell, anticipation, or memory, may elicit a strong sensation of nausea through the cerebral cortex.<sup>14</sup> Finally, visceral afferent nerve pathways from the GI tract have numerous neurotransmitters that provide input to the VC. Major neurotransmitters and receptors involved in vomiting include serotonin, dopamine, histamine type 1, acetylcholine, opioid, and neurokinin receptors.<sup>12,13</sup>

The VC is triggered by different stimuli in the CNS and GI tract, sending impulses to the salivation center, vasomotor center, respiratory center, and cranial nerves, and then to the pharynx and GI tract, after which nausea and/or vomiting may occur.<sup>14</sup> [Table 19-1](#) lists several stimuli that may elicit N/V; however, many of these are not self-limiting and require medical evaluation and treatment.<sup>12-16</sup> Causes discussed in this chapter (motion sickness, pregnancy, viral gastroenteritis, and overeating) may be self-treatable or prevented with proper patient education.

Emesis, or vomiting, is thought to be a complicated defense response secondary to a variety of different mechanisms.

Retching may occur after subjective feelings of nausea. The abdominal and diaphragmatic musculature may contract or relax, and the associated coordinating circuitry involves other areas such as the laryngeal or pharyngeal muscles. The epiglottis closes to prevent aspiration, the soft palate is elevated, a retrograde contraction occurs while the gastric fundus relaxes, and the stomach contents move into the esophagus and are expelled as vomiting begins.<sup>14</sup>

Vomiting center. Key: ACh = Acetylcholine; CNS = central nervous system; D<sub>2</sub> = dopamine; GI = gastrointestinal; H<sub>1</sub> = histamine type 1; 5-HT<sub>3</sub> = serotonin.

Nausea and vomiting of motion sickness are produced by overstimulation of the labyrinth (inner ear) apparatus.<sup>2</sup> The three semicircular canals in the labyrinth on each side of the head are responsible for maintaining equilibrium. Postural adjustments are made when the brain receives nerve impulses initiated by the movement of fluid in the canals. When the head is rotated on two axes simultaneously, unusual motion patterns may produce motion sickness. Inaccurate interpretation of visual stimuli while standing or sitting motionless may also produce motion sickness. For instance, a person may experience motion sickness when watching a film taken from a roller coaster, watching an airplane performing aerobatics, or extending the head upward while standing on a rotating platform.<sup>2</sup> Individuals differ in their response to motion sickness stimuli, such as flying and boating, but no one is immune. Regardless of the type of stimulus-producing event, motion sickness is easier to prevent than to treat with antiemetics that target the primary neurotransmitters acetylcholine and histamine type 1 in the vestibular apparatus.<sup>17</sup> In pregnancy, it is unclear which neurotransmitters are the cause of N/V, as it is thought to be multifactorial.<sup>17</sup> A Cochrane review published in 2010 found that certain nonprescription antiemetics, such as doxylamine and dimenhydrinate, are generally effective in NVP, but little information exists on fetal outcomes.<sup>3</sup> Approximately 10% of women with NVP will require treatment with medication,<sup>18</sup> but providers may avoid antiemetics until dehydration, weight loss, or electrolyte imbalances occur.<sup>16</sup>

Nausea and vomiting secondary to acute gastroenteritis are caused by intestinal irritation. The visceral afferent nerves are mediated primarily through dopamine, serotonin, acetylcholine, and histamine type 1 receptors; therefore, therapy is targeted at those neurotransmitters.<sup>12,14,16,17</sup>

Gut distension and decreased GI emptying may stimulate mechanoreceptors and may be responsible for eliciting N/V related to overeating.<sup>8</sup>

### Clinical Presentation of Nausea and Vomiting

Nausea and vomiting consist of three different processes: (1) nausea (characterized by a person's subjective feeling of a need to vomit); (2) retching (involuntary rhythmic diaphragmatic and abdominal contractions); and (3) vomiting

(rapid, forceful expulsion of the GI tract contents).<sup>12,13,16</sup> Although most cases of N/V are self-limiting, a patient may show signs and symptoms that warrant medical referral. Possible acute complications of vomiting include dehydration, esophageal tears manifested by blood in the vomitus, aspiration, malnutrition, electrolyte and/or acid-base abnormalities, diaphragmatic herniation, and Mallory-Weiss syndrome.<sup>16</sup> Dehydration and electrolyte imbalances are the major concerns associated with vomiting. Signs and symptoms of dehydration include dry mouth, decreased skin turgor, excessive thirst, little or no urination, dizziness, lightheadedness, fainting, and reduced blood pressure.<sup>16</sup> These symptoms warrant medical referral for further evaluation.

**TABLE 19-1 Primary Causes of Nausea and Vomiting**

<i>GI Tract (visceral afferent nerves)</i>	<i>CNS Disorders</i>	<i>Other Disorders</i>
<p><b>Mechanical Obstruction</b> GI obstruction (e.g., PUD, gastric carcinoma, pancreatic disease); small intestine obstruction</p> <p><b>Motility Disorders</b> Gastroparesis (e.g., DM, drug-induced, postviral); chronic intestinal pseudo-obstruction; IBS; anorexia nervosa; idiopathic gastric stasis</p> <p><b>Peritoneal Irritation</b> Appendicitis; bacterial peritonitis; pancreatitis</p> <p><b>Infections</b> Viral gastroenteritis<sup>a</sup> (e.g., norovirus, rotavirus); food poisoning (e.g., toxins from <i>Bacillus cereus</i>, <i>Staphylococcus aureus</i>, <i>Clostridium perfringens</i>); hepatitis A or B; acute systemic infections</p> <p><b>Topical Gastrointestinal Irritants</b> Alcohol; NSAIDs; antibiotics, iron</p>	<p><b>Vestibular Disorders</b> Labyrinthitis; Ménière's syndrome; motion sickness<sup>a</sup></p> <p><b>Increased Intracranial Pressure</b> CNS tumor; subdural or subarachnoid hemorrhage; pseudotumor cerebri</p> <p><b>Infections</b> Meningitis; encephalitis</p> <p><b>Psychogenic</b> Anticipatory vomiting; bulimia; psychiatric disorders (anxiety)</p> <p><b>Other CNS Disorders</b> Migraine headache</p> <p><b>Irritation of CTZ (medication-induced)</b> Chemotherapy; opiates; theophylline or digoxin toxicity; antibiotics; radiation therapy; drug withdrawal (e.g., opiates, BDZs)</p>	<p>Cardiac disease (e.g., MI, HF); urologic disease (e.g., stones, pyelonephritis); overeating<sup>a</sup></p> <p>DM (e.g., DKA); renal disease (e.g., uremia); adrenocortical crisis (e.g., Addison's disease); pregnancy<sup>a</sup></p>

Key: BDZ = Benzodiazepine; CNS = central nervous system; CTZ = chemotrigger receptor zone; DKA = diabetic ketoacidosis; DM = diabetes mellitus; GI = gastrointestinal; HF = heart failure; IBS = irritable bowel syndrome; MI = myocardial infarction; NSAIDs = nonsteroidal anti-inflammatory drugs; PUD = peptic ulcer disease.

<sup>a</sup> Self-treatable or preventable disorders.

Source: References 8, 9, 11, 12, 14, and 15.

In infants and small children, recurrent or protracted N/V (with accompanying diarrhea) may lead to marked dehydration and electrolyte imbalance that should not be ignored. Parents should be educated to recognize signs and symptoms of dehydration, such as dry mucous membranes, decreased skin turgor, irritability, altered mental status, and weight loss (Table 19-2).<sup>19-21</sup> The child should be referred for further evaluation if there are any exclusions for self-care of N/V.<sup>6,19</sup>

## Treatment of Nausea and Vomiting

### Treatment Goals

The goals of treating N/V are to (1) provide symptomatic relief, (2) identify and correct the underlying cause, (3) prevent and correct complications, and (4) prevent future occurrences.

### General Treatment Approach

Most acute cases of N/V are self-limiting and will resolve spontaneously. A clear evaluation should be made to determine whether a patient is a candidate for self-treatment. The algorithms in Figures 19-2 and 19-3 outline the self-care treatment options and exclusions for self-care of N/V in adults<sup>16,22,23,24</sup> and children,<sup>19,20,21</sup> respectively.

Severe cases of vomiting can result in dehydration or electrolyte imbalances. This may necessitate further evaluation or hospitalization. Treatment of nausea and vomiting can involve pharmacologic prescription and nonprescription therapies, as well as nonpharmacologic options. Pharmacologic nonprescription options are limited and include antihistamines. Because most cases of N/V are acute, the nonpharmacologic treatment is primarily directed to correct dehydration and electrolyte imbalances. Commercial oral rehydration salt (ORS) solutions should be recommended to prevent these complications. These products contain sodium, chloride, potassium, and a carbohydrate such as glucose or dextrose to restore loss of electrolytes and also restore loss of fluids.

**TABLE 19-2 Signs and Symptoms of Dehydration in Children**

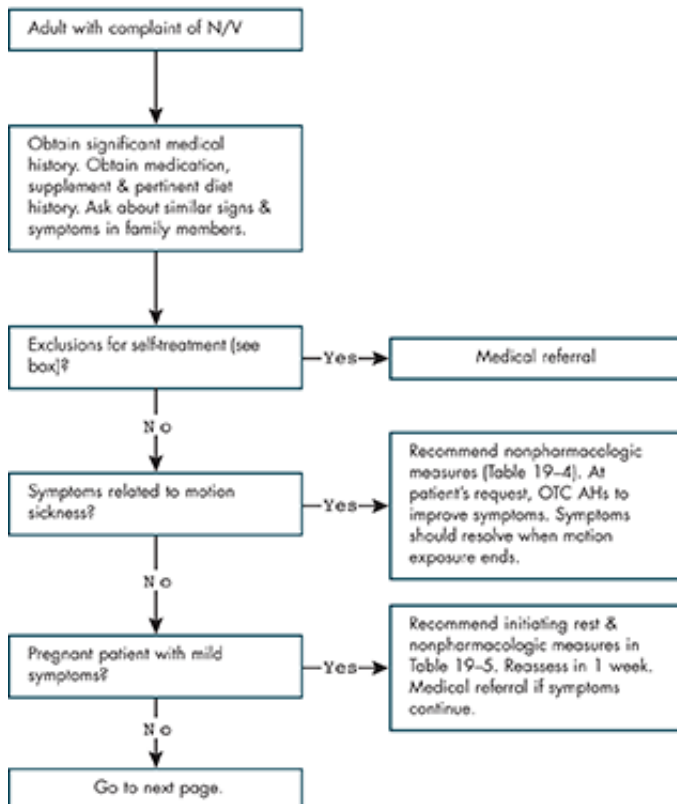

• Dry mouth and tongue
• Sunken and/or dry eyes
• Sunken fontanelle
• Decreased urine output (dry diapers for several hours)
• Dark urine
• Fast heartbeat
• Thirst (drinks extremely eagerly)
• Absence of tears when crying
• Decreased skin turgor
• Unusual lethargy, sleepiness, decreased alertness, or irritability
- Body is “floppy”
- Lightheadedness when sitting or standing up (in older children)
- Difficulty in waking up the child (may indicate severe dehydration)
• Weight loss
- Noticeable decrease in abdominal (“tummy”) size
- Clothes or diaper fits loosely
- <3% body weight loss, indicating minimal or no dehydration
- 3%-9% body weight loss, indicating mild-moderate dehydration
- ≥9% body weight loss, indicating severe dehydration

Source: References 18-20 and 23.

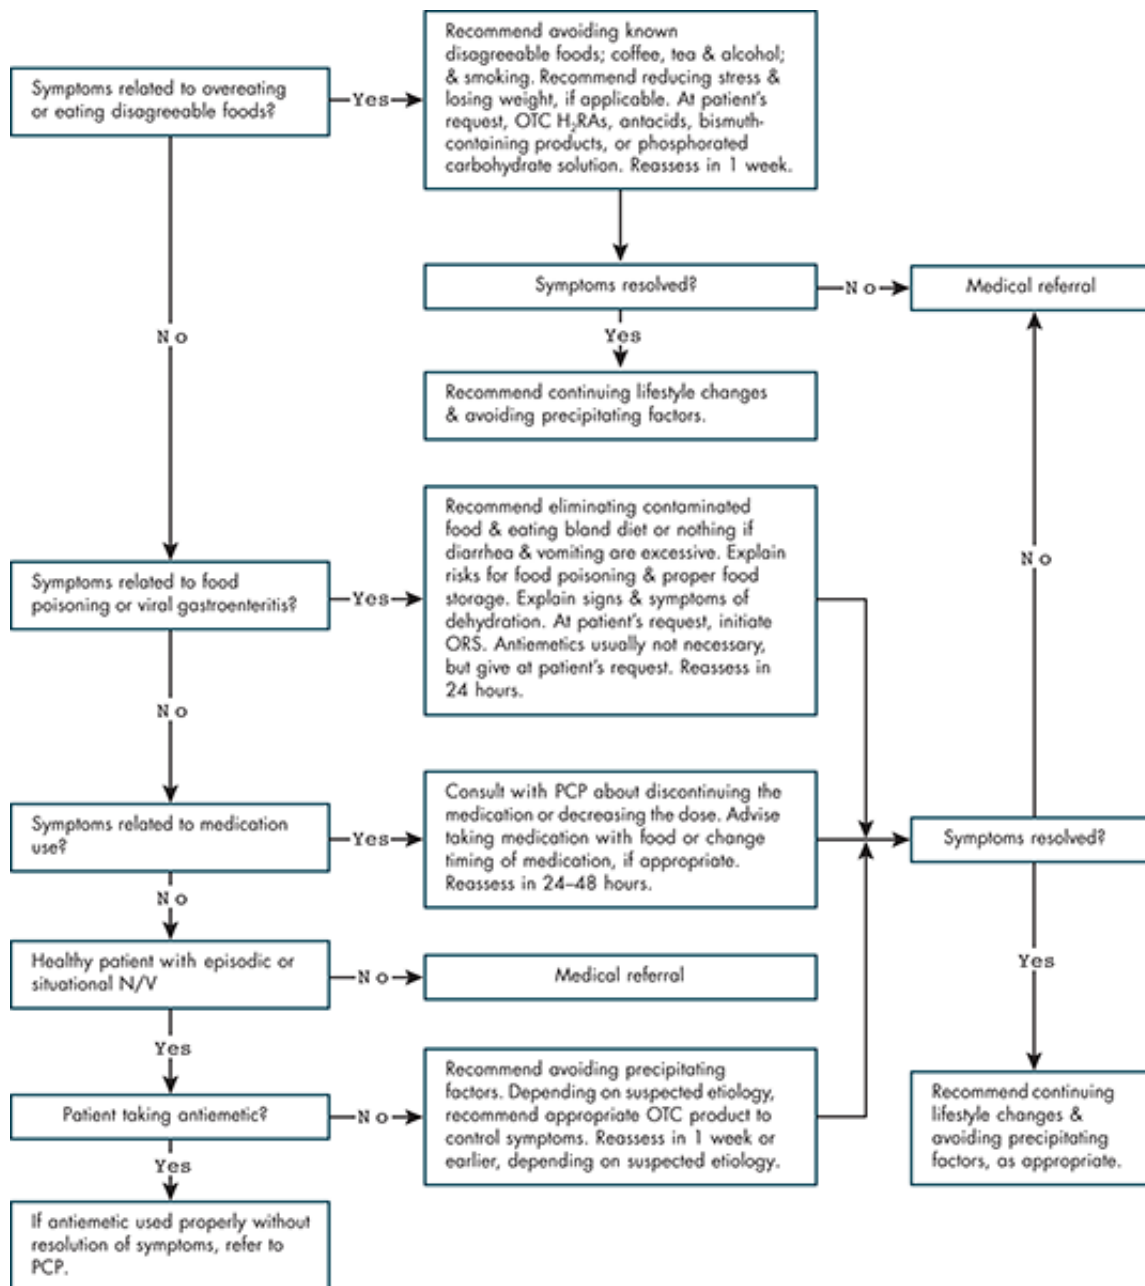

### Exclusions for Self-Treatment

- Urine ketones and/or high BG with signs of dehydration in patients with DM (may indicate DKA or HHS)
- Suspected food poisoning that does not clear up after 24 hours
- Severe abdominal pain in the middle or right lower quadrant (may indicate appendicitis or bowel obstruction)
- N/V with fever and/or diarrhea (may indicate infectious disease)
- Severe right upper quadrant pain, especially after eating fatty foods (may indicate cholecystitis or pancreatitis)
- Blood in the vomitus (may indicate ulcers, esophageal tears, or severe nosebleed)
- Yellow skin or eye discoloration and dark urine (may indicate hepatitis)
- Stiff neck with or without headache and sensitivity to brightness of normal light (may indicate meningitis)
- Head injury with N/V, blurry vision, or numbness and tingling
- Persons with glaucoma, BPH, chronic bronchitis, emphysema, or asthma (may react adversely to OTC antiemetics)
- Pregnancy (severe symptoms) or breastfeeding
- N/V caused by cancer chemotherapy; radiation therapy; serious metabolic disorders; CNS, GI, or endocrine disorders
- Drug-induced N/V: adverse effects of drugs used therapeutically (e.g., opioids, NSAIDs, antibiotics, estrogens); toxic doses of drugs used therapeutically (e.g., digoxin, theophylline, lithium); ethanol
- Psychogenic-induced N/V: bulimia, anorexia
- Chronic disease-induced N/V: gastroparesis with DM; DKA or HHS with DM; GERD

### Nonpharmacologic Therapy

ORS can be used for dehydration associated with vomiting or diarrhea.<sup>25</sup> In cases of vomiting, absorption of fluids may be compromised by continuous emesis in some patients. The World Health Organization (WHO) in conjunction with the United Nations Children's Fund (UNICEF) developed a solution for the treatment of dehydration.<sup>26</sup> The WHO/UNICEF ORS has a total osmolarity of 245 mOsm/L and includes 13.5 g/L of carbohydrates, 75 mmol/L of sodium, 20 mmol/L of potassium, 65 mmol/L chloride, and 30 mmol/L of a base. A simple, glucose-based ORS solution can be made by mixing one-half teaspoon of salt and 6 teaspoons of sugar in 1 liter of clean water.<sup>27</sup> In third world countries with low health literacy, this formula is roughly explained as a pinch of salt and a handful of sugar. Although glucose-based ORS solution does not contain potassium, supplementation with bananas or orange juice could be given. The glucose-based ORS solution is more isomolar and therefore more effective at rehydrating than water alone. Commercially available products and common examples can be found in [Table 19-3](#).

Sports drinks such as Gatorade or Powerade often do not contain the recommended balance of electrolytes. The preferred ratio of sugar to sodium is 3:1. Original formula Gatorade contains a sugar-to-sodium ratio of 15:1. Dilution of sports drinks with water by the patient may be an option, but it is difficult to achieve accurate sugar-to-sodium ratios, plus sports drinks are often available in multiple formulations. Too much sugar may draw water into the gastrointestinal tract and facilitate further dehydration. Likewise, sodas such as ginger ale or cola and fruit juices such as apple may also contain too much sugar.<sup>28</sup>

The typical dosing of ORS solution varies according to the level of dehydration and the age and weight of the patient. For minimal dehydration, children weighing less than 10 kg should be given 60–120 mL of solution after each vomiting episode; children weighing 10 kg or over should be given 120–240 mL per episode. Mild-moderate dehydration should be treated with 50–100 mL/kg over 3–4 hours. Severe dehydration should be referred to emergency care for intravenous rehydration.<sup>28</sup> Adults should also be rehydrated but may gauge their need according to thirst. Replacing 30%–50% of the fluid loss in the first 24 hours is preferred.<sup>16</sup>

Oral rehydration should be offered 10 minutes after the last episode of vomiting and should be offered in small increments. In general, 5 mL of ORS solution may be given to children every 5 minutes, and 15 mL may be given to older children and adults every 5 minutes.<sup>28</sup> Dosage forms such as Pedialyte Freezer Pops may offer the slow administration desired in active vomiting.

**TABLE 19-3 Selected ORS Solution Therapy**

Solution	Carbohydrate (g/L)	Sodium (mmol/L)	Potassium (mmol/L)	Chloride (mmol/L)	Base (mmol/L)	Total Osmolarity (mOsm/L)
WHO/UNICEF	13.5	75	20	65	30	245

ORS						
Enfalyte	30	50	25	45	34	200
Pedialyte	25	45	20	35	30	250
Rehydralyte	25	75	20	65	30	305
CeraLyte	40	50-90	20	NA	30	220

Key: NA = Not applicable; ORS = oral rehydration salt.

Source: Reference 27.

Other nonpharmacologic measures such as those listed in [Table 19-4](#) can also be tried to minimize and prevent motion sickness.<sup>2</sup> Because teratogenicity is a major consideration, many providers are reluctant to prescribe medications for pregnant women. Similarly, many of the medications are excreted in breast milk of lactating women, so nonpharmacologic approaches may be recommended in these populations, although such measures are not evidence based ([Table 19-5](#)).<sup>29</sup>

### Pharmacologic Therapy

Selection of a nonprescription medication for N/V is largely determined by the potential cause.

#### Nausea Associated with Motion Sickness

Antihistamines are effective and generally safe and well tolerated for nausea and vomiting related to motion sickness. A detailed description of antihistamines can be found in Chapter 11. Meclizine is the only FDA-approved nonprescription agent for the prevention of nausea, vomiting, or dizziness associated with motion sickness. Both doxylamine and diphenhydramine have been used as off-label treatments for nausea. [Table 19-6](#) lists age-specific dosages and maximum daily limits for these antiemetics.<sup>30</sup> Because of their anticholinergic effects, antihistamines may thicken bronchial secretions and should be used with caution in patients with respiratory conditions such as asthma, chronic bronchitis, and emphysema. In addition, the mydriatic effects of antihistamines may exacerbate angle-closure glaucoma. The urinary retention effects of antihistamines may also exacerbate symptoms of benign prostatic hypertrophy. Other side effects of nonprescription antihistamines include dry mouth, confusion, dizziness, tremors, and constipation.<sup>17</sup> Drowsiness is also a common adverse effect of antihistamines. Patients should avoid concomitant use with other CNS depressants, such as alcohol, hypnotics, and sedatives. This drowsiness, coupled with the potential for blurred vision, may inhibit the ability to safely drive or operate heavy machinery. Meclizine may be less sedating than doxylamine and diphenhydramine. Paradoxical stimulatory reactions such as insomnia, nervousness, and irritability may occur in some patients. Diphenhydramine is a mild-moderate inhibitor of the cytochrome P450 (CYP) 2D6 enzyme. Therefore, it should be used with caution with other medications metabolized by CYP2D6, such as certain opiates, psychiatric medications, beta blockers, and antiarrhythmics. Some case reports have noted that ultrarapid metabolizers of CYP2D6 may be at a higher risk for this paradoxical excitation. In the United States, approximately 1-2% of the population are estimated to be ultrarapid metabolizers.<sup>31</sup>

#### TABLE 19-4 Nonpharmacologic Measures to Prevent Motion Sickness

• Avoid reading during travel.
• Focus the line of vision fairly straight ahead (e.g., seat the patient in a position that allows vision out of the car window).
• Avoid excess food or alcohol before and during extended travel.
• Stay where motion is least experienced (e.g., front of the car; near the wings of an airplane; or midship [midway between bow and stern], preferably on deck).
• Avoid strong odors, particularly from food or tobacco smoke.
• Drive the vehicle if possible.

Source: Reference 2.

#### TABLE 19-5 Nonpharmacologic Measures to Prevent NVP

• Make sure you have fresh air in the room where you sleep.
• Before getting out of bed, eat several dry crackers and relax in bed for 10-15 minutes.
• Get out of bed very slowly, and do not make any sudden movements.
• Before eating breakfast, nibble on dry toast or crackers.
• Make sure there is plenty of fresh air in the area where meals are prepared and eaten.
• Eat four to five small meals per day instead of three large meals. Do not overeat at meals.
• Do not drink fluids or eat soups at mealtime. Instead, drink small sips of liquid between meals.
• When nauseated, try small sips of carbonated beverages or fruit juices.
• Avoid greasy or fatty foods such as fried foods, gravy, mayonnaise, and salad dressing, as well as spicy or acidic foods (citrus fruits and beverages, tomatoes).
• If necessary, eat food that is chilled rather than warm or hot (cold foods tend to be less nauseating).
• Eat dry, bland, and high-protein foods.

**TABLE 19-6 Dosage Guidelines for Nonprescription Antiemetic Antihistamines<sup>a</sup>**

Agent	Dosage (maximum daily dosage)		
	Adults and Children ≥ 12 Years	Children 6 to <12 Years	Children 2 to <6 Years
Cyclizine	50 mg 30 minutes before travel, then 50 mg every 4-6 hours (200 mg)	25 mg every 6-8 hours (75 mg)	Not recommended
Dimenhydrinate	50-100 mg every 4-6 hours (400 mg)	25-50 mg every 6-8 hours (150 mg)	12.5-25 mg every 6-8 hours (75 mg)
Diphenhydramine	25-50 mg every 4 hours (300 mg)	12.5-25 mg every 4 hours (150 mg)	6.25 mg every 4 hours (25 mg)
Meclizine	25-50 mg 1 hour before travel (50 mg)	Not recommended	Not recommended

<sup>a</sup> Take antihistamines at least 30-60 minutes before travel; then take continuously for the duration of travel.

Source: Reference 41.

### Nausea Associated with Food or Beverages

Nausea and vomiting may be associated with overindulgence in food or beverage or consumption of disagreeable foods, and it may present as heartburn, indigestion, and upset stomach. Antacids and histamine type 2-receptor antagonists (H<sub>2</sub>RAs) are approved to relieve symptoms associated with acid indigestion and sour stomach. However, antacids have marginal efficacy for the treatment of N/V secondary to nonulcer dyspepsia. Prolonged and predominant nausea and bloating may be a sign of gastrointestinal motility dysfunction and may require prescription pro-motility agents.<sup>32</sup>

Bismuth subsalicylate may have some benefits for nausea associated with consumption or nonulcer dyspepsia.<sup>33</sup> Bismuth subsalicylate is approved to treat various GI complaints, including nausea, heartburn, and fullness. An in-depth discussion of bismuth subsalicylate can be found in [Chapters 13 and 16](#).

Phosphorated carbohydrate solution (PCS) may also be useful in nausea associated with a food or beverage. This solution is a mixture of dextrose (glucose), levulose (fructose), and phosphoric acid.<sup>34</sup> The hyperosmolar solution is believed to relieve N/V by direct local action on the GI tract wall that may decrease smooth muscle contraction and delay gastric emptying time.<sup>35</sup>

Alternatively, concentrated cola syrup has been used, which also contains the sugars and phosphoric acid that are in PCS. Because commercially available soda is often at a 5:1 water-to-syrup ratio, substituting soda is not

recommended, even if flattened. PCS should be given in adults at 15-30 mL every 15 minutes until distress subsides. Taking more than 5 doses in 1 hour is not recommended. Children 2-12 years can take 5-10 mL every 15 minutes. Dosing should not be diluted, and other fluids should be avoided immediately before or after taking PCS.<sup>34</sup> Possible adverse effects of PCS are stomach pain and diarrhea. Each 5 mL of PCS contains 3.74 grams of total sugar,<sup>36</sup> so caution should be used in patients with diabetes. Likewise, patients with hereditary fructose intolerance should avoid using PCS.

### Product Selection Guidelines

Several factors that should be considered in the choice of antiemetic products include whether the patient is pregnant or lactating, the patient is a child or of advanced age, and the patient has any limitations such as hepatic or renal impairment. These factors may affect drug selection and dosing. Furthermore, the product should also be compatible with the patient's lifestyle, concurrent medication use, sensitivity to certain product ingredients such as dyes or fructose, and preference for frequency of dosing. Hence, product selection guidelines should be compatible with special populations and patient factors and should consider patient preferences such as whether the product is chewable or contains alcohol (Table 19-7).

**TABLE 19-7 Selected Nonprescription Antiemetic Products**

<i>Trade Name</i>	<i>Primary Ingredients/Features</i>
Bonine Chewable Tablets	Meclizine HCl 25 mg
Dramamine Less Drowsy Tablets	Meclizine HCl 25 mg
Bonine Kids Chewable Tablets	Cyclizine HCl 25 mg
Marezine Tablets	Cyclizine HCl 50 mg
Dramamine Orange Chewable Tablets	Dimenhydrinate 50 mg
Emetrol Cherry Flavor Liquid	Phosphoric acid 21.5 g/5 mL; dextrose 1.87 g/5 mL; fructose 1.87 g/5 mL
Pepto-Bismol Tablets, Suspension, Chewable Tablets	Bismuth subsalicylate 262 mg
BioBand <sup>a</sup>	Acupressure band worn on one wrist
ReliefBand NST (Nerve Stimulation Model)	Acupressure band worn on one wrist
Sea-Band	Acupressure band worn on both wrists

<sup>a</sup> See <http://www.biobands.com/instructions.htm> for guidelines on using this product.

### Special Populations

#### Pregnancy

Several nonpharmacologic recommendations can be made to help control NVP. For prevention of mild nausea, frequent small meals and avoidance of spicy or fatty foods or sensory stimuli that may provoke symptoms can be used. Bland carbohydrates, such as crackers, and high-protein snacks may be beneficial, especially in the morning. However, there is little published evidence supporting dietary changes for prevention of N/V. The American College of Obstetricians and Gynecologists (ACOG) recommends taking a multivitamin at the time of conception to decrease the severity of NVP in patients with a history of NVP.<sup>29</sup> This may not be useful if pregnant patients are presenting with nausea, but it may be an option for future preconception counseling.

Pyridoxine is pregnancy category A at recommended daily allowance (RDA) doses of 1.9 mg/day. It is Pregnancy Category C at doses above the RDA.<sup>37</sup> Pyridoxine is also excreted in breast milk. Extremely high doses of pyridoxine (600 mg/day) may inhibit prolactin secretion. The ACOG recommends pyridoxine with or without doxylamine as first-line pharmacotherapy for NVP.<sup>29</sup> From 1957 to 1983 a combination product of pyridoxine and doxylamine was available on the U.S. market. It has since been voluntarily removed because of lawsuits associated with congenital

anomalies; however, current evidence does not support these claims.<sup>38</sup> Today, the combination product may be compounded by pharmacists.<sup>29</sup> Ginger may be as effective as pyridoxine for treating NVP. See the complementary therapies section in this chapter for further discussion.

### Patients of Advanced Age

Antihistamines should be used with caution in patients of advanced age because of the increased risk of adverse effects. The anticholinergic and sedative effects may not be tolerable in this patient population. The American Geriatrics Society treats these medications as potentially inappropriate and strongly recommends avoiding antihistamines in patients of advanced age.<sup>39</sup> In addition, a comprehensive medication review may be necessary in this population to identify and resolve any potential drug-related problems, including drug interactions. PCS may be used if the patient does not have uncontrolled blood glucose levels or hereditary fructose intolerance. Acupressure, or any acustimulation products such as acupressure bands, should not be used in patients with pacemakers. Other nonpharmacologic options such as avoiding trigger foods and scents could also be considered.

### Lactation

Antihistamines may adversely affect the mother's milk supply and should be avoided in nursing mothers. Bismuth subsalicylate should also be used cautiously according to the American Academy of Pediatrics. Although the bismuth is poorly absorbed, the salicylate is excreted and eliminated slowly in the milk.<sup>40</sup> There is little evidence on the safety of ginger use in lactating women.

### Children

In newborns and infants, vomiting may rapidly lead to dehydration and acid-base disturbances. Vomiting is different from simple regurgitation, which is common in infants. Vomiting is distinguished as being more forceful and containing larger amounts of emesis. In newborns, vomiting may be caused by GI tract obstruction. In infants, vomiting may be a sign of gastroesophageal reflux disease (GERD). Nausea and vomiting can occur in children for a variety of reasons, including GI obstruction, central nervous system abnormalities, and infection.<sup>41</sup> The Centers for Disease Control and Prevention (CDC) classifies dehydration in children as mild if less than 3% of body weight is lost, moderate if 3%-9% is lost, and severe if greater than 9% of body weight is lost.<sup>28</sup> Moderate-severe cases of dehydration should be referred for treatment. Mild-moderate cases of dehydration should be treated with oral rehydration therapy as described in this chapter and in [Chapter 16](#). Antihistamines may diminish mental alertness and occasionally produce paradoxical excitation in young children.<sup>30</sup> Bismuth subsalicylate is not recommended in children because of the potential risk of Reye's syndrome, especially in children exposed to viral illness.<sup>40</sup>

### Complementary Therapies

Some evidence supports the use of complementary therapies such as ginger, pyridoxine (vitamin B<sub>6</sub>), and acupressure bands in nausea.

### Ginger

Ginger (*Zingiber officinale*) has been used for nausea related to pregnancy, motion sickness, and surgery.<sup>42</sup> A 2010 Cochrane review suggested that ginger may be superior to placebo in preventing NVP. The review reported no difference in spontaneous abortion, congenital abnormalities, or other fetal adverse outcomes, although the included studies may not have had sufficient power.<sup>3</sup> Other data are limited regarding the safety of ginger in pregnancy. Larger doses of ginger may lead to mild adverse GI effects including heartburn, diarrhea, and mouth irritation.<sup>43</sup> Some evidence suggests that ginger may have anticoagulant and hypotensive effects. In some countries, such as Finland and Denmark, ginger carries cautionary warnings for its use in pregnancy.<sup>44</sup> Ginger can be dosed at 250 mg of the root given orally four times daily for nausea. The total daily dose of 1 gram has also been given in 2-3 divided doses. Caution should be used in formulations that exceed the 1 gram daily recommended dose. Ginger may be as effective as pyridoxine for treating N/V. Compared with dimenhydrinate, ginger may cause fewer adverse effects.<sup>45</sup> (See [Chapter 51](#) for an in-depth discussion of ginger.) Most ginger ale products are often artificially flavored or contain amounts of ginger that are too insignificant to be therapeutic.

### *Pyridoxine* (Vitamin B<sub>6</sub>)

Pyridoxine is a water-soluble B vitamin that is important in various metabolic functions, including protein metabolism, hemoglobin synthesis, and neurotransmitter function.<sup>37</sup> The RDA of pyridoxine in healthy adults is 1.3-2 mg/day. Pyridoxine may be used in NVP. Typical dosing of pyridoxine for nausea is 10-25 mg three times a day. Pyridoxine is generally well tolerated. Large doses (>200 mg/day) of pyridoxine over longer periods of time (>2 months) may result in adverse effects such as peripheral neuropathy, weakness, lethargy, and nystagmus. Pyridoxine has had mixed results for efficacy in treating N/V. Overall data suggest that pyridoxine is effective.<sup>29</sup> Pregnancy-related nausea and vomiting is an off-label indication for pyridoxine. Some evidence suggests that pyridoxine may be more effective in severe cases of N/V.<sup>46</sup>

### Acupressure

The use of acupressure involves direct pressure on the pericardium-6 (P6) point on either wrist. The P6 point is located approximately two thumb widths from the middle crease of the wrist (see [acupuncture-points.org](http://acupuncture-points.org)). Pressure can be applied either with the finger or a wristband. Data suggest that both the finger and a wristband are effective in reducing the rate of nausea and vomiting in pregnancy and motion sickness.<sup>47,48</sup> In some studies, a high placebo rate is seen (i.e., pressure at a different anatomical site). The “dosing” of acupressure can vary from as needed, to 10 minutes three times a day, to continuous pressure. There are mixed results on the efficacy of each of the dosing regimens.<sup>48</sup>

### Aromatherapy

The use of peppermint oil for the treatment of N/V does not have reliable evidence to support its efficacy. In addition, the use of isopropyl alcohol may be more effective than a saline placebo but less effective than other standard antiemetic medications (both prescription and nonprescription). This lack of efficacy was found in studies that looked at the use of rescue antiemetics for postoperative nausea and vomiting. Evidence is lacking to support aromatherapy for self-treatment of N/V.<sup>49</sup>

### Summary of Treatment Options

Nonprescription antihistamines may be appropriate to prevent or control N/V associated with motion sickness. In general, antihistamines may cause drowsiness and anticholinergic adverse effects that can limit their use in young children, persons of advanced age, and lactating women.

PCS may be used in N/V associated with overeating. Other agents, such as antacids, H<sub>2</sub>RAs, and bismuth subsalicylate, have also been used. PCS should be avoided in patients with hereditary fructose intolerance. Bismuth subsalicylate should be avoided in children and patients sensitive to salicylates.

ORS is important in patients with dehydration secondary to vomiting. It provides a more balanced electrolyte distribution during rehydration. Smaller but more frequent doses of ORS solution are given to patients who are actively vomiting and may have trouble holding down fluids. All age groups, including pregnant and lactating women, may safely use ORS solution.

Complementary agents such as ginger, vitamin B<sub>6</sub> (pyridoxine), acupressure, and aromatherapy have also been used for N/V. There is mixed data for safety and efficacy of these treatment options. According to the American College of Obstetricians and Gynecologists, pyridoxine is a first-line agent for pregnancy-related nausea and vomiting. Acupressure and ginger have better efficacy data than aromatherapy.

### Assessment of Nausea and Vomiting: A Case-Based Approach

Vomiting is a symptom produced not only by benign processes but also by serious illnesses, and it may cause various complications. Physical assessment of the patient may help to determine whether some of the complications of N/V listed in the section Clinical Presentation of Nausea and Vomiting have occurred. Physical assessment should include the patient's general appearance, mental status, and volume status, and the presence of any abdominal pain. Evaluation of vital signs such as blood pressure, heart rate, temperature, and weight is also pertinent. Evaluation of concurrent signs and symptoms is useful in determining the potential cause of vomiting. It is also vital to determine whether a toxin could be the cause of the acute onset of vomiting. Therefore, asking about possible ingestion of a toxin, especially in preschoolers and adolescents, is necessary. Detailed information about the patient's medical history related to the GI tract is especially helpful in determining potential causes.

A major concern with vomiting is the loss of fluids and the inability to eat or drink. This situation may result in dehydration and electrolyte disturbances. Self-care is inappropriate for patients with dehydration, severe anorexia, weight loss, or poor nutritional status. Medical evaluation for dehydration should be provided when severe vomiting or diarrhea persists for more than several hours in children or for 48 hours in adults.<sup>23,24</sup>

Providers should be aware that some patients might use nonprescription antiemetics to self-treat the early stages of a serious illness. Therefore, to avoid potential additive toxicity, providers should ask patients what they have already

used to treat the symptoms. Many patients choose to self-medicate with various nonprescription products to avoid a medical office visit. However, providers should be cautious about recommending self-medication for N/V symptoms and should ask appropriate questions to determine whether medical referral is indicated.

Cases 19-1 and 19-2 are examples of the assessment of patients presenting with vomiting.

### Patient Counseling for Nausea and Vomiting

Providers should stress that treatment of N/V must focus on identifying and, if possible, correcting the underlying cause. Patients prone to overeating, eating disorders, or motion sickness should try to avoid behaviors or situations that cause N/V. Patients should be advised that acute vomiting typically requires only symptomatic treatment because it is usually self-limiting and will resolve spontaneously. If the cause of the symptoms is known and self-treatment is appropriate, proper use of the recommended product should be explained. Patient education should also include information about possible adverse effects, as well as signs and symptoms that indicate further medical attention is warranted. The box Patient Education for Nausea and Vomiting lists specific information to provide patients.

### Evaluation of Patient Outcomes for Nausea and Vomiting

After a provider has provided information or suggestions for self-management and treatment of N/V, a follow-up assessment of the patient should occur within 24 hours of the initial encounter. This evaluation may best be accomplished by a follow-up phone call and then, if desired by the patient, a scheduled appointment. The follow-up should include an assessment of whether the N/V has diminished or abated; whether the patient has any residual related symptoms, such as signs or symptoms of dehydration; whether abnormal vital signs such as tachycardia have returned to normal; and whether the patient is afebrile. If the patient had prolonged N/V (>24-48 hours) or a change in or worsening of symptoms that required immediate referral for medical evaluation, the provider should follow up to determine whether the patient sought medical help and what type of treatment was administered. It is also important for the provider to assess whether he or she needs to provide any further counseling or answer additional questions. The provider should also use this opportunity to provide reassurance and support.

#### Case 19-1

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient has had frequent episodes of nausea and occasional vomiting; this has been going on for 3-4 days. The episodes last a few hours during the main part of the day. She has maintained her appetite.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Symptoms seem to worsen when the patient smells coffee brewing and when she wakes up in the morning. Her husband now buys coffee instead of brewing it at home, but she still gets nauseated at work.
c. description of the patient's efforts to relieve the symptoms	The patient eats some dry toast and takes a few sips of ginger ale or water. She does not like the idea of taking "drugs" for her nausea.
d. patient's identity	Annabelle Grace

e. age, sex, height, and weight	28 years old, female, 5 ft 5 in., 135 lb
f. patient's occupation	Loan officer
g. patient's dietary habits	Balanced diet with plenty of fruits and vegetables
h. patient's sleep habits	Averages 7-8 hours per night.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Patient found out she is 7 weeks pregnant, has started taking a prenatal vitamin, and denies use of dietary supplements.
j. allergies	Penicillin: rash
k. history of other adverse reactions to medications	Stomach upset with codeine
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Nausea lasting a few hours during the main part of the day; occasional vomiting. She does not like the smell of certain foods; NVP is likely.
3. Identify exclusions for self-treatment (Figure 19-2).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Recommend self-care with: - Nondrug strategies (dietary and environmental changes [Table 19-5]). - Acupressure or acustimulation bands. - OTC pyridoxine. - OTC doxylamine. - OTC phosphorated carbohydrate solution. - Ginger. (2) Recommend lifestyle modifications until health care provider may be consulted. (3) Make a medical referral. (4) Take no action.

<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Because the patient does not appear dehydrated and can drink small amounts of ginger ale and water, and she can tolerate dry toast, you encourage her to continue to take sips of liquids and eat toast. She does not have signs/symptoms of dehydration, such as fast heartbeat, decreased skin turgor, noticeable weight loss, or clothes that fit loosely. A therapeutic alternative is the use of acupressure bands because the patient has stated that she would prefer not to use "drugs" if possible. If symptoms persist, then she can try doxylamine 12.5 mg 3-4 times a day and vitamin B <sub>6</sub> 10 mg 3-4 times a day. Other nonpharmacologic suggestions in <a href="#">Table 19-5</a> should be followed. If symptoms persist, she should consult her provider.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You probably have nausea and vomiting of pregnancy, or NVP. The acupressure bands may work, but if they do not, a combination of the antihistamine doxylamine and vitamin B <sub>6</sub> may help. These products should be taken 3-4 times a day. You may also benefit from other nonpharmacologic techniques ( <a href="#">Table 19-5</a> ), such as continuing the dry toast or eating bland foods and crackers in the morning before arising, sleeping in a well-ventilated room, and avoiding strong odors. If you do not feel better, you may want to contact your provider."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Published information regarding acupressure bands has shown that they may help with NVP. However, the evidence-based guidelines of the American College of Obstetricians and Gynecologists state that doxylamine and vitamin B <sub>6</sub> , up to 4 tablets daily, may help your symptoms. Because you are able to drink fluids and are not dehydrated, seeking medical care may not be necessary at this time. However, if nausea or vomiting worsens, medical attention for further evaluation is necessary."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. appropriate dose and frequency of administration	(1) "Wear acupressure bands." (2) "Add vitamin B <sub>6</sub> 10 mg combined with 12.5 mg of doxylamine (one-half of a 25 mg tablet). Doxylamine is available in the United States as an OTC sleep aid (Unisom SleepTabs 25 mg)."
b. maximum number of days the therapy should be employed	(1) "Wear acupressure bands continually." (2) "There are no limits to the number of days that vitamin B <sub>6</sub> and doxylamine can be taken."
c. product administration procedures	(1) "Wear the band on each wrist, 2 finger widths up from the first wrist crease." (2) "Take vitamin B <sub>6</sub> and doxylamine with a small glass of water 3-4 times a day."
d. expected time to	"Expected time to onset of relief and degree of relief are variable for all products and

onset of relief/degree of relief that can be reasonably expected	measures.”
e. most common side effects	(1) “Acupressure bands are not likely to cause side effects.” (2) “Vitamin B <sub>6</sub> is not likely to cause any side effects. Drowsiness is the most common side effect of doxylamine; therefore, it is important not to drive or operate machinery while taking doxylamine. Other possible side effects include dry mouth, dry eyes, nasal congestion, urinary retention, and constipation.”
f. patient options in the event that condition worsens or persists	“Medical attention is necessary if the NVP does not improve or if side effects from the OTC product occur.”
g. product storage requirements	“Store at 59°F-86°F.”
h. specific nondrug measures	See <a href="#">Table 19-5</a> for dietary and other measures.
Solicit follow-up questions from the patient or caregiver.	(1) “Will any of these products hurt my baby?” (2) “What other products could I use instead?”
Answer the patient’s or caregiver’s questions.	(1) “These products have been used by many other pregnant women and have not caused harm to the mother or baby. They are considered Pregnancy Category A, which is the safest class.” (2) “Another product used for nausea during pregnancy is an acustimulation device that is worn as a wristwatch on a single wrist, but this product is expensive. Ginger can also be considered. It has comparable efficacy to pyridoxine. Phosphorated carbohydrate solution may also be tried. If these products do not work, then medical attention is necessary to consider a prescription product for your nausea.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Monitor for episodes of nausea and vomiting.

Key: NA = Not applicable; NKDA = no known drug allergies; NVP = nausea and vomiting of pregnancy; OTC = over-the-counter.

### Case 19-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient’s symptoms and medical history, including:	
a. description of symptom(s)	Patient has had six episodes of nausea, vomiting, and diarrhea in the past 10

(i.e., nature, onset, duration, severity, associated symptoms)	hours. The patient seems somnolent and quiet except for violent episodes of vomiting or diarrhea.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Symptoms worsen when the patient's mother attempts to provide small sips of Gatorade.
c. description of the patient's efforts to relieve the symptoms	Patient's mother tried to get the child to eat a few bites of soda crackers or drink sips of fluid.
d. patient's identity	Ryan John
e. age, sex, height, and weight	18 months old, male, 25 inches, 23 lb (26 lb on previous day)
f. patient's occupation	NA
g. patient's dietary habits	Normal healthy diet, consisting of cereals, mashed vegetables, pasta, rice, chicken, yogurt, milk, and juice
h. patient's sleep habits	Up at 7:00 am; in bed at 7:30 pm; naps for 2 hours from 1-3 pm.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Children's multivitamin
j. allergies	NKDA
k. history of other adverse reactions to medications	None
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Patient has had several episodes of nausea, vomiting, and diarrhea. The patient appears drowsy and unusually lethargic, and his body appears floppy. The child appears dizzy when he stands up and his abdomen seems somewhat flat. He has had a dry diaper for several hours. Although the child appears to cry, few tears are noted. Patient appears dehydrated and may have viral gastroenteritis.
3. Identify exclusions for self-treatment (Figure 19-3).	On the basis of his signs/symptoms, patient appears severely dehydrated (Table 19-2).
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and	Options include: (1) Recommend that patient's mother administer: - OTC oral rehydration salt (ORS) solution. - OTC phosphorated carbohydrate solution. - An acupressure band.

share this information with the patient or caregiver.	(2) Recommend that patient's mother administer self-care modalities until a health care provider can be consulted. (3) Refer patient for further medical evaluation. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Ryan is unable to drink small amounts of fluid or eat small bites of crackers. He also has signs/symptoms of dehydration (appears drowsy and lethargic; has a floppy body, dizziness, flat abdomen; has lost 3 pounds since the previous day; has a dry diaper and sheds few tears). On the basis of these signs/symptoms, the patient's mother should immediately take the child for medical evaluation and attempt to administer small sips of ORS on the way to the emergency department.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Your child needs to be seen by a health care provider because he appears dehydrated. Please have someone drive you and your child to the emergency room at the hospital. On the way, administer 1 teaspoonful of ORS every 1-2 minutes."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Your child's symptoms (floppy body, flat abdomen, weight loss, dry diaper, few tears) indicate that he is dehydrated. Because he has been unable to drink sufficient fluids or eat anything to counter the dehydration, he needs medical attention."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	Is there a nonprescription medication that might work so that I don't have to take him to the emergency room?
Answer the patient's or caregiver's questions.	No. Your child is dehydrated; he needs urgent medical care so that he can feel better and get well.
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Monitor for signs of dehydration, including weight. Look for normal behaviors and activities.

Key: NA = Not applicable; NKDA = no known drug allergies; ORS = oral rehydration solution; OTC = over-the-counter.

#### Patient Education for Nausea and Vomiting

The objectives of self-treatment are to (1) improve the symptoms of occasional, self-limited nausea and vomiting (N/V), (2) identify and correct the underlying cause, (3) prevent and correct complications of vomiting, and (4) prevent future occurrences. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Nondrug Measures

- To prevent NVP, eat small, frequent meals that are low in fat content. Sleep in a room with fresh air. Also, try eating crackers before getting up in the morning. Try lying down to relieve the symptoms once they occur (Table 19-5.)
- To prevent motion sickness in young children, place them in a car seat that allows them to look out the windows (Table 19-4.) Try acupressure wristbands to prevent motion sickness in adults or older children.
- To prevent nausea associated with overeating, avoid foods or beverages known to cause nausea; consume foods and beverages in moderation.

### Nonprescription Medications

#### **Antacids, Histamine Type 2 Receptor Antagonists ( $H_2$ Ras), and Bismuth Subsalicylate**

- Take antacids,  $H_2$ RAs (e.g., ranitidine or famotidine), or bismuth subsalicylate for nausea caused by overeating. Follow product instructions for dosages. (See Chapters 13 and 16 for additional information on these medications.)

#### **Phosphorated Carbohydrate Solution**

- Take phosphorated carbohydrate solutions for nausea and vomiting associated with upset stomach caused by viral gastroenteritis, food indiscretions, and pregnancy. (Table 19-6 lists selected brand-name products.)
- Give 1-2 tablespoonsful (15-30 mL) of the solution to adults at 15-minute intervals until vomiting stops. For children ages 2-12 years old, give 1-2 teaspoonsful (5-10 mL). Do not give more than 5 doses in 1 hour.
- Do not dilute the solution, and do not allow the patient to consume other liquids for 15 minutes after taking a dose.
- Patients with hereditary fructose intolerance should not take this product.
- Patients with diabetes should consult their medical provider before taking this product.

#### **Antihistamines**

- Take antihistamines for self-treatment of N/V caused by motion sickness.
- To prevent motion sickness, take antihistamines at least 30-60 minutes before departure. Continue taking the medication during travel. Follow the dosage guidelines in Table 19-6.
- While using antihistamines, avoid driving or operating hazardous machinery or engaging in tasks that require a high degree of mental alertness. Drowsiness is the most common adverse effect of these medications.
- Patients with asthma, narrow-angle glaucoma, obstructive disease of the GI or genitourinary tract, or benign prostatic hypertrophy should consult a health care provider before using antihistamines.
- Caution patients that antihistamines may increase the sedative effects of alcohol, tranquilizers, hypnotics, and sedatives. Antihistamines may produce excitability in children or mental confusion in persons of advanced age.
- Do not take oral diphenhydramine products if topical (external) diphenhydramine preparations are being used.

#### **Oral Rehydration Salt (Ors) Solution**

- If needed, take an ORS to prevent dehydration secondary to vomiting and diarrhea.
- Consider placing ORS solution in the refrigerator to improve taste. Alternatively, the patient can use freezer pops or another dosage form to improve palatability.

#### **When to Seek Medical Attention**

- Seek medical attention if there are signs and symptoms of serious dehydration associated with N/V.
- Seek medical attention if vomiting does not stop after 5 doses of a phosphorated carbohydrate solution.

#### **Key Points for Nausea and Vomiting**

- N/V are symptoms of an underlying disorder; therefore, treatment should focus on identifying and correcting the underlying cause.
- Nonprescription antiemetic medications are suitable for preventing and controlling the symptoms of occasional self-limiting N/V.
- Overeating, food poisoning, viral gastroenteritis, and motion sickness may cause self-limiting N/V.
- Antacids, nonprescription  $H_2$ RAs, or PCS may improve symptoms associated with indigestion from overeating.
- Antihistamines are the agents of choice to treat N/V secondary to motion sickness.
- Agents that may be used safely to treat N/V in all persons 2 years of age and older, as well as NVP, include

acupressure/acustimulation devices and PCS.

- Uncomplicated NVP may be treated with pyridoxine, doxylamine, PCS, ginger, or acupressure/acustimulation devices.
- Loss of fluids and the inability to eat or drink because of N/V may result in dehydration and electrolyte disturbances. This primary complication of N/V should be treated with ORS.
- A patient who presents with complications related to N/V may not be a candidate for self-treatment but instead should be referred for medical evaluation.

## Handbook of Nonprescription Drugs &gt; Chapter 20. Poisoning

## Poisoning: Introduction

Poisoning is the leading cause of injury death, surpassing motor vehicle traffic deaths and deaths from firearms, and it is a major public health problem.<sup>1</sup> Deaths involving opioid analgesics have increased exponentially since 1999 along with sales of opioid pain relievers and admissions for opioid pain reliever treatment; deaths from opioid analgesics have far exceeded the deaths from heroin and cocaine.<sup>2</sup> Emergency department visits for nonmedical use of certain prescription medications increased dramatically between 2004 and 2008.<sup>3</sup> The most dramatic increase involved opioid analgesics (111% increase), but significant increases also were noted with certain benzodiazepines, zolpidem, and carisoprodol.

Older adults may be especially vulnerable to adverse effects and poisoning from nonprescription medication given their comorbid conditions and the potential for interactions with chronic medications. Acetaminophen is one of the leading nonprescription pain relievers. It also is a leading cause of poisoning reported to U.S. poison control centers for both unintentional and intentional poisonings. More than 600 products containing acetaminophen are on the market; thus misunderstanding their use and unintended misuse are common for all ages.<sup>4,5</sup> The Acetaminophen Awareness Coalition, whose members include the American Pharmacists Association, the National Association of Boards of Pharmacy, and the National Community Pharmacists Association, launched a Web site ([www.knowyourdose.org](http://www.knowyourdose.org)) to educate patients and consumers about how to use acetaminophen correctly. Several initiatives to promote safe acetaminophen use include converting pediatric liquid acetaminophen preparations to one strength and highlighting the ingredient acetaminophen on nonprescription labels.

Nonmedical use of prescription medications and abuse of nonprescription medications by adolescents are concerns, according to data from the National Survey on Drug Use and Health.<sup>6</sup> Abuse of attention-deficit/hyperactivity disorder medications in adolescents reported to poison control centers rose 76% over an 8-year period.<sup>7</sup>

Most poisonings in young children are unintentional, whereas poisonings in other age groups may be unintentional or intentional (e.g., suicide attempts, substance abuse, or medication misuse). The majority of poisonings are a result of ingestion of a substance, but poisonings also may occur after a toxin is inhaled or comes in contact with the skin and eyes. Bites and envenomations are other potential sources of toxin exposures. First aid for poisonings focuses on minimizing the extent of the exposure and stemming the progression or development of toxicity.

Poison control centers are 24-hour resources for poison information, clinical toxicology consultation, and poison prevention education. They are staffed around the clock with pharmacists, nurses, physicians, and physician's assistants with additional training in clinical toxicology. They are available for consultation with health care professionals as well as with the public. The entire United States and its territories are covered by a network of poison control centers. A poison control center should be contacted for assessment and treatment of poisonings, as well as for educational materials on poison prevention. Figure 20-1 shows the nationwide poison control center number and logo.

In 2011, a total of 57 poison control centers serving the United States and territories reported 2,334,004 cases to the National Poison Data System of the American Association of Poison Control Centers.<sup>8</sup> The majority of poison exposures (49.05%) occur in children younger than 6 years, of which 89% involve children 3 years of age and younger.<sup>8</sup> Nonprescription and prescription medications are frequently responsible for potentially toxic exposures reported to poison control centers. Nonprescription products, such as analgesics, cough and cold preparations, topical preparations, vitamins, and antihistamines, are among the most common substances ingested by young children. The large number of nonprescription medications involved in pediatric exposures reflects the common use and availability of these products in the home. Other common substances involved in poison exposures in children younger than 6 years include cosmetics and personal care products, cleaning substances, foreign bodies or toys, pesticides, and antimicrobials.

Nearly 70% of poison exposures reported to poison control centers are managed onsite, usually in a residence. Only 11.3% of children younger than 6 years are managed in a health care facility, and major effects or fatal outcomes occur in less than 1%.<sup>8</sup> Poison control centers are cost effective and have a favorable cost-benefit ratio.<sup>9</sup> A significant portion of the cost savings results from home observation, as well as from the reduction of unnecessary emergency medical transport and treatment costs. Poison control center consultation results in shorter length of hospital stay and lower charges for those patients who require hospitalization.<sup>10,11</sup> A policy analysis group reviewed the existing literature on the cost savings associated with use of a poison control center and estimated medical care savings and reduced productivity loss of \$13.39 per year per dollar of poison control center funding.<sup>12</sup> A recent study of pediatric poison exposures treated in a tertiary children's hospital found that 18.6% of visits were for nontoxic exposures that could have been managed on site by the poison control center. Children with nontoxic exposures were more likely to be covered by Medicaid or no insurance (73%) and had a mean charge of \$286 per patient.<sup>13</sup> Health care professionals are encouraged to work closely with their local poison control centers to ensure the most appropriate, cost-effective care of the poisoned patient.

Nationwide toll-free telephone number to access a poison control center. (Source: Reprinted with permission from the American Association of Poison Control Centers, Alexandria, Virginia.)

Unintentional childhood poisonings remain a common cause of injury-related morbidity, requiring significant expenditures of health care dollars for inpatient and outpatient care. Unintentional poisonings are one of the leading causes of injury-related hospitalizations in preschool children; however, fatalities among preschoolers have declined significantly since the early 1970s. According to a recent analysis of the National Electronic Injury Surveillance System-All Injury Program (NEISS-AIP), an estimated 58,000 children younger than 6 years are evaluated in emergency departments annually for unintentional medication-related exposures.<sup>14</sup> Hospitalization or specialized medical care was required in nearly 16% of cases. The most common categories of medications were acetaminophen, cough and cold medications, antidepressants, and nonsteroidal anti-inflammatory drugs (NSAIDs).

The National Safety Council reported 50 deaths caused by unintentional poisoning in children younger than 5 years in 2011.<sup>15</sup> Only 26 of the 1158 fatalities reported by poison control centers in 2011 involved children younger than 6 years.<sup>8</sup> Medications and illicit drugs (excluding ethanol) were the primary substances responsible for fatalities. Child-resistant closures (CRCs) legislated through the Poison Prevention Packaging Act (PPPA) of 1970 help prevent unintentional poisonings. These closures have been responsible for a decline in pediatric fatalities associated with prescription and nonprescription medications.<sup>16</sup> Although CRCs have improved child safety, exemptions to the law allow dispensing medications without CRCs.<sup>17</sup> A recent analysis of NEISS data revealed that an estimated 55% of nonfatal poisonings in children younger than 5 years treated in an emergency department involved a product regulated by the PPPA.<sup>18</sup> Whereas child-resistant closures may reduce unintentional pediatric poisoning, use of nonstandard liquid measuring devices and caregiver misinterpretation of nonprescription medication labels increase the risk for pediatric poisoning. Further work is needed to improve the format and content of nonprescription labels to improve caregiver understanding of the medication and dosing instructions.<sup>19,20,21</sup>

## Clinical Presentation of Poisoning

Poisons can affect every organ system. Signs and symptoms of poisoning can range in severity from mild to life threatening. For some drugs, toxicity after overdose is similar to the drug's adverse effect profile with therapeutic use. For example, ibuprofen overdose is characterized primarily by nausea, vomiting, and abdominal pain. Patients with diphenhydramine overdose may exhibit sedation or stimulation (e.g., agitation or hallucinations), tachycardia, hypertension, dry mouth, and dilated pupils from the drug's antimuscarinic properties. Overdoses of other drugs,

such as aspirin, result in multiorgan system effects including gastrointestinal (GI), central nervous system (CNS), metabolic, cardiovascular, pulmonary, and hematologic toxicity. A lack of symptoms immediately after a poison exposure does not preclude toxicity. Patients may be asymptomatic initially, but they can develop severe toxicity hours after ingestion of some sustained-released or enteric-coated products or products that delay gastric emptying or slow GI motility (e.g., antihistamines). For other drugs (e.g., acetaminophen) and some chemicals (e.g., methanol and acetone), clinical effects are delayed while the substance is metabolized to active or toxic metabolites. The time course of acetaminophen overdose is related to formation and covalent binding of a toxic metabolite to hepatic cells. As a result, a relatively mild initial clinical course characterized by nausea, vomiting, anorexia, and malaise can be followed by severe hepatic and renal toxicity 3-5 days later. Keep in mind that symptoms may be due to causes other than poisoning. Regardless of the cause of symptoms, if symptoms are serious enough, they warrant medical attention.

### Treatment of Poisoning

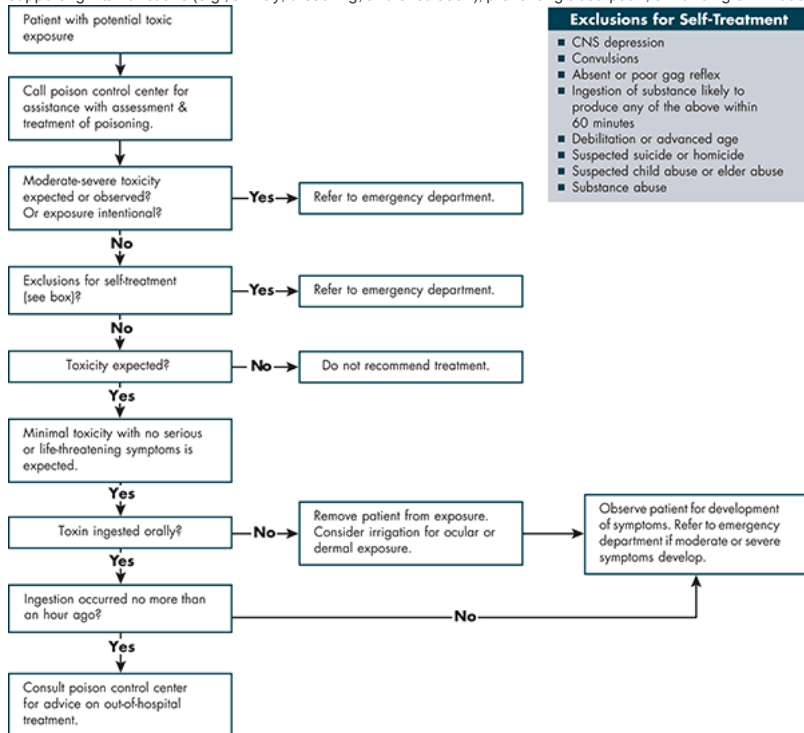

Most unintentional poison exposures in small children result in minimal, if any, adverse effects and require no treatment other than observation. Although self-treatment may be appropriate, health care providers, caregivers, and patients are encouraged to seek counsel from the nearest poison control center before attempting any treatment.

#### Treatment Goals

The primary goal of home or prehospital therapy is to prevent absorption of toxins or stem the progression of toxicity, thus minimizing morbidity and mortality.

#### General Treatment Approach

The first step in assessing a potential poison exposure is to determine whether the patient has symptoms and whether the exposure puts the patient at risk of toxicity. Many exposures are, in fact, nontoxic or minimally toxic because either the substance has a very low inherent toxicity or the amount consumed is too low to cause toxicity. A decision regarding the option for self-treatment depends on the reason or circumstance of the poison exposure, toxicity of the agent, and general health status of the patient. Self-treatment should be considered only if the ingestion is unintentional and the potential for toxicity is assessed as minor. Any inadvertent exposure to a toxin that can potentially result in moderate-severe toxicity, as well as all intentional exposures, should be referred immediately to a hospital. If the patient exhibits potentially life-threatening clinical effects (e.g., coma, convulsions, or syncope), transportation to an emergency department should be arranged immediately through the emergency 911 system. Additional exclusions for self-treatment can be found in Figure 20-2. Hospital care includes observing the patient, supporting vital functions (e.g., airway, breathing, and circulation), preventing absorption, enhancing elimination, and using antidotes.

Self-care for poisoning. Key: CNS = Central nervous system.

The majority of individuals who do not require immediate hospital referral are managed with on-site observation only and no specific treatment.<sup>8</sup> In some instances, the approach is to attenuate the exposure by irrigating or preventing further absorption. The nonprescription drug activated charcoal may prevent or reduce the absorption of some ingested substances. However, its routine use is not recommended without consultation with a poison control center. In the past, ipecac syrup, nonprescription cathartics, or both were recommended to induce vomiting or decrease absorption of substances by facilitating their elimination through the GI tract. However, ipecac syrup is no longer available, and cathartics by themselves are not beneficial in the treatment of a poisoned patient. Figure 20-2 outlines self-care of exposure to poisons.

#### Nonpharmacologic Therapy

Inhalation exposures are managed by removing the patient from the toxic fumes to fresh air. Irrigation may be beneficial to decrease the contact time of a chemical with the skin or mucosal surface. Skin surfaces should be washed with soap and water (usually twice) to decrease the contact time of a chemical exposure, taking care to include nail beds and hair when appropriate. Irrigation of the eye with water should be initiated immediately after an ocular exposure to a chemical or drug not intended for ocular use (e.g., inadvertent ocular administration of an otic preparation). If an irritating chemical has been swallowed, the administration of a small amount of fluids may decrease the contact time of the chemical with the mucosal surface. Neutralization after a chemical contacts skin or eyes or for ingested substances is not recommended.

The administration of oral fluids after an ingestion of a drug is not recommended. The administration of a large amount of fluids should be discouraged because the fluids are likely to result in spontaneous vomiting, which is risky in some situations. The fluids theoretically may facilitate dissolution of a solid dosage form, thereby enhancing its absorption. Administering fluids after ingestions of drugs should be considered for drugs that are known to have a high risk of esophageal impaction, such as bisphosphonates, or those that may cause renal injury owing to dehydration, such as ibuprofen or other NSAIDs. Manually stimulating the gag reflex at the back of the throat with either a blunt object or a finger may induce vomiting, but this practice is not recommended and can lead to soft palate injury.

#### Pharmacologic Therapy

Activated charcoal, an adsorbent, and ipecac syrup, an emetic, are the only approved self-treatments for ingested poisons. In 2011, ipecac syrup was used in less than 0.01% of cases reported to poison control centers, and activated charcoal was used in 2.9% of cases.<sup>8</sup> In some of these cases, it is likely that ipecac was administered by parents or caregivers before consulting the poison control center. The American Academy of Pediatrics Committee on Injury, Violence, and Poison Prevention and other organizations recommend that ipecac no longer be used or that its use be strictly limited because of lack of documented benefit and potential for misuse.<sup>22</sup> Although the Code of Federal Regulations still states that ipecac syrup is considered the emetic of choice for certain poisoning scenarios, ipecac syrup is no longer commercially available as a nonhomeopathic product.<sup>23</sup> Therefore, it is no longer a viable option for self-treatment of poisoning. Pharmacists should recommend that existing supplies in the home be discarded. Controversy surrounds the use of activated charcoal as a self-treatment, given the lack of evidence that it improves outcome and its poor tolerability.

#### Treatment with Activated Charcoal

Activated charcoal is a tasteless, gritty, fine, black insoluble powder made from the pyrolysis of various organic materials.<sup>24</sup> Its large surface area of 950-2000 m<sup>2</sup>/g makes activated charcoal a highly effective adsorbent.<sup>24</sup>

Activated charcoal has been shown to adsorb a large number of commonly ingested drugs and many other toxic agents. These substances are bound in the internal surface of the pores of the

charcoal molecule, thereby preventing their absorption. Activated charcoal is not absorbed from the GI tract. As the ratio of activated charcoal to toxin increases, the proportion of bound toxin increases.<sup>24</sup> Highly ionized substances, such as potassium and lithium, are poorly adsorbed by activated charcoal. Activated charcoal does not bind well to alcohols or glycols (e.g., ethanol, methanol, or ethylene glycol), hydrocarbons, mineral acids and alkali, heavy metals (e.g., iron, lead, and arsenic), or cyanide (Table 20-1). The presence of food in the GI tract may reduce the efficacy of activated charcoal.

**TABLE 20-1 Contraindications to GI Decontamination with Activated Charcoal as Self-Treatment**

Category	Inclusion Criteria	Recommendation
Patient condition	Coma, seizures, syncope, airway or breathing problems, blood pressure or pulse irregularities, hallucinations, and severe agitation	Refer to hospital for evaluation.
Reason or circumstance	Intentional self-harm, substance abuse, malicious intent	Refer to hospital for medical and psychiatric or social service evaluation.
Ingestion of low-viscosity hydrocarbons and terpenes	Gasoline; kerosene; mineral seal oil (furniture polish); naphtha (lighter fluid); pine oil (cleaners); turpentine (paint removers); mineral oil	Contact poison control center.
Ingestion of caustic substances	Methacrylic acid (artificial nail primers); sodium silicate and carbonate (automatic dishwashing detergents); sulfuric acid (automotive battery, drain cleaners, toilet bowl cleaners); sodium hydroxide (Clintest tablets, drain cleaners, oven cleaners, hair relaxers); hypochlorites (bleach, pool chlorine); thioglycolates (hair relaxers); hydrofluoric acid (rust removers); hydrochloric acid (toilet bowl cleaner)	Contact poison control center.
Ingestion of substances not adsorbed by charcoal	Ethanol (alcoholic beverages, colognes, mouthwashes, aftershaves); isopropyl alcohol (rubbing alcohol); methanol (windshield washer fluid); ethylene glycol (antifreeze); ionized substances (potassium); metals (iron, lithium, lead, arsenic); cyanide (potassium cyanide, acetonitrile artificial nail remover, laetrile)	Contact poison control center.

Key: GI = Gastrointestinal.

Activated charcoal is approved by the Food and Drug Administration for use as an emergency antidote in the treatment of an ingested poison. The usual dose of activated charcoal is approximately 1 g/kg (Table 20-2).<sup>24</sup> This dose provides an estimate of the amount of activated charcoal to administer, rounding to the nearest full or half-full bottle. Activated charcoal is available premixed with water, sorbitol (for catharsis), or water and carboxymethylcellulose. Examples of nonprescription activated charcoal products are Actidose-Aqua or Liqui-Char with or without sorbitol generally available at concentrations of 15 or 25 g/120 mL and 50 g/240 mL. Activated charcoal slurries are prone to settling, so they should be vigorously shaken before administration. Activated charcoal also is available as a powder for reconstitution into an oral suspension just before use; this product should be stirred thoroughly or vigorously shaken after water is added. Flavoring agents have been used to try to increase the palatability of activated charcoal. Activated charcoal is most effective if given within 1 hour after ingestion. Repeat doses of activated charcoal (given in a health care facility setting only) may enhance the elimination of some drugs (e.g., phenobarbital and theophylline) after they are absorbed into the systemic circulation.

Activated charcoal combined with sorbitol also is available to improve palatability and act as a cathartic, shortening transit time of the activated charcoal complex through the GI tract and preventing constipation. Sorbitol-containing activated charcoal products are not recommended in children younger than 1 year or when multiple doses of activated charcoal are administered. In these situations, the risk of fluid and electrolyte disturbances and hypotension is higher. Most activated charcoal products marketed specifically for home use do not contain sorbitol. Activated charcoal capsules marketed as a dietary supplement for GI complaints or other ailments should not be used to manage poisonings because the surface area of charcoal in these products is too small to effectively adsorb toxins.

Activated charcoal is used primarily for patients managed in a health care facility. Although this agent is available as a nonprescription drug, it is not available in most homes, nor is it routinely recommended for home use by poison control centers. Health care providers should consult their poison control center to determine whether to promote routine availability of activated charcoal in the home.

The most common adverse effects of activated charcoal are vomiting and black stools. Vomiting occurs in 12%-20% of patients receiving activated charcoal.<sup>24</sup> One-fifth of children younger than 18 years who were given activated charcoal for poisoning vomited a median time of 10 minutes after initiation of charcoal administration. More serious complications, such as pulmonary aspiration and GI obstruction, are associated more often with administration of multiple doses of activated charcoal.

**TABLE 20-2 Activated Charcoal Dosing Information**

Age	Dose
0-12 months <sup>a</sup>	10-25 grams
1-12 years	25-50 grams
>12 years	25-100 grams

<sup>a</sup>Used primarily in a health care setting in this age group.

Source: Reference 24.

Activated charcoal is contraindicated in patients in whom the GI tract is not anatomically (e.g., following caustic injury) or functionally (e.g., ileus) intact. Following bariatric surgery patients may not tolerate charcoal or may need smaller, more frequent doses. Activated charcoal also is contraindicated in patients at high risk for aspiration without airway protection (Table 20-1). Activated charcoal should not be administered after ingestion of substances that it does not adsorb, unless the presence of other ingestants that are adsorbed by charcoal is suspected.

#### Pharmacotherapeutic Considerations for Activated Charcoal

Studies have demonstrated that the effectiveness of GI decontamination decreases significantly with increasing time interval since ingestion. For most overdoses, GI decontamination with activated charcoal should be performed early, usually within an hour of the ingestion.<sup>25</sup>

There is no convincing evidence that activated charcoal improves patient outcomes, and its utility in adults with intentional overdoses has been questioned, particularly in patients with mild-moderate poisoning.<sup>26,27</sup> A position statement by the American Academy of Clinical Toxicology and the European Association of Poison Control Centers and Clinical Toxicologists concluded that activated charcoal may be considered for a potentially toxic amount of a poison ingested up to 1 hour before treatment. There are insufficient data to support or exclude use of charcoal when poison ingestion occurred more than 1 hour previously.<sup>24</sup> The majority of studies upon which the position statement was based were conducted in a controlled research or hospital environment.

Poison control centers vary in recommending home use of activated charcoal. Home administration of activated charcoal is usually intended for patient management outside a health care facility, but sometimes the agent is given to provide early prehospital GI decontamination in patients who subsequently are transported to an emergency department. Data on prehospital administration provide insight into the potential difficulty in administering activated charcoal in the home. A study of prehospital emergency medical technicians or paramedics reported that charcoal was not given to 15.4% of patients in whom administration was attempted; in 71% of these cases the reason was patient refusal.<sup>28</sup>

Consideration of home use of activated charcoal requires addressing the following questions: What are the benefits? Will children drink it at home? Does home administration shorten the interval between the overdose and charcoal administration? Is it safe to give at home?<sup>29</sup> Eldridge et al.<sup>29</sup> cited two studies (21 children total) that questioned whether activated charcoal can be successfully administered at home after researchers found that most children did not drink a full dose administered by parents. Three other studies (217 children total) reported that a full dose was administered in 64% of children and a partial dose was ingested in 16% of 157 children.<sup>29</sup> Problems with these studies include reliance on parent reports and lack of validation of the accuracy of the amount of charcoal administered.

Home administration shortens time to charcoal administration.<sup>29,30</sup> When administered at home, charcoal is generally given within the desired 1 hour. Consideration should be given to the relative benefit of parents administering charcoal to children before arrival at the emergency department compared to the risk associated with possible delay in emergency department treatment if charcoal was administered earlier.

To date, experience with home administration of activated charcoal has shown that it is relatively safe. GI effects have been reported, with the main adverse effect being vomiting. There is concern that if home use of activated charcoal becomes more prevalent and parents administer charcoal when it is contraindicated (e.g., hydrocarbon ingestion or altered mental status with compromised airway), serious adverse effects such as aspiration may increase.<sup>29</sup> Before a health care provider recommends use of activated charcoal, a poison control center should be consulted.

#### Assessment of Poisoning: A Case-Based Approach

After obtaining the history of the exposure to a poison and performing an initial assessment of the patient's condition, the health care provider must decide whether to refer the patient directly to

an emergency treatment facility, to manage him or her at home, or not to recommend any specific treatment. Clearly patients with serious clinical effects including altered mental status (e.g., stupor, coma, seizures, agitation, or hallucinations), respiratory distress, or changes in cardiovascular status (e.g., syncope or hypotension) are not candidates for self-care and should be transported immediately to the emergency treatment facility. Alternatively, recognizing nontoxic or minimally toxic exposures that can be managed outside a health care facility is an essential component of self-treatment of poisoning. Involving the poison control center in this triage and treatment decision is important because poison control centers have considerable experience managing poisoned patients and specialized resources that are not usually available to providers. The nationwide toll-free poison control center number, 800-222-1222, connects callers to the center near them (Figure 20-1).

Self-treatment at home is primarily intended for un-intentional poison exposures in children younger than 6 years in whom no or, at most, minimal toxicity is expected. In addition, unintentional inhalation or skin or eye exposures in any age group, with possible minimal toxicity, often can be self-treated.

If an individual inquires about purchasing activated charcoal, the pharmacist must determine whether these drugs are being purchased for an acute situation, in which case the poison control center should be contacted to assess the appropriateness of self-treatment. The poison control center will need information about the patient (age, weight, medical history, and whether the patient is currently experiencing clinical effects), the toxin (name of the toxin, dose, route of exposure, and time since exposure), and what treatment, if any, has already been administered. Cases 20-1 and 20-2 provide examples of assessment of patients who have been poisoned.

#### Patient Counseling for Poisoning

After patients are removed from toxic fumes, they should be counseled about when to seek medical attention (e.g., difficulty breathing, or worsening or persistent symptoms). In the home or other nonindustrial setting, fumes often are soluble, irritant gases (e.g., chlorine), so clinical effects are evident immediately and usually resolve soon after exposure stops. Patients also should be counseled about ventilating the room to disperse the vapor. If the exposure resulted from mixing products such as bleach and ammonia, the patient should be warned not to mix household products in the future. If carbon monoxide is suspected, the patient should be instructed to have the source turned off or removed (e.g., malfunctioning furnace, stove, or vehicle). The poison control center should be contacted to assess the severity and expected duration of clinical effects in symptomatic patients and the possibility of delayed onset in asymptomatic patients. Home carbon monoxide detectors are important home safety devices, and homeowners should be encouraged to install them to prevent or minimize carbon monoxide exposures.

Patients with eye exposures should be counseled on how to irrigate the eye at home under the faucet. Contact lenses should be removed before irrigation. Instructions should include running the water at room temperature and at a low pressure. Irrigating the eyes in the shower or using a clean cup to pour water into the eyes may be an easier alternative in children. Placing a damp washcloth on the eye or irrigating with small-volume nonprescription eyewashes is ineffective. Finally, eye drops, including topical vasoconstrictors, should not be used after irrigation. Patients with skin exposures should be counseled to remove clothing, if necessary, and wash affected areas thoroughly. For eye and skin exposures, counseling should stress the importance of immediate irrigation or washing.

If the poison control center in a region recommends activated charcoal for home use, pharmacies in that area should stock the appropriate product, and pharmacists should educate parents that activated charcoal should never be used without first consulting a poison control center staff member. Patients who purchase activated charcoal for immediate use following the recommendation of a poison control center should be counseled to ensure appropriate drug use, including provision of instructions on preparation (depending on the formulation). The pharmacist also should explain potential adverse effects, as well as signs and symptoms that indicate medical attention should be sought.

Counseling older adults on self-managing their medications can prevent poisonings and adverse drug reactions. Polypharmacy means that older adults are at risk for errors relating to dose, dosage regimen, and possibly administration techniques. Educating them about the potential for interactions, including drug-drug, drug-food and drug-alcohol, is important. Remind them that they should seek advice before mixing nonprescription or herbal products with prescription medications. Counseling older adults should emphasize the importance of ongoing communication with their health care providers to assure both efficacy and safety of their medication regimen.

Patients who are taking multiple prescriptions and using a regular pill minder should be advised to purchase a locking pill minder if they are around young children. When loading the device, they should place a paper or cardboard underneath the pill minder to catch stray pills that might fall on the floor. Pharmacists also can prevent therapeutic 10-fold error types of poisonings by always dispensing 1 mL oral syringes for prescription medications that are dosed in infants at less than 1 mL, such as metoclopramide. The box Patient Education for Toxic Exposures lists specific information to provide parents, caregivers, or patients.

Counseling should include providing the nationwide toll-free number for the poison control center (Figure 20-1) and promoting poison prevention practices, including purchase of nonprescription drugs and household products with child-resistant packaging. However, caregivers should be reminded that child-resistant closures are not child proof, regardless of whether a product has a child-resistant closure, it should be stored up and out of reach of small children and preferably in a locked cabinet. The Up and Away campaign ([www.upandaway.org](http://www.upandaway.org)) is a new initiative developed by PROTECT, a public-private initiative (Preventing Overdoses and Treatment Errors in Children Taskforce) in partnership with the Centers for Disease Control.

#### Case 20-1

Relevant Evaluation Criteria	Scenario/Model Outcome
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	A man asks the pharmacist for a recommendation for a single product that can treat his cold and flu symptoms but won't make him drowsy during the day. For the past week he has been taking a multisymptom product marketed for cold, flu, and sinus congestion, a product marketed for head congestion on occasion, and several doses a day of acetaminophen for his sinus headache. He states he sometimes feels drowsy and jittery.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Symptoms are exacerbated when both products are taken together.
c. description of the patient's efforts to relieve the symptoms	On occasion he has taken a nighttime nonprescription sleep aid to help him sleep.
d. patient's identity	Sam Silver
e. age, sex, height, and weight	35 years old, male, 6 ft 1 in., 175 lb
f. patient's occupation	Marketing representative
g. patient's dietary habits	2 cups of coffee in the morning with several caffeinated soft drinks in the afternoon
h. patient's sleep habits	5 hours nightly
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Cold, flu, and sinus product contains phenylephrine 5 mg, chlorpheniramine 2 mg, and acetaminophen 325 mg. The head congestion product contains dextromethorphan 10 mg, phenylephrine 5 mg, and acetaminophen 325 mg. He estimates he has taken 1-2 of each of these products for the past 3 days. He also has taken 1-2 extra-strength acetaminophen tablets at least 3 times daily for a sinus headache over the same 3-day period.
j. allergies	Medications—none, but he has bad seasonal allergies.
k. history of other adverse reactions to medications	None
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Sam's jitteriness is likely related to taking two products with phenylephrine in addition to caffeine. His drowsiness is likely related to the chlorpheniramine and dextromethorphan. In addition, all three products contain acetaminophen. His total daily acetaminophen dose is 1650 mg, which is below the recommended maximum daily dose.

3. Identify exclusions for self-treatment (Figure 20-2).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Counsel Sam to avoid taking multiple cough and cold products together because they often contain the same or similar ingredients. (2) Counsel Sam to check all prescription and nonprescription medications and to avoid taking more than one product that contains acetaminophen at the same time. (3) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Help Sam choose a nonprescription product that meets his needs.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Sam should be counseled about the use of more than one cough and cold product at the same time and about products with acetaminophen."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Sam experienced adverse effects from his therapeutic regimen, but they were not significant enough to warrant further treatment."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"Is it okay to take a sleep aid as well as acetaminophen for a headache to help me sleep?"
Answer the patient's or caregiver's questions.	"Some nonprescription sleep aids also contain acetaminophen."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Ask the patient to call to update you on his response to your recommendations, or you could call him in a week to evaluate the response.

Key: NA = Not applicable.

#### Case 20-2

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	A mother asks the pharmacist about treatment options for her previously healthy 2-year-old daughter, who was found with an open aspirin bottle. The now empty bottle of 325 mg aspirin originally contained 50 tablets and 42 had been used previously. The ingestion happened 1 hour ago. The child vomited once and is sleepy. Mom states that child vomited 15 minutes ago, and mom saw one partially dissolved tablet in the vomit. The child is sleepy and looks a little pale. When asked if child is breathing faster than normal, mom nods "yes."
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	NA
c. description of the patient's efforts to relieve the symptoms	Mom gave the child some juice to drink after she vomited.
d. patient's identity	Emily Gold
e. age, sex, height, and weight	2 years old, female, 32 in., 22 lb
f. patient's occupation	NA
g. patient's dietary habits	She ate lunch 2 hours before the exposure.
h. patient's sleep habits	It is close to her nap time.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Healthy; takes no medications.
j. allergies	NKDA
k. history of other adverse reactions to medications	None
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Acute unintentional overdose of aspirin. Although mom saw a partially dissolved tablet, one should assume that close to 8 tablets were ingested. Therefore, she ingested 8 aspirin 325 mg; total dose of 2.6 grams or 260 mg/kg.

3. Identify exclusions for self-treatment (Figure 20-2).	Emily is sleepy. She has taken a toxic dose of aspirin.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Contact the poison control center for recommendations regarding whether to refer Emily to an emergency department for possible GI decontamination and evaluation. (2) Have her mother administer an OTC treatment to decrease absorption at home. (3) Have her mother administer oral fluids to dilute the aspirin. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The poison control center should be contacted immediately. The center will determine whether it is safe to manage the child at home.
6. Describe the recommended therapeutic approach to the patient or caregiver.	No treatment should be provided at home because the child has ingested a toxic dose, has vomited and may continue to vomit, and needs medical management. Doses above 150 mg/kg cannot be managed at home. The poison control center recommends that Emily be treated at the hospital.
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Emily has ingested a large dose of aspirin that can cause her to become even sleepier and can affect her breathing and heart. It can cause abnormal blood values that could become dangerous. There are specific blood tests and therapies that can only be done in the hospital. If the hospital is near, you can transport her in your private vehicle, but she must be taken immediately. If you live farther away from a hospital or feel uncomfortable taking her by yourself, call 911."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"I have ipecac syrup at home. Can I give it instead of taking her to the hospital?"
Answer the patient's or caregiver's questions.	"No, ipecac syrup is no longer recommended and should be discarded. Also, Emily needs to be treated in a hospital."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Determine which hospital Emily will be transported to. The poison control center will call ahead to make them aware that Emily is on her way in, provide information on the situation, and provide recommendations on laboratory evaluation and treatment. The poison control center will follow up to check on how Emily is doing and to provide additional recommendations if needed.

Key: GI = Gastrointestinal; NA = not applicable; NKDA = no known drug allergies; OTC = over-the-counter.

#### Patient Education for Toxic Exposures

The objectives of self-treatment are to (1) minimize exposure and reduce development of toxicity by removing the patient to fresh air, irrigating the skin or eyes, or preventing absorption of potentially toxic agents in the GI tract and (2) treat patients with minimally toxic ingestions at home under the supervision of a poison control center. For most patients, carefully following the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Treatment

- For eye exposures, immediately irrigate with water for 10-15 minutes.
- For skin exposures, immediately wash with soap and water.
- For inhalation exposures, immediately remove the patient to fresh air.

#### When to Seek Medical Attention

Referral to an emergency department by contacting 911 directly is appropriate if the patient:

- Is lethargic or comatose or is having convulsions or hallucinations.
- Has decreased respirations or is having difficulty breathing.
- Has abnormal blood pressure or pulse.
- Has taken medications that may produce a rapid decline in consciousness or convulsions.

#### Evaluation of Patient Outcomes for Poisoning

Patients who have inhaled potentially toxic fumes or spilled or splashed a substance on their skin or in their eye should be reassessed for symptoms after removal to fresh air or irrigation. If clinical effects are minimal and resolve within a relatively short period of time (e.g., under 30 minutes), the patient may be observed at home. If symptoms persist or worsen, the patient should be referred to a primary care provider or the emergency department, depending on the severity of symptoms and immediacy of need for medical evaluation. The poison control center can facilitate the referral to the appropriate health care facility and provide treatment recommendations to the health care provider.

Patients who receive activated charcoal should be contacted afterward at least once to determine whether any symptoms related to the exposure develop. The time of the call depends on what substance was ingested, how rapidly it is absorbed, and when symptoms would be anticipated. If clinical effects develop and are minor, the patient may be observed at home. If more significant effects develop, the patient should be referred to an emergency department for treatment. If the poison control center recommended self-treatment with activated charcoal, the center staff should remain involved in subsequent decisions regarding the appropriateness of continued home treatment of these patients.

#### Key Points for Poisoning

- Poison exposures are a common cause of pediatric and adult injury.
- Medication errors are a common cause of drug-related toxicity, especially in older adults.
- Minimizing the duration or limiting the extent of the exposure is the rationale for most self-treatment practices.
- There are no data demonstrating that self-treatment for poisoning with activated charcoal improves patient outcomes. Use only upon recommendation of a poison control center.
- Self-treatment should be considered only for unintentional poison exposures that are likely to cause no or minimal toxicity (i.e., no serious or life-threatening symptoms; Figure 20-2).
- Health care providers should consult with the poison control center for guidance on patient assessment and on decisions for the appropriateness of self-treatment.
- Referral directly to the poison control center should be considered for complicated cases, including those with unclear patient histories or lacking specific product or toxin information, and to ensure case follow-up.
- All patients who exhibit potentially life-threatening clinical effects (e.g., seizures or coma) should be referred to an emergency department through the emergency 911 system.

## Handbook of Nonprescription Drugs &gt; Chapter 21. Ostomy Care and Supplies

**Ostomy Care and Supplies: Introduction**

An ostomy is an opening or outlet through the abdominal wall created surgically for the purpose of eliminating waste. The opening is usually made by bringing a portion of the bladder, colon, small intestine, or ureters through the abdominal wall. The opening of the ostomy is called the *stoma* (from the Latin word for mouth).

The creation of an ostomy may be a dramatic, life-changing event. Therefore, it is important for health care providers to provide reassurance, support, and education for the patient and family. An understanding of improvements in surgical procedures, ostomy supplies, and outcomes can allay much of a patient's fear and anxiety. The goal in ostomy care is to enable the individual to resume his or her lifestyle—to be a person, not a patient. A person with an ostomy carefully notes the reactions of providers to the disorder; any negative response may reinforce the patient's negative feelings about the ostomy.

More than 700,000 Americans are currently living with an ostomy.<sup>1</sup> Ostomy surgery is performed on individuals of all ages and for many conditions, both acquired and congenital. When medically advisable, the current surgical trend in ostomy surgery is laparoscopic surgery. Patients report experiencing less pain, quicker recovery, and less scarring compared to traditional ostomy surgery.

**Indications for Ostomies**

Ostomies may be permanent or temporary, and they are performed in individuals ranging from neonates to the elderly. Reasons for performing ostomies include congenital anomalies (e.g., imperforate anus and Hirschsprung's disease), inflammatory bowel disease, familial polyposis, cancer, radiation damage, pressure ulcers, trauma, and any other need to divert the urinary or fecal stream.<sup>2,3</sup> The type of ostomy depends on the condition being treated.

The two most common disorders leading to ileostomy surgery are (1) ulcerative colitis, which affects the large intestine and rectum, and (2) Crohn's disease, which may involve any part of the gastrointestinal (GI) tract. Other conditions that may result in an ileostomy include traumatic injury, cancer, familial polyposis, and necrotizing enterocolitis.

The most common reasons for colostomy surgery are (1) cancer of the colon or rectum, (2) diverticulitis, and (3) trauma. Other indications include obstruction of the colon or rectum, genetic malformation, radiation colitis, and loss of anal muscular control. In some cases, a temporary colostomy may be performed to protect areas of the colon that have been surgically repaired. Healing of a diseased or damaged bowel may take several weeks, months, or years, but eventually the colon and rectum are reconnected and bowel continuity is restored. [Figure 21-1](#) shows the location of various types of colostomies.

Urinary diversions are created to correct bladder loss or dysfunction, which can be caused by cancer, neurogenic bladder, genetic malformation, or interstitial cystitis.

**Types of Ostomies**

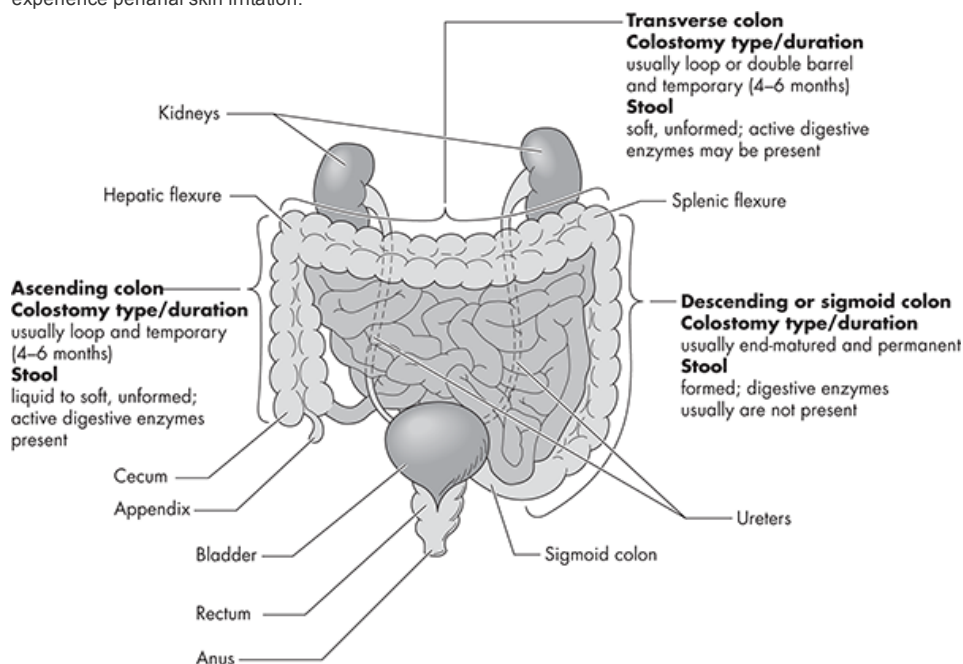

The three basic types of ostomies are (1) ileostomy, (2) colostomy (the most common type), and (3) urinary diversion (see Color Plates, photographs 2A-I). Each type of ostomy has several variations depending on the location of the stoma, the reason for the surgical procedure, or whether the procedure renders a patient continent.

**Ileostomy**

An ileostomy is surgically created by bringing a portion of the ileum through the abdominal wall (see Color Plates, photograph 2A). Initially, the discharge is liquid, but as the ileum adapts, it assumes some of the absorptive functions of the colon and the discharge may become semisoft. The discharge is continuous and contains intestinal enzymes that may irritate the peristomal skin.

Several types of continent ileostomies exist (see Color Plates, photograph 2B). An internal pouch is created from the ileum, and an intussusception (a slipping of a length of intestine into an adjacent portion) of the bowel is used to create a "nipple" that renders the patient continent for stool and flatus. The pouch is periodically emptied by inserting a catheter through the nipple, which is attached to the skin usually in the right lower quadrant, into the pouch. At first, the pouch holds about 75 mL, but it stretches with use so that, at 6 months postoperatively, it may hold 600-800 mL and can be drained three to five times daily. Patients do not need to wear an external pouching system, but they often wear a gauze pad or stoma cap.

The restorative proctocolectomy (S pouch or J pouch) ileoanal reservoir spares the rectum of patients with ulcerative colitis or familial polyposis. The colon is removed and the diseased mucosa is stripped from the rectum, and an internal pouch is created from the ileum. The distal end of the small intestine is stapled or hand sewn to the remaining rectal tissue. The sphincter is preserved and ostomy pouching systems are unnecessary. However, a patient undergoing this procedure may have a temporary (about 3-6 months) stoma to protect the healing pouch. Patients will have more frequent bowel movements and may experience perianal skin irritation.

Anatomic drawing of the lower digestive and urinary tracts depicting location and permanence of colostomies. (Source: Adapted with permission from *Am J Nurs.* 1977;77:443.)

### Colostomy

A colostomy is created by bringing a portion of the colon through the abdominal wall. The discharge may be semisoft, paste-like, or formed depending on the portion of bowel used (Figure 21-1).

*Ascending colostomies* are uncommon. The ascending colon is retained, but the rest of the large bowel is removed or bypassed (see Color Plates, photograph 2C). The stoma is usually on the right side of the abdomen. The discharge is semisoft and a pouch must be worn at all times.

The transverse colon is the site of most temporary colostomies (Figure 21-1). A loop of the transverse colon is lifted through the abdominal incision, and a rod or bridge (which is removed within 1-2 weeks) is placed under the loop to give it support while the stoma heals. The discharge is usually semiliquid or very soft. *Loop colostomies* have one large opening but two tracts (see Color Plates, photograph 2D). The proximal tract discharges fecal material, and the distal tract secretes small amounts of mucus. A pouching system must be worn at all times. A person with a loop colostomy may also pass a minimal amount of stool or mucus through the rectum. This is a normal occurrence.

For a *double-barrel transverse colostomy*, the bowel is completely divided by bringing both the proximal end and the distal end through the abdominal wall, and then suturing them to the skin (see Color Plates, photograph 2E). The distal stoma may also be called the mucous fistula.

*Descending and sigmoid colostomies* are fairly common; generally the stoma is on the left side of the abdomen (see Color Plates, photograph 2F). The fecal discharge has a paste-like consistency and at times may consist of formed stool. This type of colostomy may be regulated by irrigation; therefore, a pouching system may not be needed. However, many patients prefer a pouch to irrigation. Not everyone with a descending or sigmoid colostomy is a good candidate for irrigation or prefers irrigation. Factors to consider in making the decision to irrigate include the presence or absence of stomal complications and the patient's normal stooling pattern, psychomotor ability, and willingness to commit the time required to properly irrigate the ostomy.

### Urinary Diversions

Urinary diversion surgery diverts the urine through an opening in the abdominal wall. Urinary stomas should function immediately after surgery. The broad term for a urinary diversion is *urostomy*.

The *ileal conduit* is the most common type of urinary diversion (see Color Plates, photograph 2G). After the bladder is removed, ileal and colon conduits are created by implanting the ureters into an isolated loop of bowel; one end of the bowel loop is sutured, and the distal end is brought to the surface of the abdomen. The stoma looks similar to the stoma in an ileostomy or colostomy. A pouching system must be worn continuously. Mucous shreds will be present in the urine if both the small intestine and the large intestine are used to create the diversion (see Color Plates, photograph 2H). Because the ileum is used to create an ileal conduit, some people incorrectly refer to the ileal conduit as an ileostomy. Clarification of the type of effluent (stool or urine) will help in selecting the correct type of pouch.

In a *ureterostomy*, one or both ureters are detached from the bladder and brought to the outside of the abdominal wall, where a stoma is created. This procedure is used less frequently because the ureters tend to narrow unless they have been dilated permanently because of previous disease (see Color Plates, photograph 2I).

A *cystostomy* is performed when blockage or narrowing of the urethra occurs. Urine is diverted from the bladder to the abdominal wall. A pouch must be worn continuously. An infant may use diapers instead of a pouch.

The *continent urinary diversion* is available for selected patients, but its use requires that certain criteria be met. An Indiana pouch is a type of continent urostomy in which a pouch is created from part of the cecum and ileum, with a portion of the ileum brought through the abdominal wall to create a stoma. The ureters are attached to the cecum pouch. The remaining ileum is reattached to the colon for normal digestive flow. The ileocecal valve is left intact and becomes part of the continence mechanism, preventing urine from exiting the pouch. The internal pouch is emptied by inserting a catheter into the stoma to drain the urine. Patients are usually placed on a strict schedule and will catheterize the stoma often enough to avoid leakage. The new pouch may hold up to 600 mL of urine. An external pouching system is not necessary. Most patients wear a gauze pad or stoma cap. The orthotopic neobladder is a rebuilt bladder. The small intestine is used to create a pouch, and the pouch is then attached to the native urethra. This procedure allows patients to void using their urethra, but voiding relies on the patients using their abdominal muscles to empty the neobladder.

### Management of Ostomies

#### Management Goals

The ideal ostomy pouching system should be leak-proof, odor-proof, comfortable, easily manipulated, inconspicuous, safe, and as inexpensive as possible. Because the patient has lost a normal body function, the pouching system assists the patient in managing that loss, and it becomes almost a part of the body. It is common for patients and their families to find discussing ostomy needs difficult or embarrassing, especially during the first several weeks or months after surgery. The ostomy industry is highly specialized and rapidly changing as it tries to improve designs, resulting in a wide range of choices. Pouch selection is extremely personal and is based on the patient's specific needs and abilities and on the cost of the system.

#### General Management Approach

Adult and adolescent patients must be taught self-care skills to manage the ostomy, including (1) sizing the stoma, (2) cutting a pouch or skin barrier to fit the stoma (or selecting a precut pouch or barrier), (3) cleaning the skin, (4) applying paste (caulking) or powder if necessary, (5) applying the pouch, (6) removing the pouch, and (7) emptying the pouch. Patients must be prepared for effluent from the stoma at any time.

Patients are most likely to achieve optimal outcomes if a pouching system is properly fitted (Figure 21-2) and if the stoma is cared for appropriately. The provider should always be aware of the sensitive nature of the topic and ensure that privacy is respected during all discussions. Failure to provide a comfortable environment in which to discuss problems, concerns, and alternatives may cause patients to avoid such discussions and may result in less-than-optimal outcomes. Follow-up assessment and care may be accomplished through a telephone call or scheduled appointment or during the patient's routine visits to purchase supplies or medications.

Frequent changes in the pouching system and accessories should signal a potential problem, as should the use of multiple products intended for the same purpose. In many cases, patients may be referred to a primary care provider or wound, ostomy, and continence (WOC) nurse for follow-up of problems identified by a health care provider. Complications such as impotence; peristomal hernia; and stenosis, prolapse, retraction, or peristomal skin injury require medical referral. In some cases, however, self-care is appropriate, particularly by experienced ostomy patients.

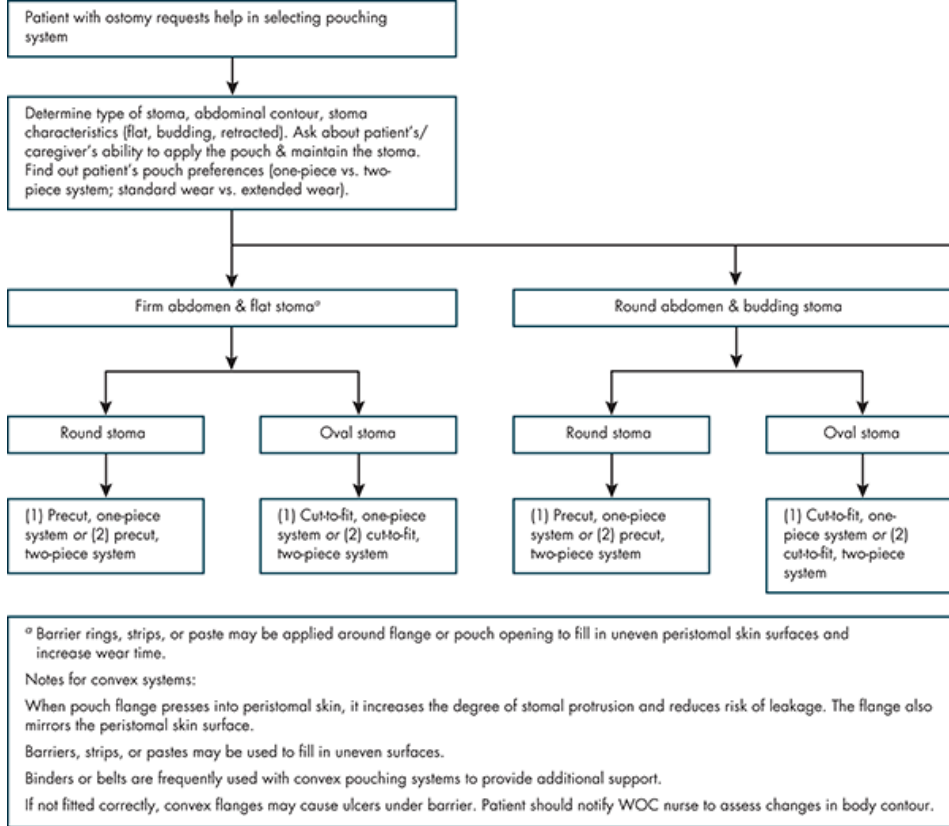

The presence of an ostomy and its location in the gastrointestinal or urinary system should always be noted on the patient's profile to minimize medication-related risks. It is helpful to maintain a record of current and past ostomy products that the patient has used and any problems that the patient has experienced. This information can be useful in making future recommendations.

#### Types of Ostomy Pouches

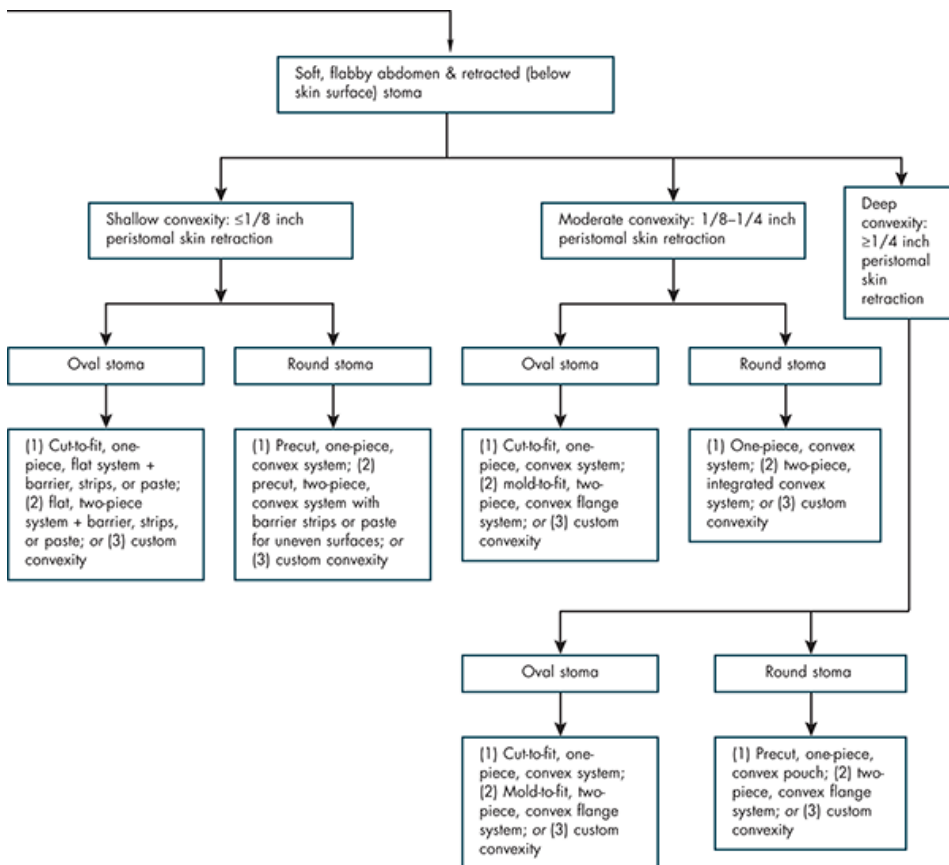

The surgical technique used to create the stoma influences the pouching system required, the complexity of the pouching procedure, and the risks of stomal and peristomal complications (e.g., necrosis, stenosis, or hernia). In the past, most ostomy pouches were reusable. The advantages of reusable pouching systems were their durability, availability in numerous configurations, and relatively low cost. Their disadvantages were that they required cleaning before each use, were heavy, tended to retain odor, and often required a separate skin barrier.

Ostomy patients are now fitted with odor-proof, lightweight, disposable pouching systems. The health care provider measuring the stoma should ensure a clearance of 1/16-1/8 inch between the barrier opening and stoma, whether the barrier is precut or cut to fit. Most pouches incorporate a solid skin barrier in each flange or one-piece pouch, which eliminates the need for a separate skin barrier. Disposable equipment is available in one- and two-piece systems (Figure 21-3). The one-piece system, in which the skin barrier and the pouch are available in one piece, is easy to apply, especially for patients with impaired manual dexterity. In the two-piece system, the skin barrier is separate from the pouch. This allows patients to access the flange easily and change the pouch, if desired,

without removal of the flange from the skin. The flange is easy to apply and is generally more pliable and adaptable to different abdominal contours. One- and two-piece pouching systems are also available for young children. Although pouches are available for infants, some ostomies are managed with a diaper instead. If a diaper is used, care must be taken to avoid skin irritation from a caustic effluent. Moisture barrier ointments and creams are required for neonates and infants who are only diapered. The decision to diaper or pouch is based on the location of the stoma, the type and amount of effluent, and the child's activity. Once a child is crawling or exploring, it is difficult to keep stool contained in a diaper.

Selection of ostomy pouching system. Key: WOC = Wound, ostomy, and continence.

Both one- and two-piece pouch systems are available in drainable, high-output, closed-end, and urostomy styles. Drainable styles are used when bowel regulation cannot be established; they allow for easy and frequent emptying. A closed-end system requires the wearer to remove and discard the pouch when it

is almost full. Closed-end systems are used by patients who have regulated colostomies, have one or two formed bowel movements within 24 hours, or routinely irrigate the ostomy to remove output. The goal is to avoid output between irrigations; however, this outcome may not occur immediately, and output can also be affected by the patient's diet, activity, and illness. Urostomy systems allow a constant output of urine and easy emptying throughout the day through a narrow valve opening. At night, most urostomy patients connect their pouch to dependent drainage to prevent overfilling of the pouch.

#### Fitting and Application

Reusable and disposable pouches are available in transparent and opaque styles and in various sizes. The pouch opening may be cut to fit or presized. Other options in skin barriers include a flat or convex skin barrier. When convex barriers are indicated, they are available with round, oval, or moldable openings. Measuring the stoma to determine the proper fit of a pouch is an important part of ostomy care. The diameter of the round stoma is measured at the base, where the mucosa meets the skin; this area is considered the widest measurement. Oval stomas should be measured at their widest and narrowest diameters. A stoma may swell if the adhesive fits too tightly or slips, or if the patient falls or experiences a hard blow to the stoma. It is important to periodically reassess the size for proper fitting.

Sample ostomy appliances: **A**, ConvaTec Esteem Synergy two-piece closed-end pouch; **B**, ConvaTec Esteem Synergy skin barrier with tape collar; **C**, ConvaTec Esteem Synergy drainable pouch with InvisiClose outlet; **D**, ConvaTec Esteem Synergy skin barrier without tape collar; **E** and **F**, Hollister New Image two-piece pouching system with Lock'n Roll closure: pouch and flange views, respectively. (A-D reprinted with permission from ConvaTec, a Bristol Myers Squibb Company, Skillman, NJ; E and F reprinted with permission from Hollister Incorporated, Libertyville, Illinois.)

Other considerations in fitting the pouch include body contour, stoma location, skin creases and scars, and ostomy type. The lack of uniformity in types of ostomies and ostomy equipment makes it difficult to give standard instructions for application. In addition, the stoma and the contour of the surrounding area change over time, necessitating continuous adjustments to pouches and accessories. In general, when a rigid faceplate or flange is used, the opening should provide a clearance of 1/16-1/8 inch around the stoma. Less clearance (0-1 mm) is required with a flexible barrier. A WOC nurse is an excellent source of assistance in custom fitting these pouching systems.

#### Wearing Time

The pouch should be emptied when it is one-third to one-half full to prevent leakage. With a two-piece system, the closed-end pouch is simply removed from the flange and thrown away. Patients who want to save on pouch costs may use the two-piece drainable system and alternate the use of two pouches. The full pouch is removed and replaced by a second pouch; the first pouch is then emptied, washed, and reused when the second pouch is changed. One-piece, closed-end systems are removed and disposed of once or twice daily; those that can be drained can be left in place as long as they are comfortable and there is no leakage. The flange and skin barrier may be left in place for 3-7 days depending on the condition of the skin and skin barrier. Average wear time is 4 days. The skin barrier is constructed from a material called a hydrocolloid. The hydrocolloid softens in the presence of moisture. As the hydrocolloid softens, less adhesive is present to secure the seal. Therefore, a person with a high liquid output or very moist skin (heavy perspiration) may find that the skin barrier must be changed in 3-4 days. A person with solid to semisolid stool may be able to wear the skin barrier longer than 4 days. Although activities such as swimming or playing tennis may decrease the wear time of the pouch, this decreased time should not discourage participation in physical activities. New pouch adhesives can effectively keep the system in place during these activities. Because water will not enter the stoma, it is not necessary to cover it while bathing or showering. The patient doesn't need to cover a continent stoma when swimming. However, the pouching system can be secured with waterproof tape (e.g., Hy-Tape and Pink Tape) by taping around the edges of the wafer/flange to prevent leakage of output from the stoma.

#### Product Selection Guidelines

The selection of products must be tailored to the patient's activity level and, if present, specific disabilities. Some systems require manipulation that a patient with arthritis may not be able to perform. Special products are also available to assist patients who have poor vision. In general, patients with visual or physical impairments will do best with one-piece systems because these systems have precut pouches and require minimal manipulation. Waterproof materials or a stoma cover should be included with the system. [Table 21-1](#) lists ostomy manufacturers. Their Web sites list all available products and product information. No particular device will prevent patients who are confused from reaching and dislodging the pouching system (e.g., patients with Alzheimer's disease). It may be helpful to dress these patients in garments that make it difficult for them to reach the pouch. Dressing infants in one-piece clothing will help prevent them from exploring and pulling off their pouches.

#### Ostomy Accessories

##### Belts

Special elastic belts that attach to various pouching systems provide additional support. However, not all ostomy patients need to wear belts. Indications for their use are a deeply convex flange, short pouch-wearing time, high activity level (especially in children), heavy perspiration, and personal preference. Some patients may find that wearing a belt for just a few hours after changing their pouch helps the adhesive adhere, thereby increasing wear time and decreasing the risk of leakage. Belts that are too tight may cause skin ulcers. To be effective, the belt must be kept even with the belt hooks. If the belt slips up around the waist, it may cause poor adherence and, possibly, cut the stoma. Women may find that pantyhose and a panty girdle are excellent alternatives to a belt.

Many belts contain latex, so the patient should be asked about a latex allergy before a belt is recommended.

#### Skin Barriers, Powders, and Pastes

Skin barriers, powders, and pastes are available for special skin problems (Table 21-2). Skin barriers are intended to protect the skin immediately adjacent to the stoma from stoma discharge and to serve as a means of attaching a pouching system. They correct imperfections in the skin surface, allowing the pouching system to fit securely. Powders are used on weeping skin to absorb excessive moisture and support healing, but excessive powder must be dusted off or sealed with a no-sting liquid skin preparation before pouch application. Pastes (which are not a glue but have a paste-like consistency) are used to seal the area around the stoma and fill creases in the skin. Pastes produce a flat surface for application of other skin barriers and can be used to caulk the edge of the skin barrier.

**TABLE 21-2 Selected Ostomy Skin Barriers, Adhesives, Adhesive Removers, Belts, Powders, Cleaners, and Air Vent System**

Hollister Adapt Lubricating Deodorant	Available in 8 ounce bottle or 8 mL packs. Facilitates emptying of pouch by providing lubrication
Coloplast Brava: rings, strips, strip paste	Moldable strips/paste to fill in uneven surfaces
ConvaTec AllKare Adhesive Remover Wipes	Helps prevent skin damage by easing removal of all adhesives; has oily residue; skin should be washed after use
ConvaTec AllKare Protective Barrier Wipes	Thin film protects against skin stripping; excellent liquid skin barrier for adhesives, tapes, and self-adhesive dressings
ConvaTec Eakin Cohesive Seals	Moldable, double-sided adhesive seals designed to help prevent skin damage; absorbs moisture and forms a gel to further protect skin; adheres to moist, sore skin; suitable for all types of ostomies (especially hard-to-fit stomas); can be used with pastes and all skin barriers and pouching systems
ConvaTec Stomahesive Paste	Pectin product; helps prevent leakage and skin irritation by filling in uneven surfaces; new easy-to-squeeze tube
ConvaTec Stomahesive Powder	Pectin base; light dusting applied to denuded skin to promote healing
Hollister Adapt Barrier Rings, Strips, Paste	Custom (molded, bent, shaped, and stacked) convex barrier rings; barrier strips can mold and stack; paste in easy-to-squeeze tube
Hollister Medical Adhesive	Improves adhesive contact between skin and barrier
Hollister M9 Cleaner/Decrystallizer	Cleans urinary drainage systems; pH balanced and nonacidic
Hollister M9 Odor Eliminator	Available in spray or drops, scented or unscented; is an enzyme that helps to neutralize odor

Hollister Adapt Powder	Light dusting applied to denuded skin to promote healing
Hollister Universal Remover Wipes	Removes adhesives and barriers; available as spray and wipes
KEM Air VENT System (OSTO-EZ-VENT)	Quickly and easily releases gas buildup in ostomy pouches
Nu-Hope Barrier Rings and Strips	Karaya/pectin; moldable rings and strips
Nu-Hope Cement	Natural rubber; hexane; excellent adherence for difficult pouching
Nu-Hope Support Belt	Standard 2½-inch opening; 3- to 9-inch widths; customized belts available; provides excellent support to prevent parastomal herniation; prolapse overbelt and custom openings available
Smith & Nephew Adhesive Remover	Helps prevent skin damage by easing removal of all adhesives
Torbot Skin Cement	4 ounce can; natural rubber; hexane; excellent adherence for difficult pouching
3M No Sting Wipes	Does not contain alcohol; thin film protects against skin stripping; excellent liquid skin barrier for adhesives, tapes, and self-adhesive dressings

Solid skin barriers are preattached to the pouch (one-piece system) or provided separately (two-piece system) and may be custom-cut (sizable) or precut (presized). Some manufacturers will custom cut the barriers; however, in most cases, the patient or WOC nurse modifies the barrier to fit the stoma. The opening in the skin barrier should match the size and shape of the patient's stoma. To apply a skin barrier, the patient should place a bead of skin barrier paste either around the stoma or directly to the inside edge of the skin barrier, apply the skin barrier to dry wrinkle-free skin, and then press the skin barrier around the stoma to improve adherence. Newer moldable seals are now available from major manufacturers.

Solid skin barriers may melt if exposed to high temperatures. Therefore, during the summer and especially when traveling, the solid skin barrier should be put in an insulated box (ice is not required) to minimize the risk of melting. Pouches should not be left in the car during the day, unless the car is completely shaded and the outside temperature is not extremely high.

#### Absorbent Gel Packets and Flakes

Absorbent gel packets and flakes (e.g., Ileosorb and Par-Sorb) dissolve as the pouch fills, turning the liquid effluent into a gel. They reduce noise caused by sloshing of stomal fluids, control odor, prevent peristomal skin irritation, and prevent leakage, especially at night while the patient sleeps.

#### Cleansing and Special Skin Care Products

Cleansing of the stoma and surrounding skin is best done with plain water. If soap is used, it should be rinsed off thoroughly and the skin should be dried before a new pouching system is applied. Use of moisturizers and products containing lanolin, petrolatum, or oils should be avoided because they prevent the pouching system from adhering to the skin.

#### Adhesives

Adhesives, in the form of cements or tapes, may be used by some to keep the pouch in place. Hypoallergenic tape may be used to support the pouch. A strip may be applied across the top, bottom, and sides of the flange, with half on the flange and half on the skin. Waterproof tape may be used during swimming or bathing. Solvents are available to remove adhesive residue; however, solvents or adhesive removers must be removed from the skin prior to application of the new pouching system.

#### Irrigating Sets

Irrigating sets can be used to maintain control of output without the use of a pouch in patients with colostomies who are candidates for irrigation. Irrigation is similar to performing an enema at the site of the stoma. Approximately 1000 mL of lukewarm tap water is instilled into the bowel through a cone inserted in the stoma. The bowel then expands, causing peristalsis and elimination of waste through the stoma. A good candidate for irrigation is an adult patient who has a colostomy distal to the splenic flexure; does not have a history of irritable bowel syndrome or a disability; has good mentation, manual dexterity, and appropriate bathroom facilities (running water); and is not undergoing chemotherapy or radiation therapy. For the process to be safe and effective, the patient should use a colostomy irrigation set rather than a standard enema set.

Frequency of irrigation depends somewhat on a patient's normal bowel habits. The recommended frequency is to irrigate at the same time every day and eventually to regulate irrigation to every other day. Patients take approximately 6 weeks to become regulated. After achieving control, the patient may wear a security pouch or a piece of gauze, a stoma cover, or a cap over the stoma. Irrigation is not necessary for health; it is merely one method of colostomy management. Patients should use this procedure only if desired and instructed in technique by a WOC nurse or primary care provider.

#### Deodorizers

If needed, deodorizers are available as liquids or tablets. Liquid concentrates, which are available as companion products with most ostomy pouches, can be placed directly into the pouch to neutralize odor. DevKo external tablets may also be placed into the pouch to decrease odor. Derifill internal deodorant tablets (active ingredient is 100 mg chlorophyllin copper complex sodium) may also be used. The purpose of the deodorizers is to lessen the odor upon emptying; no odor should be detectable when the pouch is on and adequately sealed.

#### Changes in Diet

Diet does not generally play an important role in ostomy management. Most patients can eat their usual diet, including all the food they ate before surgery if they chew their food well. However, it is wise to remain on a diet low in fiber for the first 6 weeks after surgery to allow the intestine to heal and the swelling to resolve. The usual diet can be resumed after that time.

The effects of various foods on ostomy output are summarized in [Table 21-3](#). Patients with a urostomy may want to avoid foods that cause odor. Patients with colostomies, especially those who irrigate, should avoid foods that cause loose stools. (This problem varies among individuals.) Because they have no control over passage of gas, patients with a fecal ostomy may prefer to reduce their intake of gas-forming foods. Products such as alpha-d-galactosidase may be used to control gas (see [Chapter 14](#)). Patients with ileostomies are more prone to intestinal obstruction from high-fiber foods eaten in large quantities or eaten exclusive of other foods ([Table 21-4](#)).<sup>4,5</sup> Thoroughly chewing high-fiber foods and eating them in small amounts and with other types of food will help prevent food blockage. The patient should be instructed how to manage a food blockage. [Table 21-5](#) lists signs and symptoms of blockage; [Table 21-6](#) describes its management.

#### TABLE 21-3 Effects of Food on Stoma Output

<b>Foods That Thicken Stool</b>	Applesauce; bananas; bread; buttermilk; cheese; marshmallows; milk; pasta, boiled; peanut butter, creamy; potatoes; pretzels; rice; tapioca; toast; yogurt	<b>Foods That Loosen Stool</b>	Beer and other alcoholic beverages; chocolate; dried or string beans; fried foods; greasy foods; highly spiced foods; leafy green vegetables (lettuce, broccoli, spinach); prune or grape juice; raw fruits (except bananas); raw vegetables, fruit juices, milk	<b>Foods That Cause Stool Odor</b>	Asparagus; beans; cabbage-family vegetables (onions, cabbage, brussels sprouts, broccoli, cauliflower); cheese; eggs; fish; garlic; some spices; turnips	<b>Foods That Cause Urine Odor</b>	Asparagus; seafood; some spices	<b>Foods That Combat Urine Odor</b>	Buttermilk; cranberry juice; yogurt	<b>Foods That Cause Gas</b>	Beans (dried, string, or baked); beer; cabbage-family vegetables (onions, cabbage, brussels sprouts, broccoli, cauliflower); carbonated beverages; corn; cucumbers; dairy products; mushrooms; peas; radishes; spinach; spicy foods	<b>Foods That Color Stool</b>	Beets; berries; chocolate; fats; fish; meat (large amounts of red meat); milk; red gelatin; vegetables

**TABLE 21-6 Conservative Management of Food Blockage**

<ol style="list-style-type: none"> <li>Sit in warm tub bath to relax abdominal muscles.</li> <li>Massage the peristomal area while in the knee-to-chest position to attempt dislodgement of fibrous mass.</li> <li>If stoma is swollen, remove pouch and replace with a pouch that has a larger stoma opening.</li> <li>If able to tolerate fluids (i.e., not vomiting) and passing stool, increase intake of fluid and electrolytes, but avoid solid foods. Drink one glass of liquid each time pouch is emptied. Juices such as grape juice exert a mild cathartic effect.</li> </ol>
---

5. If vomiting, not passing stool, or both, do not take liquids or solid food orally.
6. Notify a primary care provider or WOC nurse if any of the following develops:
  - Stool output stops (complete blockage).
  - Conservative measures (listed above) fail to resolve symptoms.
  - Signs of partial obstruction persist (Table 21-5).
  - Inability to tolerate fluids or replace fluids and electrolytes develops.
  - Signs and symptoms of fluid and electrolyte imbalance (Table 21-7) develop.

Source: Reference 4.

### Complications of Ostomies

Persons with ostomies may experience both psychological and physical complications. The health care provider should be prepared to address these complications or to refer patients to their primary care provider or a WOC nurse. These nurses are often based in hospitals or home health care agencies. The United Ostomy Associations of America is an organization that provides peer support for patients. Before surgery, patients should receive a thorough explanation that describes what procedure will be performed, what to expect during the postsurgical recovery period, and what pouching and supplies will be used. The following information on potential complications can be used to assist patients seeking advice after their surgery.

#### Psychological Complications

Some patients anticipating ostomy surgery fear that they will not be able to continue their former job, participate in sports, perform sexually, or have children. These patients need reassurance that an ostomy rarely impairs their ability to carry out such activities. Contacting the local United Ostomy Associations of America is of utmost importance in assisting with the rehabilitation of these patients; both providers and patients may contact this organization. Patients may also want to find a local WOC nurse. Patient education and counseling on ostomy care provides information and support before and after ostomy surgery. Literature is available from all of the major ostomy product manufacturers, the United Ostomy Associations of America, and the American College of Surgeons.

#### Physiologic Complications

The major physiologic consequence of a GI ostomy is fluid and electrolyte imbalance. This is most problematic in patients with a liquid or semisoft stoma discharge, such as ileostomies or ascending and transverse colostomies. Patients with these types of ostomies must maintain adequate fluid intake to compensate for loss of the absorptive function of the colon and loss of ileocecal valve function. Patients with ileostomies lose about 500-1000 mL of fluid daily through the stoma, whereas individuals with a normally functioning colon lose 100-200 mL daily.<sup>3</sup> During illnesses, patients with ileostomies, especially infants, are particularly vulnerable to fluid and electrolyte imbalance caused by vomiting and diarrhea. Caregivers and patients should be counseled regarding common signs and symptoms of imbalance (Table 21-7).<sup>4,5</sup>

Because the GI tract is the site of nutrient absorption, some patients with ostomies may experience deficiencies. For example, iron and vitamins D<sub>2</sub> and D<sub>3</sub> are absorbed in the small intestine; riboflavin is absorbed in the upper GI tract; vitamin B<sub>12</sub> is absorbed in the terminal ileum; phytonadione is absorbed in the proximal small intestine; menadione is absorbed in the distal small intestine; and calcium, pyridoxine, pantothenic acid, biotin, choline, inositol, carnitine, vitamins C and E, and thiamine (vitamin B<sub>1</sub>) are absorbed in various sites within the intestinal tract (specific sites not identified). Vitamin A deficiency may be seen in individuals with disease of the terminal ileum (e.g., Crohn's disease). Hypophosphatemia and hypomagnesemia are present in individuals with calcium deficiency caused by malabsorption. In addition, copper deficiency, which interferes with the absorption of iron, has been reported in individuals who have undergone intestinal bypass surgery. Folic acid absorption requires interaction with enzymes present in the upper part of the jejunum; therefore, most absorption of folic acid takes place in the proximal part of the small intestine.<sup>6,7,8,9</sup> The effect of ostomy surgery on absorption of vitamins and minerals has not been well studied; however, patients with ileostomies or colostomies should be monitored for signs and symptoms of deficiencies.

Patients with a urostomy, an ileostomy, or an ascending colostomy must include an adequate amount of fluid in their diets to prevent the precipitation of crystals or kidney stones in the urine. In addition, they may have an increased incidence of gallbladder stone formation. Patients with a urostomy should adjust their diet to produce acidic urine, thereby reducing the risk of infection and crystal formation around the stoma. Cranberry products have been studied in the prevention of recurrent urinary tract infections. Evidence does not support the use of cranberry products for the treatment of urinary tract infections.<sup>10,11,12,13,14,15</sup> (See Chapter 51 for an in-depth discussion of cranberry.)

**TABLE 21-7 Signs and Symptoms of Fluid and Electrolyte Imbalance**

Adults	Infants
Increased thirst	Depressed fontanel
Dry mouth and mucous membranes	Lethargy
Orthostatic hypotension	Sunken eyes
Decreased urine volume	Weak cry
Increased urine concentration (dark in color)	Decreased frequency of wet diaper
Sunken eyes	Increased urine concentration (dark in color)
Extreme weakness	
Flaccid muscles	
Diminished reflexes	
Muscle cramps (abdominal and leg)	
Lethargy	
Tingling or cramping in feet and hands	
Confusion	
Nausea and vomiting	
Shortness of breath	

Source: References 4 and 5.

#### Systemic Complications

Constipation is caused by the regular use of constipating analgesics or other medications or by a patient's eating habits. Constipation may be a problem in patients with descending and sigmoid colostomies. Treatment depends on the cause and may include dietary changes or medication adjustment. Patients having problems with constipation should be encouraged to avoid the foods listed in Table 21-3 that can thicken the stool.<sup>4,5</sup>

Certain foods can cause diarrhea in ostomy patients (Table 21-3).<sup>4,5</sup> Gut pathology (e.g., ulcerative colitis, Crohn's disease, or *Clostridium difficile* colitis) or obstruction caused by a food bolus can also cause diarrhea. Medications, influenza, and food poisoning are other potential causes. Diarrhea is a special problem in patients with ileostomies and ascending colostomies because they cause impaired fluid and electrolyte reabsorption. Patients with chronically loose stools may want to use an absorptive agent (e.g., Ileosorb or Par-Sorb) designed for use in the pouch. Absorptive agents do not correct the problem; they assist in coping with the problem. Increased fiber (e.g., Metamucil or Citrucel) may be used to help correct diarrhea in patients with a colon. Antidiarrheals may be ordered

to slow transit time and decrease output. In addition, an unexpected high or decreased output or no output in a patient with an ileostomy may represent a partial small-bowel obstruction. In this case, the patient needs to seek emergency medical attention.

Intestinal gas may be related to food. Eliminating foods that cause gas from the diet may solve the problem (Table 21-3). Use of simethicone to reduce gas production or pouches with gas filters may be helpful. Odor is not normal except when the pouching system is changed or emptied. Otherwise, odor may be an indication of poor hygiene, leakage, or failure to properly connect the pouch to the skin barrier. The provider should review proper care and connection of the pouching system with patients who are concerned about odor. Oral deodorants that will act in the digestive system to eliminate odors from digested foods are discussed in the section Deodorizers.

#### Local Complications

The normal stoma is shiny, moist, and either pink or red. The stoma does not contain nerve fibers, so it does not transmit pain or other sensations. In an adult, the stoma size is approximately  $\frac{1}{2}$ -3 inches depending on the portion of the bowel or urinary tract used. The stoma gradually shrinks after surgery and reaches its permanent size within 6 weeks.

Skin irritation around the stoma can result from stoma effluent contacting the skin for a prolonged period of time. Ostomy pouching systems and accessories can also irritate skin because of poor fit or the materials used in their composition. The peristomal skin may look weepy or erythematous and have papules and macules. The Ostomy Skin Tool (OST) is a new standardized peristomal skin assessment tool that was developed by WOC nurses and an ostomy manufacturing company. This tool has three clinical parameters: discoloration, erosion, and tissue overgrowth.<sup>16</sup> The patient may use a skin barrier powder, ostomy cream, or barrier to protect the skin, although a properly fitting pouching system should be the first priority.

**Denuded peristomal skin** is caused by erosion of the epidermis by digestive enzymes. The eroded or denuded epidermis may bleed, and it is painful when touched and when the pouch is applied. Denuded peristomal skin occurs when an improper pouch is worn, when the pouch opening is too big or too small, or when the pouch has leaked and not been promptly replaced. These problems can allow the output to come in contact with the skin. The output produced by patients with ileostomies is particularly irritating to skin. The patient should be referred to a WOC nurse or primary care provider for treatment. Once the etiology of the denuded skin is determined and corrected, a skin barrier powder may be applied to the peristomal skin before the pouch is applied. A skin barrier powder may be composed of a pectin or karaya powder, which absorbs skin moisture and provides a dry surface. A liquid skin barrier may be used over the powder so the pouching system can adhere. This is called "crusting." The pouch should be changed more often to reduce the risk of further irritation. Treatment should be continued until the skin is intact.

**Contact dermatitis** is characterized by burning, stinging, itching, and red or denuded skin. This complication usually results from an allergic reaction to the pouching system or an accessory. A patch test will identify the allergen in patients who have a history of allergy, a reaction to adhesive tape, eczema, or psoriasis, as well as in those who have very fair skin. Patients exhibiting sensitivity may need to change products. A fabric pouch cover may be helpful if the allergy is to the pouch itself. Special precautions are necessary in patients with a latex allergy. On request, a manufacturer will provide written information regarding the natural latex rubber content of its products and packaging (see the manufacturer's Web site). In some products, the latex source is a dry, natural latex rubber, which is used to seal blister packs that contain nonlatex products.

**Alkaline dermatitis** (encrustation) may occur in patients with urinary diversions because of the alkaline nature of the output. The stoma or peristomal skin may feel gritty, like sandpaper. Alkaline dermatitis, which renders the stoma extremely friable, is a common cause of blood in the pouch. A cloth soaked with a solution of one-third white vinegar to two-thirds water should be applied to the involved area for 5 to 10 minutes at least once weekly before the pouching system is put on. Patients who use a two-piece system can apply the solution as often as three to four times daily. The vinegar may cause the stoma to blanch, but blanching is not indicative of damage. The two-piece pouching system allows the wearer to remove the pouch and access the stoma if the stoma is involved in the encrustations. Treatment for alkaline dermatitis is acidification of the urine. Patients should avoid alkaline ash foods, such as citrus fruits and juices; paradoxically these foods are acidic when consumed but are excreted in alkaline form. Increasing fluid intake to between 2 and 3 quarts daily may reduce alkalinity. Use of a urinary appliance with an antireflux feature is recommended because this feature prevents urine from contacting the skin when the patient is lying down.

**Hyperplasia** (an overgrowth of skin) occurs when the pouch opening is too large. There is no pain in the early stages, but later the affected skin cells multiply and cause agonizing pain. The condition resembles a mucosal polyp and may also be called *hyperkeratosis* or *pseudoverrucous lesion*. Treatment entails ensuring that the pouch has the correct opening size and that the seal is secure. The seal is achieved with paste, paste strips, or a moldable seal or skin barrier ring that will mold into the irregular surfaces. Other management approaches include cauterization using silver nitrate sticks and/or surgical removal.

**Mechanical injury** is caused by a poorly fitting appliance or skin barrier, a stoma that is difficult to access, or tight-fitting clothing. A poorly fitting pouching system can be corrected by measuring the stoma before each purchase of supplies, selecting a skin barrier of the proper size, and adjusting the size of the skin barrier opening, if necessary. The opening should be  $\frac{1}{16}$ - $\frac{1}{8}$  inch larger than the stoma. New "moldable flanges" should fit at the mucocutaneous junction. Patients experiencing mechanical injury should be encouraged to contact a WOC nurse.

**Skin stripping** refers to inadvertent sloughing or removal of the top layer of skin around the stoma. The skin around the stoma may be irritated from use of a strong adhesive or removal of the skin barrier in a rough manner. The skin barrier should be removed by pushing the skin away from the barrier, not by pulling the barrier away from the skin. Adhesive removers are useful in preventing skin damage if the stoma is new or the peristomal skin is fragile. After use of adhesive removers, the peristomal skin must be cleaned to remove all adhesive remover residue because blistering, irritation, or ineffective adhesion of a new pouching system may occur.

**Stenosis** of the stoma results from the formation of scar tissue. Excessive scar tissue is usually caused by improper surgical construction, postoperative ischemia, active disease, or alkaline stomatitis or dermatitis. Although dilation of the stoma is often advocated to prevent or palliate this problem, the only cure is revision of the stoma.

**Excessive sweating** under the pouch can decrease wearing time and cause monilial infection. A skin sealant or cement plus a belt may be necessary to hold the pouching system in place. Purchasing or making a cover or bib to keep the pouch material from touching the skin can alleviate discomfort from perspiration underneath the collection pouch.

**Folliculitis**, an inflammation of the hair follicles, is characterized by redness at the base of the hair follicles around the stoma. Aggressive removal of any adhesive around the stoma can remove hairs, resulting in irritation and infection. Using an electric razor to shave the areas on which adhesive will be applied may help prevent folliculitis. Because folliculitis is related to an overgrowth of staphylococci on the skin, the use of an antibacterial wash should be considered; in some advanced cases, use of an oral antibiotic may be considered.

**Infections** are not more frequent in patients with ostomies, with the possible exceptions of patients with Crohn's disease, diabetes, or ruptured diverticulitis, or those undergoing radiation or chemotherapy. In some cases, however, infections under the pouching system can be problematic. Candidal infection may be a problem in patients who wear a pouch continuously. A dark, warm, moist environment promotes the growth of *Candida* species. The primary symptoms are itching and rash. If the infection is allowed to continue unchecked, the skin will become denuded, the pouching system will not stick, and additional skin irritation will result from the output.

If the skin is indurated, swollen, and red, an abscess may be present, which may necessitate incision and draining. Culture and susceptibility testing should be performed, and an appropriate antibiotic should be prescribed for topical use, systemic use, or both. Patients should be encouraged to contact a WOC nurse for assistance. Minor candidal infections may be treated with nystatin powder or 2% miconazole powder. Excessive powder should be brushed off before the pouch is applied. Antifungal preparations are generally used every pouch change for 1 week after the skin has become clear. In treatment of candidal infections, it is important to ascertain whether the patient is taking antibiotics. Any antibiotic, but especially a broad-spectrum agent, changes the flora of the skin, and the entrenched *Candida* can become difficult to eradicate. Therefore, in patients with an ostomy being treated with antibiotics, it is often helpful to continue using nystatin powder or 2% miconazole powder for 1 month after all signs of candidal infection are gone.<sup>17,18</sup>

**Peristomal hernia** is a protrusion of the colon or ileum through a defect in the fascia in the area around the stoma. It usually occurs if the abdominal wall is weak or the stoma was placed lateral to the rectus muscle. The patient may complain of a bulge when standing or sitting, pain, pouching difficulties, leakage, and peristomal skin irritation. Modification of the pouching system or technique may help to alleviate some of the symptoms of a peristomal hernia. An ostomy support belt or binder may be used to provide comfort and possibly prevent further herniation. The patient should be referred to the WOC nurse for a plan of care. Surgery may be required if the patient has increased pain at the site, has increased herniation, or develops signs of stoma obstruction.

**Fistula** is the formation of an opening between two internal organs or from inside the body to the skin. Enterocutaneous fistulas can occur in patients with or without an ostomy. This complication is most often a manifestation of Crohn's disease. Other causes include cancer, abscess formation, foreign body retention,

radiation, tuberculosis, and trauma. If a fistula has excessive drainage, an ostomy pouching system may be applied to contain the drainage and prevent the skin from becoming denuded.

**Prolapse** is a telescoping of the bowel through the stoma. This problem results when the opening in the abdominal wall is too large. Women with ileostomies may experience prolapse of the ileostomy during pregnancy. Other causes include inadequate fixation of the bowel to the abdominal wall; poorly developed fascial support; or increased abdominal pressure associated with tumors, coughing, or crying (the latter being of special concern in infants). The danger of prolapse is the resulting decrease in blood supply to the bowel outside the abdominal cavity.

A prolapse may be reduced by having the patient lie on his or her back and apply continuous pressure on the most distal part of the stoma. Once the prolapse is reduced, a rigid pouching system should be avoided because of the risk of strangulation of the stoma. The patient should apply a flexible pouch with a resized opening while lying on his or her back. A support belt may also be used. Surgical correction may be required if the stoma becomes purple or ecchymotic or continues to prolapse.

**Retraction**, a recession of the stoma to a subnormal length at or below skin level, is caused by several factors. Active Crohn's disease and weight gain may lead to this damage of the skin surface. If the retraction is not severe, use of a convex pouching system and an elastic belt may be adequate. In other cases, surgical correction may be required.

**Organic impotence** is caused by a radical resection of the rectum or bladder, which results in disruption of nerves and vascular supply. Male patients who are impotent should be referred to a urologist for evaluation and treatment.

#### Medication Absorption Challenges for Ostomies

An understanding of the absorption characteristics of medications is important to optimize their effectiveness in patients with ostomies. The upper portion of the small intestine is the major absorptive site for many medications. However, certain preparations rely on an intact colon for drug absorption.<sup>18,19</sup> Both prescription and nonprescription medications should be reviewed to assess the best formulation for the patient. Potential drug interactions and side effects should be addressed in the drug therapy plan. [Table 21-8](#) lists some general drug management principles for patients with colostomies, ileostomies, and urostomies.<sup>18,19</sup>

#### Drug Absorption

Patients with ostomies should be instructed to check the pouch for undissolved tablets or tablet fragments whenever they take solid oral medications. If the absorptive areas of the intestine have been altered, coated or sustained-release preparations may pass through the intestinal tract without being absorbed, potentiating drug failure. In addition, some medications are contained within a wax matrix (e.g., Slow K) from which the active drug leaches as the tablet moves through the GI tract. [Table 21-9](#) lists a broad selection of medications and their potential to cause adverse effects, which vary with different dosage forms.<sup>21-33</sup>

#### Antibiotics

In general, antibiotics may alter the normal flora of the intestinal tract, causing diarrhea or fungal infection of the skin surrounding the stoma.

**TABLE 21-8 General Drug Management Principles**

<i>Type of Ostomy</i>	<i>General Management</i>
Ileostomy, colostomy	Avoid medications that are sustained release, extended release, or enteric coated or that contain a wax matrix. Liquid, crushed, and chewable preparations are preferred.
Ileostomy, colostomy	Do not crush medications before first consulting an appropriate health care provider.
Ileostomy, colostomy	Check pouch for undissolved tablets.
Ileostomy, colostomy, urostomy	Review medication plans for potential drug interactions and/or adverse effects.
Ileostomy, colostomy, urostomy	Alert patients to medication-induced color changes to urine and/or stool.

Source: References 18 and 19.

#### Sulfa Drugs

Sulfa drugs should be used with caution, given that crystallization in the kidney may occur more often in patients who have difficulty with fluid balance. To minimize this problem, patients should increase fluid intake.

#### Diuretics

Diuretics can increase the amount of fluids and electrolytes lost through urostomies and can add to the losses already inherent in patients with ileostomies. Diuretics should be used with caution. Frequent monitoring of fluid balance and serum electrolytes is required.

#### Laxatives

Because of the risk of electrolyte imbalance and dehydration, ileostomy patients should never use laxatives unless they have been prescribed. Patients with colostomies may use laxatives, but only under close supervision. If the patient is constipated, a prescriber may recommend a stool softener.

#### Antacids

Products that contain calcium may cause stone formation in patients with a urostomy. Magnesium-based products can cause diarrhea in patients with ileostomies. If patients have problems with constipation, they should avoid aluminum-based antacids, which can also cause constipation.

#### Urine and Stool Discoloration

Patients with ostomies have to adapt to many challenges in their life. Encouraging them to become involved in their health care and health care plans helps to alleviate much of the fear and anxiety often expressed by these patients. Some medications can cause color changes in the urine and/or feces. These events can be unsettling to an uninformed patient and cause unnecessary anxiety. [Table 21-10](#)<sup>34-37</sup> lists common medications that cause color changes. The health care provider should discuss these possible events with their patients.

**TABLE 21-9 Potential Effects of Selected Prescription Drugs in Patients with Ostomies**

<i>Class</i>	<i>Type of Ostomy</i>	<i>Potential Effects</i>
Histamine <sub>1</sub> -receptor antagonists	Ileostomy, colostomy, urostomy	No problems have been reported with cetirizine, loratadine, or fexofenadine.
Anti-inflammatories	Ileostomy	NSAIDs are associated with GI irritation and bleeding. Use with caution if history of GI ulceration or bleeding exists (COX-2 inhibitors may have lower risk profile). No problems have been reported with Celecoxib.
Opiates	Colostomy	Tramadol's opiate agonist activity can cause constipation, similar to opiates such as oxycodone. Liquids, IR products, or patches are preferred to avoid erratic absorption associated with ER products.
Selective serotonin reuptake inhibitors	Ileostomy	No problems have been reported with sertraline, citalopram, or fluoxetine. Hyponatremia and diarrhea have been reported with paroxetine, requiring close monitoring of fluid and electrolyte status.

Antipsychotics	Colostomy, ileal conduit	Constipation has been reported with olanzapine and clozapine and can occur with all anticholinergic drugs. Reported delayed lithium toxicity requires close monitoring of serum levels in patients with ileal conduits.
Antidiabetics	Ileostomy	Possible dose-related GI effects are related to variable absorption of metformin, a weak base primarily absorbed in the small intestine. Some patients have experienced increased stoma output, requiring a change in their antidiabetic regimen. No problems have been reported with other antidiabetic agents.
Anticonvulsants	Ileostomy	Erratic absorption has been reported with enteric-coated and SR products. Use of liquids or IR products is generally recommended.
Antilipidemics	Ileostomy, colostomy, urostomy	No problems have been reported with use of HMG-CoA reductase inhibitors.
Cardiac/antihypertensive drugs	Ileostomy	Fluid and electrolyte abnormalities are common with diuretics. Careful monitoring is recommended during use of ACE inhibitors. Hyperkalemia may be a particular problem.
GI medications	Ileostomy, colostomy	Diarrhea is associated with all PPIs, requiring careful monitoring of fluid and electrolyte status. No problems have been reported with H <sub>2</sub> RAs. Avoid laxatives in patients with ileostomies owing to risk of severe fluid and electrolyte disturbances.
Antimicrobial agents	Ileostomy, urostomy, colostomy	Altered normal bowel flora and diarrhea related to broad-spectrum antibiotics can be a significant problem for patients with ileostomies. High doses of ciprofloxacin are associated with alkaline urine; if used, urinary acidification to avoid bacterial overgrowth in urostomy patients requires close monitoring.
Other drugs	End jejunostomy, ileostomy	Some reports of drug failure are associated with malabsorption of warfarin in patients with short-bowel syndrome. Length of the functionally intact proximal small bowel is important in cyclosporine dosing; if liquid formulation or IV is required, more frequent monitoring is recommended. Variable volume of distribution and increased clearance of gentamicin have been reported in patients with ileostomies, possibly requiring more frequent monitoring. Highly variable bioavailability of digoxin (depends on length of remaining bowel) requires monitoring for drug failure.

Key: ACE inhibitors = Angiotensin-converting enzyme inhibitors; COX-2 = cyclooxygenase-2; ER = extended release; GI = gastrointestinal; HMG-CoA = hydroxymethyl glutaryl coenzyme A; H<sub>2</sub>RAs = histamine type 2 receptor antagonists; IR = immediate release; IV = intravenous; NSAID = nonsteroidal anti-inflammatory drug; PPI = proton pump inhibitor; SR = sustained release.

Source: References 20-33.

### Dietary Supplements

Herbal products are not regulated by the Food and Drug Administration (FDA) because they are considered dietary supplements. Moreover, not all ingredients contained in a product are listed on the label. Herbal supplements can interact with medications and cause a variety of adverse effects. Patients with ostomies who desire to use herbal agents should do so only under medical supervision.

#### Assessment of Patients with Ostomies: A Case-Based Approach

In most cases, ostomy surgery necessitates the use of a pouching system designed to collect the waste material normally eliminated through the bowel or bladder. Because each ostomy patient is different, one patient may benefit from a particular type of pouch or accessory, whereas another may develop problems with the same products. Moreover, a patient's needs may change over time. A pouching system or accessory that previously produced ideal outcomes may no longer be appropriate because of changes in body contour caused by aging, pregnancy, weight change, or concurrent medical conditions. As the rate of obesity continues to rise, so do the challenges for health care providers caring for the special needs of that ostomy population.

Patients who must have an ostomy often are apprehensive about how the surgery will proceed, how to manage the ostomy, and how they will be perceived by others. An ostomy patient's self-esteem may also be affected. Therefore, a special effort should be made to ensure the patient's privacy and to gain the patient's confidence during the assessment. Cases 21-1 and 21-2 illustrate assessment of patients with ostomies.

#### Case 21-1

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient's symptoms began during the summer when she was at the beach and perspired a lot.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	She has experienced itching and rash underneath her urostomy for the past week, and now the skin is becoming denuded and weepy. Her pouch has started to leak more often. She usually wears this pouching system for 1 week, but now she can keep it on for only 24 hours.
c. description of the patient's efforts to relieve the symptoms	The patient applied pectin-based powder before appliance changes, but her symptoms have not resolved.
d. patient's identity	Dora Smith
e. age, sex, height, and weight	60 years old, female, 5 ft 6 in., 150 lb
f. patient's occupation	Retired
g. patient's dietary habits	MNT diet for diabetes
h. patient's sleep habits	NA

i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Glucophage 500 mg twice daily, Flovent 220 mg 2 puffs twice daily, albuterol 2 puffs every 6 hours as needed; underwent ileal loop for bladder cancer 2 years earlier
j. allergies	Aspirin
k. history of other adverse reactions to medications	None
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Since the summer, Dora has developed a rash and itching. The rash appears to be caused by infection of denuded skin around the stoma caused by Dora's leaking pouching system and perspiration. Dora's diabetes is another related factor.
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Dora to a WOC nurse. (2) Recommend application of 2% miconazole powder to affected area with each pouch change. (3) If 2% miconazole is not effective, have Dora see her primary care provider for a prescription for nystatin powder to apply to the affected area with each pouch change. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	OTC treatment with a powder containing 2% miconazole is appropriate for Dora. She should also change her pouching system more frequently.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You can use an OTC powder containing 2% miconazole to treat the rash and itching. You should change your pouching system more often and apply the powder at each change to prevent these symptoms from occurring again."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Seeing a wound, ostomy, and continence nurse or your primary care provider is very important to treat this situation."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	"Wash peristomal skin per your usual routine. Apply 2% miconazole powder sparingly, and massage it into the peristomal skin. Dust off excess powder. A sealant (3M No Sting Skin Prep, etc.) may be applied to enhance the pouch seal. Apply the pouch. Use the miconazole powder with each pouch change until 1 week after the rash has resolved. You should change the appliance every other day until the rash clears; then you can return to once-a-week appliance changes. If rash and itching continue, consult a WOC nurse or your primary care provider."
Solicit follow-up questions from the patient or caregiver.	"How long should I continue using the 2% miconazole or the nystatin powder?"
Answer the patient's or caregiver's questions.	"Use for 1 week after rash has resolved. You may use it as needed if the rash develops again."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Ask the patient to call and update you within a week. If the itching has not improved, have the patient schedule an appointment with the WOC nurse.

Key: MNT = Medical nutrition therapy; NA = not applicable; OTC = over-the-counter; WOC = wound, ostomy, and continence.

### Patient Counseling for Ostomy Care

The pharmaceutical care needs of a patient with an ostomy include procurement and distribution of ostomy supplies and selection of appropriate products. Monitoring a patient's management of the ostomy and counseling the patient on special needs (e.g., skin care, diet, fluid intake, and drug therapy) are other important components of ostomy care for these patients.

Counseling of an ostomy patient should be done in a sensitive and caring manner. An ostomy patient's self-esteem is often damaged; therefore, when assisting a patient with ostomy needs, special care must be taken to avoid verbal or facial expressions that might convey negative feelings regarding the procedure. Peer support can be especially helpful to such patients. Patients should be provided a list of local and national ostomy associations and a list of product manufacturers

who can supply information about product use (Table 21-1). Patients can also receive assistance by contacting a WOC nurse in their area ([www.wocn.org](http://www.wocn.org)). The following self-help books should also be recommended to patients with ostomies:

- Barrie B. *Second Act*. New York, NY: Scribner; 1997.
- Benirschke R. *Alive & Kicking*. San Diego, CA: Rolf Benirschke Enterprises; 1999.
- Benirschke R. *Embracing Life*. San Diego, CA: Rolf Benirschke Enterprises; 2009.
- Benirschke R. *Great Comebacks*. San Diego, CA: Rolf Benirschke Enterprises; 2002.
- Elsagher B. *I'd Like to Buy a Bowel Please! Ostomy A to Z*. Andover, MN: Expert Publishing; 2006.
- Elsagher B. *If the Battle Is Over Why Am I Still in Uniform? Humor as a Survival Tactic to Combat Cancer*. Andover, MN: Expert Publishing; 2005.
- Kupfer B, Foley-Bolch K, Kasouf MF, et al. *Yes We Can*. Worcester, MA: Chandler House Press; 2000.
- Ruggieri P. *Colon & Rectal Cancer. A Patient's Guide to Treatment*. Omaha, NE: Addicus Books; 2001.

A patient with an ostomy has to adapt to many challenges in his or her life. Encouraging the patient to become involved in his or her health care and health care plans helps to alleviate much of the fear and anxiety often expressed by ostomy patients. The patient should be encouraged to express problems and concerns so that his or her ability to achieve self-treatment objectives can be better assessed. Health care providers or managers should also consider patients' special needs for conditions unrelated to the ostomy. The box Patient Education for Ostomy Care lists specific information health care providers should give patients with an ostomy.

#### Case 21-2

Relevant Evaluation Criteria	Scenario/Model Outcome
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient has developed leakage from his ileostomy pouching system in the past few weeks. He also noticed redness and denuded skin around his ileostomy. Pain at the site is also frustrating the patient.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Since his surgery 1 year ago, the patient has gained 30 pounds. He usually changes his pouch twice a week, but now he has to change it every day and continues to have leakage and redness.
c. description of the patient's efforts to relieve the symptoms	Patient applied skin barrier powder and skin sealant to protect skin, but he continues to have skin irritation and leakage.
d. patient's identity	Kevin Lerner
e. age, sex, height, and weight	31 years old, male, 5 ft 11 in., 175 lb
f. patient's occupation	Graphic designer
g. patient's dietary habits	High-fiber diet with junk food
h. patient's sleep habits	NA
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Nasonex 2 spray in each nostril once daily or 1 spray in each nostril once daily; Imodium A-D 2 mg taken 30 minutes before each meal or every 6 hours while the stool is liquid or volume is high. Kevin developed ulcerative colitis 7 years ago. After a major bleeding episode and failure of medical management, he underwent total colectomy and ileostomy.
j. allergies	Latex
k. history of other adverse reactions to medications	None
l. other (describe) _____	Patient has been nervous about family issues and has been constantly eating, which has increased his weight.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Leakage, burning sensation, and denuded skin around his ileostomy are caused by abdominal creases from increased weight.
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or	Options include: (1) Refer Kevin to a WOC nurse for further assessment and treatment. (2) Recommend use of a skin barrier powder to improve peristomal skin, followed by application of a skin sealant.

caregiver.	(3) Recommend use of a convex pouch and belt for support. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Assessment of the stoma and skin indicates that a convex pouch with a belt for support is needed. Upon further discussion, Kevin says he prefers a one-piece convex pouch with belt versus a two-piece pouch.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Because your stoma has retracted to skin level, you will need a convex pouch with a belt for support. Treat skin around the stoma with a skin barrier powder, such as Stomahesive powder, and a skin sealant, such as 3M No Sting Skin Prep, before applying the pouch. Change the pouching system every 2 days until the peristomal skin is free of burning and is no longer denuded; then resume pouch changes twice a week." "Losing some weight will also decrease the retraction of the stoma."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Pouch leakage, denuded skin, and pain will decrease with proper follow-up with a WOC nurse to modify your pouching technique. Refer to the local chapter of the United Ostomy Associations of America for peer support to improve your self-esteem and body image." (See <a href="#">Table 21-1</a> .)
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	See <a href="#">Figure 21-2</a> for proper assessment of convexity, and <a href="#">Figure 21-3</a> and <a href="#">Table 21-2</a> for proper pouching and skin accessories.
b. maximum number of days the therapy should be employed	"Change pouch twice a week."
c. product administration procedures	"Wash peristomal skin as usual. Apply thin layer of powder. Massage powder into skin well and dust off excess powder. Apply skin sealant before applying the pouch."
d. expected time to onset of relief	"With proper convexity and powder application, leakage and excoriation should decrease within 24 hours. You will notice a decrease in the burning sensation."
e. degree of relief that can be reasonably expected	"You should notice a decreased intensity of symptoms within 24-48 hours."
f. most common side effects	"Some ostomates have had an allergic reaction to the powder or pouch adhesive."
g. side effects that warrant medical intervention should they occur	"Consult a WOC nurse if burning, stinging, or local irritation occurs."
h. patient options in the event that condition worsens or persists	"Consult a WOC nurse or your primary care provider if leakage or burning continues after 1 week of treatment."
i. product storage requirements	"Store pouch away from heat."
j. specific nondrug measures	"Change pouch every 2 days until peristomal skin is clear."
Solicit follow-up questions from the patient or caregiver.	"What happens if I can't lose weight, I develop more creases, and my stoma retracts more?"
Answer the patient's or caregiver's questions.	"Consult a WOC nurse; you may need another type of pouching system. In addition, obesity is now epidemic; consult a nutritionist for a proper diet program."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Ask the patient to call you at the next pouch change to ensure that no further leakage has occurred and that the skin has improved. If the leakage continues, have the patient call the WOC nurse.

Key: NA = Not applicable; WOC = wound, ostomy, and continence.

#### Key Points for Ostomy Care

- Patients with ostomies may experience both psychological and physical complications after ostomy surgery. Their issues should be addressed, and they

should be referred to their primary care provider, WOC nurse, and/or United Ostomy Associations of America.

- The objectives of self-care of an ostomy are to understand how the stoma functions, to effectively manage it, to understand the proper use of the pouching system and accessories, to avoid complications that result from improper use, and to reduce the risks of other complications.
- Patients should be advised about the effects of food on stomal output and the need to monitor for signs and symptoms of dehydration.
- The selection of an appropriate pouching system depends on the patient's body contour, manual dexterity, and type of ostomy.
- The ideal ostomy pouching system should be leak-proof, odor-proof, comfortable, and easy to use. Providers can assist the patient in achieving these outcomes.
- Patients should be counseled on the effects of medications:
  - Use of liquid, crushed, or chewable medications is preferable.
  - Coated or sustained-release medications should be used with caution because if the GI tract has been shortened, full absorption may not occur. Most tablets should not be crushed or chewed.
  - Caution is warranted with use of antibiotics and diuretics. Antibiotics can cause diarrhea or fungal infections of the skin around the stoma. Diuretics can cause dehydration or electrolyte imbalance in patients with ileostomies.
  - Laxatives, antidiarrheals, or other medications that alter GI motility should be used with caution. Laxatives can increase fecal output in patients with ileostomies, whereas antidiarrheals decrease the fecal output.

#### Patient Education for Ostomy Care

The objectives of self-care of ostomies are to (1) understand how the stoma functions and how to manage it; (2) understand the proper use of the pouching system and accessories, and avoid complications that result from improper use; and (3) reduce the risk of other types of complications. For most patients, carefully following the product instructions and the self-care measures listed here will help to ensure optimal therapeutic outcomes.

#### Pouching System Selection and Use

- Use only the type of pouching system recommended for your type of ostomy.
- If your system no longer fits well, consult your WOC nurse or primary care provider before changing to a different type of pouching system.
- Do not consider skin irritation to be inevitable; identify the cause and correct and treat the irritation as soon as it occurs.
- If possible, identify the cause for leakage around the pouching system and correct the problem immediately. Consult your WOC nurse or primary care provider if you cannot determine the cause.
- Establish a routine for ostomy care. Keep the routine simple; use as few accessories as possible.

#### Effects of Medication Use

- Sustained- or extended-release medicines may undergo erratic absorption, which makes their effect unpredictable. These medications should be used with caution. Coated medications, as well as sustained- or extended-release medications, should not be crushed or chewed.
- Use caution when taking antibiotics and diuretics. Antibiotics can cause diarrhea or fungal infections of the skin around the stoma. Diuretics can cause dehydration or electrolyte imbalance in individuals with ileostomies.
- Use caution when taking laxatives, antidiarrheals, or other medications that alter gastrointestinal motility. Laxatives can increase fecal output in individuals with ileostomies, whereas antidiarrheals decrease the fecal output.
- Know which medications will discolor the urine or feces ([Table 21-10](#)).

#### When to Seek Medical Attention

- Consult your WOC nurse or primary care provider about using nonprescription medications to treat diarrhea or constipation. Return for reevaluation of the problem after 1 week of treatment.
- See your WOC nurse if you experience any of the following complications:
  - Depression and anxiety
  - Sexual dysfunction
  - Abdominal pain
  - Narrowing of the stoma
  - A bulge near the stoma
  - An extension of the bowel through the stoma
  - Recession of the stoma to a subnormal length
  - Bleeding from or around the stoma
  - Pain when touching the skin around the stoma or when applying the appliance
  - Overgrowth of the skin around the stoma

Handbook of Nonprescription Drugs > Chapter 22. Essential and Conditionally Essential Nutrients

### Essential and Conditionally Essential Nutrients: Introduction

Vitamin and mineral supplements represent one of the largest and most widely used over-the-counter product categories in the United States today. Vitamin- and mineral-containing supplements in combination with multivitamin and multimineral products accounted for 42% of all dietary supplement sales in the United States in 2011, with annual sales of \$12.4 billion.<sup>1</sup> Thirty-three percent of the U.S. population uses a multivitamin-multimineral supplement on a routine basis, with use increasing over the past 25 years.<sup>2,3</sup> Although nutrition experts agree that foods are the preferred source of vitamins and minerals and that most individuals can easily meet their daily requirements by eating a balanced diet, experts agree less about the extent to which the U.S. population consumes such a diet. The lack of overt symptoms of nutritional deficiency in this country supports the position that most Americans receive adequate intake of vitamins and minerals from dietary sources; however, concern is growing that subclinical deficiencies may be contributing to chronic diseases. This concern emphasizes the importance of encouraging the selection of nutrient-dense foods throughout the life cycle. Health-conscious consumers often seek nutritional supplements as a means of prevention and self-treatment for a myriad of actual or perceived health ailments. Marketing claims and natural product enthusiasts encourage these self-care behaviors by promoting use of nutrient supplementation, often in doses well above established tolerable upper limits.<sup>4</sup> However, the issue of who will benefit from or be harmed by the use of nutritional supplements is unresolved. Regular use of supplements can help some people meet their recommended dietary requirements; however, a potential risk exists that some users will exceed the tolerable upper intake levels of some nutrients.<sup>4</sup> Currently, little to no available evidence supports the use of supplements for cancer prevention. In fact, evidence suggests the potential for increased cancer risk with certain nutrients at higher doses when used for prolonged periods of time.<sup>5</sup> The United States Preventive Services Task Force (USPSTF) evaluated randomized trials of vitamin supplementation with beta-carotene, vitamins A, C, and E, folic acid, or antioxidants in the prevention of cancer or cardiovascular disease.<sup>6</sup> The evidence was conflicting and insufficient to support regular supplementation for this purpose, and potential harm was associated with beta-carotene supplementation in certain populations. Current American Cancer Society Guidelines indicate that dietary supplementation is not associated with a reduction in cancer risk and instead recommend eating whole foods as part of an overall healthy diet.<sup>7</sup> Results from the Women's Health Initiative support the USPSTF and American Cancer Society's positions, having found no benefit of multivitamin supplementation for either postmenopausal women in terms of reduction of cardiovascular disease or cancer risk or overall mortality.<sup>8</sup> Further, the National Institutes of Health-sponsored State-of-the-Science Conference concluded that insufficient evidence exists to support routine use of multivitamin and multimineral supplements for primary prevention of chronic diseases.<sup>9</sup> Beyond their risk of toxicity, one of the greatest dangers of food fads, use of multiple supplements, and large doses of single vitamins is that some people use them in place of sound medical care. The lure of marketing or the desire to self-treat may attract desperate or uninformed patients who have serious illnesses, thereby placing them at greater risk because they delay seeking appropriate medical attention. Furthermore, drug-nutrient interactions can be significant, yet they are often overlooked as part of the patient's medical history. For these reasons, practitioners should be well aware of the potential use—as well as the benefits and risks—of various nutrient supplements.

*Editor's Note:* This chapter is based on the 17th edition chapter of the same title, written by Yvonne Huckleberry and Carol J. Rollins.

### Epidemiology/Etiology of Nutritional Deficiencies

Although overt nutrient deficiency is rare in the United States, the prevalence of subclinical nutrient deficiencies is unknown. Specific patient populations may be at higher risk of deficient nutrient intakes because of pathophysiologic, physiologic, behavioral, or economic situations (Table 22-1).<sup>10</sup> Because foods contain numerous other compounds that are important for health maintenance and disease prevention, health care professionals play an important role in educating patients on nutrient-dense food choices before vitamin and/or mineral supplementation is recommended.

### Pathophysiology of Nutritional Deficiencies

A comprehensive discussion of the pathophysiology of vitamin and mineral deficiencies is outside the scope of this chapter. The reader is referred to standard medical and nutrition textbooks for such information.

**TABLE 22-1 Factors Contributing to Nutritional Deficiency**

• Inadequate dietary intake resulting from substance abuse, poverty, eating disorders, dementia, or restrictive diets
• Poor dentition, swallowing difficulty, or xerostomia
• Loss of taste, smell, or sight perception
• Decreased absorption resulting from cystic fibrosis, short bowel syndrome, Roux-en-Y gastric bypass, gastric hypochlorhydria, or chronic diarrhea
• Inability to buy or prepare meals because of tremor, fatigue, or arthritic pain
• Anorexia caused by reduced physical activity, social isolation, pain, disease, or depression
• Lack of knowledge about balanced nutrition
• Increased metabolic requirements resulting from severe injury, infection, trauma, pregnancy, or prolonged physical exercise
• Medications affecting judgment, coordination, memory, appetite, nutrient absorption, gastric pH, or gastrointestinal tract function

### Clinical Presentation of Nutritional Deficiencies

A vitamin deficiency may evolve in several stages, and clinical signs may not be present until prolonged and significant deficiency occurs (Table 22-2).<sup>10</sup> Attributing clinical symptoms to a single nutrient deficiency is difficult, as symptoms may overlap and reflect multiple rather than individual nutrient deficiencies. Signs and symptoms of specific vitamin and mineral deficiencies are discussed in the individual micronutrient sections later in the chapter.

Globally speaking, poor nutrition increases the risks of chronic disease, infection, and complications associated with reproduction, acute illness, surgery, and chemotherapy. For the pediatric population, growth, development, and learning may be compromised. For adults, poor nutrition over a lifetime can exacerbate the aging process, causing earlier morbidity and mortality. Balanced nutrition (with varied food choices providing adequate protein, appropriate calories, vitamins, and minerals) is essential for health through all stages of the life cycle.

### Nutrient Supplementation

Vitamin and mineral supplements should be used as *adjuncts* to a balanced diet and not as substitutes for nutritious food. Although nutritional supplements can be obtained without a prescription and are typically self-prescribed, they are complex agents with specific indications. Medical assessment should precede their use, especially if daily intakes exceed the dietary reference intakes (DRIs) for a specific nutrient. Furthermore, patients should be reminded that vitamins and minerals are often better absorbed from food sources than from supplements. Practitioners may refer patients to a registered dietitian for personalized counseling on diet modification as well as nutritional supplementation.

**TABLE 22-2 Stages in Evolution of Vitamin Deficiency**

1. Inadequate nutrient delivery, synthesis, or absorption
2. Depletion of nutrient stores
3. Biochemical changes

4. Physical manifestations of deficiency
5. Morbidity and mortality

#### Intent of Use

Nutritional supplement use is intended to prevent nutritional deficiencies, replenish compromised nutrient stores, or maintain the present nutritional status. Nonprescription nutritional supplements are not intended for the self-treatment of vitamin deficiencies.

#### General Approach to Use

If a patient's diet is not providing the daily required amount of micronutrients necessary for normal growth and function, supplementation with vitamins and minerals may be appropriate, provided the patient has no underlying pathology or contraindication to use. A once-daily multivitamin with minerals providing no more than 100% of the DRIs should suffice in most cases. Patients should be reminded that healthy individuals derive no established benefit from supplementing nutrients in doses above the DRI; also, tolerable upper limits for daily use should not be exceeded without medical supervision.

Practitioners should counsel patients regarding the potential disparity between a product's actual contents and its label. The potential for labeling inaccuracy exists because, despite U.S. regulations requiring that the actual content of a vitamin or mineral supplement be greater than or equal to the product's labeling (to account for shelf-life losses and differences between manufacturer product batches), dietary supplements are not assessed for compliance or standardization by any government agency.<sup>11</sup> Unlike prescription drugs, dietary supplements do not require proof of safety or efficacy before being marketed, and inspection for production under good manufacturing practices has not been required since passage of the Dietary Supplement Health and Education Act (DSHEA) in 1994. However, the United States Pharmacopeia (USP) provides a Dietary Supplement Verification Program that allows product labeling with the USP mark if the tested product meets specific requirements, including verification of the product's ingredients and amounts; effective disintegration and dissolution for absorption; absence of harmful contaminants; and safe, sanitary, well-controlled manufacturing.<sup>12</sup> Practitioners should advise patients to look for the USP mark on vitamin and mineral supplement labels.

Some patients require supplemental macronutrients (e.g., fat, protein, and carbohydrates) in addition to micronutrients because they are unable to consume all required daily nutrients. Liquid nutritional supplements for that purpose (e.g., Ensure and Boost) are discussed in [Chapter 23](#).

#### Nonpharmacologic Therapy

The best method for avoiding nutritional deficiencies is to consume a balanced diet each day that includes foods from sources high in several essential nutrients. To guide consumers in selecting a balanced diet while allowing for individual preferences, the U.S. Department of Health and Human Services released the reference Dietary Guidelines for Americans, 2010.<sup>13</sup> In these guidelines, consumers are advised to regularly choose a variety of nutrient-dense foods in moderate portion sizes, as exemplified in the *MyPlate* figure ([Figure 22-1](#)). Each food group represented on *MyPlate* provides a significant source of essential nutrients. For example, the dairy group is a major source of calcium, whereas the fruit and vegetable groups are sources of fiber and the primary sources of antioxidant vitamins. By selecting a variety of foods within the various groups and eating the appropriate number of servings from each food group daily, consumers can "balance" their diet relative to essential and conditionally essential nutrients. *MyPlate* is an evidence-based tool that is both user friendly and comprehensive for assessing the need for nutrient supplementation. When performing a nutritional assessment and determining the need for multivitamin supplementation, practitioners should inquire about the patient's intake from these food groups.<sup>13</sup>

*MyPlate*. (Source: Image from [www.choosemyplate.gov](http://www.choosemyplate.gov).)

#### Pharmacologic Therapy

Although situations exist in which high doses of specific vitamins and minerals are reported to be of therapeutic benefit, megavitamin enthusiasts' claims have not been confirmed objectively. To the contrary, as noted earlier, some clinical trials have suggested potential harm from supplementation originally claimed to be beneficial. These are described within the individual micronutrient sections.

Vitamins and minerals that have therapeutic value in the treatment of medical conditions (e.g., niacin therapy for hyperlipidemia) are being used as drugs rather than as supplements for disease prevention or health maintenance. Deficiency states should be treated under medical supervision. Furthermore, prolonged ingestion of megadoses of vitamin and mineral supplements has not been evaluated in large-scale clinical trials for safety and efficacy in many cases. Some vitamins (e.g., A, D, niacin, and pyridoxine) and minerals (e.g., iron and fluoride) are known to be toxic in high doses. Therefore, patients should be cautioned against initiating high-dose self-medication with vitamins and minerals. Practitioners should discourage chronic, high-dose ingestion of any nutrient without proper medical supervision.

#### Vitamins

Vitamins are nutrients that cannot be synthesized in the body in sufficient quantities and must be obtained through the diet. Conditionally essential vitamins have adequate endogenous production in most circumstances, but there are conditions (e.g., cardiovascular disease) in which dietary intake is essential to meet requirements. Vitamins are

used as both dietary supplements and therapeutic agents to treat deficiencies or other pathologic conditions. DRIs have replaced the traditional recommended dietary allowances (RDAs) as reference values of daily nutrient intake recommended by the Food and Nutrition Board of the Institute of Medicine of the National Academies (Tables 22-3 and 22-4).<sup>14,15</sup> The DRIs include four reference categories: estimated average requirements (EARs), RDAs, adequate intakes (AIs), and tolerable upper intake levels (ULs). EARs are values obtained after a careful review of the literature on specific nutrients. The EARs provide nutrient intake values that are estimated to meet the requirements of half of the healthy individuals in a specific gender and age group. The RDA is defined as the amount of a nutrient needed per day for maintenance of good health. This value is set at 2 standard deviations above the EAR as an estimate of daily nutrient intake sufficient to meet the requirements of nearly all (97%-98%) healthy individuals of a specified age group and gender. AIs are used as recommended intakes for nutrients for which inadequate scientific data exist to establish an EAR with confidence. Finally, the ULs are the highest dose of nutrient intake that may be consumed daily without risk of adverse effects in the general population. ULs are based on current literature, but they are not available for all nutrients (Table 22-5).<sup>14,15</sup> DRIs should be used as guidelines for nutritional assessment in healthy individuals; adjustment according to strenuous physical activity or the presence of disease may be necessary. As nutritional supplements, vitamins are usually dosed at 50%-150% of the DRI values. Practitioners should advise caution with high-dose supplements that provide greater than 200% of the DRI. As therapeutic agents, vitamins should be recommended only for specific evidence-based medical indications.

The Food and Drug Administration (FDA) has published a less comprehensive set of values to be used for food and dietary supplement labeling.<sup>16</sup> Nutrients are listed as a percentage of daily value (%DV). These values are based on the recommended intakes for a 2000-calorie diet for adults older than 18 years. The vitamin or mineral supplement label includes a box with the heading Supplement Facts. In addition to information on serving size and servings per container, the label lists all required nutrients that are present in the dietary supplement in significant amounts and the %DV, if a reference has been established. It also lists all other dietary ingredients that are present in the product (including botanicals and amino acids) for which no %DV has been established. The %DV is based on DRI values for adults and for children ages 4 years and older, unless the product is designed for children younger than 4 years or for women who are pregnant or lactating.

**TABLE 22-3 Dietary Reference Intakes (DRIs): Recommended Dietary Allowances and Adequate Intakes, Vitamins Food and Nutrition Board, Institute of Medicine, National Academies**

Note: This table (taken from the DRI reports; see [www.nap.edu](http://www.nap.edu)) presents recommended dietary allowances (RDAs) in **bold type** and adequate intakes (AIs) in regular type

followed by a *single* asterisk (\*). Both RDAs and AIs may be used as goals for individual intake. RDAs are set to meet the needs of almost all (97%-98%) individuals in a group. For healthy breast-fed infants, AI is the mean intake. AI for other life stage and gender groups is believed to cover the needs of all individuals in the group, but lack of data or uncertainty in the data prevents being able to specify with confidence the percentage of individuals covered by this intake.

<sup>a</sup> As retinol activity equivalents (RAEs). 1 RAE = retinol 1 mcg, beta-carotene 12 mcg, alpha-carotene 24 mcg, or beta-cryptoxanthin 24 mcg. To calculate RAEs from retinol equivalents (REs) of provitamin A carotenoids in foods, divide REs by 2. For preformed vitamin A in foods or supplements and for provitamin A carotenoids in supplements, 1 RE = 1 RAE.

<sup>b</sup> Cholecalciferol 1 mcg = vitamin D 40 IU.

<sup>c</sup> In the absence of adequate exposure to sunlight.

<sup>d</sup> As alpha-tocopherol. Alpha-tocopherol includes *RRR*-alpha-tocopherol, the only form of alpha-tocopherol that occurs naturally in foods, and the *2R*-stereoisomeric forms of alpha-tocopherol (*RRR*-, *RSR*-, *RRS*-, and *RSS*-alpha-tocopherol) that occur in fortified foods and supplements. It does not include the *2S*-stereoisomeric forms of alpha-tocopherol (*SRR*-, *SSR*-, *SRS*-, and *SSS*-alpha-tocopherol), also found in fortified foods and supplements.

<sup>e</sup> As niacin equivalents (NE). Niacin 1 mg = tryptophan 60 mg; 0-6 months = preformed niacin (not NE).

<sup>f</sup> As dietary folate equivalents (DFE). 1 DFE = food folate 1 mcg = folic acid 0.6 mcg from fortified food or as a supplement consumed with food = supplement 0.5 mcg taken on an empty stomach.

<sup>g</sup> Although AIs have been set for choline, insufficient data exist to assess whether a dietary supply of choline is needed at all stages of the life cycle; the choline requirement may be met by endogenous synthesis at some of these stages.

<sup>h</sup> Because 10%-30% of people of advanced age may malabsorb food-bound B<sub>12</sub>, those older than 50 years should meet their RDA mainly by consuming foods fortified with B<sub>12</sub> or a supplement containing B<sub>12</sub>.

<sup>i</sup> In view of evidence linking folate intake with neural tube defects in the fetus, all women capable of becoming pregnant should consume folate 400 mcg from supplements or fortified foods, in addition to intake of food folate from a varied diet.

<sup>j</sup> RDA assumes that women will continue consuming folic acid 400 mcg from supplements or fortified food until their pregnancy is confirmed and they enter prenatal care, which ordinarily occurs after the end of the periconceptual period, the critical time for formation of the neural tube.

*Note:* This table presents recommended dietary allowances (RDAs) in **bold type** and adequate intakes (AIs) in regular type followed by a *single* asterisk (\*). Both RDAs and AIs may be used as goals for individual intake. RDAs are set to meet the needs of almost all (97%-98%) individuals in a group. For healthy breast-fed infants, AI is the mean intake. AI for other life stage and gender groups is believed to cover the needs of all individuals in the group, but lack of data or uncertainty in the data prevents the ability to specify with confidence the percentage of individuals covered by this intake.

Frequently, "natural" vitamin products are supplemented with synthetic vitamins. For example because the amount of vitamin C that can be acquired from rose hips (the fleshy fruit of a rose) is relatively small, synthetic vitamin C is added to prevent too large a tablet size. However, this addition may not be noted on the label, and the price of the partially natural product is often considerably higher than that for the completely synthetic—but equally effective—product. Patients should be informed that the body cannot distinguish between a vitamin molecule derived from a synthetic source and one derived from a natural source, and that most synthetic vitamins are equal to the more expensive "natural" vitamins.

**TABLE 22-5 Adult Tolerable Upper Intake Levels of Selected Micronutrients**

<i>Nutrient</i>	<i>Tolerable UL (mg/day)</i>
Vitamin A	3
Vitamin D	0.1 (4000 IU/day)
Vitamin E	1000
Vitamin C	2000
Folate	1
Niacin	35
Vitamin B <sub>6</sub>	100
Choline	3500
Calcium	3000 mg/day (9-18 years of age) 2500 mg/day (19-50 years of age) 2000 mg/day (≥50 years of age)
Iron	45
Magnesium	350
Phosphorus	4000 (9-70 years of age) 3000 (≥70 years of age)
Copper	10
Fluoride	10
Iodine	1.1
Manganese	11
Molybdenum	2
Selenium	0.4
Zinc	40

Vitamins are grouped into two broad classifications: fat-soluble and water-soluble. Vitamins A, D, E, and K are fat-soluble vitamins. They are soluble in lipids and are usually absorbed into the lymphatic system of the small intestine before passing into general circulation. Their absorption is facilitated by bile. These vitamins are stored in body tissues, so ingestion of excessive quantities may be toxic. Deficiencies occur when fat intake is limited or fat absorption is compromised. Disease states that may cause malabsorption of fat-soluble vitamins include celiac disease, cystic fibrosis, obstructive jaundice, hepatic cirrhosis, and short-bowel syndrome. These deficiencies may also be precipitated by drugs that affect lipid absorption, such as cholestyramine, which binds bile acids, thereby hindering lipid emulsification; orlistat, which inhibits gastric and pancreatic lipases in the intestinal lumen; and mineral oil, which is an unabsorbed oil that increases fecal loss of fat-soluble vitamins. A daily multivitamin supplement is recommended by the manufacturer for those taking orlistat; refer to [Chapter 26](#) for a more comprehensive discussion on the use of orlistat for weight loss.

Vitamin C and the B-complex vitamins (riboflavin, thiamin, B<sub>6</sub>, B<sub>12</sub>, niacin, pantothenic acid, biotin, and folic acid) are water-soluble vitamins. These vitamins are generally not stored in the body, and excessive quantities tend to be excreted in the urine. Therefore, daily intake of these vitamins is desirable for optimal health.

#### **Vitamin A**

The designation *vitamin A* refers to a large group of compounds that includes the retinoids (e.g., retinol) and the carotenoids (e.g., alpha-carotene and beta-carotene). Biochemical changes occur in some of these compounds during absorption in the intestine to form active vitamin A. Other compounds (e.g., the carotenoids, lutein, and lycopene) are not converted to active vitamin A but have other health-promoting properties. These compounds can be found in dark green vegetables and red, orange, or deep yellow vegetables and fruits.

In healthy adults, more than 90% of the body's supply of vitamin A is stored in the liver. Because of this generous reserve, the risk of deficiency during short-term periods of inadequate intake or fat malabsorption is minimal. Infants and young children, however, are more susceptible to vitamin A deficiency because they have not established the necessary reserves.

**Function.** Vitamin A is essential for normal growth and reproduction, normal skeletal and tooth development, and proper functioning of most organs of the body (notably, the specialized functions of the eye involving the conjunctiva, retina, and cornea). Vitamin A is thus indicated in preventing and treating symptoms of vitamin A deficiency, such as xerophthalmia (dry eye) and nyctalopia (night blindness). Synthesis of the glycoproteins necessary to maintain normal epithelial cell mucous secretions also requires vitamin A. This mucosal barrier is vital to the body's defense against bacterial infections in the upper respiratory system.

**Dietary Sources.** See [Table 22-6](#).<sup>13,17</sup>

**Deficiency.** Vitamin A deficiency is rare in well-nourished populations. However, approximately 500,000 children worldwide develop blindness each year because of vitamin A deficiency.<sup>18</sup> Conditions such as celiac or Crohn's disease, pancreatic disorders, cancer, tuberculosis, pneumonia, and prostate disease, as well as therapy with corticosteroids, may cause excessive excretion of vitamin A. Fat malabsorption may impair vitamin A absorption. Neomycin, cholestyramine, or orlistat may cause significant malabsorption of vitamin A as well as other fat-soluble vitamins; long-term use may precipitate fat-soluble vitamin deficiencies. In the United States, vitamin A deficiency occurs more often from diseases of fat malabsorption than from malnutrition.

One of the earliest symptoms of vitamin A deficiency is night blindness.<sup>18</sup> Other characteristic clinical findings include follicular hyperkeratosis, loss of appetite, impaired taste and smell, and impaired equilibrium. Some of these findings may be masked by concurrent deficiencies of other nutrients. The drying and hyperkeratinization of the skin caused by the disruption of vitamin A-dependent epithelial integrity predisposes patients to infections.

**Dose/DRI.** Vitamin A is indicated for use in the treatment and prevention of vitamin A deficiency.<sup>19</sup> To avoid toxicity, the patient's dietary intake of vitamin A should be estimated when determining a dose for supplementation.

The DRI values for vitamin A are measured in micrograms of retinol activity equivalents (RAEs). The Food and Nutrition Board recommends RAEs as a way to determine the amount of absorption of carotenoids, as well as their degree of conversion to vitamin A in the body. These RAEs are listed in [Table 22-7](#). RAEs replace the former designation of retinol equivalents (REs) used to calculate total vitamin A values from various dietary sources.

TABLE 22-6 Food Sources Rich in Selected Nutrients

Vitamin	Food Sources
Vitamin A	Liver, milk fat, egg yolk, yellow and dark green leafy vegetables, apricots, cantaloupe, peaches, carrots
Vitamin D	Vitamin D-supplemented milk, egg yolk, liver, salmon, tuna, sardines, milk fat
Vitamin E	Wheat germ, vegetable oils, margarine, green leafy vegetables, milk fat, egg yolks, nuts
Vitamin K	Liver, vegetable oil, spinach, kale, cabbage, cauliflower
Vitamin C	Green and red peppers, broccoli, spinach, tomatoes, potatoes, strawberries, citrus fruit, kiwi
Vitamin B <sub>12</sub>	Liver, meat, poultry, oysters, clams, dairy products
Folate	Liver, lean beef, wheat, whole-grain cereals, eggs, fish, dry beans, lentils, green leafy vegetables
Niacin	Lean meats, fish, liver, poultry, many grains, eggs, peanuts, milk, legumes
Pantothenic acid	Eggs, kidney, liver, salmon, yeast, some present in all foods
Vitamin B <sub>6</sub>	Meats, cereals, lentils, legumes, nuts, egg yolk, milk
Riboflavin	Meats, poultry, fish, dairy products, green leafy vegetables, enriched cereals and breads, eggs
Thiamin	Legumes, whole-grain and enriched cereals and breads, wheat germ, pork, beef
Biotin	Liver, egg yolk, mushrooms, peanuts, milk, most vegetables, bananas, yeast
L-Carnitine	Dairy products, meat
Choline	Egg yolk, cereal, fish, meats
Calcium	Dairy products, sardines, clams, oysters, turnip greens, mustard greens
Iron	Liver, meat, egg yolk, legumes, whole or enriched grains, dark green vegetables, shrimp
Magnesium	Whole-grain cereals, tofu, nuts, legumes, green vegetables
Phosphorus	Milk, meat, poultry, fish, seeds, nuts, egg yolk
Chromium	Liver, fish, clams, meats, whole-grain cereals, milk, corn oil
Cobalt	Organ meats, oysters, clams, poultry, milk, cream, cheese
Copper	Liver, shellfish, whole grains, cherries, legumes, poultry, oysters, chocolate
Manganese	Vegetables, fruits, nuts, legumes, whole-grain cereals
Molybdenum	Legumes, cereals, dark green leafy vegetables, organ meats, milk
Selenium	Meat, grains, onions, milk
Silicon	Cereal products, root vegetables
Vanadium	Shellfish, mushrooms, parsley, dill seed, black pepper
Zinc	Oysters, shellfish, liver, beef, lamb, pork, legumes, milk, wheat bran

The DRI values for vitamin A are listed in Table 22-3. The UL of 3 mg vitamin A daily in adults has been established on the basis of congenital birth defect risks and liver abnormalities associated with vitamin A toxicity.<sup>14</sup> Evidence suggests that high-dose vitamin A intake, even if below the established UL, may be associated with an increased risk of bone fractures.<sup>20</sup>

Clearly, if the practitioner determines that vitamin A supplementation is appropriate, a nonprescription multivitamin containing no more than the DRI value of vitamin A should be recommended. Preferably, a significant percentage of total vitamin A content should be contributed by beta-carotene because beta-carotene intake is not associated with the risk of fractures or vitamin A toxicity. Beta-carotene's improved safety profile may be related to limitations in absorption and conversion to retinol.<sup>20</sup> However, the increased cancer risk associated with beta-carotene supplementation in those who smoke should be kept in mind (see Safety Considerations, below). High-dose vitamin A or beta-carotene therapy should never be undertaken without close medical supervision.

**Safety Considerations.** Because vitamin A is stored in the body, high doses of it can lead to a toxic syndrome known as hypervitaminosis A. The incidence of hypervitaminosis A is increasing because of publicity regarding the potential therapeutic benefits of vitamin A in cancer, skin disorders, and wound healing. Long-term administration of vitamin A is unlikely to cause toxicity when administered at doses less than 10,000 IU per day of retinol or equivalents; however, the risk for toxicity may increase in individuals with chronic renal or liver disease, and in those with low body weight, protein malnutrition, alcohol consumption, or vitamin C deficiency.<sup>19</sup> Headache is a predominant symptom, but it may be accompanied by diplopia (double vision), nausea, vomiting, vertigo, fatigue, or drowsiness. Treatment consists of discontinuing vitamin A supplementation, which should result in complete recovery. Although beta-carotene toxicity is not likely, eating large amounts of carrots in the daily diet may result in carotenemia, which can produce a yellow skin hue. Pregnant women or women of childbearing age should avoid vitamin A doses above the DRI because of the teratogenic risk. For this reason, women of childbearing age should carefully evaluate the total vitamin A content of all dietary supplements and fortified foods consumed regularly. These patients should be reminded not to take other dietary supplements when a prescription prenatal vitamin is dispensed.

TABLE 22-7 Retinol Activity Equivalents

1 retinol activity equivalent	= 1 retinol equivalent
= 1 mcg retinol	
= 12 mcg beta-carotene	
= 24 mcg alpha-carotene	
= 24 mcg beta-cryptoxanthin	
= 3.33 IU vitamin A activity from retinol	
= 10 IU vitamin A activity from beta-carotene	

The potential role of vitamin A as a cancer-preventing antioxidant prompted large randomized controlled trials evaluating supplementation for patients at risk of lung cancer. In the Alpha-Tocopherol, Beta Carotene (ATBC) Cancer Prevention Study, more than 29,000 male smokers were randomized to receive 50 mg alpha-tocopherol, 20 mg beta-carotene, both supplements, or placebo. After 8 years of study, findings suggested no benefit to supplementation.<sup>21</sup> Furthermore, those who received beta-carotene supplementation appeared to be at greater risk of lung cancer.

Similar results were shown in a subsequent study, the Beta-Carotene and Retinol Efficacy Trial (CARET).<sup>22</sup> This study included more than 18,000 participants randomized to receive either 30 mg beta-carotene and 25,000 IU retinyl palmitate or placebo. Enrollees were either smokers, previous smokers, or those exposed to asbestos. After an average of 4 years of participant enrollment, the CARET trial was prematurely ended because of the association of higher rates of lung cancer, cardiovascular disease, and death in those receiving supplementation. Furthermore, these effects were observed for years after the exposure to supplementation, although the increased risks of disease were not statistically significant. Such trials confirm that vitamin supplementation cannot provide the same health benefits as a diet rich in fruits and vegetables.

**Potential Drug-Nutrient Interactions.** See [Table 22-8](#).

#### Vitamin D (Calciferol)

A number of chemical compounds are associated with vitamin D activity. Cholecalciferol (vitamin D<sub>3</sub>) is the naturally occurring form of vitamin D that is synthesized in the skin from endogenous or dietary cholesterol on exposure to ultraviolet radiation (sunlight). Ergocalciferol (vitamin D<sub>2</sub>), which is used as a food additive, differs only slightly in structure from cholecalciferol. Metabolic activation of vitamin D requires hydroxylation by both the liver and the kidneys. The metabolite, 25-hydroxycholecalciferol (calcidiol), is formed by the liver and then hydroxylated by the kidneys to its active form, 1,25-dihydroxycholecalciferol (calcitriol). Therefore, either renal or hepatic dysfunction may result in clinical manifestations of vitamin D deficiency, including hypocalcemia unresponsive to over-the-counter vitamin D supplementation. These patients require a hydroxylated vitamin D preparation available only by prescription.

**Function.** Vitamin D, which has properties of both a hormone and a vitamin, is necessary for the proper formation of bone and for mineral homeostasis. It is closely involved with the activity of parathyroid hormone, phosphate, and calcitonin in maintaining homeostasis of serum calcium levels. Adequate vitamin D intake and supplementation used in conjunction with sufficient calcium, not vitamin D alone, may reduce the risk of bone fractures and falls in postmenopausal women with osteoporosis when dosed according to clinical evidence.<sup>23,24</sup> Other nonskeletal effects (e.g., reduced overall mortality and risk of diabetes, cancer, multiple sclerosis, and risk of allergies and asthma) have been evaluated in controlled clinical trials with varying results.<sup>25</sup> Recent clinical data suggest that vitamin D deficiency may be associated with increased risk of cardiovascular diseases, including hypertension, coronary artery disease, and cardiomyopathy.<sup>26</sup> Vitamin D supplementation may be associated with reduced mortality in heart failure patients, although much of this literature is derived from retrospective database review rather than prospective clinical investigation.<sup>27</sup> Regarding cancer risks, practitioners should advise individuals to avoid excess supplementation because some people may show greater risk of breast, esophageal, prostate, and pancreatic cancers.<sup>25,28</sup> Additional controlled trials are needed to confirm the health benefits, risks, and role of vitamin D supplementation for specific patient populations. Further, as data on vitamin D supplementation and the role of serum level monitoring continue to evolve, dosing recommendations for prescription-only vitamin D formulations that are based on serum monitoring may be considerably higher.

**Dietary Sources.** Milk and milk products are the major sources of preformed vitamin D in the United States, given that milk is routinely supplemented with 100 IU (2.5 mcg) of vitamin D per cup. Other sources of vitamin D are listed in [Table 22-6](#).

**Deficiency.** Vitamin D deficiency may result from inadequate intake; gastrointestinal (GI) diseases (e.g., hepatobiliary disease, malabsorption, or chronic pancreatitis); chronic renal failure; inadequate sunlight exposure or dark skin pigment; hereditary disorders of vitamin D metabolism; obesity or gastric bypass therapy; or long-term therapy with antiepileptic medications (e.g., phenytoin, carbamazepine, and primidone). Older patients' aging skin may not synthesize vitamin D efficiently, and the converting process that takes place in the liver and kidneys may also be compromised. The altered physiologic actions—in addition to older patients' reduced sun exposure, absorption, and dietary intake of vitamin D—leave the elderly at increased risk of vitamin D deficiency.

The signs and symptoms of vitamin D deficiency are reflected as calcium abnormalities, specifically those involved with bone formation. Vitamin D deficiency has also been associated with muscle weakness, an increased risk of falls, and an increased risk of cardiovascular disease and certain cancers.<sup>28</sup>

**TABLE 22-8 Micronutrient-Drug and Micronutrient-Micronutrient Interactions**

Micronutrient	Drug/Micronutrient	Effect	Precautionary Measures
<b>Vitamins</b>			
Vitamins A, E (large doses)	Warfarin	Increased anticoagulation and risk of bleeding	Take only recommended U.S. DRIs.
Vitamins A, E, D, K, C	Cholestyramine, colestipol, orlistat, or mineral oil	Decreased vitamin absorption	Avoid prolonged use of cholestyramine, colestipol, orlistat, or mineral oil.
Vitamin D	Phenytoin, carbamazepine, barbiturates	Increased metabolism of vitamin D	Ensure adequate dietary intake of vitamin D.
Corticosteroids	May impair metabolism of vitamin D	Ensure adequate dietary intake of vitamin D.	
Vitamin K		Broad-spectrum antibiotics (long-term therapy)	Vitamin K deficiency induced by decreased gut flora Ensure adequate dietary intake of vitamin K.
Warfarin	Decreased anticoagulation	Keep daily intake of vitamin K consistent.	
Vitamin E (large doses)	Antagonizes function of vitamin K	Avoid chronic supplementation with high-dose vitamin E.	
Vitamin A (large doses)	May interfere with vitamin K absorption	Avoid chronic supplementation with high-dose vitamin A.	
Vitamin B <sub>12</sub>	Metformin, colchicine, anticonvulsants, ascorbic acid supplements, gastric acid lowering agents, tetracyclines, and long-term use of antibiotics	Potential decreased absorption of cyanocobalamin	Clinical significance is unknown.
Folic acid		Phenytoin and	Possible Monitor for

				possibly other related anticonvulsants (chronic use)	inhibition of folic acid absorption, leading to megaloblastic anemia; subsequent increased folic acid supplementation may decrease serum phenytoin levels and complicate seizure control	megaloblastic anemia. Consult with neurologist regarding supplementation, if possible.
Trimethoprim	Weak folic acid antagonism; decreased activity/effectiveness; rare occurrence of megaloblastic anemia in patients with low folic acid level at onset of trimethoprim therapy	Monitor for megaloblastic anemia.				
Pyrimethamine (large doses)	Possible megaloblastic anemia	Monitor for megaloblastic anemia.				
Methotrexate	Folic acid antagonism; decreased activity/effectiveness	Monitor use of folic acid in patients on maintenance regimens for psoriasis or rheumatoid arthritis.				
Sulfasalazine	Decreased folic acid absorption when these agents are administered together	Separate dosing of these agents.				
Niacin	Oral hypoglycemic agents; Sulfinpyrazone and probenecid	Decreased hypoglycemic effects; possible inhibited uricosuric effects	Monitor blood glucose with regular finger sticks.			
Vitamin B <sub>6</sub>			Isoniazid	Pyridoxine antagonism, manifested as perioral numbness resulting from peripheral neuropathy	Routinely take 50 mg/day of pyridoxine hydrochloride with isoniazid, or 10 mg of pyridoxine for each 100 mg of isoniazid.	
Phenobarbital and phenytoin	Decreased serum drug levels	Consider monitoring levels in patients taking high-dose pyridoxine.				
Levodopa	Levodopa antagonism; decreased effectiveness	Avoid supplemental pyridoxine or, if possible, substitute levodopa-carbidopa for levodopa.				
<b>Minerals</b>						
Calcium					Iron, zinc, magnesium	Inhibited nutrient absorption caused by high calcium intake Separate dosing by at least 2 hours.
Corticosteroids	Inhibited calcium absorption from gut; increased bone fractures and osteoporosis	Consider calcium supplementation.				
Aluminum-containing	Decreased calcium absorption	Separate dosing by at least 2				

antacids, phosphates, cholestyramine		hours.			
H <sub>2</sub> -blockers, proton pump inhibitors	Decreased absorption of calcium carbonate, which requires an acidic environment	Consider calcium citrate supplementation.			
Levothyroxine	Reduced drug absorption	Separate dosing by 4 hours.			
Tetracyclines, fluoroquinolones	Decreased antibiotic absorption	Separate dosing by 2 hours before or 6 hours after the antibiotic.			
Phenytoin, carbamazepine, phenobarbital	Decreased calcium absorption by increasing metabolism of vitamin D	Consider calcium and vitamin D supplementation.			
Magnesium		Tetracyclines, fluoroquinolones	Decreased antibiotic absorption	Separate dosing by 2 hours before or 6 hours after the antibiotic.	
Levothyroxine	Reduced drug absorption	Separate dosing by 4 hours.			
Phosphorus	Sucralfate or antacids containing magnesium, calcium, or aluminum	Decreased absorption of phosphorus	Ensure adequate intake of dietary phosphorus.		
Iron			Antacids	Decreased iron solubility and absorption	Separate dosing by at least 2 hours.
Tetracyclines, fluoroquinolones	Decreased antibiotic and iron absorption	If concurrent administration is medically necessary, take tetracycline or fluoroquinolone 2 hours before or 6 hours after taking iron.			
Levothyroxine	Decreased drug absorption	Separate dosing by 4 hours.			
<b>Trace Elements</b>					
Copper	Zinc, high-dose vitamin C	Copper antagonism		Micronutrients may compete for absorption and utilization; ensure supplements are administered in balanced doses, or monitor for signs of deficiency.	
Fluoride	Magnesium, aluminum, calcium	Decreased effect and absorption of fluoride		Separate supplementation by at least 2 hours.	
Iodine (potassium iodide)	Lithium salts	Possible additive hypothyroid effects		Monitor thyroid function tests.	
Zinc		Copper	Possible decreased copper levels	High-dose, prolonged zinc supplementation may require copper supplementation.	
Tetracyclines, fluoroquinolones	Possible decreased antibiotic absorption	Separate dosing by 2 hours before or 6 hours after the antibiotic.			

Key: DRI = Dietary reference intake.

The classic vitamin D deficiency state is rickets; osteoporosis with increased risk of fractures also occurs. Vitamin D increases calcium and phosphate absorption from the small intestine, mobilizes calcium from bone, permits normal bone mineralization, improves renal reabsorption of calcium, and maintains serum calcium and phosphorus levels. As serum calcium levels fall, compensatory mechanisms (e.g., increased secretion of parathyroid hormone) become activated in an attempt to restore serum calcium homeostasis. Long-term increases in parathyroid hormone secretion ultimately lead to secondary hyperparathyroidism. If physiologic mechanisms fail to make the appropriate adjustments in calcium and phosphorus levels, demineralization of bone ensues to maintain essential plasma calcium levels. During growth, demineralization leads to a failure of bone matrix mineralization, widening of the epiphyseal plate from weight load on softened bone structures, and deformed joints. In adults, such demineralization may lead to severe osteomalacia.

The incidence of rickets in the United States is low but not absent. Rickets is most likely to occur in children who abstain from milk and in infants breast-fed by mothers who receive an inadequate intake of vitamin D.

**Dose/DRIs.** Most people obtain the AI for vitamin D from dietary sources and from exposure to sunlight (Table 22-3). People regularly exposed to sunlight will generally have no dietary requirement for vitamin D. However, substantial segments of the U.S. population receive limited sunlight exposure, especially during the winter months. Regular use of sunscreen is broadly encouraged to prevent skin cancer, but that protection limits vitamin D synthesis in the skin and warrants careful consideration of vitamin D intake from dietary sources.

Vitamin D is FDA approved for the treatment of hypocalcemia and hypophosphatemia associated with hypoparathyroidism. Prescription vitamin D analogues (e.g., calcitriol) are FDA-approved for the treatment of secondary hyperparathyroidism in patients with chronic renal failure.<sup>19</sup>

If the practitioner determines that vitamin D supplementation is appropriate on the basis of poor dietary intake or inadequate exposure to sunlight, a multivitamin supplement containing cholecalciferol (vitamin D<sub>3</sub>) 15-20 mcg (600-800 IU) taken daily should be recommended. Some evidence suggests that vitamin D intake of up to 25 mcg (1000 IU) daily may have health benefits. The current UL for vitamin D is 100 mcg (4000 IU) daily, although this value may be increased in the future. Data gathered from the recent upswing in use of prescription-only high-dose (50,000 IU weekly) vitamin D supplements suggests such doses are safe and necessary to achieve adequate serum concentrations.

**Safety Considerations.** Taking more than the UL of vitamin D daily may lead to adverse effects, including anorexia, hypercalcemia, soft tissue calcification, kidney stones, renal failure, and increased risk of certain types of cancer.<sup>15</sup> Patients receiving doses above the UL (e.g., doses used for treatment of rickets or based on low serum concentrations) should be under medical supervision and closely monitored for these adverse effects.

**Potential Drug-Nutrient Interactions.** See Table 22-8.

#### Vitamin E (Tocopherol)

The term *vitamin E* refers to the tocopherols and the tocotrienols, which are compounds naturally occurring in plants.

**Function.** Vitamin E functions primarily as an antioxidant, protecting cellular membranes from oxidative damage or destruction. This process may be aided by selenium and vitamin C. Vitamin E may also have a role in heme biosynthesis, steroid metabolism, and collagen formation.

Vitamin E supplements, often combined with other antioxidants, have been promoted for treatment of numerous diseases (e.g., atherosclerosis, diabetes, cancer, Parkinson's disease, and Alzheimer's disease). These recommendations are often based on observational studies in which regular intake of fruits and vegetables rich in antioxidants have shown beneficial effects in health maintenance and prevention of disease. However, clinical trials have suggested a lack of benefit with vitamin E supplementation in reducing risks of cardiovascular events or mortality, stroke, cancer prevention, diabetes, or Alzheimer's disease.<sup>29,30,31</sup> On the contrary, antioxidant supplementation that includes vitamin E may be associated with an increased risk of congestive heart failure in certain populations, increased risk of hemorrhagic stroke in adults, and an increased risk of fetal loss when given to prevent preeclampsia.<sup>31,32,33</sup>

Practitioners should keep in mind that vitamin supplementation is not necessarily benign and has not shown benefit over a well-balanced diet, especially when taken in excess of the DRI.

**Dietary Sources.** See Table 22-6.

**Deficiency.** Vitamin E deficiency is extremely rare but may occur in two groups: premature infants with very low birth weight and patients who do not absorb fat normally. For example, neurologic abnormalities responsive to supplemental vitamin E have been reported in some patients with biliary disease and cystic fibrosis. Vitamin E deficiency has also been associated with symptoms of peripheral neuropathy, intermittent claudication, muscle weakness, and hemolytic anemia.

**Dose/DRIs.** The recommended dietary allowance for vitamin E is reported as milligrams of alpha-tocopherol. However, most food and nutrient supplement labels list vitamin E content in international units. Note that 1 mg of alpha-tocopherol vitamin E is equivalent to 1.49 IU.

The average diet contains approximately 3-15 mg/day of vitamin E; therefore, large doses in excess of the DRI are not necessary unless the patient is experiencing fat malabsorption. The FDA-approved use of vitamin E is for prevention and treatment of hemolytic anemia associated with deficiency.<sup>19</sup>

Vitamin E requirements may vary in proportion to the amount of polyunsaturated fatty acids in the diet. The polyunsaturated fatty acid content of the U.S. diet has increased, and the plant oils responsible for the increase are rich in tocopherol. The lack of evidence of deficiency at the present intake supports the current adult RDA of 15 mg/day. The UL for vitamin E is 1000 mg daily.

**Safety Considerations.** Potential risks associated with vitamin E supplementation are described in the preceding section.

**Potential Drug-Nutrient Interactions.** Vitamin E has been reported to enhance warfarin anticoagulation, possibly by inducing vitamin K deficiency.<sup>19</sup> This and other potential drug-nutrient interactions are listed in Table 22-8.

#### Vitamin K

Phytonadione (vitamin K<sub>1</sub>) is present in many vegetables. Menaquinone (vitamin K<sub>2</sub>) is a product of colonic bacterial metabolism. Menadione (vitamin K<sub>3</sub>) is a synthetic compound that is 2-3 times as potent as the natural vitamin K.

**Function.** Vitamin K has important roles in normal physiology. First, it promotes the synthesis of clotting factors II, VII, IX, and X in the liver. Second, it activates these factors, along with the anticoagulation proteins C and S. The clotting factors remain inactive in the liver in the presence of warfarin or in the absence of vitamin K. When vitamin K is administered, normal activity of the clotting factors resumes. Third, vitamin K is key in the activation of osteocalcin, which appears to play a role in bone mineralization and the prevention of osteoporosis.<sup>34</sup>

**Dietary Sources.** See Table 22-6.

**Deficiency.** The DRI value for vitamin K is 90-120 mcg/day for adults, depending on age and sex.<sup>14</sup> The microbiologic flora of the normal gut synthesizes enough menaquinone to supply a significant part of the body's requirement for vitamin K. Therefore, the incidence of deficiency among healthy, well-nourished individuals is low. Interference with bile production or secretion may contribute to vitamin K deficiency because vitamin K absorption in the small intestine requires bile. Malabsorption syndromes and bowel resections may decrease vitamin K absorption. Liver disease may also cause symptoms of vitamin K deficiency if hepatic production of the prothrombin clotting factor is decreased. Other potential causes of deficiency include intestinal disease or resection and chronic, broad-spectrum antibiotic therapy. A deficiency may be evidenced by unusual bleeding and demonstrated by a prolonged prothrombin time (PT). Lower dietary intake of vitamin K compared to higher intake may also be associated with increased risk of osteoporotic fractures. However, well-designed trials are needed to confirm this association.<sup>34</sup>

**Dose/DRIs.** The DRI values for vitamin K are listed in Table 22-3. Vitamin K<sub>1</sub> (phytonadione) is FDA-approved for use in neonates at birth (1 dose of 1 mg) to prevent hemorrhage. This dose is necessary because placental transport of vitamin K is low, and the neonate has yet to acquire the intestinal microflora that produce the vitamin. Other approved uses include the prevention and treatment of hypoprothrombinemia caused by drug-induced deficiency and the treatment of hemorrhage.<sup>19</sup> A UL for vitamin K has not been established.

**Safety Considerations.** Even in large amounts over an extended period, vitamin K does not produce toxic manifestations.

**Potential Drug-Nutrient Interactions.** Consistent dietary intake of vitamin K (70-140 mcg/day) does not usually interfere with warfarin anticoagulant activity. However, sudden changes in the dietary or supplemental intake of vitamin K can significantly alter the patient's PT and international normalized ratio (INR). Other potential drug interactions with this vitamin are listed in Table 22-8.

#### Vitamin C (Ascorbic Acid)

Vitamin C is the most easily destroyed of all the vitamins because of its sensitivity to heat, oxygen, and alkaline environments. Although it is a relatively simple compound, vitamin C is a powerful antioxidant that serves to protect the capillary basement membrane.

**Function.** Vitamin C is necessary for the biosynthesis of hydroxyproline, a precursor of collagen, osteoid, and dentin. It also assists in the absorption of nonheme iron from food by reducing the ferric iron in the stomach to ferrous iron. However, use of vitamin C supplementation with iron is generally not necessary for patients with normal gastric acidity who are taking adequate iron supplementation.

Large doses of vitamin C (500-1000 mg/day) have been promoted to prevent and treat the common cold. However, such claims are largely unsupported by well-designed controlled clinical studies.<sup>18,35</sup> Consumption of 5 servings or more of fruits and vegetables daily (≥200 mg vitamin C) has been associated with a lower incidence of cancer, heart disease, stroke, and certain eye diseases.<sup>36</sup> However, currently available data supporting vitamin C supplementation above the DRI for the prevention or treatment of these chronic conditions are inadequate.<sup>35</sup>

**Dietary Sources.** Vitamin C has been called the "fresh food" vitamin, and most of the daily intake is derived from vegetables and fruit sources (Table 22-6).

**Deficiency.** Characteristics of vitamin C deficiency include fatigue, capillary hemorrhages and petechiae, swollen hemorrhagic gums, and bone changes. A deficiency may also impair wound healing. A profound dietary deficiency can eventually lead to scurvy, producing widespread capillary hemorrhaging and a weakening of collagenous structures.

Scurvy is rare in the United States because it develops only with chronically inadequate consumption of vitamin C. Infants who are fed artificial formulas without vitamin supplements may develop symptoms of scurvy. In adults, however, scurvy occurs after 3-5 months of a diet free of vitamin C.

**Dose/DRI.** Practitioners are rarely confronted with overt symptoms of vitamin C deficiency. Only 10 mg/day of vitamin C prevents scurvy; a normal diet containing fresh fruits and vegetables contains many times this amount. The DRI values for vitamin C are listed in [Table 22-3](#). Supplementation of 100-125 mg/day has been recommended for smokers, on the basis of higher daily ascorbic acid losses observed in these individuals.<sup>35</sup> The UL for vitamin C is 2 g/day.

Most adult multivitamin supplements contain 60-100 mg of vitamin C, an appropriate amount to consume if supplements are required. A daily dose greater than 400 mg is rarely indicated, and excess intake is excreted in the urine. In patients with a severe vitamin C deficiency as evidenced by clinical signs of scurvy, 100-300 mg/day of vitamin C for at least 2 weeks is recommended to replenish body stores.<sup>19</sup> Infants who do not have vitamin C supplements in their formula should receive 40-50 mg/day; infants who are breast-fed by well-nourished mothers will receive a sufficient amount. If a supplement is warranted for an adult, practitioners may recommend a multivitamin product containing 60-200 mg of vitamin C to be taken once a day. Vitamin C is FDA approved for use in the prevention and treatment of scurvy and to acidify the urine.<sup>19</sup>

**Safety Considerations.** The practitioner is urged to weigh the relative risks and benefits of ascorbic acid therapy. Short-term use to promote wound healing in potentially deficient patients may warrant a trial of ascorbic acid with medical supervision. Megadoses, however, may cause nausea, stomach cramps, diarrhea, and nephrolithiasis. Ascorbic acid toxicity can also lead to hemolysis in patients deficient in glucose 6-phosphate dehydrogenase. Rebound scurvy in infants whose mothers took megadoses of vitamin C during pregnancy has occurred on sudden withdrawal of ascorbic acid. Vitamin C in doses of 1 g/day with 400 IU of vitamin E resulted in an increased risk of fetal loss or perinatal death when given as prenatal supplementation.<sup>33</sup> Patients with diabetes mellitus, recurrent renal calculi, or renal dysfunction should also avoid prolonged use of high-dose vitamin C supplementation.

**Potential Drug-Nutrient Interactions.** See [Table 22-8](#).

#### Vitamin B<sub>12</sub> (Cyanocobalamin)

Vitamin B<sub>12</sub> is the most complex vitamin molecule, and it exists in several forms, all of which contain the element cobalt. The term *vitamin B<sub>12</sub>* refers to all cobalamins that have vitamin activity in humans. Cyanocobalamin, the common pharmaceutical form of the vitamin, is the most stable of the cobalamins.

**Function.** Vitamin B<sub>12</sub> is active in all cells, especially those in the bone marrow, the central nervous system (CNS), and the GI tract. It is also involved in fat, protein, and carbohydrate metabolism. A cobalamin coenzyme functions in the synthesis of DNA and in the synthesis and transfer of single-carbon units (e.g., the methyl group in the synthesis of methionine and choline). Vitamin B<sub>12</sub> participates in methylation reactions and cell division, usually in concert with folic acid. Vitamin B<sub>12</sub> is necessary for the metabolism of folates; therefore, a folate deficiency may be observed as a feature of vitamin B<sub>12</sub> deficiency. Vitamin B<sub>12</sub> is also necessary for the metabolism of lipids and the formation of myelin.

Vitamin B<sub>12</sub> has been studied in relation to elevated levels of homocysteine, an amino acid that requires vitamins B<sub>12</sub>, B<sub>6</sub>, and folate as cofactors for metabolism.

Hyperhomocysteinemia has been identified as an independent risk factor for cardiovascular disease. Supplementation with folate, vitamin B<sub>6</sub>, and vitamin B<sub>12</sub> has been shown to reduce plasma homocysteine levels. However, this has not been proven to lower the risk of major coronary or major vascular events in individuals at increased risk for cardiovascular disease.<sup>37</sup>

**Dietary Sources.** Vitamin B<sub>12</sub> is found almost exclusively in animal protein ([Table 22-6](#)).

**Deficiency.** In healthy individuals who have no dietary restrictions, vitamin B<sub>12</sub> deficiency is rare because the body stores so much vitamin B<sub>12</sub> in the liver that a deficiency would take approximately 3 years to develop. Vitamin B<sub>12</sub> deficiency may be caused by poor absorption or utilization, or by an increased requirement or excretion of this vitamin. In patients with conditions that affect absorption (e.g., those with ileal diseases, intestinal resection, or gastrectomy), the reabsorption phase of the enterohepatic cycle is affected, and deficiency may occur. Patients older than 50 years are at increased risk of vitamin B<sub>12</sub> deficiency resulting from the inability to absorb food-bound vitamin B<sub>12</sub>.

Reduced intestinal motility, achlorhydria, and use of gastric acid-lowering agents in this patient population contribute to bacterial overgrowth in the small intestine, resulting in more microorganisms utilizing available vitamin B<sub>12</sub>.<sup>38</sup> In addition, atrophic gastritis is a condition that affects 10%-30% of older adults, and it can result in pernicious anemia as a result of inadequate production of gastric intrinsic factor, which is necessary for vitamin B<sub>12</sub> absorption. For these reasons, vitamin B<sub>12</sub> supplementation from either fortified foods or a dietary supplement is recommended for this age group; prescription-only vitamin B<sub>12</sub> injections may be necessary for the treatment of pernicious anemia.<sup>39</sup>

Long-term treatment with metformin can induce malabsorption of vitamin B<sub>12</sub>, thereby contributing to the development of vitamin B<sub>12</sub> deficiency.<sup>40</sup> In fact, vitamin B<sub>12</sub> deficiency has been reported after as little as 3 months of metformin therapy.<sup>38</sup>

Vegetarians who do not consume any animal products (including infants breast-fed by vegetarian mothers) are also at risk for developing vitamin B<sub>12</sub> deficiency. Vitamin B<sub>12</sub> supplementation should be encouraged for these patients.

The symptoms of vitamin B<sub>12</sub> deficiency mimic those of folate deficiency and are manifested in organ systems with rapidly duplicating cells. One such organ system is the hematopoietic system resulting in macrocytic anemia. The GI tract is also affected, with glossitis and epithelial changes occurring along the entire digestive tract. Because vitamin B<sub>12</sub> is necessary for the maintenance of myelin, deficiency states produce many neurologic symptoms (e.g., paresthesia, peripheral neuropathy, unsteadiness, poor muscular coordination, mental confusion, agitation, hallucinations, and overt psychosis).

Practitioners should caution patients that an accurate diagnosis of a suspected anemia via laboratory assessment of the complete blood cell count and differential is essential in selecting effective treatment. For example, anemia resulting from a folic acid deficiency should be treated with folic acid; pernicious anemia should be treated with vitamin B<sub>12</sub>; and iron-deficiency anemia should be treated with iron. Practitioners should avoid use of a "shotgun" antianemia preparation that contains multiple hematinic factors.

**Dose/DRI.** The DRI values for vitamin B<sub>12</sub> are listed in [Table 22-3](#). Oral forms can be used if the deficiency is caused by inadequate intake; high-dose oral supplementation may be appropriate for deficiencies caused by malabsorption, although intramuscular or deep subcutaneous administration is sometimes used given poor oral bioavailability.

Vitamin B<sub>12</sub> is FDA approved for use in the treatment of pernicious anemia and vitamin B<sub>12</sub> deficiency. Other approved uses include supplementation during periods of increased requirements (e.g., pregnancy, thyrotoxicosis, hemorrhage, malignancy, liver disease, or kidney disease).<sup>19</sup> Patients who have undergone bariatric surgery (e.g., gastric bypass) require lifelong vitamin B<sub>12</sub> supplementation to prevent deficiency. A UL has not been established for vitamin B<sub>12</sub>.

Hydroxocobalamin, a prescription-only product equal in hematopoietic effect to cyanocobalamin, may be appropriate for some patients. It is more extensively bound to proteins at the site of injection and in plasma, making renal excretion slower and prolonging the duration of action.

**Safety Considerations.** Excessive doses have not resulted in toxicity; however, nondeficient patients taking large quantities of the vitamin have reported no benefit.

**Potential Drug-Nutrient Interactions.** See [Table 22-8](#).

#### Folic Acid (Pteroylglutamic Acid, Folate)

**Function.** Folate is an important nutrient that is essential for cell division, DNA production, and brain and spinal cord development. It is also used in the metabolism of various amino acids. Folic acid refers to the synthetic version of this vitamin found in nutritional supplements and in fortified foods; folate is the naturally occurring form found only in food sources.

Folic acid, whether contained in a nutritional supplement or consumed through dietary sources, is not biologically active and must undergo *in vivo* enzymatic conversion to the usable form. Following consumption, folic acid is converted to dihydrofolate, which is then converted to tetrahydrofolate by the enzyme dihydrofolate reductase. Tetrahydrofolate is then converted by methylenetetrahydrofolate reductase (MTHFR) to the biologically active form, L-methylfolate.<sup>41</sup> A significant percentage of the population may have a genetic polymorphism of MTHFR that results in inadequate enzyme activity.<sup>42</sup> Patients with this polymorphism cannot convert folic acid to its active form. This has major implications for pregnant women because folic acid supplementation in patients with this polymorphism is not effective at reducing the risk of neural tube defects.<sup>41</sup> Other genetic defects in folate metabolism may lead to abnormalities in homocysteine metabolism (leading to elevated homocysteine levels), which has been associated with neural tube defects.<sup>43</sup> Folate deficiency is closely linked with deficiency of other water-soluble vitamins; low plasma concentrations of folate, vitamin B<sub>6</sub>, and vitamin B<sub>12</sub> have been associated with elevated concentrations of homocysteine, which may increase the risk of cardiovascular disease. Folate supplementation may reduce elevated serum homocysteine concentrations, although this effect has not translated into improved cardiovascular outcomes.<sup>39</sup>

**Dietary Sources.** Foliates are present in a wide variety of food sources. Primary food sources are listed in [Table 22-6](#). Foliates are heat labile, so the folic acid content of food depends on how the food is processed. Many commercially prepared carbohydrate foods (e.g., breads and pasta) are now fortified with folic acid.

**Deficiency.** The requirements for folic acid are related to metabolic rate and cell turnover, and increased amounts of folic acid are needed during pregnancy, lactation, and infancy. Infection, hemolytic anemia, blood loss (in which red blood cell production must be increased to replenish blood supply), and hypermetabolic states (e.g., hyperthyroidism) also increase folic acid requirements. Because folic acid deficiency has been associated with an increased risk of neural tube defects in newborns, supplementation for all women of child-bearing age is recommended.

Causes of folic acid deficiency include alcoholism, malabsorption, food faddism, and liver disease. Iatrogenic causes are associated with administration of certain medications, including dihydrofolate reductase inhibitors (e.g., methotrexate or trimethoprim), anticonvulsants, and sulfasalazine.<sup>19</sup>

A deficiency of folic acid results in impaired cell division and protein synthesis. Symptoms of folic acid deficiency are similar to those of vitamin B<sub>12</sub> deficiency, including sore

mouth, diarrhea, and CNS symptoms (e.g., irritability and forgetfulness). The most common laboratory-identified feature of folic acid deficiency is megaloblastic anemia (an anemia characterized by large erythroblasts circulating in the blood).

Because vitamin B<sub>12</sub> is essential for the metabolism of folates, a megaloblastic anemia responsive to folic acid administration is a feature of vitamin B<sub>12</sub> deficiency. Folic acid given without vitamin B<sub>12</sub> to patients with inadequate intrinsic factor (pernicious anemia) or vitamin B<sub>12</sub> deficiency would correct the anemia but would not stop the damage to the CNS (characterized by lack of coordination, impaired sense of position, and various behavioral disturbances). Because of the potential for folic acid to mask the signs—but not the progression—of vitamin B<sub>12</sub> deficiency, patients should receive an appropriate medical evaluation for the cause of anemia rather than an empiric vitamin supplement.

**Dose/DRI.** The DRI values for folic acid are listed in Table 22-3. Folate is FDA-approved for use in the treatment of megaloblastic anemias caused by folate deficiency. Folate also is approved for prevention of neural tube defects of the newborn.<sup>19</sup>

All women of childbearing age should consume synthetic folic acid at a dose of 400 mcg/day from fortified foods and/or dietary supplementation in addition to the folate obtained from food sources.<sup>14</sup>

Individuals known to have a polymorphism in MTHFR should receive a prescription vitamin containing biologically active derivatives of folic acid, available in forms such as L-methylfolate, 5-methyltetrahydrofolate calcium salt, and (6S)-5-methyltetrahydrofolate glucosamine salt.<sup>41</sup>

The supplemental dose of folic acid for correction of a deficiency in adults is usually 1 mg/day, particularly if the deficiency occurs with conditions that may increase the folate requirement or suppress red blood cell formation (e.g., pregnancy, hypermetabolic states, alcoholism, or hemolytic anemia). Doses larger than the UL of 1 mg/day are not necessary, except in some life-threatening hematologic diseases. Maintenance therapy for deficiencies may be stopped after 1-4 months if the diet contains at least one fresh fruit or vegetable daily. For chronic malabsorption diseases, folic acid treatment may be life-long, and parenteral doses may be required.

**Safety Considerations.** Folic acid toxicity is virtually nonexistent because of its water solubility and rapid excretion. Doses up to 15 mg/day have been given without toxic effect. The UL is set to minimize the risk of masking vitamin B<sub>12</sub> deficiency. Several drugs, when taken chronically, may increase the need for folic acid (Table 22-8).

### Niacin (Nicotinic Acid)

The physiologically active form of niacin is niacinamide. Niacin and niacinamide are constituents of the coenzymes nicotinamide adenine dinucleotide and nicotinamide adenine dinucleotide phosphate.

**Function.** The niacin coenzymes are electron transfer agents; that is, they accept or donate hydrogen in the aerobic respiration of all body cells. Niacin is a unique vitamin because humans can synthesize it from dietary tryptophan, with about 60 mg of tryptophan being equivalent to 1 mg of niacin. Most individuals receive about 50% of their niacin requirement from tryptophan-containing proteins and the rest as preformed niacin or niacinamide.

**Dietary Sources.** See Table 22-6.

**Deficiency.** The classic and only described niacin deficiency state is pellagra. Pellagra is rare, occurring most often in alcoholics, poorly nourished persons of advanced age, and individuals on diets that severely restrict sources of niacin. It may also occur in areas where large quantities of corn are consumed, as some of the niacin found in corn is bound to undigestible constituents, making it unavailable for absorption. Other causes of pellagra include isoniazid therapy and decreased tryptophan conversion, as in Hartnup disease and carcinoid tumors.

Clinical findings of niacin deficiency include the “three D’s” of dermatitis, diarrhea, and dementia, often accompanied by neuropathy, glossitis (beefy red tongue), stomatitis, and proctitis. Patients manifest a characteristic rash with well-demarcated lesions of hard, cracked skin with blackish pigmentation that is crusty and scaly. Lesions occur primarily on sun-exposed areas, including dorsal surfaces of the hands, arms and feet, on the neck (Casal necklace), and face. Secondary infections may occur in such lesions. The entire GI tract is generally affected, with atrophy of the epithelium. Inflammation of the small intestine may be associated with episodes of occult bleeding and/or diarrhea.

**Dose/DRI.** The DRI values for niacin are listed in Table 22-3. The recommended UL for this vitamin in adults is 35 mg/day.<sup>14</sup>

Niacin requirements are increased after a severe injury, infection, or burn, or when the patient has an acute illness; has substantially increased caloric expenditure or dietary caloric intake; or has a low tryptophan intake (e.g., a low-protein diet or a high intake of corn as a staple in the diet). The FDA-approved use of both niacin and niacinamide is the prevention and treatment of pellagra. Niacin, but not niacinamide, is also approved for adjunctive treatment of hyperlipidemia and hypercholesterolemia.<sup>19</sup>

Niacin or niacinamide, 150-500 mg daily in divided doses, is used for treatment of pellagra. Daily dosages of 1-2 grams 3 times per day, up to 8 g/day, of niacin (*not* niacinamide) are used to treat hypercholesterolemia and hyperlipidemia. Niacin increases beneficial high-density lipoprotein cholesterol and decreases concentrations of potentially harmful triglycerides, total cholesterol, and low-density lipoprotein cholesterol by mechanisms unrelated to its function as an essential micronutrient. However, such high dose niacin therapy should not be undertaken as self-care; close medical supervision is required because of potentially serious drug-induced toxicity.

**Safety Considerations.** Niacinamide is associated with little toxicity; conversely, niacin toxicity can involve GI symptoms (e.g., nausea, vomiting, and diarrhea), hepatotoxicity, skin lesions, tachycardia, and hypertension. Patients should be forewarned that therapeutic doses of niacin may cause flushing and a sensation of warmth, especially around the face, neck, and ears. This reaction, which is prevalent upon initiation of therapy, may be diminished with aspirin 325 mg or ibuprofen 200 mg taken 30-60 minutes before the niacin dose, provided no contraindications exist. Alternatively, the extended-release formulation may cause less flushing but has a greater risk of gastric and hepatic side effects. Itching or tingling and headache may also occur with niacin supplementation. These effects will usually subside or decrease in intensity within 2 weeks of continued therapy. If niacin causes GI upset, it should be taken with meals.

Because of the adverse effects on the GI tract, high doses of niacin are contraindicated in patients with gastritis or peptic ulcer disease. Niacin can provoke the release of histamine, so its use in patients with asthma should be undertaken carefully. Niacin may also impair liver function, disturb glucose tolerance, and cause hyperuricemia. Patients prescribed therapeutic doses of this nutrient must be monitored regularly for potential adverse effects.

**Potential Drug-Nutrient Interactions.** See Table 22-8.

### Pantothenic Acid

Pantothenic acid is a water-soluble vitamin of the B-complex family.

**Function.** Pantothenic acid is a precursor of coenzyme A (CoA), a product that is active in many biological reactions and plays a primary role in cholesterol, steroid, and fatty acid synthesis. Pantothenic acid is important for acetylation reactions and the formation of citric acid for the Krebs cycle, and it is crucial in the intraneuronal synthesis of acetylcholine. It also is important in gluconeogenesis; synthesis and degradation of fatty acids; synthesis of sterols, steroid hormones, and porphyrins; and in the release of energy from carbohydrates.

**Dietary Sources.** Pantothenic acid is widely distributed in foods (Table 22-6).

**Deficiency.** Because pantothenic acid is contained in many foods, deficiency states are rare and hard to detect. In malabsorption syndromes, it is difficult to distinguish pantothenic acid deficiency symptoms from those of other deficiencies. Symptoms of pantothenic acid deficiency include somnolence, fatigue, cardiovascular instability, abdominal pain, and paresthesia of hands and/or feet followed by hyperreflexia and muscular weakness in the legs. Administration of pharmacologic doses of pantothenic acid reverses these symptoms and has even been used to eliminate burning feet syndrome.

**Dose/DRI.** All values for this vitamin are listed in Table 22-3. There is no established UL for pantothenic acid.

**Safety Considerations.** Pantothenic acid generally is considered nontoxic, even in large doses. Doses as high as 10 g/day of calcium pantothenate have been given to young men for 6 weeks with no toxic symptoms. However, ingestion of more than 20 grams has been reported to result in diarrhea and water retention.

**Potential Drug-Nutrient Interactions.** Significant drug-nutrient interactions with pantothenic acid have not been reported.

### Vitamin B<sub>6</sub> (Pyridoxine)

This water-soluble vitamin exists in three forms: pyridoxine (vitamin B<sub>6</sub>), pyridoxal, and pyridoxamine. Although all three forms are equally effective in nutrition, pyridoxine hydrochloride is the form most often used in vitamin formulations.

**Function.** Vitamin B<sub>6</sub> serves as a cofactor for more than 60 enzymes, including decarboxylases, synthetases, transaminases, and hydroxylases. It is important in heme production and in the metabolism of homocysteine. As previously stated, hyperhomocysteinemia is a potential risk factor for cardiovascular disease, and it has been shown to respond particularly to folic acid supplementation but also to vitamin B<sub>6</sub>. Whether the impact of these nutrients on homocysteine levels results in improved clinical outcomes has yet to be determined.<sup>37</sup> Vitamin B<sub>6</sub> has also been suggested as a potential treatment of carpal tunnel syndrome, premenstrual syndrome (PMS), depression, and migraine.

Unfortunately, no clinical research evidence supports use of vitamin B<sub>6</sub> for these ailments.<sup>44</sup>

**Dietary Sources.** See Table 22-6. Cooking destroys some vitamin B<sub>6</sub>.

**Deficiency.** Causes of vitamin B<sub>6</sub> deficiency include alcoholism, severe diarrhea, food faddism, malabsorptive syndromes, drugs (isoniazid and penicillamine), and genetic diseases (cystathioninuria and xanthurenic aciduria).

The symptoms of severe vitamin B<sub>6</sub> deficiency in infants include irritability and convulsive disorders. Medical referral is indicated, and treatment with vitamin B<sub>6</sub> hydrochloride generally normalizes the electroencephalogram and resolves clinical symptoms. Symptoms in adults whose diets are deficient in vitamin B<sub>6</sub> or who have been given a vitamin B<sub>6</sub> antagonist are difficult to distinguish from symptoms of niacin and riboflavin deficiencies. These symptoms include pellagra-like dermatitis; oral lesions; peripheral neuropathy; scaliness around the nose, mouth, and eyes; and dulling of mentation. Serious deficiency symptoms include convulsions, peripheral neuritis, and sideroblastic anemia.

**Dose/DRI.** DRI values for vitamin B<sub>6</sub> are listed in Table 22-3. The FDA-approved use of this vitamin is for treatment of vitamin B<sub>6</sub> deficiency, including drug-induced deficiency as seen with isoniazid.<sup>19</sup> Daily doses up to 250 mg of vitamin B<sub>6</sub> have been used in the treatment of hyperhomocysteinemia.<sup>37</sup> However, the UL for this vitamin is 100 mg daily for

adults.<sup>14</sup>

Treatment of sideroblastic anemia requires 50-200 mg/day of pyridoxine hydrochloride to aid production of hemoglobin and erythrocytes. Several vitamin B<sub>6</sub>-dependent inborn errors of metabolism have been shown to respond to large doses of vitamin B<sub>6</sub>.

**Safety Considerations.** Vitamin B<sub>6</sub> may be toxic in high doses. A severe sensory neuropathy similar to that observed with the deficiency state has been reported when gram quantities were taken to relieve symptoms of PMS. Similar symptoms have been reported in women taking doses as small as 50 mg/day for PMS. Recovery occurred slowly upon withdrawal of vitamin B<sub>6</sub>.

High daily doses of vitamin B<sub>6</sub> (200-600 mg) inhibit prolactin. Prenatal vitamins, which contain 1-10 mg per dosage unit, do not appear to have a significant antiprolactin effect.

**Potential Drug-Nutrient Interactions.** See [Table 22-8](#).

#### Riboflavin (Vitamin B<sub>2</sub>)

Riboflavin is a water-soluble vitamin essential for cellular growth and maintenance of vision, mucous membranes, skin, nails, and hair.

**Function.** Riboflavin is a constituent of two coenzymes: flavin adenine dinucleotide and flavin mononucleotide. It is involved in numerous oxidation and reduction reactions, including the cytochrome P450 reductase enzyme system involved in drug metabolism.

**Dietary Sources.** See [Table 22-6](#).

**Deficiency.** Riboflavin deficiency, although rare, may be caused by inadequate intake, alcoholism, or malabsorptive syndromes. Deficiency of this vitamin may occur in association with other vitamin B-complex deficiency states (e.g., pellagra) or during pregnancy. Early signs of riboflavin deficiency may involve ocular symptoms, as the eyes become light sensitive and easily fatigued. The patient may develop blurred vision; itching, watering, sore eyes; and corneal vascularization, which causes a bloodshot appearance of the eye. Clinical findings of more advanced deficiency include stomatitis, seborrheic dermatitis, and magenta tongue.

**Dose/DRI.** The DRI values for riboflavin are listed in [Table 22-3](#). The need for riboflavin appears to increase during periods of increased cell growth, such as during pregnancy and wound healing. Absorption is enhanced when taken with food. The FDA-approved use of riboflavin is in the prevention and treatment of riboflavin deficiency.<sup>19</sup> No UL has been determined for this vitamin.

Limited data suggest high-dose riboflavin (400 mg daily) may be effective in the prevention of migraine. An open-label study of 23 patients suggested reduced incidence of migraine, but no effect on duration or intensity.<sup>45</sup> Further study on riboflavin therapy for migraine prevention is warranted.

**Safety Considerations.** The use of riboflavin typically causes a yellow-orange fluorescence or discoloration of the urine. Patients who report this effect should be reassured that this color is normal. There is no known toxic concentration.

**Potential Drug-Nutrient Interactions.** No significant drug interactions have been reported for riboflavin.

#### Thiamin (Vitamin B<sub>1</sub>)

Thiamin is a water-soluble, B-complex vitamin available in oral tablet and injectable dosage forms.

**Function.** Thiamin's active form, thiamin pyrophosphate (formerly known as cocarboxylase), plays a vital role in the oxidative decarboxylation of pyruvic acid; in the formation of acetyl CoA, which enters the Krebs cycle; and in other important biochemical conversion cycles. Thiamin is necessary for myocardial function, nerve cell function, and carbohydrate metabolism. The amount of thiamin required increases with increased carbohydrate consumption.

**Dietary Sources.** Dietary sources highest in thiamin are listed in [Table 22-6](#). The thiamin content of food can be destroyed by heat, oxidation, and an alkaline environment but is stable through frozen storage.

**Deficiency.** The primary causes of thiamin deficiency are generally inadequate diet, alcoholism, malabsorptive syndromes, prolonged diarrhea, chronic furosemide therapy, increased requirements (e.g., pregnancy), and food faddism.

Thiamin deficiency in the United States is found primarily in alcoholics. Not only is their diet often nutritionally deficient, but alcohol ingestion also impairs thiamin absorption and transport across the intestine, and it also increases the rate of destruction of thiamin diphosphate. Thiamin deficiency, also known as beriberi, may present with neuromuscular symptoms such as peripheral neuritis, weakness, and Wernicke's encephalopathy. Cardiac dysfunction may also be observed, possibly accompanied by edema, tachycardia on minimal exertion, enlarged heart, and electrocardiographic abnormalities. Because of these risks, a vitamin supplement containing thiamin should be prescribed for alcoholic patients.

**Dose/DRI.** The DRI values for thiamin are listed in [Table 22-3](#). Signs and symptoms of thiamin deficiency are preferably treated with intravenous thiamin. However, long-term supplementation may be recommended for patients at risk of continued losses, such as those prescribed high-dose furosemide therapy. The FDA-approved use of thiamin is for the treatment of thiamin deficiency.<sup>19</sup>

**Safety Considerations.** The kidney easily clears excessive thiamin intake, and oral doses of 500 mg have been found to be nontoxic.

**Potential Drug-Nutrient Interactions.** Diuretics have been shown to increase the urinary excretion of thiamin. Therefore, patients on chronic diuretic therapy (e.g., those with congestive heart failure or hypertension) may be at risk of subclinical thiamin deficiency and associated cardiovascular complications. Recommending supplementation with 100% of the DRI for this vitamin is reasonable.<sup>46</sup>

#### Biotin (Vitamin H)

Biotin is included in several multivitamin preparations.

**Function.** Biotin, a member of the B-complex group of vitamins, is required for various metabolic functions, including carbohydrate, fat, and amino acid metabolism. Several biotin-dependent enzymes are known to exist.

**Dietary Sources.** Food sources of biotin are listed in [Table 22-6](#). In addition to food sources, colonic flora probably synthesizes a considerable amount of biotin, which is then absorbed from the large intestine into the bloodstream.

**Deficiency.** Deficiency states of biotin are rare but appear to result in symptoms of nausea, vomiting, lassitude, muscle pain, anorexia, anemia, and depression. Dermatitis, a grayish color of the skin, and glossitis may be among the physical findings; hypercholesterolemia and cardiac abnormalities may also occur.

Biotin deficiency in humans can be caused by ingesting a large number of raw egg whites. Raw egg whites contain avidin, a protein that binds biotin, thereby preventing its absorption. Individuals undergoing a rapid weight-loss program with intense caloric restriction and those with chronic malabsorption may not obtain adequate biotin and should receive supplementation.

**Dose/DRI.** See [Table 22-3](#).

**Safety Considerations.** Adverse effects have not been reported with biotin therapy.

#### Vitamin-Like Compounds and Pseudovitamins

Vitamin-like compounds, or pseudovitamins, are substances that have a chemical structure very similar to that of vitamins but lack the usual physiologic or biochemical actions. That is, they are not essential for specific body functions of growth, maintenance, and reproduction.

##### Choline

Choline is contained in most living cells and in foods. It is usually present in the form of phosphatidylcholine, commonly known as lecithin, and in several other phospholipids found in cell membranes. Intestinal mucosal cells and pancreatic secretions contain enzymes capable of splitting phospholipids to release choline. Choline is also found in sphingomyelin and is highly concentrated in nervous tissue.

**Function.** Choline, a precursor in the biosynthesis of acetylcholine, is an important donor of methyl groups used in the biochemical formation of other substances in vivo. It can be biosynthesized in humans. Furthermore, choline and inositol are considered to be lipotropic agents (i.e., agents involved in the mobilization of lipids). They have been used to treat fatty liver and abnormal fat metabolism, but their efficacy has not been established.

**Dietary Sources.** Although choline is found in food sources, it is also synthesized in the body. Therefore, choline most likely is not a vitamin. Choline is obtained from the diet as either choline or lecithin. Food sources are listed in [Table 22-6](#).

**Deficiency.** A deficiency state has not been identified in humans, possibly because choline is readily available in the diet and is synthesized in the body.

**Dose/DRI.** See [Table 22-3](#) for DRI values. An average diet furnishes ample choline daily. The recommended UL for choline is 3.5 g/day.<sup>14</sup>

**Safety Considerations.** The administration of large doses of lecithin has been associated with sweating, GI distress, vomiting, and diarrhea.

**Potential Drug-Nutrient Interactions.** No drug interactions have been reported.

#### Minerals

Minerals constitute about 4% of body weight. These micronutrients are present in the body in a diverse array of organic compounds (e.g., phosphoproteins, phospholipids, hemoglobin, and thyroxine). They function as constituents of many enzymes, hormones, vitamins, and inorganic compounds (e.g., sodium chloride, potassium chloride, calcium, and phosphorus) that are present as free ions. Different body tissues contain various quantities of different minerals. For example, bone has a high content of calcium, phosphorus, and magnesium, whereas soft tissue has a high quantity of potassium. Minerals are involved in regulating cell membrane permeability, osmotic pressure, and acid-base and water balance. In addition, certain ions act as the mediators of action potential conduction and neurotransmitter action.

A well-balanced diet is required to maintain proper mineral balance. Optimal mineral intake values for humans are still imprecise; only AIs are available for trace element minerals such as chromium, fluoride, and manganese. Similarly, the possible adverse effects of long-term ingestion of high-dose mineral supplements are often unknown, and high doses of one mineral can decrease the bioavailability of other minerals and vitamins.

## Calcium

The most abundant cation in the body is calcium (about 1200 grams). Approximately 99% of calcium is present in the skeleton, and the remaining 1% is present in the extracellular fluid, intracellular structures, and cell membranes. Calcium is a major component of bones and teeth. The calcium content in bone is continuously undergoing a process of resorption and formation. In people of advanced age, the resorption process predominates over formation, and a decrease in calcium absorption efficiency results in a gradual loss of bone density that leads to osteoporosis. This effect can be minimized by encouraging optimal calcium and vitamin D intake throughout the life cycle and by encouraging regular participation in weight-bearing exercise.

**Function.** Calcium is important for several reasons, as it activates a number of enzymes and is required for acetylcholine synthesis. Calcium increases cell membrane permeability, aids in vitamin B<sub>12</sub> absorption, regulates muscle contraction and relaxation, and catalyzes several steps in the activation of plasma-clotting factors. Calcium is also necessary for the functional integrity of many cells, especially those of the neuromuscular and cardiovascular system.

**Dietary Sources.** Dietary sources of calcium are listed in Table 22-6. Teenagers experiencing rapid growth and bone maturation need to consume adequate calcium through dairy products (especially milk) or through a nutritional supplement. Most adults can easily meet calcium RDAs by incorporating dairy products into their diets daily. Each 8-ounce serving of nonfat milk contains about 300 mg of calcium. As an alternative, calcium supplements are usually well tolerated in daily doses of less than 2 grams. Table 22-9 lists selected calcium supplements.

Practitioners should evaluate the dietary intake of calcium (including calcium-fortified foods) before recommending daily calcium supplementation. Calcium fortification is found in numerous nontraditional sources (e.g., juices, breads, and breakfast bars). To optimize calcium absorption, patients should avoid co-ingestion with bran, whole-grain cereals, or high-oxalate foods (e.g., cocoa, soybeans, or spinach); for those using a supplement, a product co-formulated with vitamin D should be recommended.

**Deficiency.** Decreased calcium concentrations may have profound and diverse consequences, including convulsions, tetany, behavioral and personality disorders, mental and growth retardation, and bone deformities (the most common being rickets in children and osteomalacia in adults). Changes that occur in osteomalacia include softening of bones, rheumatic-type pain in the bones of the legs and lower back, general weakness with difficulty walking, and spontaneous fractures. Common causes of hypocalcemia and associated skeletal disorders include malabsorptive syndromes; hypoparathyroidism; vitamin D deficiency; renal failure with impaired activation of vitamin D; long-term anticonvulsant therapy (with increased breakdown of vitamin D); and decreased dietary intake of calcium, particularly during periods of growth, pregnancy and lactation, and among people of advanced age.

**Dose/DRIs.** The RDAs for calcium are listed in Table 22-4. Oral calcium supplements are FDA approved for use in the treatment and prevention of calcium deficiency, which may result in rickets, osteomalacia, or osteoporosis. Other FDA-approved uses include treatment of acid indigestion and hyperphosphatemia associated with end-stage renal disease.<sup>19</sup> The recommended UL for calcium is 2-3 g/day for individuals older than 1 year.<sup>15</sup>

**TABLE 22-9 Selected Nonprescription Calcium Supplements**

Trade Name	Primary Ingredients Per Serving
Caltrate 600+D Tablets	Elemental calcium 600 mg (as carbonate); vitamin D 200-800 IU (depending on formulation)
Citracal Maximum Caplets	Elemental calcium 630 mg (as citrate); vitamin D 500 IU
Os-Cal Calcium+D3 Chewable Tablets	Elemental calcium 500 mg (as carbonate); vitamin D 600 IU
Tums Regular Strength Chewable Tablets	Elemental calcium 400 mg (as carbonate)
Viactiv Calcium Soft Chews plus D	Elemental calcium 500 mg (as carbonate); vitamin D 500 IU; vitamin K 40 mcg

Recommendations for calcium intake are based on elemental calcium content, not the calcium salt. Because labels can be misleading, practitioners should be familiar with the many salt forms and the different percentages of calcium in each, including carbonate (40%), citrate (21%), lactate (13%), gluconate (9%), and phosphate salts (23%-39%).<sup>47</sup> Calcium carbonate and calcium phosphate salts are insoluble in water and should be taken with meals to enhance absorption, which is optimal in a low pH. Patients requiring supplementation who have achlorhydria or who are on chronic therapy with histamine<sub>2</sub> antagonists or proton pump inhibitors may benefit most from taking one of the water-soluble salt formulations (e.g., calcium citrate), which are absorbed more readily in basic environments.

The small intestine controls calcium absorption. Patients ingesting relatively low amounts of calcium absorb proportionately more calcium than those with adequate intake; patients taking large amounts of calcium excrete more as fecal calcium. Optimal absorption occurs with individual doses of 500 mg or less; therefore, patients taking more than 500 mg of supplemental calcium should be encouraged to take calcium in divided doses.<sup>15</sup> In conjunction with adequate calcium and vitamin D intake, weight-bearing exercise is essential in maintaining bone mass.

High intake of calcium and vitamin D may be effective in the prevention of premenstrual syndrome.<sup>48</sup> Numerous studies have evaluated the relationship between calcium intake and the risk of colon cancer; however, the results of these studies have been inconsistent. Further research to better define this relationship is needed.

Claims have also been made in relation to calcium intake and weight loss or maintenance. However, randomized controlled trials have found no relationship between higher calcium intakes and body weight.<sup>49</sup>

**Safety Considerations.** Calcium in doses greater than 3 g/day can be harmful. Large amounts taken as dietary supplements or antacids can lead to high levels of calcium in the urine and to the formation of renal stones; development of the latter may result in permanent renal damage. Development of hypercalcemia is possible (particularly in patients taking concomitant high-dose vitamin D preparations) and is associated with anorexia, nausea, vomiting, constipation, and polyuria. Increased deposition of calcium in soft tissue can also occur with hypercalcemia. The USPSTF is more conservative regarding calcium intake and recommends that daily calcium intake not exceed 1000 mg.<sup>50</sup> USPSTF's recommendation is based on the fact that insufficient evidence exists to determine whether calcium supplementation can reduce fractures in community-dwelling adults and on concerns that high-dose supplementation may increase the risk of adverse effects.

The relationship between dietary and supplemental calcium intake and increased cardiovascular disease risk has caused much controversy and uncertainty in the medical community over the past several years. According to results of a prospective study conducted in 388,229 men and women ages 50-71 years designed to evaluate the effects of both dietary and supplemental calcium intake on mortality from cardiovascular disease, heart disease, and stroke, supplemental calcium intake at a dose more than 1000 mg/day was associated with an increased risk of death from heart disease in men.<sup>51</sup> Supplemental calcium intake at any dose in women, on the other hand, was not found to correlate with increased risk of cardiovascular disease, heart disease, or cerebrovascular death in this trial. Moreover, dietary calcium intake was found to be unrelated to increased risk of cardiovascular death in either men or women, underscoring the importance of dietary calcium intake over supplemental calcium use. Results from a post-hoc analysis of the Women's Health Initiative dataset also identified no increased risks of myocardial infarction, coronary heart disease, total heart disease, stroke, or overall cardiovascular disease in postmenopausal women receiving 1000 mg/day elemental calcium carbonate plus 400 IU/day of vitamin D<sub>3</sub>.<sup>52</sup> Clearly, more information is necessary to further elucidate the correlations between calcium supplementation and cardiovascular disease risk. Patients considering calcium supplementation should undergo a complete dietary and lifestyle evaluation to determine the possible risks and benefits of supplementation with this mineral.

Calcium intake has also been suggested to influence risk of prostate cancer. In fact, three trials have found an increased risk for prostate cancer with calcium intakes greater than 1500 mg daily from either supplements or dietary sources.<sup>49</sup> Recommending calcium intakes closer to the DRI/RDA for those at risk of prostate cancer is reasonable until further evidence clarifies this association.

Practitioners should counsel patients regarding potential constipation associated with calcium supplementation and the importance of adequate hydration, dietary fiber, and physical activity in preventing this side effect.

**Potential Drug-Nutrient Interactions.** See Table 22-8.

## Iron

Iron is widely available in the U.S. diet. Iron absorption from the intestinal tract is controlled by the body's need for iron, the intestinal lumen conditions, the food source of iron, and the other components of the meal (e.g., the meal's vitamin C content).

**Function.** Iron plays an important role in oxygen and electron transport. In the body, it is either functional or stored. Functional iron is found in hemoglobin, myoglobin, heme-containing enzymes, and transferrin, which is the transport form of iron. Stored iron is primarily found in the hemoglobin of red blood cells, which contain 60%-70% of total body iron. The remainder is stored primarily in the forms of ferritin and hemosiderin in the intestinal mucosa, liver, spleen, and bone marrow.

**Dietary Sources.** Dietary iron is available in two forms: heme and nonheme iron. Heme iron is found in meats and is reasonably well absorbed. Nonheme iron (e.g., that found in enriched grains and dark green vegetables) constitutes most of the dietary iron but is poorly absorbed. Therefore, the published values of iron content in foods are misleading because the amount absorbed depends on the nature of the iron. Although specific ways to calculate the iron absorption from a given meal exist, the available iron content of foods is often estimated by assuming that about 10% of the total iron (heme plus nonheme) is absorbed if no iron deficiency exists. In the iron-deficient state, iron absorption improves, so as much as 20% may be absorbed and utilized from an average diet. However, this estimate is not valid in the absence of heme iron. Less iron is absorbed from vegetarian diets.

Ingested nonheme iron (which is mostly in the form of ferric hydroxide) is solubilized in gastric juice to ferric chloride, then reduced to the ferrous form, and finally chelated to substances such as ascorbic acid, sugars, and amino acids. Chelates have a low molecular weight and can be solubilized and absorbed before they reach the alkaline medium of the distal small intestine, where precipitation may occur. When released at the spleen, liver, bone marrow, intestinal mucosa, and other iron storage sites, the iron is combined

with apoferritin to form ferritin or hemosiderin. As needed, ferritin is released into the plasma, where it is oxidized to the ferric state and bound to a beta-globulin to form transferrin. Iron is used in all cells of the body; however, most of it is incorporated into the hemoglobin of red blood cells.

**Deficiency.** The major source of iron loss is through blood loss (e.g., hemorrhagic loss and menstruation). Iron is also lost from the body by the sloughing of skin cells and GI mucosal cells, and by excretion in urine, sweat, and feces. Excess iron loss may result in iron deficiency. Early symptoms of iron deficiency are vague. Although pallor and easy fatigability may be associated with iron deficiency, they can be attributed to other causes and are nonspecific findings. Other signs and symptoms of iron-deficiency anemia include split or "spoon-shaped" nails, sore tongue, angular stomatitis, and dyspnea on exertion. Coldness and numbness of the extremities may also be reported. Hypochromic microcytosis, as evidenced by a decreased mean corpuscular volume and low hemoglobin concentration (decreased mean corpuscular hemoglobin concentration), characterizes iron deficiency on laboratory assessment.

Iron-deficiency anemia is a widespread clinical problem and the most common form of anemia in the United States. Although it causes few deaths, it does contribute to poor health and suboptimal performance. Iron deficiency results from inadequate intake (e.g., inadequate diet or malabsorption) or increased demands (e.g., pregnancy and lactation, growth, blood loss, or treatment with erythropoietic stimulating agents). Because normal iron losses through the urine, feces, and skin are minimal, and because the majority of total body iron is efficiently stored and conserved (recycled), iron deficiency caused by poor diet or malabsorption develops very slowly over the course of several months. Despite fortification of flour and educational efforts regarding proper nutrition, iron deficiency remains a problem, especially during the following four life periods:

- During childhood (younger than 2 years): Children obtain low iron content from cow's milk.
- During adolescence: In addition to blood loss during menses, young women experience rapid growth, which entails an expanding red cell mass and the need for iron in myoglobin.
- During and after pregnancy: Women face the expanding blood volume of pregnancy, the demands of the fetus and placenta, and the blood loss of childbirth.
- During later years: Persons of advanced age (i.e., 65 years or older) often consume inadequate dietary iron, demonstrate compromised absorption caused by achlorhydria, and experience an increased incidence of GI tract blood loss resulting from malignancy, gastric ulceration, or use of nonsteroidal anti-inflammatory drugs. However, the prevalence of elevated iron stores may be significantly greater than the prevalence of iron deficiency in this age group. Therefore, absent a confirmed diagnosis of iron-deficiency anemia, routine supplementation is not recommended for this age group.

Supplemental iron may be warranted for women with heavy or prolonged menstrual blood loss or for individuals who frequently donate blood. Iron may also be indicated during recovery from disease- and injury-associated blood loss (e.g., peptic ulcer disease, esophageal varices, cancer, and traumatic injury such as motor vehicle accidents). In addition, infants being fed human milk may need supplemental iron beginning between the ages of 4-6 months if iron-rich foods are not introduced into the diet. Chronic use of drugs such as salicylates, nonsteroidal anti-inflammatory drugs, corticosteroids, or anticoagulants may cause drug-induced blood loss. This effect may be the result of direct irritation of the gastric mucosa or the increased bleeding tendency these medications cause. Iron supplementation should be used cautiously, if at all, in patients at high risk for GI bleeding.

**Dose/DRI.** The DRI values for iron are listed in Table 22-4. Because of the GI side effects associated with oral iron supplementation, the UL for elemental iron has been set at 45 mg/day for adults.<sup>14</sup> Oral iron supplements are FDA approved for the prevention and treatment of iron-deficiency anemia.<sup>19</sup>

When iron supplementation is appropriate, the practitioner will need to evaluate which iron product is best. The choice should be based on how well the iron preparation is absorbed and tolerated, on the amount of elemental iron per dose, and on its price. Because ferrous salts are absorbed 3 times more efficiently than ferric salts, an iron product of the ferrous group is usually appropriate. Ferrous sulfate is the standard against which other iron salts are compared.

Ferrous sulfate contains 20% elemental iron, or about 65 mg in a 325 mg tablet. In patients with iron deficiency, 20% of the elemental iron (12 mg) may be absorbed. Maximum incorporation of iron into red blood cells and replacement of stores is supported by 36-48 mg of elemental iron daily; thus, the usual therapeutic dose for treating iron deficiency is 2-4 (325 mg) ferrous sulfate tablets daily for 3 months. Inadequate response or worsening symptoms during this time indicate the patient should consult a primary care provider. In cases of severe or chronic iron deficiency, when serious medical conditions have been ruled out, continuous maintenance doses of 3-4 (325 mg) ferrous sulfate tablets daily for 3-6 months should normalize hemoglobin and replace iron stores (in the absence of ongoing bleeding).

Table 22-10 lists comparison data on various iron salts.<sup>53</sup>

Ferrous salts may be given in combination with ascorbic acid to improve iron absorption. The practitioner can encourage the consumption of fruit or juice high in ascorbic acid or a vitamin C supplement to be taken with the iron, if necessary. Combination products with iron and ascorbic acid are also available, but these products can be expensive, and the dose of vitamin C is often inadequate. Chemicals that may decrease iron absorption include phosphates in eggs and milk, carbonates, oxalates, tannins, and phytates in cereals.

**Safety Considerations.** All iron products tend to irritate the GI mucosa and may produce nausea, abdominal pain, constipation, and (less frequently) diarrhea. These adverse effects may be minimized by reducing the dose or by giving iron with meals; however, food may decrease the amount of iron absorbed by as much as 50%. Practitioners may want to recommend that iron be initiated on an empty stomach; they should instruct the patient to change this routine and take the iron with food, if GI side effects occur.

A frequent side effect of iron therapy is constipation. This adverse effect has prompted the formulation of iron products that also contain a stool softener (e.g., docusate). During iron therapy, stools commonly have a black, tarry appearance because of the presence of unabsorbed iron in the feces. Unfortunately, this symptom may also indicate GI blood loss and a serious medical problem. Medical evaluation is indicated if an underlying GI condition is suspected, or if a history of GI disease exists. If the stool does not darken somewhat during iron therapy, however, the iron product may not have disintegrated properly or released the iron.

Iron must be dispensed and stored in a child-resistant container. Accidental poisonings with iron occur most often in children, who are attracted to the sugar-coated, colored tablets or who may accidentally overdose on chewable multivitamins containing iron. Such poisoning is considered a medical emergency, and any accidental ingestion of iron should be referred for evaluation by a medical provider or to a Poison Control Center. The clinical outcome depends on the speed and adequacy of treatment.

Symptoms of acute iron poisoning include abdominal pain, vomiting, diarrhea, electrolyte imbalances, and shock. In later stages, cardiovascular collapse may occur, especially if the cause has not been properly recognized and treated as a medical emergency. Treatment of iron toxicity may begin immediately at home after consultation with a Poison Control Center or local emergency department.

**Potential Drug-Nutrient Interactions.** See Table 22-8.

**TABLE 22-10 Common Nonprescription Oral Iron Formulations**

<i>Iron Formulation</i>	<i>Typical Dose</i>	<i>Percent Elemental Iron</i>	<i>Comparison Data</i>
Ferrous sulfate	325 mg/tablet	20% (65 mg/tablet)	The gold standard for supplementation; available in multiple dosage forms; extensive history of use; proven effective; and economical. Delayed-release and enteric-coated products may improve tolerability, but iron absorption may be reduced.
Ferrous fumarate	60 mg/tablet	33% (20 mg/tablet)	No advantage over ferrous sulfate; however, may be better tolerated for some individuals.
Ferrous gluconate	225 mg/tablet	12% (27 mg/tablet)	No advantage over ferrous sulfate; however, may be better tolerated for some individuals.

Source: Reference 55.

## Magnesium

Magnesium is essential for all living cells. It is the second most plentiful cation of intracellular fluids and the fourth most abundant cation in the body. About 2000 mEq magnesium are present in an average 70 kg adult, with about 50% of this amount in the bone, about 45% as an intracellular cation, and about 1%-5% in the extracellular fluid.

**Function.** Magnesium is required for normal bone structure formation and the proper function of more than 300 enzymes, including those involved with adenosine triphosphatase (ATP)-dependent phosphorylation, protein synthesis, and carbohydrate metabolism. Extracellular magnesium is critical to both the maintenance of nerve and muscle electrical potentials and the transmission of impulses across neuromuscular junctions.

Magnesium tends to mimic calcium in its effects on the CNS and skeletal muscle. Magnesium deficiency blunts the normal response of the parathyroid glands to hypocalcemia. Therefore, tetany, caused by a lack of calcium, cannot be corrected with calcium unless hypomagnesemia is also corrected. Similarly, magnesium deficiency impairs the transport of potassium into cells; therefore, hypokalemia cannot be corrected in the presence of magnesium deficiency.

**Dietary Sources.** Individuals who consume fresh foods regularly should not develop magnesium deficiency because all unprocessed foods contain magnesium (albeit in widely varying amounts). Food sources highest in magnesium are listed in Table 22-6. Processing (during which the germ and outer layers of cereal grains are removed) results in significant loss of available magnesium.

**Deficiency.** Deficiency states are usually caused by GI or renal losses. Examples include malabsorptive syndromes, acute or chronic diarrhea, steatorrhea, and drug-induced magnesium wasting in the urine, as seen with alcohol abuse, diuretic therapy, long-term use of proton pump inhibitors, and nephrotoxins (e.g., amphotericin B). Symptoms of magnesium deficiency may include neuromuscular irritability, increased CNS stimulation, delirium, and convulsions.

**Dose/DRI.** The DRI values for magnesium are listed in Table 22-4. Oral magnesium supplements are FDA approved for use in the treatment and prevention of

hypomagnesemia.<sup>19</sup> The recommended UL for magnesium is 350 mg/day for older children and adults.<sup>14</sup>

**Safety Considerations.** No evidence is available to suggest that oral intake of magnesium is harmful to individuals with normal renal function, although diarrhea may occur with large doses. Hypermagnesemia can occur with overzealous use of magnesium sulfate (Epsom salts) or magnesium hydroxide (milk of magnesia) as a laxative, or with use of magnesium-containing antacids in patients with severe renal failure. Hypermagnesemia may cause diminished deep tendon reflexes and varying degrees of muscle weakness, lethargy, and sedation. These effects may progress to stupor and coma, especially at high serum concentrations. Cardiovascular symptoms may include hypotension and dysrhythmia.

**Potential Drug-Nutrient Interactions.** See [Table 22-8](#).

#### Phosphorus

Phosphorus is present throughout the body, but approximately 85% of the body's store is located in bone.

**Function.** Phosphorus is essential for many metabolic processes. It serves as an integral structural component of the bone matrix as calcium phosphate, and it is a functional component of phospholipids, carbohydrates, nucleoproteins, and high-energy nucleotides. Plasma phosphate levels are under the tight biologic control of parathyroid hormone, calcitonin, and vitamin D. DNA and RNA structures contain sugar-phosphate linkages. Cell membranes contain phospholipids, which regulate the transport of solutes into and out of the cell. Many metabolic processes depend on phosphorylation. The adenosine diphosphate (ADP)-ATP system (which provides a mechanism for the storage and release of energy for use in all of the body's metabolic processes) involves phosphorus compounds. Additionally, an important buffer system of the body consists of inorganic phosphates.

Calcium and phosphorus have a reciprocal relationship. Both minerals are regulated partially by parathyroid hormone. Secretion of parathyroid hormone stimulates an increase in serum calcium levels through increased bone resorption, gut absorption, and reabsorption in renal tubules. Parathyroid hormone also causes a decrease in the reabsorption of phosphate by the kidney. Therefore, when serum calcium is high, serum phosphate is generally low, and vice versa.

**Dietary Sources.** Phosphorus is present in nearly all foods, especially protein-rich foods and cereal grains ([Table 22-6](#)).

**Deficiency.** Because nearly all foods contain phosphorus, deficiency states usually do not occur unless induced. For example, patients receiving aluminum hydroxide as an antacid for prolonged periods may exhibit hypophosphatemia, characterized by weakness, anorexia, malaise, pain, and bone loss. Aluminum binds dietary phosphorus, forming insoluble and poorly absorbed complexes.

**Dose/DRI.** The DRI values for phosphorus are listed in [Table 22-4](#). The FDA-approved use for phosphorus is to alleviate signs and symptoms of deficiency. The recommended UL for phosphorus is 4 grams/day for older children and most adults.<sup>14</sup>

**Safety Considerations.** GI side effects (e.g., diarrhea and stomach pain) have been reported with oral supplementation of phosphate salts.

**Potential Drug-Nutrient Interactions.** See [Table 22-8](#).

#### Trace Elements

Trace elements, which are present in minute quantities in plant and animal tissue, are considered essential for numerous physiologic processes. Zinc and manganese are trace elements. "Ultratrace" minerals have been defined as those elements with an estimated dietary requirement of less than 1 mg/day. The essential ultratrace minerals include arsenic, boron, cobalt, copper, chromium, iodine, molybdenum, nickel, selenium, and silicon. Lithium and vanadium possibly are essential minerals, but further study is required. Bromine, cadmium, fluorine, lead, and tin are not considered essential.

#### Chromium

Approximately 5 mg chromium is present in the normal adult, and levels are known to decline with age.

**Function.** Chromium is a component of glucose tolerance factor. This dietary organic chromium complex potentiates the activity of insulin.

Chromium combines with picolinic acid (a metabolite of tryptophan) to form chromium picolinate (a form of chromium with enhanced bioavailability). Chromium picolinate in doses of 200 mcg/day, has been promoted for the general population as an aid in controlling diabetes, lowering cholesterol, producing weight loss, and increasing muscle mass. However, reliable data are insufficient to support any therapeutic value of chromium supplementation in the absence of a diagnosed deficiency.

**Dietary Sources.** See [Table 22-6](#).

**Deficiency.** Deficiency of trivalent chromium (the chemical form present in the diet) is manifested by glucose intolerance, elevated circulating insulin, glycosuria, fasting hyperglycemia, elevated serum cholesterol and triglycerides, neuropathy, and encephalopathy.

**Dose/DRI.** Chromium intake in the United States is low (about 50 mcg/day) compared with that of other countries. The estimated DRI values for chromium are listed in [Table 22-4](#). Oral administration of trivalent chromium has a relatively high margin of safety, and no UL for chromium has been set.<sup>14</sup>

**Safety Considerations.** Oral chromium has not been reported to be toxic. However, the hexavalent forms of chromium can be toxic and carcinogenic. These forms are encountered through industrial exposure and may enter the body through inhalation or cutaneous absorption.

**Potential Drug-Nutrient Interactions.** Drug interactions have not been reported for chromium.

#### Cobalt

Cobalt is an essential component of vitamin B<sub>12</sub>.

**Function.** Cobalt's nutritional functions are the same as those for cyanocobalamin and are discussed in the section (see Cyanocobalamin [Vitamin B<sub>12</sub>]).

**Dietary Sources.** Cobalt is an integral part of vitamin B<sub>12</sub>; therefore, the normal dietary sources of cobalt are the same as for vitamin B<sub>12</sub> ([Table 22-6](#)).

**Deficiency.** No deficiency state for cobalt is reported to exist in humans.

**Dose/DRI.** No DRI values exist for cobalt.

**Safety Considerations.** Large doses of cobalt may result in goiter, congestive heart failure, and myxedema. Cardiomyopathy has also been described. Cyanosis and coma may result from accidental ingestion by children.

**Potential Drug-Nutrient Interactions.** No interactions have been reported with cobalt.

#### Copper

Copper ions exist in two states: the cuprous ion and the cupric ion (a potent oxidizing agent). Copper is similar to zinc in the complexes it forms with a number of the same chelating agents. Copper is found in virtually all tissues of the body, but concentrations are highest in the liver, brain, heart, and kidney.

**Function.** Copper is essential for the proper structure and function of the CNS, and it plays a major role in iron metabolism. Ceruloplasmin, one of the copper metalloenzymes, is especially important in converting absorbed ferrous iron to transported ferric iron. Other copper-containing enzymes are cytochrome oxidase, dopamine beta-hydroxylase, and superoxide dismutase.

**Dietary Sources.** See [Table 22-6](#).

**Deficiency.** Copper deficiency is uncommon in humans, with a few notable exceptions. Deficiencies have been observed in premature infants; in severely malnourished infants that are fed milk-based, low-copper diets; following Roux-En-Y gastric bypass in individuals who do not consume a supplement; and in patients receiving parenteral nutrition with inadequate copper.

One of the prominent features of copper deficiency is impaired iron absorption, which results in hypochromic anemia. Spontaneous rupture of major vessels may also be observed in deficiency states.

**Dose/DRI.** The DRI values for copper are listed in [Table 22-4](#). For protection against possible hepatotoxicity, the recommended UL for copper is 10 mg/day for adults.<sup>14</sup>

**Safety Considerations.** Copper sulfate doses in excess of 250 mg produce vomiting.

Wilson's disease is an inborn error of metabolism resulting in copper retention. These individuals must avoid any copper supplementation. Wilson's disease results in CNS, kidney, and liver damage. Acute symptoms of copper toxicity include nausea, vomiting, diarrhea, hemolysis, convulsions, and GI bleeding. Symptoms respond to treatment with penicillamine.

Supplementation should be avoided in patients with severe hepatic dysfunction or cholestasis, as biliary clearance of copper may be compromised.

**Potential Drug-Nutrient Interactions.** See [Table 22-8](#).

#### Fluoride

Available therapeutic forms of fluoride include sodium fluoride, acidulated phosphate fluoride, and stannous fluoride. Sodium fluoride contains about 45% fluoride ion, whereas stannous fluoride contains about 24% fluoride ion.

**Function.** Fluoride occurs normally in bones and tooth enamel as a calcium salt. Intake of small amounts has been shown to reduce tooth decay markedly, presumably by making the enamel more resistant to the erosive action of acids produced by bacteria in the oral cavity.

**Dietary Sources.** Fluoride is present in soil and water, but the content varies widely from region to region. Most municipal water supplies are fluoridated to 1 ppm of fluoride, a level that has been shown to be safe and to reduce dental caries in children by nearly 50%. Estimates of fluoride intake from food, beverages, and water vary greatly, depending on the presence of fluoridated drinking water.

**Deficiency.** Fluoride deficiency states in humans, other than potential dental decay, have not been described.

**Dose/DRI.** The DRI values for fluoride are listed in [Table 22-4](#). The recommended UL for this trace element is 10 mg/day for older children and adults.<sup>14</sup>

Fluoride is FDA approved for use in the prevention of dental caries.<sup>19</sup> Fluoride is a normal constituent of the diet, given that it occurs in soils, water supplies, plants, and animals. All sources of fluoride should be evaluated before supplementation is recommended for children whose home water supply is low in fluoride. Children may obtain fluoride from other water sources (e.g., day care or school) or from other beverages (e.g., soft drinks, juices, and bottled water that may contain varying amounts of fluoride).<sup>54</sup>

Sodium fluoride is available by prescription as oral tablets and solutions, topical solutions, and gels, as well as in combination products. Nonprescription topical rinses containing fluoride 0.01%-0.02% (e.g., sodium fluoride) and gels containing 0.4% stannous fluoride (e.g., Gel-Kam) are rinsed or brushed onto the teeth to reduce sensitivity and prevent dental cavities.

**Safety Considerations.** Excessive fluoride can be toxic. Acute toxicity should not result from the low levels present in drinking water but may result from the administration of excessive doses of fluoride supplements. Because acute toxicity affects the GI system and the CNS, it can be life threatening. Symptoms include salivation, GI distress, muscle weakness, tremors, and (rarely) seizures. Because fluoride binds calcium, symptoms of calcium deficiency (including tetany) may also be seen. Eventually, respiratory and cardiac failure may occur. All accidental ingestions of fluoride in children should be referred for evaluation by a medical practitioner or Poison Control Center, as fluoride intoxication may be fatal. Treatment includes precipitation of the fluoride by using gastric lavage with calcium hydroxide 0.15% solution, intravenous administration of dextrose and saline for hydration, and treatment with calcium to prevent tetany.

Chronic fluoride toxicity is manifested as changes in the structure of bones and teeth. Tooth enamel, if still under development, acquires a mottled appearance consisting of white, patchy plaques occurring with pitting brown stains. Prolonged ingestion of water that contains more than 2 ppm of fluoride has resulted in a significant incidence of mottling. Extremely large doses (e.g., 20-80 mg/day) have resulted in chalky, brittle bones that tend to fracture easily, a condition known as crippling skeletal fluorosis.

**Potential Drug-Nutrient Interactions.** See [Table 22-8](#).

#### Iodine

The thyroid gland contains about one-third of the iodine in the body, stored in the form of a complex glycoprotein, thyroglobulin. The only known function of thyroglobulin is to provide thyroxine and triiodothyronine, which are hormones that regulate the metabolic rate of cells, thereby influencing physical and mental growth, nervous and muscle tissue function, circulatory activity, and nutrient utilization.

**Function.** Iodine is an essential micronutrient required to synthesize thyroxine and triiodothyronine. High concentrations of iodine inhibit the release of these hormones.

**Dietary Sources.** The primary dietary source of iodine is iodized salt, which contains 1 part of sodium or potassium iodide per 10,000 parts (0.01%) of salt. A dose of about 95 mcg of iodine can be obtained from about one-fourth teaspoon of salt (1.25 grams). In the United States, most of the table salt sold is iodized; however, salt used in food processing and for institutional use is not. Additional dietary sources of iodine include saltwater fish and shellfish. Produce may also be a source of iodine; the iodine content of produce reflects that of the soil in which it was grown.

**Deficiency.** A moderate iodine deficiency can lead to thyroid hypertrophy, resulting in goiter; severe deficiency results in hypothyroidism. The consumption of foods from diverse locations and the addition of iodide to table salt have essentially eliminated goiter as a health problem in the United States.

**Dose/DRI.** Because of the fortification of salt, the iodine content of typical diets in the United States is still well above the DRI values for adults ([Table 22-4](#)). Iodine supplements are unwarranted for most individuals. Potassium iodide is available as a tablet, syrup, and solution, and it is included in various combination products.

**Safety Considerations.** Some individuals are allergic to iodine or organic preparations containing iodine and may develop a rash. Symptoms of chronic iodism (iodine intoxication) may include an unpleasant taste and burning in the mouth or throat, along with soreness of the teeth or gums. Increased salivation, sneezing, eye irritation, and eyelid swelling can occur. In addition, prolonged use of iodine supplementation can result in hypothyroidism.<sup>18</sup> A UL of 1.1 mg/day in adults has been recommended.<sup>14</sup>

**Potential Drug-Nutrient Interactions.** See [Table 22-8](#).

#### Manganese

The body concentrates its stores of manganese in the liver, pancreas, kidney, muscle, and bone.

**Function.** Manganese is required for the utilization of glucose; the synthesis of mucopolysaccharides of cartilage; the biosynthesis of steroids, cholesterol, and fatty acids; and the biological activity of pyruvate carboxylase.

**Dietary Sources.** Manganese is widely available in foods; primary dietary sources are listed in [Table 22-6](#).

**Deficiency.** Manganese deficiency is extremely rare, and the only theorized method of manganese deficiency is insufficient dietary intake.

**Dose/DRI.** Manganese is poorly absorbed after oral administration; however, sufficient quantities are present in the average diet to maintain appropriate levels. A supplemental dose or dietary intake of 2 to 5 mg/day is considered safe and adequate. The estimated RDAs for manganese are listed in [Table 22-4](#). The recommended UL of 11 mg/day in adults is based on data that showed no adverse effects with long-term consumption at this level.<sup>14</sup>

**Safety Considerations.** Toxicity is rare for orally administered manganese. Toxicity has been observed, however, from inhalation of dust and industrial fumes containing manganese. Intravenous administration has resulted in toxicity from accumulation of manganese in the brain. Because of the reduced biliary clearance of manganese in patients with severe liver dysfunction or cholestasis, supplementation should be avoided under those conditions.

**Potential Drug-Nutrient Interactions.** Drug-manganese interactions have not been reported.

#### Molybdenum

Molybdenum is an ultratrace mineral that only rarely has been associated with deficiency. Practitioners monitoring patients on long-term parenteral nutrition must be aware of the potential for deficiency in this population.

**Function.** Molybdenum readily changes its oxidation state and acts as an electron transfer agent in oxidation-reduction reactions. It may also function as an enzyme cofactor and is involved in the metabolism of sulfur and purines.

**Dietary Sources.** The molybdenum content of food varies depending on its growth environment and/or food source. Dietary sources of molybdenum are listed in [Table 22-6](#).

**Deficiency.** Molybdenum is a cofactor for several flavoprotein enzymes and is found in xanthine oxidase. Because xanthine oxidase is involved in the oxidation of xanthine to uric acid, high molybdenum intake has been associated with gout-like symptoms. Symptoms of molybdenum deficiency may include tachycardia, tachypnea, headache, lethargy, and disorientation. Congenital deficiency of specific molybdenum cofactors results in severe neurologic dysfunction and mental retardation.

**Dose/DRI/Safety Considerations.** The human molybdenum requirement is low and is easily furnished by the average diet ([Table 22-4](#)). Supplements are rarely warranted. On the basis of animal studies showing impaired reproduction and growth with prolonged intake of excessive molybdenum, a UL of 2 mg/day in adults is recommended.<sup>14</sup>

**Potential Drug-Nutrient Interactions.** No significant drug interactions have been reported with molybdenum.

#### Selenium

Selenium is present in all tissues and is generally incorporated into organic compounds involving amino acids (e.g., methionine or cysteine). Selenium compounds are about 80% absorbed. The highest concentrations are in the kidneys and liver; the lowest are in the lungs and brain. The kidney is the primary route of excretion, although losses can also occur through the GI tract.

**Function.** Selenium is an antioxidant that serves as part of glutathione peroxidase. This enzyme protects cells from the peroxidase-induced oxidative damage that occurs with cellular metabolism. The antioxidant properties of selenium have prompted evaluation for its use in cancer prevention. Numerous animal and in vitro studies indicate selenium may have anticarcinogenic effects, although human studies to-date indicate mixed results and inconsistent findings as to which individuals may benefit from selenium supplementation.<sup>55</sup>

Additional trials evaluating the role of selenium in cancer risk reduction are warranted.

**Dietary Sources.** See [Table 22-6](#). The selenium content of food depends on the soil in which the plants are grown.

**Deficiency.** Selenium is an essential trace element in humans, but deficiencies are not common in the general population. Selenium deficiency has been reported in patients with alcoholic cirrhosis, likely resulting from dietary insufficiency or altered selenium metabolism. Deficiency has been rarely reported in patients on long-term parenteral nutrition. Limited evidence in humans suggests that deficiency results in cardiomyopathy, musculoskeletal pain, bleaching of the hair and skin, and abnormal nail beds. Epidemiologic studies suggest that cancer and heart disease may be common in areas of low selenium availability. Keshan disease (a cardiomyopathy that occurs almost exclusively in children) has been shown to respond to selenium.

**Dose/DRI.** The DRI values for selenium are listed in [Table 22-4](#). The UL for this mineral in adolescents and adults is 400 mcg/day.<sup>14</sup>

**Safety Considerations.** Toxic effects of selenium may include loss of hair and nails, skin lesions, muscular weakness, fatigue, and CNS abnormalities.

**Potential Drug-Nutrient Interactions.** No significant drug interactions with selenium have been reported.

#### Zinc

Zinc is an integral part of at least 70 metalloenzymes, including carbonic anhydrase, lactic dehydrogenase, alkaline phosphatase, carboxypeptidase, aminopeptidase, and alcohol dehydrogenase.

**Function.** Zinc is a cofactor in the synthesis of DNA and RNA. It is involved in the mobilization of vitamin A from the liver and in the enhancement of follicle-stimulating hormone and luteinizing hormone. Zinc is essential for normal cellular immune functions, as well as for spermatogenesis and normal testicular function. It is also important in the stabilization of membrane structure.

The divalent ion is most commonly found and used in the body. Zinc has a relatively rapid turnover rate. The balance between zinc absorption from the small intestine and excretion through the feces is efficiently regulated by the body. Vegetarians may require higher amounts of zinc because diets high in fiber and phytates hinder zinc absorption.

**Dietary Sources.** Most dietary zinc (about 70%) is derived from animal products ([Table 22-6](#)).

**Deficiency.** Zinc deficiency is not widespread in the United States. Marginally low zinc values have been associated with birth defects, growth retardation in children, and slow wound healing in adults. Additional symptoms include immunologic abnormalities, impaired taste and smell, delayed sexual maturation, hypogonadism, hypospermia, and dermatitis.

Malabsorptive syndromes, infection, major surgery, alcoholism, pregnancy, lactation, and high-fiber diets rich in phytates predispose individuals to zinc deficiency. Zinc depletion is relatively rare but may be seen in patients on long-term parenteral nutrition and in patients with GI tract abnormalities (e.g., fistulas and prolonged, severe diarrhea). Zinc deficiencies adversely affect DNA, RNA, carbohydrate, and protein catabolism. Iron supplements decrease zinc absorption just as zinc supplements decrease iron absorption, likely resulting from competition for the same transport system. If these minerals are taken with a meal, the adverse interaction is less pronounced. In patients with

impaired wound healing, zinc supplementation may be marginally beneficial.

**Dose/DRI.** The DRI values for zinc are listed in [Table 22-4](#). Typical Western diets supply 10-15 mg of zinc per day. Because only 10%-40% of zinc is absorbed from the GI tract, ingestion of zinc sulfate 220 mg (50 mg of elemental zinc) will supply 5-20 mg of zinc. Treatment of suspected deficiencies usually involves short-term administration of elemental zinc. Patients with large GI losses through fistulas, ostomies, or stool require larger supplemental doses of zinc. At doses above 40 mg elemental zinc per day, copper deficiency may be induced. On the basis of this interaction, the UL for elemental zinc is 40 mg daily in adults if therapy with zinc is going to be long term.<sup>14</sup> Absorption of zinc supplements may be reduced if taken with foods high in calcium or phosphorus.

Zinc has been evaluated in numerous studies as a potential treatment for the common cold. However, zinc formulations and doses have varied, and trial results have been conflicting. Insufficient evidence exists at this time to recommend zinc supplementation for the treatment or prevention of the common cold.<sup>56</sup>

**Safety Considerations.** Because ingestion of 2 grams or more of zinc sulfate has resulted in GI irritation and vomiting, zinc should be taken with food. Zinc is also toxic; however, the emetic effect that occurs after consumption of large amounts may minimize problems with accidental overdose. Reported signs of zinc toxicity in humans include vomiting, dehydration, poor muscle coordination, dizziness, and abdominal pain.

**Potential Drug-Nutrient Interactions.** See [Table 22-8](#).

#### Multivitamin and Multimineral Supplements

Multivitamin and multimineral supplements, as previously described, are not intended to supplant a healthy, balanced diet but rather to augment dietary sources and support general health. Specific nutrients of concern for inadequate intake specified by the *2010 Dietary Guidelines for Americans* include dietary calcium, vitamin D, and potassium.<sup>13</sup> However, multivitamin and multimineral supplements do not target these or any specific nutrients, but rather provide a broad range of micronutrients. When such a product is being evaluated for an individual, the practitioner should consider recommending a preparation that contains the basic and essential vitamins and minerals, including the following: vitamins C, B<sub>1</sub> (thiamin), B<sub>2</sub> (riboflavin), B<sub>3</sub> (niacin), B<sub>6</sub> (pyridoxine), B<sub>9</sub> (folic acid), B<sub>5</sub> (pantothenic acid), A, E, D<sub>2</sub> or D<sub>3</sub> (cholecalciferol), and K, as well as biotin, potassium, iodine, selenium, borate, zinc, calcium, magnesium, manganese, molybdenum, and beta carotene. The multitude of different multivitamin products available over-the-counter warrant further consideration of an individual's age and sex to assure selection of a formulation that is most likely to meet individual nutritional needs. Most multivitamins formulated for women ages 18-50 years contain increased amounts of iron and folic acid to prevent anemia related to menstrual blood loss and neural tube defects in those of child-bearing age. Multivitamins formulated for men younger than 50 generally contain higher amounts of certain vitamins and less iron. Finally, senior multivitamins formulated for individuals older than age 50 may contain more calcium and certain B vitamins (like B<sub>6</sub> and B<sub>12</sub>) but do not contain iron. Individuals should be reminded to refer to the product labeling for directions for use and not to exceed the recommended intake.

#### Assessment of Nutritional Adequacy: A Case-Based Approach

Assessing an individual's nutritional status is difficult in the ambulatory environment. Clinical impressions are often erroneous, given that the stages between well-nourished and poorly nourished states are not readily evident. However, guidelines may help provide a more objective assessment of an individual's nutritional status. Practitioners should exercise good observational skills, know which questions yield helpful information (see cases for examples of questions), and know which population groups tend to be at risk for particular deficiencies. By asking key questions, the practitioner may detect cultural, physical, environmental, and social conditions that suggest inadequate vitamin intake. The more specific the information obtained from the individual, the more helpful the practitioner can be in determining the need for nutritional supplementation. Questions about the absence of food-types in the diet and about previous treatment of similar symptoms may also be important.

Although most nutritional assessment measures are beyond the scope of routine pharmacy practice, the pharmacist can observe the physical status of the patient. For example, an individual's fingernails may indicate malnutrition if the nails are not lustrous and are dark at the upper ends. The texture, amount, and appearance of hair may indicate the patient's nutritional status. The eyes (particularly the conjunctiva) may indicate vitamin A and iron deficiencies. The mouth may show stomatitis, glossitis, or hypertrophic or pale gums. Poor dentition may limit the foods that an individual is able to eat, thereby compromising intake from certain food groups, such as protein. Visible goiter, poor skin color and texture, obesity or thinness relative to bone structure, and the presence of edema may also indicate malnutrition. The pharmacist should be able to recognize overt but nonspecific symptoms of vitamin and mineral deficiencies for which prompt referral to a primary care provider may be crucial. Additionally, pharmacists should refer individuals at risk for nutritional deficiency or with increased metabolic demands (e.g., the elderly, chronic alcohol abusers, and pregnant and lactating women) for appropriate medical evaluation as necessary.

Checking a patient's medication history is important because of the number of potential drug-micronutrient interactions ([Table 22-8](#)). Practitioners are also responsible for referring patients with a suspected serious illness to a primary care provider. Just as nutritional deficiencies may lead to disease, disease may lead to nutritional deficiencies. Patients may present with one or more deficiencies, which may be very difficult to identify. Rarely in the United States do practitioners encounter patients with severe deficiencies resulting in diseases such as scurvy, pellagra, or beriberi. However, milder forms of malnutrition may be seen.

Cases 22-1 and 22-2 are examples of the assessment of patients with nutritional inadequacy.

#### Patient Counseling for Nutrient Supplementation

The public is often exposed to exaggerated and fraudulent claims concerning vitamin products. The practitioner should keep up with medical and pharmaceutical literature and should not support or appear to support claims until they are substantiated by reliable clinical studies. Patients inquiring about such claims should be educated regarding increased potential risk with nontraditional use of vitamins.

Patients purchasing a nonprescription liquid dietary supplement should be instructed on its proper use and storage, including dilution and preparation techniques. In addition, the practitioner should counsel the patient on possible adverse effects (e.g., diarrhea or constipation).

The box Patient Education for Nutritional Deficiencies lists specific information to provide patients. The practitioner could also refer the consumer to Web sites and printed literature with evidence-based recommendations for vitamin and mineral supplementation, such as those listed in the reference section of this chapter.

#### Case 22-1

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient inquires about information found in a magazine that touted supplementation with various vitamins to help prevent cancer. He indicates that he currently takes Centrum Silver each day along with his other prescription medications.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	NA
c. description of the patient's efforts to relieve the symptoms	NA
d. patient's identity	Patrick McLaughlin
e. age, sex, height, and weight	68 years old, male, 6 ft 3 in., 190 lb
f. patient's occupation	Retired school teacher; widowed

g. patient's dietary habits	Eats alone: typically cereal, milk, and juice or fruit for breakfast; soup or sandwich for lunch; easy meals for dinner (e.g., frozen dinners with protein, starch, vegetable).
h. patient's sleep habits	NA
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Patient has a history of heartburn, high cholesterol, and high blood pressure. Every morning he takes pantoprazole 40 mg; the combination hydrochlorothiazide/lisinopril 12.5/20 mg; 2 omega-3 fish oil capsules; and 1 Centrum Silver multivitamin. After dinner, he takes atorvastatin 40 mg. When he has a migraine, he takes acetaminophen 1000 mg plus aspirin 650 mg. <sup>a</sup>
j. allergies	Sulfa
k. history of other adverse reactions to medications	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	The patient's age and dietary habits may warrant consideration of a multivitamin supplement. Evidence from a recent large-scale study indicated men taking a daily senior multivitamin experienced a reduction in cancer risk; however, cancer is a multifactorial disease. No evidence to date supports the use of multivitamins to completely negate cancer risk. <sup>57</sup>
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Assess the client's perceived need for the nutrient supplements. (2) Evaluate dietary intake from food groups, encouraging at least 5 servings of produce, 3 servings of low-fat dairy products, 2 servings of protein, and 6 servings of whole-grain food sources daily. (3) Discuss which nutrients may need supplementation on the basis of the patient's patterns of dietary intake, age, and special requirements. Evaluate Centrum Silver for adequacy, while avoiding intakes above the UL. (4) Discuss the lack of data and potential harm associated with mega doses of vitamins. (5) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Regular intake of a well-balanced diet that includes fruit, vegetables, whole grains, and low fat dairy and lean protein sources is recommended for patients with high blood pressure. A multivitamin and mineral supplement that includes vitamin B <sub>12</sub> and a balance of other nutrients would be reasonable for this elderly patient who needs simple, easy meals and is on chronic acid suppression therapy. He should also be evaluated for adequate calcium and vitamin D intake.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"A nutrient-rich diet, as described, has been shown to be beneficial in the prevention of many diseases, including hypertension and cancer. This could be done by adding a fruit or vegetable to your mid-day meal or as a snack. Choose whole grain breads and cereals. Look for healthy frozen meals and soups as opposed to those with much hidden fat and salt. It would be reasonable to continue your daily multivitamin supplement to ensure you are meeting daily nutritional needs. If you are not regularly consuming dairy products, calcium and vitamin D supplementation is recommended. Check your intake from supplemented products, such as some orange juice brands, and the multivitamin as well."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"There is no evidence that vitamin supplements, in the absence of deficiency, can completely reduce cancer risk. In the recent study alluded to, the effect of the multivitamin on cancer risk reduction was observed only in those men without a family history of cancer; men having a family history of cancer did not experience the same benefit. Furthermore, authors found no difference on the incidence of a specific type of cancer or on the incidence of cancer-related mortality between the treatment and placebo groups. <sup>57</sup> When selecting a multivitamin, be sure to compare the level of supplementation of each nutrient, including calcium and vitamin D, compared with the DRI. Additional supplementation in excess of the DRI is often unnecessary unless specifically recommended by your doctor."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	"Consider one USP-approved senior multivitamin daily that contains no more than 100% of DRI for nutrients."
b. maximum number of days the therapy should be employed	NA
c. product administration procedures	"You may take your multivitamin with your current medications in the morning. However, check with your pharmacist about taking your vitamin with any newly prescribed medications."
Solicit follow-up questions from the patient or caregiver.	"What about antioxidant vitamins? Do they prevent cancer?"
Answer the patient's or	"Data from well-designed trials do not support antioxidant supplementation for the prevention or treatment of cancer. In fact, some trials

caregiver's questions.	have suggested potential harm is associated with supplementation of vitamins A, E, and C, selenium, and other nutrients in relation to cancer risk. Therefore, dosing of these nutrients above the DRI cannot be recommended at this time."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome	Enquire about patient's compliance with multivitamin recommendations and dietary modification. If necessary, reinforce the recommendations.

Key: DRI = Dietary reference intake; NA = not applicable; UL = upper intake level; USP = United States Pharmacopeia.

<sup>a</sup> See [Chapter 5](#), Acetaminophen and [Table 5-3](#), for information on the manufacturer's voluntary reduction of maximum daily dosages of Tylenol products sold in the United States.

### Case 22-2

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient's daughter approaches the pharmacy counter seeking a recommendation. She reports her elderly mother recently fell at home; she believes that if her mother falls again, her mother may fracture her hip. She wants her mother to start a calcium and vitamin D supplement after reading that such supplements can reduce fracture risk.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	NA
c. description of the patient's efforts to relieve the symptoms	NA
d. patient's identity	Elizabeth Small
e. age, sex, height, and weight	84 years old, female, 5 ft 4 in., 110 lb
f. patient's occupation	Homemaker; grandmother
g. patient's dietary habits	Eggs, juice, and tea with milk for breakfast; soup or a sandwich for lunch; easy-to-prepare microwavable meals for dinner
h. patient's sleep habits	NA
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Suffers from high blood pressure, gastroesophageal reflux disease, insomnia, and depression. Each morning, Mrs. Small takes enalapril 2.5 mg and omeprazole 40 mg. At bedtime, she takes mirtazapine 30 mg and zolpidem 5 mg as needed.
j. allergies	NKA
k. other (describe)	Family history of glaucoma and osteoporosis
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	According to recent warnings, use of chronic acid suppressive medications can reduce dietary calcium intake and potentially increase fracture risk. Furthermore, given Mrs. Small's history of a fall and family history of osteoporosis, she may warrant further medical evaluation.
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Focus on potential drug-nutrient interactions in counseling her daughter about need for calcium supplementation. (2) Discuss the role of balanced nutrition as the ideal route of taking vitamins and minerals. Identify nutritional needs unique to this client and where supplementation may be recommended. (3) Refer Mrs. Small for medical evaluation and osteoporosis screening. Given her age, body habitus, and family history of osteoporosis, coupled with her recent history of non-traumatic fall and chronic use of acid suppressive therapy, she may be at an increased risk of osteoporosis and bone fracture. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Assess the client's perceived need for the nutrient supplements. Evaluate dietary intake from food groups, encouraging at least 5 servings of produce, 3 servings of low-fat dairy products, 2 servings of protein, and 6 servings of whole-grain food sources daily.

6. Describe the recommended therapeutic approach to the patient or caregiver.	Discuss the vitamin and mineral content of the various supplements and the total intake in comparison with the DRIs. "For a woman of your mother's age, a daily calcium and vitamin D intake of 1200 mg and 800 IU, respectively, is indicated. Speak with a health care provider about your mother's potential risk for osteoporosis and fracture."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Calcium and vitamin D supplementation alone may not be sufficient intervention to reduce your mother's risk of fracture from a fall if she has underlying osteoporosis. Further, her need for chronic acid suppressive therapy may further increase this risk and complicate her management. Calcium absorption from both dietary and supplement forms may be affected by stomach acid production; suppression of acid with medications like omeprazole may result in impaired calcium absorption. Alternate forms of calcium are available for supplementation; however, asking your mother's PCP whether continued use of acid suppressive therapy is also warranted."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome	Enquire about the patient's compliance with multivitamin recommendations and dietary modifications. If necessary, reinforce the recommendations

Key: DRI = Dietary reference intake; NA = not applicable; NKA = no known allergies; PCP = primary care provider; UL = upper intake level; USP = United States Pharmacopeia.

#### Patient Education for Nutritional Deficiencies

The objective of self-treatment is to prevent nutritional deficiencies or maintain present nutritional status. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Vitamins, Minerals, and Trace Elements

- To ensure proper nutrition, eat a varied diet as recommended in *MyPlate* (Figure 22-1). Vitamin supplements are not a substitute for a well-balanced diet.
- Read labels on all vitamin and mineral preparations carefully before taking them. Note the quantity of vitamins and minerals required to meet the DRI, or dietary reference intake, values.
- Do not take doses of vitamins and minerals higher than the recommended DRIs. High doses of vitamins or minerals may be dangerous and should not be taken indiscriminately.
- Take vitamin and mineral supplements with meals if you experience gastrointestinal symptoms.
- Women of childbearing age should take 400 mcg of supplemental folic acid in addition to a well-balanced diet. This has been shown to reduce the risk of neural tube defects in the fetus.
- Be aware that iron supplements or vitamins with iron may turn the stool black. This occurrence is not a cause for alarm, unless it is associated with other symptoms consistent with a gastrointestinal bleed.
- As with any medicine, store vitamin and combination vitamin/mineral supplements out of the reach of children, especially if the product contains iron. Teach children that vitamins are drugs and potential poisons and therefore cannot be taken indiscriminately.
- Be aware that therapeutic use of niacin-containing products (but not niacinamide) may cause a flushing, itching, or tingling sensation, which should decrease in intensity with continued therapy. Taking an aspirin or nonsteroidal anti-inflammatory agent 30-60 minutes before taking niacin may help decrease these effects.
- Do not self-medicate if you suspect a vitamin deficiency; consult a health care practitioner instead.

#### Evaluation of Patient Outcomes for Nutritional Adequacy

Nutritional therapy should involve a diet that is based on *MyPlate* and possibly the use of nutritional supplements. The practitioner should advise patients to return 30 days after implementing nutritional therapy (or sooner, if symptoms worsen). Patients whose symptoms have worsened should be referred to a primary care provider. Patients whose symptoms have improved while taking nutritional supplements should be encouraged to eat a healthful diet and not to rely on supplements as the primary source for vitamins and minerals.

#### Key Points for Nutritional Adequacy

- The benefits of a varied, balanced diet in terms of health maintenance and disease prevention have been demonstrated repeatedly. However, the same benefits have not been observed when suboptimal dietary intake is augmented with vitamin and mineral supplementation.
- Practitioners can assess the variety of a patient's food choices by comparing the patient's typical food pattern to that recommended in *MyPlate*. The practitioner may refer patients to a registered dietitian for personalized and more complete counseling on diet modification as well as nutritional supplementation.
- Overt vitamin or mineral deficiencies are rare in this country; however, subclinical deficiencies may be contributing to chronic disease.
- Vitamin, mineral, or multivitamin/multimineral supplementation may be appropriate on the basis of the practitioner's assessment of the patient's dietary intake, metabolic requirements, absorptive capability, and potential drug-micronutrient interactions. However, supplementation should rarely exceed 100% of the DRI. Clinical trials continue to reveal unanticipated health risks with megadoses of various micronutrients.

**Handbook of Nonprescription Drugs** > Chapter 23. Functional and Meal Replacement Foods**Functional and Meal Replacement Foods: Introduction**

Foods serve many purposes in our lives. Foremost is their role in survival; foods provide us with sustenance to maintain metabolism and be physically active. Scientific research suggests that foods also affect health and wellness, and consumers are aware of these findings. In a 2013 survey of 1005 adults selected to reflect the American population, 90% believed health benefits other than basic nutrition are associated with certain foods.<sup>1</sup> Americans also report making changes to improve the healthfulness of their diet, including making an effort to eat more fruits and vegetables (87%) and more foods with whole grains (75%).<sup>2</sup> Decisions about purchasing foods and beverages are influenced by healthfulness (61%) slightly more than convenience (53%); however, taste (87%) continues to dominate purchasing decisions, followed by price (73%). Lack of time to plan and prepare meals leads health-conscious consumers to seek convenient methods to optimize nutrition for wellness and health promotion, including fast yet healthy alternatives to traditional “sit-down” meals. In addition, more individuals are living independently with conditions or impairments that affect their ability to obtain adequate nutrients through a regular diet, and they may seek convenient methods to supplement or replace conventional meals. Although dietitians are the recognized food and nutrition experts, all health care providers should be aware of the role that foods may play in an overall plan to improve or maintain health, especially foods that have benefits beyond their basic nutrients or that help patients reach nutrient goals when healthy meals are not readily available or cannot be ingested. (Chapter 22 reviews basic nutrition.) This chapter provides an introduction to foods used for their potential health benefits (functional foods), as well as foods intended to replace regular meals (meal replacement foods).

**Drugs, Dietary Supplements, and Foods**

The Food and Drug Administration (FDA) is charged with regulating drugs, dietary supplements, and foods (Chapter 4 discusses regulatory issues). *Foods* are defined as articles used for food or drink or components of any such article, or substances providing taste, aroma, or nutritive value.<sup>3</sup> Specific FDA regulations pertain to food safety and labeling. FDA requires that all regulated foods provide assurance in advance (premarket) that ingredients are safe and that claims are substantiated, truthful, and not misleading. Particular forms or uses of foods, such as infant formulas (see Chapter 25) and medical foods, are required to meet additional criteria to ensure the safety of somewhat vulnerable groups.

**Functional Foods**

Functional foods (FF) blur the distinction between drugs and foods, as defined by FDA, much as dietary supplements did until 1994, when the Dietary Supplement Health and Education Act (DSHEA) established a distinct regulatory scheme for dietary supplements.<sup>3</sup> The term *functional food* is not officially sanctioned by FDA, and there is no legal definition or regulatory category for FF. A specific FF may be regulated as a drug or in one of several subcategories of food depending on its intended use and labeling.<sup>3,4</sup> This lack of validation of products makes it difficult to determine sales figures and market estimates; however, the global market of FF has recently been estimated at \$50 billion annually.<sup>5</sup> Probiotics represent a \$15 billion share. Projections of annual growth in FF vary widely, from 5% to 30% depending on country and product type.<sup>5</sup> Contemporary U.S. health care reforms that mandate preventive care, along with the emerging field of nutrition economics, will likely fuel the growth of FF as their role in dietary recommendations and public health policy increases, including as a primary care option.<sup>6</sup> Health care providers should be familiar with FF to fully evaluate their patients' diets in relation to preventive and proactive lifestyle changes that modify risks for chronic diseases. Unfortunately, making evidence-based decisions related to the use of FF can be difficult because few randomized controlled trials have been conducted, and for many studies, only a small number of subjects are enrolled. Epidemiologic studies generally rely on people recalling their food intake, which obscures true associations between selected food components and disease risk. If researchers are to translate the epidemiology of dietary patterns into clinical interventions, they need a detailed look at specific diets from certain geographic regions that have low and very low incidence of the major chronic diseases, along with detailed quantification and qualification of dietary phytochemical content.<sup>7</sup> Other factors to consider include the use of biomarkers and nutrigenomic and epigenomic effects of dietary phytochemicals in whole foods as bioactive food components in individuals.<sup>8</sup> This daunting complexity makes clinical trials aimed at prevention challenging to design and conduct. Isolating the food component and administering it as a dietary supplement rather than as a FF, as is done in many clinical studies, simplifies study design and reduces interactions among food components.

Unfortunately, available data do not support this approach because multiple-constituent dietary phytochemicals in the matrix of plant-based whole foods appear to be safer and more effective than single and multiple constituent high-dose dietary supplements.<sup>9-11</sup> Associations between FF or bioactive food components and health maintenance or disease prevention usually show a relative risk of less than 2.<sup>12</sup> In a traditional medical toxicology model, where exposures are generally large doses of a single component, a relative risk of less than 2 is considered weak. In contrast, nutritional exposures are broad based and occur in small doses of multiple-component mixtures within whole foods over a prolonged time. Relative risk of 1.5 should be ranked as strong for such exposures. Given the limitations of available data and the potential for complex interactions between FF and bioactive food components, lifestyle factors, and genetics, the evaluation of FF requires examination of the totality of evidence, including that from biological models and multiple types of research (preclinical, epidemiologic, clinical, and translational).<sup>12</sup> Dietary phytochemical patterns in whole foods and functional dietary patterns have become leading areas for FF science and functional nutrition in current research programs and will become more important in future research as understanding of this area evolves.<sup>11,12</sup> To compare results or combine results for analysis, researchers must include preparation methods and sources of FF (whole food, isolated component, or dietary supplement) in study reports. "Health benefits beyond those of basic nutrition" is a broad definition of FF, encompassing unmodified whole foods (fruits, vegetables, and whole-grain products) and designer foods such as purple carrots.<sup>3,4</sup> A somewhat narrower definition used by the International Life Sciences Institute restricts FF to unmodified foods with naturally occurring bioactive components.<sup>4</sup> Examples include tomatoes, for their lycopene content, and soybeans, which provide isoflavones. The Institute of Medicine (IOM) Food and Nutrition Board restricts the definition of FF to those foods in which the concentration of one or more ingredients has been altered to enhance the food's contribution to a healthful diet.<sup>3,4</sup> This definition includes foods enriched or fortified with nutrients, phytochemicals, or botanical products, including foods such as orange juice with added calcium. Elements isolated from nontraditional food sources and added to traditional foods, such as stanol esters added to margarine-type spreads, also fit this definition of FF. From the viewpoint in current biomedical paradigms, plant-based foods are considered functional because of synergy in dietary phytochemicals.<sup>6,11</sup>

### Categories of Foods Classified as Functional Foods

FF typically fit into one of five categories on the basis of statutory definitions and regulatory guidelines for health claims on food labels:

1. Foods associated with health claims recognized by FDA
2. Foods that carry structure or function claims
3. Foods for special dietary use
4. Medical foods
5. Certain conventional foods

Providers should have a basic understanding of these categories because the need for medical supervision varies by category. All labeling claims require prior approval by FDA; however, the required level of supporting science varies depending on the category under which the FF are marketed (i.e., greater supporting science is required for medical foods than for structure-function claims).

#### Foods with Health Claims

Health claims characterize the relationship between a substance (food, food component, dietary ingredient, or dietary supplement) and a disease or health-related condition.<sup>3,4,13</sup> (See [Chapters 50](#) and [51](#) for discussion of dietary supplements.) Only claims about reduction of disease risk are allowed; no claim about "diagnosis, cure, mitigation, or treatment of disease" can be made. Three types of health claims can be made for conventional foods: authorized, authoritative, and qualified. Each type of claim is associated with specific levels of supportive data and specified labeling criteria. *Authorized* health claims require publication of an FDA regulation after an extensive review of the scientific literature, along with significant scientific agreement that the food/nutrient and disease relationship is well established. Of the health claims allowed for foods, authorized claims undergo the most thorough FDA review. The exact wording of the claim statement is not specified, although the statement appearing on the food label must meet specific criteria.

Statements for authorized health claims cannot quantify the degree of risk reduction, and the terms *may* or *might* must be used to qualify the relationship between a food or dietary component and disease. The label must state that the disease or health-related condition depends on many factors, implying that diet is not the only consideration in disease management. It also must indicate that the benefit related to a disease or health-related condition is part of a total dietary pattern; thus, the need for an overall healthy diet is reinforced. No health claims are permitted for foods containing more than 13 grams of fat, 4 grams of saturated fat, 60 mg of cholesterol, or 480 mg of sodium per reference amount customarily consumed (RACC); up to double these amounts are allowed for main dishes and meal

products.<sup>13</sup> The RACC is typically one serving as defined on the product label. Health claims cannot be indicated for children younger than 2 years. [Table 23-1](#) lists authorized health claims, requirements for foods listing these health claims, and sample statements that might be used on a food label.<sup>3,4,13</sup>

Certain health claims for foods, food components, or dietary ingredients (but not dietary supplements) can be made through notification of FDA by the manufacturer after the agency receives a statement from an authoritative scientific body of the U.S. government with responsibility to protect public health or to conduct research related to human nutrition (an *authoritative* claim).<sup>3,13</sup> The National Institutes of Health, the Centers for Disease Control and Prevention, and the National Academy of Sciences are sources for authoritative claims. Significant scientific evidence supports such health claims, although FDA itself does not complete an extensive review of the data. Authoritative health claims currently recognized by the FDA and required wording for the claims statement are listed in [Table 23-1](#).<sup>3,13</sup>

**TABLE 23-1 Authorized and Authoritative Health Claims**

<i>Health Claim</i>	<i>Requirements for Foods</i>	<i>Sample Claim Statement Containing Required Components</i>	<i>Selected Foods Meeting Claim Requirements</i>
<b>Authorized Health Claims</b>			
Calcium—osteoporosis [Calcium and vitamin D—osteoporosis]	High in calcium [High in calcium and vitamin D] Bioavailable Phosphorus content no more than calcium content	Regular exercise and healthy diet with enough calcium [and vitamin D] helps teens and white and Asian women maintain good bone health, and may reduce their high risk of osteoporosis later in life.	Milk Orange juice with added calcium
Sodium—hypertension	Low sodium content	Diets low in sodium may reduce the risk of high blood pressure, a disease associated with many factors.	Fruits and vegetables, canned or frozen with no added salt, fresh
Dietary fat—cancer	Low fat “Extra lean” fish and game meat	Development of cancer depends on many factors. A diet low in total fat may reduce the risk of some cancers.	Fruits and vegetables, fresh, frozen, or canned Most cereals Nonfat and low-fat milk and dairy products
Dietary saturated fat and cholesterol—risk of coronary heart disease	Low saturated fat Low cholesterol Low fat “Extra lean” fish and game meat	While many factors affect heart disease, diets low in saturated fat and cholesterol may reduce the risk of this disease.	Fruits and vegetables, fresh, frozen, or canned Most cereals Nonfat and low-fat milk and dairy products
Fiber-containing grain products, fruits, and vegetables—cancer	Grain product, fruit, or vegetable containing dietary fiber Low fat Good source of fiber without fortification	Low-fat diets rich in fiber-containing grain products, fruits, and vegetables may reduce the risk of some types of cancer, a disease associated with many factors.	Fruits and vegetables, fresh, frozen, or canned Whole-grain breads, cereals, and pasta Brown rice

Fruits, vegetables, and grain products that contain fiber, particularly soluble fiber—risk of coronary heart disease	Fruit, vegetable, or grain product containing fiber Low saturated fat Low cholesterol Low fat Minimum of 0.6 gram soluble fiber per RACC without fortification Soluble fiber content provided on the label	Diets low in saturated fat and cholesterol and rich in fruits, vegetables, and grain products that contain some types of dietary fiber, particularly soluble fiber, may reduce the risk of heart disease, a disease associated with many factors.	Fruits and vegetables, fresh, frozen, or canned Whole-grain breads, cereals, and pasta Brown rice
Fruits and vegetables—cancer	Fruit or vegetable Low fat Good source of vitamin A or C, or dietary fiber without fortification	Low-fat diets rich in fruits and vegetables (foods that are low in fat and may contain dietary fiber, vitamin A, or vitamin C) may reduce the risk of some types of cancer, a disease associated with many factors. [X food is high in vitamin A, vitamin C, and/or is a good source of fiber.]	Broccoli Berries Green beans Carrots Cantaloupe Citrus fruits Most dark green leafy vegetables
Folate—neural tube defects	Contains at least 40 mcg folate per serving Foods in conventional form that are a good source without fortification Contains not more than the RDI for vitamin A as retinol, or preformed vitamin A or D Amount of folate must be in the nutrition label	Healthful diets with adequate folate may reduce a woman's risk of having a child with a brain or spinal cord defect.	Most dark green leafy vegetables (see <a href="#">Chapter 22</a> )
Dietary noncarcinogenic carbohydrate sweeteners—dental caries	Sugar-free Eligible substances listed in 21 CFR 101.80; examples include xylitol, sorbitol, mannitol, erythritol, d-tagatose, and sucralose Does not lower plaque pH below 5.7 when fermentable carbohydrate is present	Frequent between-meal consumption of foods high in sugars and starches promotes tooth decay. The sugar alcohols in [name of food] do not promote tooth decay. Short claim for small packages: Does not promote tooth decay.	Many “dietetic” sugar-free products marketed for people with diabetes Many low-calorie products marketed for weight loss
Soluble fiber from certain foods—risk of coronary heart disease	Low saturated fat Low cholesterol Low fat Includes one or more: (1) an eligible source of whole oat or barley with $\geq 0.75$ gram soluble fiber per RACC, (2) Oatrim containing $\geq 0.75$ gram beta-glucan per RACC, (3) psyllium husk containing $\geq 1.7$ gram soluble fiber per RACC Amount of soluble fiber per RACC must be declared in the nutrition label	Soluble fiber from foods such as [name of soluble fiber source (optional—name of food product)], as part of a diet low in saturated fat and cholesterol, may reduce the risk of heart disease. A serving of [name of food product] supplies [X] grams of the [necessary daily dietary intake for the benefit] soluble fiber from [name of soluble fiber source] necessary per day to have this effect.	Rolled oats, oatmeal Whole oats Cold cereals Barley Cereals with added psyllium
Soy protein—risk of coronary heart disease <sup>a</sup>	Contains $\geq 6.25$ grams soy protein per RACC Low saturated fat	Example 1: Foods containing 25 grams of soy protein a day, as part of a diet low in saturated fat and cholesterol, may reduce the risk of heart	

	Low cholesterol Low fat, unless fat is from whole soybeans	disease. A serving of [name of food] supplies [X] grams of soy protein. Example 2: Diets low in saturated fat and cholesterol that include 25 grams of soy protein a day may reduce the risk of heart disease. One serving of [name of food] provides [X] grams of soy protein.	
Plant sterol/stanol esters—risk of coronary heart disease <sup>b</sup>	Spreads and salad dressings must contain $\geq 0.65$ gram plant sterol esters per RACC Spreads, salad dressings, and snack bars must contain $\geq 1.7$ grams plant stanol esters per RACC Low saturated fat Low cholesterol	Example 1: Foods containing at least 0.65 gram per serving of vegetable oil sterol esters, eaten twice a day with meals for a total intake of at least 1.3 grams, as part of a diet low in saturated fat and cholesterol, may reduce the risk of heart disease. A serving of [name of food] supplies [X] grams of vegetable oil sterol esters. Example 2: Diets low in saturated fat and cholesterol that include two servings of foods that provide a daily total of at least 3.4 grams of plant stanol esters in two meals may reduce the risk of heart disease. A serving of [name of food] supplies [X] grams of plant stanol esters.	Margarine spreads with added sterol/stanol esters Orange juice with added sterol/stanol esters Nonfat milk with added sterol/stanol esters
<b>Authoritative Health Claims<sup>c</sup></b>			
Whole-grain foods—risk of heart disease and certain cancers	Must contain $\geq 51\%$ whole-grain ingredients by weight per RACC Low fat Must meet specified dietary fiber content: 3 grams/RACC of 55 grams; 2.8 grams/RACC of 50 grams; 2.5 grams/RACC of 45 grams; 1.7 grams/RACC of 35 grams	Diets rich in whole-grain foods and other plant foods and low in total fat, saturated fat, and cholesterol may reduce the risk of heart disease and some types of cancer.	Low-fat whole-grain breads and cereals Whole-grain cereals and pasta Brown rice
Potassium—risk of high blood pressure and stroke	Good source of potassium Low sodium Low total fat Low saturated fat Low cholesterol	Diets containing foods that are a good source of potassium and that are low in sodium may reduce the risk of high blood pressure and stroke.	Many fruits and vegetables (see <a href="#">Chapter 22</a> )
Fluoridated water—reduced risk of dental caries	Total fluoride $\geq 0.6$ -1 mg/L Bottled water must meet standards of identity and quality Excludes bottled water for infants	Drinking fluoridated water may reduce the risk of dental caries or tooth decay.	Bottled water containing fluoride
Saturated fat, cholesterol, and trans fat—reduced risk of heart disease	Low saturated fat Low cholesterol Quantity of trans fat on label and $< 0.5$ gram trans fat per RACC Total fat $< 6.5$ grams	Diets low in saturated fat and cholesterol, and as low as possible in trans fat, may reduce the risk of heart disease.	Fruits and vegetables, fresh, frozen, or canned Most cereals Nonfat and low-fat milk and dairy products

Key: CFR = Code of Federal Regulations; RACC = reference amount customarily consumed (usually one serving as listed on label); RDI = recommended dietary intake.

<sup>a</sup> Soy protein content of foods is available from the Agricultural Research Service, U.S. Department of Agriculture

(USDA). Nutrient Data Laboratory [database online]. [Search for “standard reference.”] Accessed at <http://www.nal.usda.gov/fnic/foodcomp/search>, May 16, 2013.

<sup>b</sup> A proposed rule amending the health claim for phytosterols and risk of coronary heart disease has been published. The claim would include use of nonesterified (free) phytosterols, broaden the range of foods to which the claim could apply, modify the dietary intake for the claimed benefit, and adjust the minimum content for a claim. Department of Health and Human Services, Food and Drug Administration. Food labeling; health claim; phytosterols and risk of coronary heart disease; proposed rule. 21 CFR Part 101. *Federal Register*. 2010;75:76526-71. Accessed at <http://edocket.access.gpo.gov/2010/pdf/2010-30386.pdf>, May 16, 2013.

<sup>c</sup> Wording in the sample claim statement for authoritative claims is required by the Food and Drug Administration.

Source: References 3, 13, and 14.

The third type of health claim is a *qualified* claim. Qualified health claims are appropriate for use when evidence of health benefits of a food, food component, or dietary supplement is still emerging; scientific research supporting the claim tends to be limited or preliminary; and the “significant scientific agreement” level of evidence required for authorized and authoritative health claims cannot be met. [Table 23-2](#) lists qualified claims and specific “qualifying” terms required by FDA to indicate that evidence for the claim is limited.<sup>3,4,14</sup> Labeling guidance issued by FDA for qualified health claims intermixes information regarding labeling of dietary supplements and conventional foods.<sup>14</sup> [Chapter 50](#) provides further discussion of qualified health claims and labeling.

#### Foods with Structure-Function Claims

Structure-function claims are commonly associated with dietary supplements but can also appear on food labels. These claims indicate the effect of consuming the product on a body structure or function. They differ from health claims in that FDA validation or authorization is not required before use, although prior notification of FDA regarding the claim is required. These claims cannot make reference regarding reduced risk of disease because such a reference would place the product under regulation as a drug.<sup>3,4,13</sup> For example, a probiotic yogurt marketed as preventing or treating diarrhea is considered a drug; however, if the label instead claims to “improve digestion,” it is considered an acceptable structure-function claim. Other examples of structure-function claims include statements that the product builds strong bones, supports the immune system, improves memory, maintains intestinal flora, improves strength, and promotes urinary tract health. Foods carrying a structure-function claim are considered FF; they are not dietary supplements when represented as a conventional food. For instance, margarine-type spreads with added stanol esters are a food, with the stanol ester considered a food additive. However, dietary supplements in food form (drinks and bars) that are labeled and marketed as dietary supplements are regulated as dietary supplements (see [Chapter 50](#)). Distinguishing FF from dietary supplements can therefore be confusing.

#### Foods for Special Dietary Use

Foods for special dietary use, as defined by FDA, include foods used to supply *particular dietary needs*, or to supplement or fortify the usual diet, and are marketed as such; they do not meet general dietary needs (see [Chapter 22](#)).<sup>3,13</sup> Particular dietary needs may exist because of physical, physiologic, pathologic, or other conditions, such as disease, convalescence, pregnancy, lactation, underweight, overweight, infancy, or need for sodium restriction. Foods intended for use as the only nutrient source in the diet and those intended to supplement the diet by increasing total dietary intake of a specific ingredient (vitamin, mineral, or other nutrient) are also considered to meet a particular dietary need. These foods are subject to general labeling requirements for foods, and medical supervision of their use is not required. By some definitions, foods for special dietary use are considered FF; however, this approach to marketing FF is seen in the food supply much less broadly than is structure-function labeling.

**TABLE 23-2 Qualified Health Claims for Conventional Foods<sup>a</sup>**

<i>Food/Nutrient</i>	<i>Disease/Condition</i>	<i>Level of Evidence</i>	<i>Comments</i>
<b>Claims Related to Cardiovascular Disease</b>			
Omega-3 fatty acids: EPA and DHA	CHD	Supportive but not conclusive research	Total fat, saturated fat, cholesterol, and sodium maximum limits apply
Walnuts	Heart disease	Supportive but	1.5 ounces of whole or chopped walnuts per day

		not conclusive research	
Nuts	Heart disease	Supportive but not conclusive research	Limited to almonds, hazelnuts, peanuts, pecans, some pine nuts, pistachio nuts, walnuts; 1.5 ounces per day
Monounsaturated fat from olive oil	CHD	Limited and not conclusive evidence	Suggested intake of about 2 tablespoons (23 grams) daily; replaces a similar amount of saturated fat and does not increase the total number of calories
Unsaturated fatty acids from canola oil	CHD	Limited and not conclusive evidence	Suggested intake of about 1.5 tablespoons (19 grams) daily; replaces a similar amount of saturated fat and does not increase the total number of calories
Corn oil and corn oil-containing products	Heart disease	Very limited and preliminary evidence	Suggested intake of about 1 tablespoon (16 grams) daily; replaces a similar amount of saturated fat and does not increase the total number of calories
<b>Claims Related to Cancer Risk</b>			
Green tea	Cancer	Highly unlikely to reduce risk	Breast cancer and prostate cancer studies evaluated
Tomatoes, tomato sauce	Prostate, ovarian, gastric, and pancreatic cancers	Unlikely, uncertain, or little scientific evidence	Few studies; major study limitations and conflicting results

Key: CHD = Coronary heart disease; DHA = docosahexaenoic acid; EPA = eicosapentaenoic acid.

<sup>a</sup> Includes only claims related to conventional foods. Claims related to dietary supplements are not included.

Source: References 3, 4, 13, 14, and 20.

### Medical Foods

Medical foods were first defined in the *Federal Register* in 1973; they were represented by an infant formula for patients with phenylketonuria, which had previously been regulated as a drug.<sup>3</sup> The Orphan Drug Act Amendments of 1988 also define medical foods and require that specific criteria be met before use and distribution. These foods are to be recommended or prescribed by a physician and used under continued medical supervision; however, many are not prescription-only products in the same manner as prescription drugs since they can be sold without a physician's written order. Medical foods do not occur naturally; rather, they are specially formulated and processed to meet *distinctive nutritional requirements* of the disease or condition for which they are intended.<sup>3</sup> Distinctive requirements for a select medicinal component in the food (or the food product as a whole) must be established by prior medical evaluation on the basis of recognized scientific principles. Providers should be able to distinguish between medical foods that require physician supervision and products that can be safely used as "nutritional self-care" by the public. (See the Medical Foods and Meal Replacement Foods section of this chapter for further discussion of medical foods.)

### Conventional Foods

Conventional foods that do not fit into any of the preceding four categories can also be classified as FF. Research on conventional FF comes from contemporary medical ethnobiology and ethnopharmacy, with the foundation being ethnic or traditional foods associated with health benefits in various cultures and supported by epidemiologic studies. For example, long-standing systems of traditional FF use in Asia are linked epidemiologically to some of the lowest cancer rates in the world and to very low incidence of other chronic diseases.<sup>15,16</sup> The strength of evidence supporting a functional role for such foods is typically weak-moderate, and clinical trials tend to be lacking; therefore, even a qualified health claim often cannot be supported at this time.<sup>4</sup> However, other foods are known in which specific compounds have been identified as the functional component, for which molecular functional nutrition and pharmacology studies have been conducted. Studies of dietary phytochemicals and fish oils have revealed a variety of specific phytochemicals and marine zoochemicals (e.g., EGCG, resveratrol, curcumin, EPA, DHA) that modulate several molecular targets at the same time and can serve collectively as agents for chronic disease prevention and

health preservation.<sup>10,17,18,19</sup> Table 23-3 provides examples of conventional foods and the components likely responsible for their role as FF, and Table 23-4 lists examples of functional components and typical food sources.<sup>4,6,8,12,20,21,22,23</sup> Figure 23-1 shows the narrowing cascade of knowledge from an extensive array of plants on Earth to the few phytochemicals identified as health modifiers; the figure also serves as an indicator of the extensive research needed to fully understand the potential of FF in health.<sup>9,10,16,19,22</sup>

**TABLE 23-3 Examples of Conventional Foods Classified as Functional Foods**

<i>Food</i>	<i>Functional Component</i>	<i>Potential Health Benefit</i>	<i>Comments</i>
Apples	Flavonols, phenols, proanthocyanidins, soluble fiber (pectin)	Decreased risk of certain types of cancer; improved glucose and cholesterol concentrations; may contribute to maintenance of heart health	Recommend one a day but amount for health benefit not defined
Banana, ripe	Prebiotics, FOS	Decreased hypertension and hypercholesterolemia	Weak evidence for 3-10 g/day
Berries; cherries	Anthocyanidins	Antioxidant functions; may contribute to healthy immune system	Recommend 1/2-1 cup/day but amount for health benefit not defined
Cinnamon	Proanthocyanidins	May contribute to maintenance of urinary tract and heart health	Weak evidence; amount for health benefit not well researched
Citrus fruits	Ascorbic acid, zeaxanthin, limonene	Decreased risk of age-related macular degeneration; decreased cancer risk	Weak-moderate evidence for decreased macular degeneration with 6 mg/day as lutein; rodent studies with limonene and cancer
Cocoa, chocolate	Flavonols	Antioxidant functions, decreased risk of coronary heart disease	Dark chocolate appears to be best
Corn	Lutein, zeaxanthin, free stanols/sterols	Decreased risk of age-related macular degeneration; may decrease risk of CHD	Weak-moderate evidence for 6 mg/day as lutein; health claim for stanol/sterol esters added to foods
Cranberry juice	Proanthocyanidins	Decreased UTI from decreased adherence of bacteria to cell walls; may also prevent adhesion of plaque-forming bacteria in the mouth	Moderate evidence for 300 mL/day to decrease UTI (58% reduction in bacteriuria in 150 elderly women in the first randomized controlled trial [1994])
Cruciferous vegetables: broccoli, brussels sprouts, cauliflower, cabbage	Glucosinolates, indoles, isothiocyanates (sulphoraphane), organosulfur compounds, thiols	Decreased risk of certain types of cancer	Weak-moderate evidence for greater than 1/2 cup/day
Dairy products, including some cheese	Conjugated linoleic acid	Decreased risk of breast cancer; possible role in improved body composition	Weak evidence for breast cancer link; animal studies suggest role in decreased body fat; necessary amount not determined for health effects
Dairy products, fermented (acidophilus milk, buttermilk,	Probiotic organisms (lactobacilli, bifidobacteria)	Maintenance of GI tract health; decreased colon cancer risk; decreased cholesterol	See discussion of probiotics in this chapter

kefir, yogurt)			
Eggs (yolk)	Lutein, zeaxanthin	Decreased risk of age-related macular degeneration	Weak-moderate evidence for 6 mg/day as lutein
Eggs, enriched with DHA	DHA	Decreased risk of CHD; increased HDL cholesterol	Chickens are fed fish oils or algae as a source of DHA
Fatty fish (wild salmon, herring)	Omega-3 fatty acids	Decreased triglycerides and risk of heart disease, including fatal and nonfatal MI	Recommend 2 meals/week with fatty fish; supportive but not conclusive evidence per qualified health claim
Flax	Phytoestrogens (lignans), alpha-linolenic acid	Decreased risk of CHD by decreasing cholesterol and platelet aggregation; weak estrogenic activity may decrease hormone-related cancers; maintenance of a healthy immune system; alpha-linolenic acid may contribute to maintenance of visual function	Weak evidence for CHD association; very weak evidence for cancer risk; amounts necessary for health benefit from flax are not defined
Garlic	Organosulfur compounds, thiols	Decreased total and LDL cholesterol; may decrease the risk of gastric cancer; promotes healthy immune function	Weak-moderate evidence for about one fresh clove daily for cholesterol; epidemiologic evidence for decreased cancer is equivocal; considerable variation exists in the amount of active compounds for available products
Grapes, red and black	Anthocyanidins, phenolic compounds	Antioxidant functions; decreased cardiovascular risk	Epidemiologic evidence suggesting inverse association with cardiovascular disease risk
Grape juice	Resveratrol	Decreased risk of MI caused by decreased platelet aggregation	Moderate-strong evidence for 8-16 ounces/day
Greens: spinach, kale, collards	Lutein, zeaxanthin	Decreased risk of age-related macular degeneration	Weak-moderate evidence for 6 mg/day as lutein
Jerusalem artichoke	Prebiotics, FOS	Decreased hypertension; decreased hypercholesterolemia	Weak evidence for 3-10 g/day
Meat (beef, lamb, turkey) and milk	Conjugated linoleic acid	Antitumor effect proposed; possible role in improved body composition	Suppression of cancer cell growth in rat studies; animal studies suggest role in decreased body fat; necessary amount not determined for health effects
Onions, leeks, scallions	Organosulfur compounds, thiols	Decreased total and LDL cholesterol	Weak-moderate evidence
Onion powder	Prebiotics, FOS	Decreased hypertension; decreased hypercholesterolemia	Weak evidence for 3-10 g/day
Rye	Phytoestrogens (lignans)	May contribute to maintenance of heart health and healthy immune system	Amounts necessary for health benefit from rye are not defined
Tea, black	Polyphenols, flavonoids	Decreased risk of CHD	Evidence is not conclusive
Tea, green	Catechins (epigallocatechin-	Decreased risk of certain types of cancer; improved CV health; weight control	Qualified health claim evaluation concluded it is highly unlikely that

	3-gallate, epigallocatechin, epicatechin-3-gallate, epicatechin)		green tea (not specifically catechins) reduces risk for cancer; prevention of CV and obesity weak (intake estimates of $\geq 4$ cups/day)
Tomatoes and processed tomato products	Lycopene	Antioxidant that efficiently decreases singlet oxygen in biological systems; possible decreased risk of certain cancers (prostate) and MI	Weak evidence based on inverse associations of tissue lycopene and cancers or MI; qualified health claim evaluation concluded it is unlikely or uncertain that tomatoes or sauce (not specifically lycopene) reduce risks
Tree nuts	Monounsaturated fatty acids, vitamin E	Decreased risk of CHD	Moderate evidence for 1-2 ounces/day; some nuts have qualified health claim

Key: CHD = Coronary heart disease; CV = cardiovascular; DHA = docosahexaenoic acid; FOS = fructooligosaccharides; GI = gastrointestinal; HDL = high-density lipoprotein; LDL = low-density lipoprotein; MI = myocardial infarction; UTI = urinary tract infection.

**TABLE 23-4 Examples of Functional Flavonoid Components in Conventional Foods**

<b>Functional Component (Subclass of Flavonoids)</b>	<b>Dietary Phytochemicals</b>	<b>Food Source</b>	<b>Potential Health Benefit</b>
Anthocyanins	Cyanidin Delphinidin Malvidin	Red, blue, and purple berries and grapes; cherries; potatoes; purple sweet potatoes; blue corn; rhubarb; plums	Augment cellular antioxidant defenses; may contribute to maintenance of brain function
Flavones	Hesperetin Naringenin	Citrus fruits and juices	Neutralize free radicals, which may damage cells; augment cellular antioxidant defenses
Flavonols	Isorhamnetin Kaempferol Myricetin Quercetin	Apples, berries, broccoli, kale, tea, onions (scallions, yellow onions; highest flavonol content in onions)	Neutralize free radicals, which may damage cells; augment cellular antioxidant defenses
Flavanols (monomers)	Catechin Epicatechin Epigallocatechin ECG EGCG	Teas (green and white), chocolate, grapes, berries, apples	May contribute to maintenance of heart health
Flavanols (polymers)	Proanthocyanidins Theaflavins Thearubigins	Teas (oolong and black), chocolate, apples, berries, red grapes	May contribute to maintenance of heart health and urinary tract health

Key: ECG = Epicatechin-3-gallate; EGCG = epigallocatechin-3-gallate.

#### Functional Foods and Biomarkers: Epigenomics and Chemoprevention

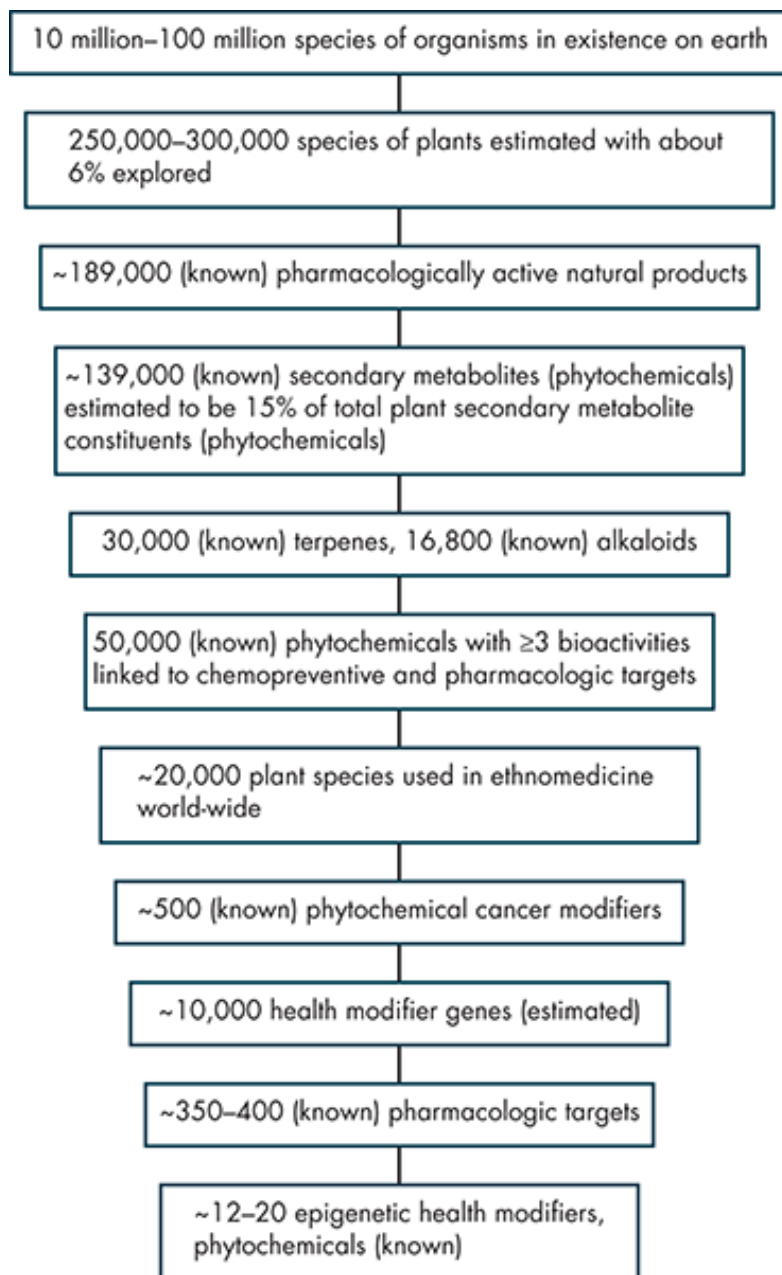

The disposition of dietary phytochemicals is similar to drugs and xenobiotics to the extent that they can be studied with respect to individual pharmacokinetics and pharmacodynamics.<sup>23</sup> Pharmacokinetic studies suggest that variations in

disease risk or preventive efficacy of certain dietary phytochemicals may be at least partially related to genetic polymorphisms in metabolism that result in altered enzyme activity; thus, the same phytochemical may have different pharmacodynamic effects with different individuals. Because of such complexities, common biomarkers used to monitor a condition or health risk may be inadequate to establish a link between a phytochemical and clinical endpoints. The IOM developed a framework for the qualification of risk biomarkers that recommends evaluation of the relationship between the clinical endpoint and the risk biomarker as well as of evidence that the intervention affecting the risk biomarker is concomitantly linked to the clinical endpoint.<sup>15,23</sup> Linking biomarkers for health and disease to epigenomics (defined as heritable changes in gene expression that occur without a change in DNA sequence)<sup>19</sup> is a major challenge in FF research.<sup>8</sup>

## Fiber

Fiber is a component of FF that has been widely studied for associations with potential health benefits. Fiber consists of dietary components that humans cannot digest, including plant cell walls; nonstarch polysaccharides from seaweed, microorganisms, or seed husks (psyllium); resistant starches; and nondigestible oligosaccharides.<sup>24</sup> The terms *dietary fiber* and *functional fiber* are related to dietary reference intakes (see [Chapter 22](#)) and distinguish between sources of fiber.<sup>24,25</sup> Total fiber is the sum of dietary and functional fiber. Dietary fiber is defined as nondigestible carbohydrates and lignin that are naturally occurring (intrinsic and intact) in plants. Functional fiber is defined as isolated nondigestible carbohydrates that have beneficial physiologic effects in humans; it includes fiber extracted or modified from plants or animal sources. Effects of fiber extracted from cell walls may differ from effects of in situ fiber because of altered chemical and physical properties. Viscosity and fermentability may be more important correlates with health effects than solubility; however, the terms *soluble fiber* and *insoluble fiber* remain pervasive in both professional and nonprofessional literature, and these terms are used here.<sup>26,27</sup>

Cascade of knowledge from plants to phytochemicals to health modifiers. (Source: Adapted from references 9, 10, 19, and 22.)

### Recommended and Actual Intake

Adequate intakes (AIs) for total fiber published by the IOM range from 21-38 g/day, with amounts for women and elderly people being lower than for men and younger people.<sup>25</sup> (See [Chapter 22](#) for general information on AIs.) AIs are based on usual caloric intake in each age group and 14 grams of dietary fiber per 1000 calories, which appears to be the amount needed to promote heart health.<sup>24,28</sup> Unfortunately, actual mean fiber intake is only about 14-16 g/day, with little progress toward meeting goals over the past two decades.<sup>29</sup>

### Soluble and Insoluble Fibers

Soluble fibers typically undergo substantial degradation and fermentation in the colon; negligible degradation and fermentation occur with most insoluble fibers. [Table 23-5](#) outlines food components, food sources, and functional fiber sources typically associated with soluble and insoluble fibers. The food sources listed are good to excellent sources of fiber, as defined by FDA.<sup>30</sup>

### Methods of Increasing Fiber Intake

[Table 23-6](#) lists ideas for increasing fiber content in the diet. Caution is advised for the use of fiber-containing products in patients with poor gastrointestinal (GI) motility or underlying GI dysfunction, including narcotic-associated dysmotility. Inadequate fluid intake may also contribute to GI distress from a high-fiber diet. It is advisable to increase fiber intake gradually, because a sudden increase can cause bloating, gas, and occasionally diarrhea. A reasonable approach is to add one or two servings of foods that are abundant in fiber, as listed in [Table 23-5](#), to the diet every few days until the goal for fiber intake is reached. Reading ingredient labels is essential to ensure adequate fiber content,

especially for breads and cereals, in which a *whole* grain should be the first ingredient listed.

### Benefits of Fiber

The generally accepted benefits of fiber are laxation effects, normalization of blood lipid concentrations, and attenuation of blood glucose response.<sup>26,30</sup> These benefits are the accepted measures of efficacy as required for label claims of fiber content in Canada; only evidence of safety is required in the United States, but appropriate evidence must support any health claim made. Benefits of fiber, such as cancer risk reduction and weight control, have been suggested in humans; however, results are limited and conflicting.

**TABLE 23-5 Components and Sources of Soluble and Insoluble Fiber**

	<i>Soluble Fiber</i>	<i>Insoluble Fiber</i>
Food component	Pectins, gums, mucilages, algal substances, and some hemicellulose	Cellulose, lignin, and most hemicellulose
Food sources with $\geq 2.5$ grams of total fiber per serving <sup>a</sup>	Cereals: oat bran (uncooked, 2/3 cup), oatmeal (cooked, 1 cup) Fruits: apples and pears with skin on, oranges (1 medium), figs and prunes (3 small) Vegetables: broccoli, carrots, cauliflower, corn, kale and other greens, dark green or loose leaf lettuce, peas, squash, zucchini (cooked, 3/4-1 cup)	Bran and whole-grain (corn, rye, wheat) products: bran cereals (dry cereal, 1/3-1 cup), brown rice (cooked, 1 cup), whole-wheat bread (2 slices) Dried beans: lima, kidney, pinto, white (cooked, 1/4-1/2 cup) Dried peas: green, split (cooked, 1/4-1/2 cup)
Functional fiber sources	Beet fiber, FOS, guar gum (galactomannan, Benefiber), inulin, karaya gum, konjac mannan, locust bean gum, pectin, psyllium (ispaghula seed husk)	Calcium polycarbophil, methylcellulose, powdered cellulose, soy polysaccharide (also has significant soluble fiber effects)

Key: FOS = Fructooligosaccharides.

<sup>a</sup> Serving size shown in parentheses. The food sources listed are good (2.5-4.9 grams of fiber per serving) to excellent (5 grams or more of fiber per serving) sources of total dietary fiber and are listed under the heading that exemplifies their predominant health effects.<sup>30</sup>

**Laxation.** Stool characteristics associated with laxation, or improved bowel function, include increased stool bulk, weight, and water content; decreased stool transit time and normalization of stool frequency to once daily; reduced symptoms of constipation; and an overall improvement in ease of defecation. Epidemiologic studies strongly support the positive role of fiber from whole grains, fruits, and vegetables in laxation. Insoluble fiber has been most frequently associated with improved laxation, although evidence also indicates some soluble fibers have similar effects. The role of functional fibers in laxation is well accepted, and adequate scientific evidence exists to support FDA approval of some fibers as nonprescription bulking agents for treatment of *occasional* constipation, as discussed in [Chapter 15](#). Studies supporting the efficacy of bulk-forming fibers in *chronic* constipation are less certain and tend to be of intermediate to low quality.

**TABLE 23-6 Methods for Increasing Fiber in the Diet**

• Eat breads containing whole-wheat grain, whole-wheat flour, or other whole grains as the first ingredient on the label. These products should replace breads from refined flours that do not include whole grains.
• Replace part of refined-grain cereals with whole-grain cereal for individuals who prefer refined cereals; or mix very high fiber cereals into a favorite brand of cereal.
• Eat oatmeal as a hot breakfast cereal, or select a cold cereal with oats or whole grain as the primary ingredient.
• Sprinkle bran on cereal, yogurt, or other foods.
• Eat brown rice, whole-wheat pasta, and whole-grain crackers rather than white rice and products from refined grains.
• Add fruit to breakfast cereals, breads, yogurt, and salads.
• Select recipes that use whole-grain flours, and/or add rolled oats to baked goods.
• Select recipes for baked goods that include apples, applesauce, carrots, pumpkins, or other fruits or vegetables as a significant ingredient.

• Add kidney, garbanzo, navy, or other beans to salads and soups, including canned soups. Rinse and drain canned beans to reduce components prone to cause gas.
• Serve fruit and/or vegetable salads with picnic lunches instead of potato chips.
• Serve canned beans (black, kidney, white, or baked) as an alternative protein source.
• Eat fresh or dried fruit for snacks and desserts; frozen and canned fruits can also be used.
• Use a low-fat refried bean dip or hummus with whole-wheat baked tortilla chips for snacks.
• Eat fruits and vegetables, including potatoes, with the skin on.
• Select snack or meal replacement bars containing at least 2.5 grams of fiber per serving.
• Include “finger food” vegetables (carrots, celery, cauliflower pieces, and broccoli flowerets) in lunch boxes and as snacks.
• For children, make animal or other fun shapes from vegetables pieces.
• Eat nuts and/or seeds for snacks, or add to mixed dishes, salads, breads, and cereals.

**Normalization of Blood Lipid Concentrations.** Data on reduced risk of coronary heart disease (CHD) are sufficient for certain fibers to support an FDA-authorized health claim (Table 23-1).<sup>3,4,13</sup> Multiple epidemiologic studies have reported a reduced risk of CHD or cardiovascular disease (CVD) with high dietary fiber intake and/or fiber-rich foods. The relationship appears to hold over many years and across ethnic groups. Table 23-7 summarizes data related to risk of CHD from several large, well-designed prospective epidemiologic studies with longer-term follow-up and pooled data studies.<sup>24,28,31,32,33,34,35</sup>

The key to fiber’s ability to lower cholesterol and reduce CHD risk appears to be consuming an adequate quantity of highly viscous fiber, primarily from whole-grain cereal (oats, barley, or rye) and beans (legumes), or from guar gum, pectin, and psyllium. Fruit fiber may have a beneficial effect relative to CHD/CVD, but the association is less clear. Vegetable fiber does not appear to be associated with reduced risk of CHD/CVD.

**Attenuation of Blood Glucose Response.** Multiple large, well-designed prospective epidemiologic and cohort studies with longer-term follow-up have reported an association between consumption of fiber and attenuation of blood glucose, improved insulin response, and/or reduced risk of diabetes, as summarized in Table 23-

7.<sup>24,28,31,32,33,34,35,36</sup> The overall conclusion from these studies is that an inverse relationship exists between risk of diabetes and intake of dietary fiber. Intake of cereal fiber appears to be most frequently related to improved glucose control and/or reduced risk of diabetes; foods most likely to provide a positive effect include cereal grains such as oats, barley, and rye. Some legumes (beans), fruits, and vegetables, as well as guar gum and pectin, may also have a beneficial effect on glucose control. Evidence suggests that nonviscous fibers, such as wheat bran, have little effect on glycemic control.

**TABLE 23-7 Summary of Selected Studies Related to Fiber and Risk of CHD and Improved Glucose Control**

<b>Study Name and Population Characteristics<sup>a</sup></b>	<b>Follow-Up Time (years)</b>	<b>Results/Conclusions</b>
Nurse’s Health Study <sup>24,31</sup> : cohort design; ≥65,000 women; ages 37-64 years	10	<b>CHD:</b> Inverse relationship between dietary fiber intake and risk of CHD only for dietary fiber from cereal sources, not fruits and vegetables; cereal fiber intake averaging 7.7 g/day reduced risk of CHD by 34%, compared with average intake of 2.2 g/day; RR 0.77 with higher fiber intake; 19% decrease in risk for CHD events per 10 g/day increase in dietary fiber and a 37% decrease per 5-gram increase in cereal fiber. <b>Glucose:</b> RR type 2 DM 2.5 for high-GL/low-cereal-fiber diet (<2.5 g/day), compared with low-GL/high-cereal-fiber diet (≥5.8 g/day); more frequent intake of dark breads, whole-grain breakfast cereals, and brown rice was associated with decreased likelihood of developing diabetes.
Nurses’ Health Study, type 2 DM subgroup <sup>32</sup> : cohort design; 7822 women; ages 37-64	Up to 26 (70,102 person-	<b>CVD:</b> RR CVD-specific mortality 0.65 for highest fifth of bran intake after multivariate adjustment. RR all-cause mortality 0.75 for highest fifth of bran intake.

years	years)	
Health Professionals' Follow-Up Study <sup>24,31</sup> : cohort design; ≥42,000 men; ages 40-75 years	6-12	<i>CHD</i> : RR fatal CHD 0.45 and RR total MI 0.59 in those averaging 28.9 grams dietary fiber/day, compared with those averaging 12.5 g/day; stronger association with cereal fiber than with fruits and vegetables; 19% decrease in risk of MI per 10 g/day increase in dietary fiber and a 29% decrease per 10 g/day increase in cereal fiber. <i>Glucose</i> : RR type 2 DM 2.17 for high-GL/low-cereal-fiber diet (<2.5 g/day), compared with low-GL/high-cereal-fiber diet (≥5.8 g/day).
Iowa Women's Health Study <sup>24,31</sup> : cohort design; nearly 36,000 women, postmenopause	6	<i>CHD</i> : About one-third decrease in risk of fatal CHD with ≥1 serving/day of whole grains, compared with those with little whole-grain intake; risk decreased with fiber from cereals, not fruits and vegetables; decreased likelihood of mortality from ischemic heart disease with more frequent intake of dark (whole-grain) bread and whole-grain breakfast cereals. <i>Glucose</i> : Inverse relationship of insoluble fiber intake from cereals and risk of DM; no relationship to fruit, vegetable, legume intake; RR diabetes 0.79 for median intake of 20.5 servings/week of whole-grain products, compared with median of 1 serving/week.
Iowa Women's Health Study <sup>33</sup> : cohort design; 27,312 women, postmenopause; ages 55-69 years	17	<i>CVD/CHD</i> : Inverse relationship between total whole-grain intake and mortality from CVD and CHD. After multivariate adjustment, RR mortality from CVD and CHD 0.73 and 0.72, respectively, for consuming ≥19 g/week versus rarely to never consuming whole-grain products. Participants were free of CVD at baseline.
Cardiovascular Health Study, fiber intake analysis <sup>28</sup> : cohort design; 3588 men and women; ages ≥65 years (average 72 at baseline)	8.6	<i>CHD/CVD</i> : Cereal fiber intake was inversely associated with incident CVD. Hazard ratio 0.79 (21% lower risk) in highest quintile of fiber intake versus lowest quintile. The difference was seen with about 4.6 grams fiber/day (2 slices whole-grain bread). Lower risk predominantly with fiber in dark bread (whole-wheat, rye, pumpernickel). Fruit and vegetable fiber intake was not associated with incident CVD. Participants were free of known CVD at baseline.
Alpha-tocopherol, beta-carotene cancer prevention study <sup>24</sup> : nearly 22,000 men; ages 50-69 years	6	<i>CHD</i> : RR CHD 0.84 for those averaging 34.5 grams dietary fiber/day, compared with those averaging 16.1 g/day with fiber intake adjusted to 2000 calories; high-fiber intake: 12.9 g/1000 cal; low-fiber intake: 5.9 g/1000 cal.
Pooled data, prospective cohort studies <sup>28</sup> : total of 91,058 men and 245,186 women in 10 studies; ages 35-98 years	6-10	<i>CHD</i> : RR for all coronary events 0.86 (14% decrease) and RR 0.73 (27% decrease) for coronary death for each 10 g/day increment of total dietary fiber. For cereal fiber, RR 0.9 for all coronary events and RR 0.75 for death; for fruit fiber, RR 0.84 and 0.7; for vegetable fiber, RR 1.00 for all coronary events and death. Similar results for men and women.
Japanese Collaborative Cohort Study for Evaluation of Cancer Risks <sup>28,35</sup> : 58,730 men and women; ages 40-79 years	14.3	<i>CHD</i> : Fiber intake from fruit and from cereal but not vegetables was inversely related to CHD mortality. Overall CHD risk was 0.79 for highest quintile of fiber versus lowest. The association for insoluble fiber was stronger than for soluble fiber. All participants were Japanese.
Atherosclerosis Risk in Communities (ARIC) Study, subset with retinal vascular caliber measurements <sup>31</sup> : 10,659 men and women; ages 45-64 years	6	<i>CVD-retinal vascular caliber</i> : Inverse dose-response relationship between wider retinal arteriolar caliber/narrower venular caliber and fiber from all sources and from cereal fiber but not from vegetable fiber. Wider retinal arteriolar caliber and narrower venular caliber provide an objective measurement associated with lower CVD risk. Participants included whites and African Americans.
Atherosclerosis Risk in Communities (ARIC)	9	<i>Glucose</i> : Inverse relationship with 1 g/day of cereal fiber intake and risk of DM in both African American and white subgroups, but statistically significant only

Study <sup>31</sup> : 12,251 men and women: 9529 whites and 2722 African Americans; ages 45-64 years		in whites; no relationship to fruit and legume intake in either subgroup. Participants were free of DM at baseline.
Insulin Resistance Atherosclerosis Study (IRAS), subgroup with carotid sonograms <sup>34</sup> : 1178 men and women; ages 40-69 years	5	<i>CVD-carotid artery intimal medial thickness (IMT) and IMT progression</i> : Inverse relationship between whole-grain intake and common carotid artery IMT and IMT progression. Carotid IMT is an objective measure related to atherosclerosis; IMT progression is associated with subsequent cardiovascular events. Multiethnic participants, with a relatively high proportion of ethnic minority at 26%.
Finnish Mobile Clinic Health Examination Survey <sup>28,31</sup> : 2286 men and 2030 women; ages 40-69 years	10	<i>Glucose</i> : Inverse relationship of cereal fiber intake and risk of DM (cereal fiber predominantly from rye; little wheat).
Nurses' Health Studies: NHS-I and NHS-II <sup>28</sup> : cohort design; total 161,737 women; NHS-I: 73,327, ages 37-64 years; NHS-II: 88,410, ages 26-46 years	12-18	<i>Glucose</i> : For each 40-gram increment in whole-grain intake, multivariate analysis indicated RR for DM of 0.54 (NHS-I) and 0.64 (NHS-II). BMI accounted for 42% and 57% of the association with RR after adjusting for BMI of 0.7 and 0.83, respectively, for NHS-I and NHS-II.
Black Women's Health Study <sup>36</sup> : cohort design; 40,078 black women with no prior history of diabetes or CVD; ages 21-69 years	8	<i>Glucose</i> : Inverse relationship between cereal fiber intake and DM (IRR 0.82). Risk of DM was 18% less for highest quintile of cereal fiber intake compared to lowest quintile. Gld associated with risk of DM (IRR 1.23) for the highest quartile versus lowest. Stronger associations for BMI < 25.

Key: BMI = Body mass index; CHD = coronary heart disease; CVD = cardiovascular disease; DM = diabetes mellitus; Gld = glycemic index; GL = glycemic load; IMT = intimal medial thickness; IRR = incident rate ratio; MI = myocardial infarction; RR = relative risk.

<sup>a</sup> Number of participants included in the analysis is not always the entire study population; number of trials included in meta-analysis.

Source: References 24, 28, and 31-36.

**Weight Loss and Maintenance.** Epidemiologic studies show a lower body mass in participants who eat a high-fiber diet and greater incidence of obesity in those with low intake of dietary fiber.<sup>24,28</sup> Interventional studies show mixed results with high-fiber diets and weight loss, although there is an association of less weight gain over time with higher intake of whole grains.<sup>35</sup> Research suggests that fiber intake may influence body weight through various mechanisms, such as delayed gastric emptying, prolonged small bowel transit time and subsequent effects on peptides associated with satiety and gut function, activation of the ileal break, and stimulation of colonic cells, resulting in production of appetite-regulating hormones.<sup>37</sup>

#### Prebiotics, Probiotics, and the Gut Microbiota

Microflora in the GI tract are known as the enteric microbiota. The GI tract hosts approximately 300-500 species of commensal bacteria, with concentrations up to 10<sup>9</sup> colony-forming units (CFU)/mL in the terminal ileum and 10<sup>12</sup> CFU/mL in the colon.<sup>38</sup> However, the enteric microbiota may be far more diverse than is currently recognized. Only within the past 15 years or so have the GI microbiome and its role in human health and disease been explored in earnest. The extent of microbiota influence on health maintenance and disease development appears significant. Although understanding of the complex interactions between the GI tract and enteric microbiota remains incomplete, the paradigm of human biology is shifting to embrace the ecology of the individual and the transgenomic and epigenomic co-metabolism of the individual with his or her own unique GI microbiome.<sup>39,40</sup> The microbiome is being

viewed by some as a “superorganism” in a symbiotic relationship with the gut mucosa.<sup>41</sup>

### Prebiotics

Prebiotics support the enteric microbiota and are typically substances fermented in the colon. Some fibers act as prebiotics. The undigested fiber enters the colon and is fermented by bacteria, primarily bifidobacteria and lactobacilli. Fermentation products, including short-chain fatty acids (acetate, butyrate, and propionate) and lactate, produce an environment favorable to growth of these beneficial bacteria. To be considered a prebiotic, fiber must selectively stimulate the growth and/or activity of one or a limited number of health-promoting bacterial species residing in the colon and benefit the host.<sup>38,41,42,43</sup>

**Sources and Intake.** Inulin-type fructans, including their partial hydrolysis product fructooligosaccharides (FOS), are the most common prebiotics. They are found in low amounts in asparagus, bananas, chicory, Jerusalem artichoke, leek, onion, soy, and wheat.<sup>43</sup> Inulin-type fructans are isolated from such sources and added to foods to attain concentrations contributing to prebiotic effects. Average intake for adults in the United States is estimated at 2.6 g/day.<sup>44</sup>

**Health Effects.** Both inulin-type fructans and FOS significantly increase bifidobacteria in humans. Doses vary greatly in studies; 5-8 g/day is thought to be adequate for prebiotic effects, and up to 20 g/day is considered an amount that should not cause bloating, distension, and flatulence.<sup>44</sup>

Beneficial effects of prebiotics supported by some human data include stool bulking and decreased constipation, better absorption of calcium and magnesium, reduced triglycerides in mildly hypercholesterolemic individuals, and stimulation of bifidobacteria growth.<sup>41,44,45</sup> Studies using prebiotics for diarrhea are conflicting; results may depend on etiology.<sup>45</sup> Improved vaccine response, decreased GI infections, stimulation of intestinal hormonal peptides, improvement of inflammatory bowel disease symptoms, and reduced tumor growth are other possible benefits of prebiotics. Some beneficial effects may be enhanced with synbiotics, a mixture of both prebiotics and probiotics that together improve host welfare.<sup>43</sup>

### Probiotics

Probiotics are nonpathogenic, living microorganisms that have a beneficial effect on the host when consumed in adequate amounts.<sup>38,43</sup> Probiotics must withstand processing, storage, and delivery of the product and survive gastric acidity, bile acid lysis, and pancreatic enzyme digestion.<sup>41,42</sup> Lactic acid-producing bacteria, especially of the genera *Lactobacillus*, *Bifidobacterium*, and *Streptococcus*, are most often used in foods and studies. Beyond early infancy, these microorganisms do not permanently colonize the GI tract and must be ingested regularly in sufficient quantity to maintain their presence. When a sufficient number of these bacteria are present, colonization by pathogenic bacteria is reduced and mucosal defenses in the GI tract are enhanced. Table 23-8 lists possible protective effects of probiotics and postulated mechanisms of action.<sup>41,45,46</sup> Health care providers should use caution when interpreting data; multiple species and strains of common probiotic bacteria exist, and effects cannot be extrapolated across species or even across different strains.<sup>43</sup> Dosing may explain variance in treatment response in published studies. The optimum dose for a given probiotic is not known; however, studies showing efficacy typically use a minimum of  $10^7$  to  $10^{10}$  CFU per dose or  $10^8$  to  $10^{10}$  CFU daily.<sup>43,47</sup>

**Sources.** Many traditional foods are fermented by bacteria and contain high concentrations of lactobacilli. Corn, cassava, millet, leafy vegetables (cabbage), and beans commonly serve as the basic food for fermentation. A few fermented foods are occasionally eaten in the United States, such as brined olives, kimchi (Korean fermented cabbage), miso, sauerkraut, and tempeh; however, the major food source of probiotic bacteria is dairy foods. Many major brands of yogurt contain probiotic bacteria, although viable cultures are not required for yogurt in the United States, and labels do not list the number of viable probiotic organisms. Liquid yogurt drinks (kefir) and cultured fluid milk, such as sweet acidophilus milk and buttermilk, can contain variable amounts of viable organisms; however, most provide adequate amounts ( $10^8$  viable organisms per gram). With the interest in probiotics, new products are appearing regularly with added probiotic organisms, sometimes with little or no data on the organisms added or on the efficacy of the combinations used.

**Health Effects.** Interest in probiotics has increased dramatically in the past decade. Research covers a wide range of disease states and all ages (premature neonate to elderly). A comprehensive review is beyond the scope of this text; only a glimpse into this active area of research can be provided. Clinical data, for the most part, are preliminary; however, moderate-quality evidence supports the use of probiotics to prevent antibiotic-associated diarrhea, including *C. difficile* diarrhea.<sup>48,49</sup> Table 23-9 lists some of the uses of probiotics and associated organisms.<sup>38,39,40,43,45-53</sup> Results may be influenced by the dose, frequency of dosing, and/or organisms in any individual probiotic product. Most studies have been small and have used isolated bacteria (classified as nutritional supplements) or foods with added probiotics, rather than foods that naturally contain the beneficial bacteria.

### Assessment of Functional Food Use: A Case-Based Approach

FF play a role in preventing disease and optimizing health. For patients who have mild signs of or are at risk for CHD,

FF may be a viable alternative to pharmacotherapy, as Case 23-1 illustrates.

**TABLE 23-8 Possible Protective Effects of Probiotics**

<i>Effect of Probiotic</i>	<i>Possible Mechanism for the Effect</i>
<b>GI Barrier Function</b>	
Induce production of protective cytokines mediating EC regeneration and inhibiting apoptosis	Action through TLRs; intestinal homeostasis and EC protection requires recognition of commensal bacteria by TLRs Induction of IL-6
Redistribute and increase expression of factors involved in maintaining EC tight junctions	Altered protein kinase C signaling
Counteract effects or inhibit production of inflammatory cytokines associated with increased EC permeability	IL-10 upregulation (regulatory cytokine) Reduced effect of TNF-alpha and INF-gamma Reduce TNF-alpha production Stimulation of IgA secretion
<b>Antimicrobial Activity</b>	
Inhibit growth of potential pathogens	Decreased luminal pH Production of bactericidal proteins (bacteriocins)
Inhibit adhesion of pathogenic bacteria to EC	Increased mucin production Reduced transepithelial resistance associated with binding of some pathogens Competitive exclusion of pathogens from EC surface binding sites due to nonspecific binding associated with the hydrophobic cell surface properties; mucus-binding pili enhance binding to mucosal surface Binding to pathogenic microorganisms, thereby preventing interaction between the microorganism and EC surface
Influence production of cryptdins by Paneth cells Alter virulence	Antibacterial action of cryptdins Altered secretion of molecules influencing expression of genes controlling virulence
<b>EC Inflammatory Responses</b>	
Alter EC cytokine production	Downregulation of bacteria-induced protein kinase C and IL-6 Inhibition of TNF-alpha-induced IL-8 production Downmodulation of genes associated with proinflammatory signal induction Attenuation of nuclear factor-kappa B activation
<b>Lymphoid Cell</b>	
Enhance antiviral activity	Inhibition of T-cell proliferation Induction of macrophages to express increased amounts of inflammatory cytokines and nitric oxide Stimulation of granulocyte colony-stimulating factor release by macrophages Increased natural killer T-cell activity
Activate macrophages	Increased antigen presentation to B lymphocytes
<b>Regulatory T-Cell Induction</b>	
Increase CD4+ (regulatory) T cells with cell-surface TGF-beta (regulatory cytokine)	Monocyte-derived dendritic cells inducing IL-10 production by T cells

Key: EC = Epithelial cell; GI = gastrointestinal; IgA = immunoglobulin A; IL = interleukin; INF = interferon; TGF = transforming growth factor; TLR = toll-like receptor; TNF = tumor necrosis factor.

Source: References 38, 41-43, and 45.

**TABLE 23-9 Evidence-Based Uses of Probiotics<sup>a</sup>**

<b>Condition/Disease</b>	<b>Probiotics Most Often Associated with Benefit</b>	<b>Comments</b>
<b>Allergy</b>		
Atopic dermatitis, prevention and treatment	<i>L. rhamnosus</i> GG, <i>B. lactis</i>	Conflicting results; several studies show decreased severity; most studies were small limited studies with good design and adequate power to support effectiveness for atopic eczema associated with cow milk allergy. Meta-analysis with 1477 infants indicated reduced eczema with selected probiotics; however, Cochrane review did not find adequate evidence to support addition of probiotics to infant formula. A subset of infants at high risk of atopic dermatitis may benefit from probiotic administration to the mother during pregnancy and to the infant for several months after birth (this should be done under the supervision of a physician and not done as self-care).
<b>Diarrhea</b>		
Acute, non-antibiotic-associated treatment in pediatrics and adult	Pediatrics: <i>L. rhamnosus</i> GG, <i>L. acidophilus</i> + <i>B. infantis</i> , <i>L. reuteri</i> ATTC 55730, <i>L. casei</i> DN-114 001, <i>S. boulardii</i> Iyo Adult: <i>Enterococcus faecium</i> LAB SF68, <i>L. rhamnosus</i> GG, <i>S. boulardii</i>	Multiple studies and meta-analyses; duration of diarrhea reduced by about 1 day. Evidence is stronger for viral gastroenteritis than for bacterial infection. Timing of administration may affect efficacy. Evidence is stronger for treatment than for prevention.
Antibiotic-associated, prevention (not <i>Clostridium difficile</i> )	Pediatrics: <i>L. rhamnosus</i> GG, <i>B. lactis</i> Bb12 + <i>Strep. thermophilus</i> , <i>S. boulardii</i> Iyo Adult: <i>B. clausii</i> , <i>Enterococcus faecium</i> LAB SF68, <i>L. rhamnosus</i> GG, <i>L. acidophilus</i> CL1285 + <i>L. casei</i> Lbc80r, <i>L. casei</i> DN-114 001 + <i>L. bulgaricus</i> +	Multiple studies in both adults and pediatric patients. Some conflicting results; however, literature supports benefit overall, except in <i>Clostridium difficile</i> -associated diarrhea.

	<i>Strep. thermophilus</i> , <i>S. boulardii</i> , VSL#3 <sup>b</sup>	
<i>Clostridium difficile</i> colitis, prevention and treatment	<i>S. boulardii</i> Iyo, <i>L. rhamnosus</i> GG, <i>L. casei</i> DN-114 001 + <i>L. bulgaricus</i> + <i>Strep. thermophilus</i> , <i>L. acidophilus</i> + <i>B. bifidum</i>	Positive results in some controlled studies; however, there are conflicting results from other studies. Meta-analysis shows benefit. Promising role as adjuvant in treatment of recurrent <i>C. difficile</i> diarrhea.
Infectious (not invasive bacterial diarrhea) and travelers' diarrhea	Pediatrics: <i>L. rhamnosus</i> GG, <i>L. reuteri</i> Adult: <i>S. boulardii</i> , <i>L. rhamnosus</i> GG	Results in randomized controlled studies are conflicting; modest positive results with some strains.
Lactose intolerance	<i>L. delbrueckii</i> subsp. <i>bulgaricus</i> , <i>Strep. thermophilus</i> ; mixed cultures in fermented milk products	Improved symptoms of lactose intolerance. Microbial beta-galactosidase improves lactose hydrolysis.
Radiation enteritis	<i>L. acidophilus</i> NDCO1748, VSL#3	Limited number of studies provide promising results; probiotic may reduce severity of diarrhea or improve consistency without improving the incidence of diarrhea. Overall, data are inadequate to establish effectiveness at this time.
Rotavirus infection	<i>L. rhamnosus</i> GG, <i>L. reuteri</i> , <i>L. casei</i> GG, <i>B. bifidum</i> , <i>B. lactis</i>	Studies in infants/children strongly support beneficial effect for prevention and treatment.
Tube-feeding associated	<i>S. boulardii</i>	Data from clinical trials are insufficient to recommend probiotic use. Limited studies available; most are small and have design limitations; conflicting results. No benefit with <i>L. acidophilus</i> and <i>L. bulgaricus</i> .
<b>IBD</b>		
Crohn's disease, induce and maintain remission	<i>E. coli</i> Nissle 1917, <i>S. boulardii</i> , VSL#3, <i>L. rhamnosus</i> GG	Small clinical studies, some with up to 1 year of follow-up; several randomized controlled trials with equivocal results. Some positive studies; however, data are inadequate to establish effectiveness. No evidence of effectiveness in maintaining remission per Cochrane review.
Pouchitis, preventing and	VSL#3	Strong evidence for effectiveness; randomized, double-blind, placebo-controlled studies. Inadequate studies to establish effectiveness for inducing

maintaining remission		remission.
Ulcerative colitis	VSL#3, <i>E. coli</i> Nissle	Randomized controlled trials have not demonstrated benefit for inducing or maintaining remission. Some positive studies with similar efficacy to anti-inflammatory medications; however, data are inadequate to establish effectiveness.
<b>IBS</b>		
Motility disorders	<i>B. animalis</i> DN-173 010 + <i>L. bulgaris</i> + <i>Strep. thermophilus</i> , <i>L. shirota</i> , <i>L. rhamnosus</i> GG, <i>L. rhamnosus</i> LC705, <i>S. boulardii</i> , VSL#3, <i>B. infantis</i>	May normalize muscle hypercontractility. Decreased bloating and flatulence in multiple studies; reduced abdominal pain or relief of constipation or diarrhea in some studies; however, there are conflicting results from other studies. Most studies are small and open label. Two larger randomized controlled trials with <i>B. infantis</i> showed positive results with a decrease in some symptoms.
<b>Immune Response</b>		
Vaccinations	<i>L. acidophilus</i> , <i>L. plantarum</i> , <i>L. johnsonii</i> , <i>L. rhamnosus</i> GG, <i>B. lactis</i>	Improved immunologic response to oral vaccinations is supported by randomized trials.
<b>Infection</b>		
Helicobacter pylori	<i>B. clausii</i> , bifidobacteria strains, <i>L. salivarius</i> , <i>L. johnsonii</i> , <i>L. rhamnosus</i> GG, <i>S. boulardii</i> lyo, <i>L. casei</i> DN-114 001 + <i>L. bulgaricus</i> + <i>Strep. thermophilus</i>	Probiotic appears to reduce treatment-related side effects and improve compliance. Meta-analysis of 14 trials indicates certain probiotics may increase eradication when used with antibiotic therapy, especially with previous treatment failure. Probiotic may inhibit colonization.
Vaginosis and vaginitis	<i>L. acidophilus</i> , <i>L. reuteri</i> , <i>L. rhamnosus</i> GG]	Decreased vaginosis was shown in women with recurrent disease in one study; however, there are conflicting results from other studies; evidence is inadequate to support effectiveness.
<b>Intestinal Permeability</b>		
NEC prevention	<i>L. acidophilus</i> + <i>B. infantis</i> , <i>B. bifidus</i> + <i>B.</i>	Strong support for effectiveness in preterm infants; Cochrane review supports supplementation of probiotics in reducing risk of severe NEC and mortality in premature infants.

<i>infantis</i> + <i>Strep.</i> <i>thermophilus</i>
---

Key: *B.* = Bifidobacterium; *E.* = Escherichia; IBD = inflammatory bowel disease; IBS = irritable bowel syndrome; *L.* = Lactobacillus; NEC = necrotizing enterocolitis; *S.* = Saccharomyces; *Strep.* = Streptococcus.

<sup>a</sup> Supported by at least one well-designed and adequately powered study and/or included in guidelines for probiotic use or disease management.

<sup>b</sup> VSL#3 contains four lactobacilli strains, three bifidobacteria strains, and *Streptomyces thermophilus*. VSL#3 is marketed as a probiotic medical food.

Source: References 38, 41, 43, and 45-52.

## Medical Foods and Meal Replacement Foods

Traditional medical foods include products developed for patients with inborn errors of metabolism (“metabolics”). Product descriptions are available on manufacturer Web sites and may be available from the federally funded Special Supplemental Nutrition Program for Women, Infants, and Children (WIC), because this program is often involved in distribution of products and patient monitoring. Enteral nutrition formulas, specialty formulas in particular, may meet the definition of a medical food; however, many are better classified as food for “special dietary use” because they are readily available without medical supervision and are marketed directly to consumers as regular foods, often as meal replacement products. Enteral formulas are typically semisynthetic liquid formulas intended for oral consumption or administration through a feeding tube. Certain liquid diets designed for use in medically supervised very-low-calorie diets or bariatric programs are classified as medical foods. Various puddings, shakes, and other solid or semisolid food forms specially formulated and processed to meet *distinctive* nutritional requirements of the disease or condition for which they are intended can also be classified as medical foods. Both liquid and solid medical foods replace regular meals or enhance nutrient intake to meet the distinctive nutritional requirements of patients. However, these products are also frequently used to meet general nutritional needs.

Providers involved with self-care counseling should determine when a product is used as a medical food to meet truly distinctive nutritional requirements, as determined by scientific studies, and when it is used as meal replacement or enhancement to meet *general* nutritional requirements. Foods intended to meet general nutritional requirements (see [Chapter 22](#)) do not need medical oversight and can be used safely for self-care. In contrast, FDA regulations state that medical foods require recommendation or prescription by a physician or authorized prescriber and ongoing medical supervision.<sup>3,13</sup> When enteral formulas are used to meet general nutritional requirements, however, third-party providers may refuse to cover the cost under insurance benefits, leaving patients with self-care responsibility.

### Case 23-1

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient’s symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient has no symptoms; she recently had a health assessment at work and was told that she is at risk of coronary heart disease because of her family history. She says she does not feel sick but she does not want to end up taking a “bunch of pills everyday” like her mother and oldest brother. She wants to do what she can to avoid heart disease and is particularly interested in “functional foods” because of a healthy lifestyle program she recently watched.
b. description of any factors	NA

that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	
c. description of the patient's efforts to relieve the symptoms	NA
d. patient's identity	Maria Bracamonte
e. age, sex, height, and weight	28 years old, female, 5 ft 5 in., 195 lb
f. patient's occupation	Third-grade teacher
g. patient's dietary habits	Eats breakfast most mornings: typically a cup of coffee and cereal bar from home or a fast food English muffin with egg and bacon. Lunch: most often a sandwich with potato chips and soft drink from the cafeteria. Afternoon snack: typically has a candy bar or granola bar. Dinner: meat (beef, pork, or chicken mostly; fish every once in a while when someone has gone fishing); potatoes or pasta most nights; fresh, frozen, or canned vegetable four to five times per week; sweet dessert (cake, pie, baked goods) or ice cream five to six times a week; typically has a soft drink with dinner, occasionally an alcoholic drink.
h. patient's sleep habits	Usually sleeps about 8 hours per night
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	None; birth control pill and multivitamin with folate
j. allergies	NKDA
k. history of other adverse reactions to medications	None
l. other (describe) _____	
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Mrs. Bracamonte has no signs/symptoms of disease but wants to follow a preventive strategy with diet.
3. Identify exclusions for self-treatment ( <a href="#">Table 23-13</a> ).	None
4. Formulate a comprehensive list of	Options include: (1) Refer Mrs. Bracamonte to her PCP for a more thorough assessment of heart

therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	disease and evaluation of her risk. (2) Refer Mrs. Bracamonte to a registered dietitian for comprehensive nutritional assessment and counseling. (3) Inform Mrs. Bracamonte of foods that have health claims associated with reduced risk of heart disease. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	A combination of the options is appropriate. (1) Provide basic information and counseling related to functional foods with health claims associated with heart disease. Emphasize authorized and authoritative health claims (Table 23-1) because these have strong scientific evidence supporting the claim. The limited evidence for qualified claims and structure-function claims can be presented along with a discussion of where they fit, if at all, in the patient's overall plan. (2) Refer Mrs. Bracamonte for cholesterol screening (or perform screening in the pharmacy) and assessment for heart disease. (3) Refer Mrs. Bracamonte to a dietitian if she wants/needs more than basic counseling on nutrition, or have her request a referral from her PCP (may be necessary for insurance coverage). (4) Weight control and heart disease should be discussed with Mrs. Bracamonte, or these issues should be suggested as part of the discussion with her PCP or a dietitian.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"A number of foods with health claims are associated with decreased risk of heart disease. For several foods, there is significant scientific agreement regarding the potential benefits. Using these foods in place of some of your current foods may reduce your risk of heart disease. However, it would also be helpful to know what your risks are, including your cholesterol level."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Given your family history, you should have your cholesterol checked periodically and be evaluated for other risk factors for heart disease. Your weight is a risk factor for heart disease for you." "I can provide you with basic information on foods that have health claims related to heart disease and that may be of benefit in maintaining heart health. Dietitians are the food and nutrition experts; they can do a comprehensive assessment of your diet and provide more in-depth dietary counseling if you want that."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	(1) Decreased dietary saturated fat and cholesterol: No more than 10% of your calories should come from saturated fat, and you should keep cholesterol in your diet at no more than 300 mg cholesterol a day, but less is better. When you use milk, you might want to try 1% milk; most people find that to be more acceptable than nonfat (skim) milk, and it is lower in fat than 2% milk, or you could try soy milk. Low-fat yogurt is also another good calcium source and is usually tolerated by people with lactose intolerance. (2) Fruits, vegetables, and grain products that contain fiber, particularly soluble fiber: Recommend replacement of white breads and pasta with whole grain. Total dietary fiber should be at least 25 g/day (AI for women 19-50 years of age). (3) Soluble fiber from oat bran, rolled oats, or whole oat flour in certain foods, or barley: Incorporate these products into the diet as replacement for breads and cereals that are not whole grain. (4) Soy protein: 25 g/day is required in conjunction with a diet low in saturated fat and cholesterol. For many people, the major dietary modifications needed to eat this much soy are very difficult to make, especially if all family members are not committed to the changes. (5) Plant sterol and stanol esters: Total intake is at least 1.3 g/day of sterol esters or 3.4

	<p>g/day of stanol esters, as part of a diet low in saturated fat and cholesterol. You usually need to eat the products at least twice a day to get the recommended amount. Some margarines and orange juice have added plant sterol/stanol esters.</p> <p>(6) Whole-grain foods: This health claim overlaps somewhat with that for “grain products that contain fiber” (#2) but does not specify “particularly soluble fiber.” Insoluble fibers are also important in health. Look for whole grains, such as whole wheat, as the first ingredient on labels.</p> <p>To make these health claims, foods must generally contain a certain amount of the component. Check food labels for these claims and for ingredient amounts.</p> <p>There are also health claims with less vigorous supporting data for which evidence suggests a benefit but research is not conclusive (does not prove a benefit); therefore, these claims may not be as effective, or the claims might be changed if new studies are reported. Because the following foods are otherwise healthy foods when used in moderation, they can still be safely incorporated into your diet.</p> <p>(1) Walnuts and several other types of nuts: 1.5 ounces a day; remember that nuts are a concentrated source of calories, so use judiciously.</p> <p>(2) Omega-3 fatty acids: specifically eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), found in salmon, lake trout, herring, and other oily fish.</p> <p>(3) Monounsaturated fats from olive oil: 23 g/day (2 tablespoons) in place of a similar amount of saturated fat. A number of salad dressings and a few soft margarines now include olive oil.</p> <p>(4) Canola oil, unsaturated fatty acids: 19 g/day (1.5 tablespoons) in place of a similar amount of saturated fat. Some cooking oil, a number of salad dressings, a few soft margarines, and some baked goods include canola oil.</p>
Solicit follow-up questions from the patient or caregiver.	<p>(1) “Are there any things I need to be aware of as I add these foods into my diet?”</p> <p>(2) “Are there any side effects from changing my diet?”</p> <p>(3) “Where can I find more information on dietary changes and diet plans to prevent heart disease?”</p> <p>(4) “May I use dietary supplements instead of changing to functional foods? Most information on the Internet is advertising for dietary supplements.”</p>
Answer the patient’s or caregiver’s questions.	<p>(1) “These foods should replace other foods in your diet so that the total calories do not increase. The more “healthful” fats must replace saturated fats and not increase the total fat intake. You will need to read food labels carefully to be sure you are getting whole grains, low saturated fats, low cholesterol, and sterol/ stanol esters in the product. Also look for the amount of soy or soluble fiber.”</p> <p>(2) “Rapid increases in fiber content of the diet can cause gas and bloating, so it is best to gradually increase the fiber in your diet. Replace 1-2 servings of white bread and pasta with whole-grain products every few days until the refined foods are totally replaced. Also add extra fiber by gradually replacing the low-fiber cereals with a whole-grain cereal or oatmeal. Fruits and vegetables can be increased gradually as well to replace snacks and desserts. Be sure to drink plenty of water when eating a high-fiber diet.”</p> <p>(3) “The FDA Web site (<a href="http://www.fda.gov">www.fda.gov</a>) includes information on health claims and food labels that you might find helpful. You could consider making an appointment with a registered dietitian, who could help develop some menus that incorporate foods you like and provide more specific plans for substituting healthier foods. Your health insurance plan may contract with a dietitian for coverage. If not, the Academy of Nutrition and Dietetics can provide the name(s) of private consultants and the contact information for a dietitian. The phone number for referrals is on their Web site (<a href="http://www.eatright.org">www.eatright.org</a>).”</p> <p>(4) “In general, foods are better than supplements. Many studies have shown beneficial effects from a diet containing fiber-rich foods and whole grains but not with isolated supplements. Psyllium, found in products like Metamucil, fits criteria for a health claim related to soluble fiber and risk of congestive heart disease, and could be used to increase soluble fiber. It also has the added benefit of reducing constipation, as do fibers from whole grains.”</p>
<b>Evaluation of Patient</b>	

Outcome	
9. Assess patient outcome.	“Can we talk about the changes you have made when you pick up your prescription refills next month?”

Key: AI = Adequate intake; FDA = Food and Drug Administration; NA = not applicable; NKDA = no known drug allergies; PCP = primary care provider.

## Enteral Formula Uses

### Tube Feeding

Enteral formulas are best known as complete nutritional replacements for patients requiring a feeding tube to meet their nutritional needs, such as stroke patients with severe dysphagia. Patients who cannot, should not, or will not take adequate nutrients by mouth are candidates for tube feeding and should be under medical care; tube feeding is not a condition conducive to safe and effective self-care. For information related to tube feeding, the reader is referred to one of the many specialized references available, to the American Society for Parenteral and Enteral Nutrition ([www.nutritioncare.org](http://www.nutritioncare.org)), or to the Oley Foundation ([www.oley.org](http://www.oley.org)), a consumer-oriented organization for support of individuals requiring intravenous or tube feeding.

Many enteral preparations currently are available. Most formulas provide nutritional support consistent with general dietary guidelines and are safe for use in self-care. Formulas intended for patients with impaired digestion and those designed for specific metabolic or clinical conditions require oversight by a health care provider. Characteristics that are likely to result in the use of a formula as a true medical food requiring medical supervision are listed in [Table 23-10](#), along with a few representative products.

### Supplementation of Nutrition Intake

Enteral products are frequently used as oral supplements for people of advanced age when effects of chronic disease and impaired mobility decrease nutrient intake. Oral nutritional supplements appear to benefit hospitalized members of this population who are undernourished at baseline; however, routine supplementation at home or for those who are well nourished in any setting is not supported by available evidence.<sup>54</sup> Finally, enteral formulas have been increasingly marketed as “meal replacements.” Marketing targets healthy individuals who perceive meal replacement products as healthier alternatives to eating fast foods or skipping a meal or those seeking portion control.

**TABLE 23-10 Enteral Formula Characteristics Consistent with Need for Medical Supervision**

<i>Characteristic</i>	<i>Examples</i>
Protein as peptides and/or free amino acids	Peptamen, Crucial, Vital
Alteration of the amino acid content by addition of individual amino acids, such as glutamine, arginine, or branch-chain amino acids	Juven, Impact, Perative
Addition of specific fatty acids to alter the inflammatory response	Oxepa
Addition of significant amounts of medium-chain triglycerides to alter absorption	Portagen, Enfaport
High percentage ( $\geq 50\%$ ) of calories from fat	Pulmocare, Nutren Pulmonary
Very high protein content ( $\geq 25\%$ of calories as protein)	Impact, Nutren Replete, Promote
Intended for patients with organ failure	Nepro, NutriRenal, NutriHep

## Classification of Enteral Nutrition Products

Enteral products are classified as polymeric formulas, oligomeric formulas, and modular components. In addition, a growing segment of meal supplement and meal replacement products, including beverages, bars, and puddings, is designed to assist in meeting nutrient goals within an appropriate caloric intake.

### Polymeric Formulas

Polymeric formulas are used most commonly. They are for individuals with normal digestive capability and contain macronutrients in the form of intact (whole) proteins, carbohydrates, and fatty acids or oils. Most individuals requiring alternative nutrition support will tolerate and do well with standard polymeric formulas. The standard formulas usually (1) are 1 kcal/mL unless concentrated to provide less free water; (2) contain a macronutrient composition typical of the American diet (carbohydrate: 45%-70%; protein: 10%-18%; and fat: 20%-40%); and (3) are isotonic to slightly hypertonic (300-450 mOsm/kg); however, flavored products are often in the range of 500 to 700 mOsm/kg. These formulas are generally safe for self-care when taken orally. Formulas listed as being generally safe for self-care are polymeric formulas (Table 23-11).

#### Oligomeric Formulas

Oligomeric products require minimal digestion and are also known as predigested, peptide, or elemental formulas. They contain free amino acids, hydrolyzed or partially hydrolyzed protein, and less complex carbohydrates. These formulas frequently alter the fat content to improve absorption in patients with impaired absorption. They are rarely consumed orally because of very poor palatability. In general, oligomeric formulas require medical supervision.

**TABLE 23-11 Meal Replacement Products/Liquid Formulas Suitable for Self-Care<sup>a</sup>**

<i>Product Name</i>	<i>Energy (kcal/mL)</i>	<i>Protein grams (% kcal)</i>	<i>CHO grams (% kcal)</i>	<i>Fat grams (% kcal)</i>	<i>Fiber grams</i>	<i>Comments</i>
<b>Routine Formula</b>						
Boost	240 (1.0)	10 (17)	41 (67)	4 (16)	None	Hypertonic
Ensure	250 (1.06)	9 (14)	40 (64)	6 (22)	None	Hypertonic
Jevity 1 Cal	250 (1.06)	10.4 (17)	6.5 (54)	8.2 (29)	3.4	Fiber from soy; isotonic
<b>Routine Formula with Extra Protein</b>						
Boost High Protein Drink	240 (1.0)	15 (24)	33 (55)	6 (21)	None	
Ensure High Protein	230 (0.97)	12 (21)	31 (55)	6 (24)	None	
<b>Routine Concentrated (High-Calorie) Formula</b>						
Boost Plus	350 (1.5)	14 (16)	45 (50)	14 (34)	None	
Ensure Plus	350 (1.5)	13 (15)	51 (57)	11 (28)	None	
Jevity 1.5 Cal	355 (1.5)	15 (17)	51 (54)	11.8 (29)	5.3 (75% I; 25% S; 10 grams FOS)	Osmolite 1.5 Cal has similar nutrient profile without fiber.
<b>Diabetic Formula<sup>b</sup></b>						
Boost Glucose Control	250 (1.06)	14 (22)	20 (35)	12 (43)	3.5 (I: 0.9; S: 2.6; FOS)	Complex CHO including tapioca starch
Glucerna 1.2 Cal	285 (1.2)	14.2 (20)	27 (35)	14.2 (45)	3.8 (I, S, FOS: 2.4)	Higher omega-3 fat content than many routine formulas; 1 and 1.5 Cal versions are available.

Nutren Glytrol	250 (1.0)	11.3 (18)	25 (40)	11.9 (42)	3.8 (I: 1.3; S: 2.5)	Amylase starch (low glycemic index)
<b>Pulmonary Formula<sup>c</sup></b>						
Pulmocare	355 (1.5)	14.8 (17)	25 (28)	22 (55)	None	High-fat content.
Nutren Pulmonary	375 (1.5)	17 (18)	25 (27)	23.7 (55)	None	High-fat content.
<b>Other Meal Replacements and Supplements</b>						
Ensure Clear	200 (0.61)	7 (20)	43 (80)	None		6.7-ounce serving package; clear liquid; not intended as sole source of nutrition.
Carnation Breakfast Essentials (powder for mixing)	220 (0.8)	13 (23)	39 (74)	0.5 (3)	<1	Put 1 packet in 1 cup fat free milk for 9-ounce serving; mixing with 2% or whole milk would increase calories as fat. Can mix with soy milk or reduced lactose milk.
Carnation Ready to Drink	220 (0.8)	14 (24)	31 (57)	5 (19)		
Glucerna Shake	200 (0.84)	10 (20)	26 (48)	7 (32)	3	Fiber from FOS and soy polysaccharide; not for tube feeding; product not intended as sole source of nutrition.
<b>Modular Components</b>						
Beneprotein	25	6 (100)	None	None	None	Listed content per 7-gram packet or 1 scoop.
ProMod Liquid Protein	100	10 (40)	14 (60)	None	None	Listed content per ounce.
Benecalorie	330 (7.5)	7 (9)	None	33 (91)	None	Listed content per 1.5-ounce serving (44 mL). Product is a modular component; add to enteral formula or foods to increase calories.

Key: CHO = Carbohydrate; FOS = fructooligosaccharides; I = insoluble fiber; S = soluble fiber.

<sup>a</sup> Amounts per 8 ounce serving unless otherwise indicated.

<sup>b</sup> Use sparingly for self-care because the fat content is relatively high compared in studies with high-fat/low-carbohydrate diets and is higher than recommended by general dietary guidelines. In accordance with recommendations from the American Diabetes Association ([www.ada.org](http://www.ada.org); see American Diabetes Association, Bantle JP, Wylie-Rosett J, et al. Nutrition recommendations and interventions for diabetes: a position statement of the American Diabetes Association. *Diabetes Care*. 2008;31(suppl 1):S61-78), monounsaturated fatty acid content tends to be higher than in many standard formulas and saturated fat content is low.

<sup>c</sup> Use sparingly for self-care because the fat content is higher than recommended by general dietary guidelines.

*Note:* The most current and detailed information is available at manufacturer Web sites, including Abbott Nutrition ([www.abbottnutrition.com](http://www.abbottnutrition.com)) and Nestlé Nutrition ([www.ensure.com/products](http://www.ensure.com/products)).

#### Modular Products

Modular products supplement a single macronutrient. Examples include protein powder, medium-chain triglyceride oil, emulsified oils, and powdered, flavorless glucose polymers. These products can be incorporated into food to increase protein and calorie content. For example, a protein powder may benefit a person of advanced age who is

having difficulty meeting protein requirements with his or her usual oral diet.

### Specialty Formulas

Specialty formulas may be either polymeric or oligomeric. They are designed to optimize the nutrient intake and improve disease management for patients with specific disease states such as renal insufficiency, diabetes mellitus, hepatic dysfunction, and carbon dioxide-retaining pulmonary dysfunction. The use of specialty formulas is controversial because data supporting improved outcomes are minimal. In general, use of specialty formulas requires medical supervision. Consultation with a registered dietitian, certified nutrition support clinician, or board-certified nutrition support pharmacist may be warranted.

Some specialty formulas, such as certain pulmonary and diabetic formulas, alter the ratio of fat and carbohydrate but contain no special dietary components. Although technically such products are medical foods, there would be little concern for most individuals who used them to replace a few meals per week. However, individuals must be encouraged to limit their use of these products unless otherwise advised by their primary care provider or a provider who specializes in nutritional management of their condition. They should advise their primary care provider when they use these products, because management of the underlying disease itself requires medical oversight. [Table 23-11](#) includes a few examples of pulmonary and diabetic formulas.

### Product Use for Self-Care

All products recommended for self-care should contain basic nutrition labeling, including serving size, calories, protein, fat, and other components consistent with food labeling so that nutrient intake can be determined in the same manner as with regular foods. Many formulas are available in a variety of flavors to reduce taste fatigue; slight differences in nutrient content may be noted among the flavors.

### Administration and Monitoring Guidelines for Enteral Nutrition

For products taken orally, the individual should be encouraged to vary flavors to avoid taste fatigue and to consume the product after an attempt to eat a well-balanced meal or a between-meal snack. Chilling may improve palatability. Once opened, the container should be kept refrigerated to prevent bacterial growth, and all open or prepared products should be discarded after 24 hours.

When products are given as tube feeding, medical supervision is recommended. Enteral nutrition practice recommendations are available at the American Society for Parenteral and Enteral Nutrition Web site ([www.nutritioncare.org](http://www.nutritioncare.org)). Referral to a nutrition support provider may be appropriate. Medical referral is appropriate for individuals who develop diarrhea, nausea, or abdominal distension when taking meal replacement formulas. Formula-related diarrhea is an osmotic diarrhea that usually stops within 24 hours of discontinuing the formula; diarrhea that persists longer is unlikely to be caused by the formula per se. Lactose intolerance is seldom an issue with enteral formulas because most formulas are lactose-free except powders prepared with milk. High-fat products can delay gastric emptying, resulting in nausea and/or bloating.

### Food-Medication Interactions

Interactions between medications and enteral formulas often are complex and poorly understood. Interactions involving a formula component have the potential to occur with either oral administration or feeding tube administration. The provider is advised to consult specialty references for a more complete list and explanation of such interactions. General practice for certain medications (including phenytoin, carbamazepine, and warfarin) is to withhold the formula for 1 or 2 hours before and after administering the medication, especially when therapeutic levels are not achieved with typical doses. It is reasonable to suggest this same precaution of separating the drug by 1 or 2 hours when formula is taken by mouth and to advise supervision of the medication response by a primary care provider. Vitamin K content of the formula should also be checked for individuals on warfarin. Although most formulas provide no more vitamin K than that of a typical diet, a few contain amounts that could interfere with anticoagulation. Manufacturers' Web sites, such as those listed in the footnotes of [Table 23-11](#), provide detailed, up-to-date information on the nutrient content of formulas.

### Other Medical Food and Meal Replacement Food

In recent years, several medical foods have become available for a range of common diseases treated in the ambulatory care setting, as shown in [Table 23-12](#). Foods used in weight-loss and bariatric programs are also medical foods requiring medical supervision when used as intended because of significant risks associated with rapid weight loss. Meal replacement foods such as Slim Fast, Weight Watchers, and Jenny Craig products are not medical foods. They can be used safely without medical supervision to help control portion size and balance nutrient intake; however, they should be used as part of an overall weight-loss plan (see [Chapter 26](#)).

#### TABLE 23-12 Medical Foods for Common Conditions

<i>Condition</i>	<i>Product (Manufacturer)</i>
Alzheimer's disease	Axona (Accera Inc.)
Depression	Deplin (Pamlab)
Depression-associated sleep disorders	Sentra PM (Targeted Medical Pharma)
Irritable bowel syndrome	VSL#3 probiotic (Sigma-Tau Pharmaceuticals)
Osteoarthritis	Limbrel (Primus Pharmaceuticals)
Osteopenia/osteoporosis	Fosteum (Primus Pharmaceuticals)
Pain and inflammation	Theramine (Targeted Medical Pharma)
Ulcerative colitis	VSL#3 probiotic (Sigma-Tau Pharmaceuticals)

**TABLE 23-13 Exclusions for Self-Care with Enteral Formulas**

<i>Condition</i>	<i>Example/Comment</i>
Organ dysfunction requiring diet modification	Renal insufficiency requiring restriction of protein and electrolytes eliminated through the kidneys (potassium, phosphorus, magnesium).
Gastrointestinal dysfunction	Poor motility: Dietary modification may be required to avoid bowel obstructions; enteral formula may be appropriate under the supervision of a primary care provider or nutrition specialist, but not as self-care. Reduced absorption: Hydrolyzed protein, modified fats, and/or relatively simple carbohydrates may be necessary for adequate absorption; monitoring for nutrient deficiencies is required. Dysphagia: Referral for medical evaluation is required. Bariatric surgery: Medical supervision is required; recommendations of primary care provider or nutrition specialist should be followed.
Significant unintended weight loss	Refer for medical evaluation to determine the etiology. Life-threatening fluid and electrolyte abnormalities can occur when refeeding these individuals; medical supervision and monitoring are required.
Disease state affected by diet, such as diabetes mellitus, chronic obstructive pulmonary disease	Enteral formula may be appropriate to meet nutritional requirements; however, use should be under the supervision of a primary care provider or nutrition specialist, but not as self-care.

### Assessment of Enteral Nutrition and Meal Replacements: A Case-Based Approach

The first step in assessing the type of meal replacement (or supplement) to recommend is to determine whether the individual has any exclusion to self-care as listed in [Table 23-13](#). If self-care is appropriate, the provider should ascertain the reason for a meal replacement or supplement so that the most appropriate product can be selected. For instance, a person of advanced age with early satiety may benefit from a concentrated formula that provides 1.5 or 2 kcal/mL, whereas a young person wanting a meal supplement for use with weight lifting may benefit from a higher-protein formula. The selected formula should be appropriate to meet the individual's specific nutritional needs according to health status while avoiding excessive or contraindicated macronutrients and micronutrients. Meal replacement products can have efficacy for the treatment of many health concerns. Traditionally, meal replacement has been considered a therapeutic intervention needed to maintain adequate nutrition in malnourished patients, to completely replace nutritional intake in patients with a physical limitation that interferes with nutritional intake such as dysphagia, or to precisely control intake of specific dietary components (calories for obesity and phenylalanine in phenylketonuria). Increasingly, nutrition products are used as lifestyle choices of self-directed therapy. This practice is particularly true of the meal replacement products used by working individuals who are too busy to prepare or eat a proper meal or who perceive these products as healthier alternatives to fast foods. Case 23-2 illustrates assessment of a patient with dysphagia and weight loss who seeks a liquid meal replacement.

### Patient Counseling for Enteral Nutrition and Meal Replacements

Advancements in enteral products and home infusion therapy are allowing more people with serious, even terminal, illnesses to be cared for at home. Enteral products are also appropriate for ambulatory patients with metabolic or digestive diseases and for persons who want to ensure adequate nutrition for their life stage. Providers serve a pivotal

role in helping patients to use the product best suited for their nutritional needs and to use it under medical supervision when appropriate. The box Patient Education for Enteral and Meal Replacement Products lists specific information to provide patients and caregivers.

### Key Points for Functional and Meal Replacement Foods

- The definition of FF typically includes “health benefits beyond those of basic nutrition.”
- Health claims are statements describing an association between a food, food component, dietary ingredient, or dietary supplement and the risk of a disease or health-related condition.
- *Authorized* and *authoritative* health claims meet the significant scientific agreement level of evidence. These claims should routinely be incorporated into counseling for lifestyle changes associated with health benefits and, when appropriate, as part of an overall plan for management of diseases associated with the claim.
- *Qualified* health claims do not meet the significant scientific agreement level of evidence; claims statements must include language that indicates the qualified nature of the health claim.
- *Structure-function* claims lack the significant scientific agreement level of evidence and make no association between the product and risk of a disease or health-related condition; they do not require validation or authorization by FDA.
- Health care providers should understand the limitations of qualified health claims and structure-function claims. When counseling for lifestyle changes, the limited scientific evidence for these claims should be clearly delineated so individuals can understand the role, or lack thereof, for these products in a healthy lifestyle.
- Foods for special dietary use meet *particular dietary needs* related to physical, physiologic, pathologic, or other conditions, such as disease, convalescence, pregnancy, lactation, underweight, overweight, infancy, or need for sodium restriction, or they supplement or fortify the usual diet; they are subject to general labeling requirements for foods and do not require use under medical supervision.
- Medical foods are specially formulated and processed to meet *distinctive nutritional requirements* (established by medical evaluation based on recognized scientific principles) of the disease or condition for which they are intended. These foods are to be recommended and used under medical supervision.
- Conventional foods classified as FF are typically associated with health benefits in epidemiologic studies; evidence supporting a functional role for these foods is weak-moderate, with clinical trials often lacking.
- Fiber is associated with improved laxation, cholesterol reduction, satiety, and probably glucose control for select fiber sources.
- Prebiotics are fermentable dietary components that selectively stimulate the growth and/or activity of one or a limited number of bacteria in the colon (bifidobacteria and lactobacilli), thereby benefiting the host.
- Probiotics are nonpathogenic, living microorganisms that have a beneficial effect on the host when consumed regularly in adequate amounts. They are often present in fermented products from milk (yogurt and kefir) or plants (sauerkraut and miso).
- Probiotics have shown beneficial effects in a number of diseases; however, the particular species and strain and the dose necessary for beneficial effects often remain controversial and may vary from condition to condition.
- Enteral nutrition products may be classified as medical foods; however, many polymeric enteral formulas are readily available and can often be used safely as a meal replacement product.
- Specialty enteral formulas should be used with medical supervision, not for self-treatment.

### Case 23-2

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient’s symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Alzheimer’s dementia symptoms, progressive. Patient is easily frustrated and demanding of attention. Patient’s daughter describes him as being very forgetful and showing more signs of Alzheimer’s dementia in the past month. At the Alzheimer’s family support meeting last week, she heard about a new food/liquid meal that is helpful with slowing Alzheimer’s progression and is requesting this product for her father.

b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	NA
c. description of the patient's efforts to relieve the symptoms	Patient is currently taking donepezil. He also takes a multivitamin-mineral supplement.
d. patient's identity	Lambert Jorgenson
e. age, sex, height, and weight	84 years old, male, 5 ft 10 in., 155 lb
f. patient's occupation	Retired truck driver
g. patient's dietary habits	Usually takes two meals daily and a couple snacks. Must be reminded to eat and encouraged to eat more than one food off his plate.
h. patient's sleep habits	Sleeps about 6 hours at night but also naps during the day.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Hydrochlorothiazide for hypertension; multivitamin/mineral supplement
j. allergies	Codeine; sulfa (rash)
k. history of other adverse reactions to medications	Ataxia with metronidazole
l. other (describe) _____	
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Patient's daughter is requesting a medical food for use in Alzheimer's dementia.
3. Identify exclusions for self-treatment.	Medical foods require medical supervision.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer patient to his PCP to discuss use of the medical food and obtain a prescription. (2) Recommend self-care with a general supplement to improve nutrient intake. (3) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	"Patient's daughter should consult with her father's PCP regarding the medical food."
6. Describe the recommended therapeutic	"You are requesting a product that requires medical supervision for

approach to the patient or caregiver.	use. The pharmacy can order the product for you once you have discussed this with your father's physician and you have a prescription."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"In addition to verifying that your father has medical supervision for using the product, a prescription may make the product eligible for coverage by your father's insurance."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"Do you know how this product works, and could I just change what I cook for my father rather than getting a prescription?"
Answer the patient's or caregiver's questions.	"The product is based on a specific type of fat that is absorbed and metabolized differently than the typical oils found in the grocery store. It must be given in an appropriate amount with a proper balance of other nutrients to achieve the desired effect."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	"Let me know when you have the prescription and want me to order the product. If you want more information on the product, you can also check the Web site ( <a href="http://www.about-axona.com">www.about-axona.com</a> )."

Key: PCP = Primary care provider.

#### Patient Education for Enteral and Meal Replacement Products

The objective of self-treatment is to provide the appropriate amounts and types of specific micronutrients and macronutrients to meet the individual's nutritional needs. For most individuals, the product instructions and self-care measures listed here will help ensure optimal therapeutic outcomes.

- Typical products provide 1 cal/mL; higher-calorie products are available if you must limit your fluid intake or can drink only a small amount at a time.
- When drinking the formula, take about 1/2-1 can at a time. You can drink the formula at room temperature, but it may taste better if chilled or semifrozen as a slush-type drink.
- Varying the flavor of the formula may reduce taste fatigue.
- For tube feeding, the product should be used as directed by your primary care or nutrition care provider. The Oley Foundation ([www.oley.org](http://www.oley.org)) provides consumer information on tube feeding.
- Keep opened containers refrigerated and covered to prevent bacterial growth; discard all remaining prepared products after 24 hours. Unopened product can be stored at room temperature.
- Use of meal replacement products as the sole or primary source of nutrition for more than a short time (2-3 weeks) requires medical supervision and should be discussed with your primary care provider. Periodic laboratory testing may be appropriate to detect electrolyte abnormalities in this situation.

#### When to Seek Medical Attention

- Monitor blood glucose levels if you have diabetes or have had high blood glucose (sugar) levels. Talk to your primary care provider if blood glucose levels are high or low.

## Handbook of Nonprescription Drugs > Chapter 24. Sports Nutrition and Performance-Enhancing Nutrients and Supplements

### Sports Nutrition and Performance-Enhancing Nutrients and Supplements: Introduction

Competing athletes exercise at various levels. Recreationally active individuals may spend 5-10 hours or more per week in physical activity, and diet alone should meet their nutritional needs. By comparison, high-volume intense training for 10-20 hours or more per week may require specific nutritional intake to maintain or enhance performance.<sup>1</sup> This chapter reviews the effects of products that contain macronutrients and nutritional supplements on physical activity and performance for both the recreational athlete and the more aggressive competitor. Food supplements and natural products are marketed as ergogenic aids to athletes and active people for three primary purposes: (1) to improve strength and power, (2) to prolong the duration of exercise by providing fuel for continued effort, and (3) to replace water and electrolytes lost from sweat to prevent dehydration and to support normal muscle contractions. Readers are referred to two guidelines for detailed discussions on this topic: (1) the International Society of Sports Nutrition (ISSN) Exercise and Sport Nutrition Review<sup>1</sup> and (2) a joint statement of the American Dietetic Association (ADA), the Canadian Dietetic Association, and the American College of Sports Medicine guidelines (ADA guidelines) for Nutrition and Athletic Performance.<sup>2</sup>

### Popularity of Sports Nutrition Products

Sports nutrition products and performance-enhancing supplements have gained wide acceptance in both highly trained athletes and mildly to moderately active individuals. Increasing numbers of consumers are choosing sports nutrition products as lifestyle alternatives to traditional beverages and snacks. In 2013, the sports nutrition market was estimated to reach \$10 billion in sales.<sup>3</sup> The market segment includes traditional carbohydrate and electrolyte sports drinks along with energy drinks with supplemental caffeine, recovery drinks, and other nutrient-enhanced soft drinks, juices, and waters. The market for solid forms includes meal replacement bars and easy-to-digest carbohydrate gels. Tablets, capsules, and powders that contain macronutrients, electrolytes, and herbal supplements are included in the supplement market.

### FDA, NCAA, Antidoping Agencies, and Regulation of Performance-Enhancing Supplements

The Food and Drug Administration (FDA) does not approve dietary supplements or validate claims of performance enhancement. Reports of nutritional supplement misbranding are common.<sup>4,5</sup> Misbranding occurs when products contain an ingredient not listed on the nutrition facts and ingredients label, or when products contain less than the stated quantity of a labeled ingredient. Unlabeled doping substances including amphetamines and anabolic steroids were found in 19% of vitamin and creatine supplements submitted for voluntary testing by Olympic athletes in 2002.<sup>4</sup> More recently, products purchased over the counter or through the Internet were found to contain the following recombinant hormones: erythropoietin, growth hormone, insulin-like growth factor, and growth-hormone-releasing protein.<sup>5</sup> The antidoping agencies state clearly that athletes are responsible for substances they ingest. A positive test results in a violation regardless of the package label. Nutritional products are tested at independent laboratories such as ConsumerLab.com, which provides reports for a fee. A list of banned substances and antidoping resources is available at these Web sites: [www.usantidoping.org](http://www.usantidoping.org), [www.wada-ama.org](http://www.wada-ama.org), and [www.consumerlab.com](http://www.consumerlab.com). Chapter 50 provides a more detailed discussion of dietary supplement regulation.
