Dietary supplements and prescription drugs are used and shared among college and high school athletes, possibly for performance gains. In 2009, the National Collegiate Athletic Association (NCAA) surveyed 20,474 athletes who participated in sports at division I, II, and III levels.<sup>6</sup> The NCAA survey reported high rates of nutritional supplement use, including a 44.5% and 13.9% rate for using an energy drink or an energy booster in the previous 12 months, respectively. Other observations include a 38.4% use of protein supplements and a 13.8% use of creatine. Use of energy drinks and protein supplements was higher than general multivitamin use (20.3%). The NCAA survey also reported that amphetamine, ephedrine, and anabolic steroid use were all reduced from previous surveys. Amphetamine use was reduced from 4.5% in 2005 to 3.7% in 2009, and anabolic steroid use was reduced from 1.7%-0.5%. Ephedrine is no longer available as a nonprescription product and its use is only 0.4%. Friends, teammates, and relatives continue to be a common source of unprescribed amphetamines. Reports of amphetamine swapping are concerning because these activities are illegal and show a willingness to break the law to improve sports or academic performance.

High school athletes are also exposed to nutritional supplements and may have access to prescription medications

that affect performance.<sup>7</sup> A survey of American high school athletes in 2007 noted that 5.9% of male seniors reported using an anabolic steroid. This survey also revealed a high rate of nutritional supplement use: 62% used a daily multivitamin, 31% used energy drinks, 22% used protein powders, and 12% used creatine. Among female athletes, 18.6% reported using a “fat burner” to lose weight. High school athletes reported greater use of these substances than college-age students; therefore, education on the safe and effective use of nutritional intervention, supplements, and performance-enhancing products is needed as early as the high school level.

The American Academy of Pediatrics (AAP) has determined that the average child engaged in routine physical activity should drink water. The AAP has taken the position that carbohydrate-containing sports drinks are not necessary and that caffeine-containing “energy drinks” should not be consumed by children and adolescents.<sup>8</sup>

### Macronutrient Use for Athletic Performance—Basic Concepts

Macronutrients (carbohydrates, fats, and proteins) play pivotal roles in athletic performance and muscle development, but each type of macronutrient has unique properties and use. Even during competition, the primary drive is to preserve muscle glycogen for “fight or flight” responses. Four primary concepts explain sports nutrition macronutrient intake and its contribution to energy provision for athletic performance. First, when not exercising, macronutrient intake is stored for use later. Second, during exercise stored macronutrients are used slowly according to the exerciser’s aerobic capacity to burn fats rather than glycogen, thus preserving glycogen. Fatty-acid oxidation is the primary fuel for aerobically intense activity, thus allowing muscle glycogen to be preserved for periods of higher intensity. Third, when faster intensities are maintained for longer durations, muscle glycogen depletes faster. Finally, at the highest intensities, an anaerobic energy system contributes energy from muscle phosphocreatine directly to depleted adenosine diphosphate (ADP), permitting restoration of muscle adenosine triphosphate (ATP).

Muscles are always seeking a state of optimal muscle glycogen. When the body’s muscles are at rest, caloric intake is converted to energy storage for use at a later time. Carbohydrate intake that exceeds current metabolic need is first converted to glycogen, which is stored in muscles and the liver for rapid, immediate use. When glycogen stores are complete, any remaining carbohydrates are converted to fatty acids for storage. Humans are biologically designed to maintain a full reserve of glycogen as an immediate energy source for short-duration, high-intensity activity such as fight or flight. At the lowest level of exercise intensity, a walking state, calorie utilization per minute is minimal, with 80% of the calories obtained from fatty-acid oxidation and the remaining 20% from carbohydrates.<sup>9,10</sup> As exercise intensity increases from walking to aerobic jogging, calorie consumption per minute increases, and fatty-acid oxidation continues to provide about 80% of the fuel.<sup>9,10</sup> Conversion of fatty acids to energy is slow and rate limited, and the conversion rate varies from athlete to athlete. The only known way to improve fatty-acid oxidation is adaptation to exercise.<sup>11</sup> No functional foods or supplements improve the rate of fatty-acid metabolism.<sup>1,2</sup> A detailed discussion on fatty-acid metabolism is beyond the scope of this chapter and can be found elsewhere.<sup>10,11</sup>

Second, calories burned per minute from fat are limited and reach a plateau; therefore, athletic performance is impaired without additional calories from other sources such as carbohydrates.<sup>9,10</sup> At the intensity of a fast run, such as a 10-km running race, fatty-acid oxidation can’t meet all of the energy requirement, and carbohydrate utilization is added to the energy derived from fats. At this level of intensity, carbohydrate utilization increases to 50% of total calorie expenditure.<sup>12</sup> The rate reaches 80%-90% for sprint events (200 meters).<sup>12</sup> Progression of exercise intensity from walking to running to sprinting is seen in many sports, and some sports, such as soccer or field hockey, have a combination of extreme high-intensity effort intermixed with efforts at a more aerobic pace. The oxidation of fatty acids is the predominant fuel until exercise intensity requires the faster energy conversion from carbohydrates.

Third, glycogen depletion is an intensity and durational concept. Marathon runners refer to muscle glycogen depletion as “hitting the wall.” A similar term, “bonking,” references the cognitive and mental attention deficits athletes can experience when glycogen depletion leads to hypoglycemia. Limited storage capacity exists for glucose as glycogen within the liver and skeletal muscle; an average 150-pound individual stores only about 2000 total calories of glycogen. High-intensity exercise over time depletes glycogen stores.<sup>9,10,13</sup> Muscle glycogen is burned initially, and as this resource is depleted, the liver releases glucose from stored glycogen to maintain serum glucose levels. When both muscle and liver glycogen stores are depleted, serum glucose decreases and athletic performance declines. Sudden drops in blood glucose levels affect the athlete’s mental acuity, attention, and focus.<sup>9,10</sup> Endurance athletes slow to an aerobic effort in which fatty-acid mobilization predominates, but they are less competitive at that rate of intensity. Athletes participating in sports that require high cognitive skill, such as shooting sports, archery, and automobile racing, experience lower performance and brain activity as their serum glucose levels decrease.<sup>1,2</sup> The rate of glycogen depletion is dependent on the intensity and duration of exercise, as well as the fitness level of the athlete.<sup>9,10</sup> Endurance runners can deplete muscle glycogen in about 2-2.5 hours at a marathon running pace and do not require carbohydrate intake unless exercising that duration or longer.<sup>1,2</sup> The same runners may deplete glycogen in 60 minutes when running at the faster intensity of a 10-kilometer run, but generally do not require carbohydrate supplements because they complete the event in less time (30-40 minutes) than it takes to deplete

muscle glycogen.<sup>1,2</sup> Team sports such as football, lacrosse, field hockey, and basketball have official game-time durations of 90 minutes or less, as well as time-outs, half-times, and player substitutions that allow for periods of aerobic recovery. For these sports and durations, glycogen depletion is not expected to occur. Very fit athletes adapt over time to a state of efficient fatty-acid utilization and require less glycogen; their carbohydrate stores are available in later stages of events compared with undertrained athletes.<sup>9,10</sup>

A fourth concept is that the highest-intensity sports, those requiring short bursts of power lasting less than 30 seconds to 1 minute, use the phosphagen system and energy stored primarily as ATP.<sup>14</sup> Examples include track and field events and weight lifting. Energy stored in phosphate bonds is depleted in a matter of seconds and then regenerates with rest. This energy system is discussed further in the section on creatine. Intermittent high-intensity sports such as football, soccer, basketball, tennis, and ice hockey use both very short (phosphagen and ATP) energy systems and intermediate (glycogen) systems over the competition range of 30-60 minutes.

## Sports Nutrition Market Basics

The sports nutrition market was developed for well-trained athletes competing at high intensities for long durations. College football players may exercise for 4 hours daily and exceed 20 hours of exercise per week. These athletes may need to provide fuel during exercise to delay or prevent glycogen depletion or may require rapid muscle glycogen restoration between morning and afternoon practices. Sports drinks can be consumed during practice or competition and have replaced the concept of carbohydrate loading prior to long-duration events. Most marathon runners and triathletes consume carbohydrates during the event.<sup>1,2</sup> Sports products also contain electrolytes to prevent deficiencies from sweat loss.

By comparison, moderate physical activity such as daily exercise for health and wellness usually occurs at a lower intensity and typically lasts 60 minutes or less per day.<sup>1,2</sup> Glycogen depletion is unlikely for recreational athletes, even if they exercise 7 hours per week; consequently, calorie-dense sports products are unnecessary for health and wellness athletes or sedentary individuals for whom performance is not an issue.<sup>1,2</sup>

### Carbohydrate-Based Products

Sugar content is listed separately from total carbohydrate in the nutrition facts on food labels. Carbohydrate-based sports nutrition products contain monosaccharides (glucose and fructose) as well as the disaccharide sucrose (glucose + fructose); these sugars provide rapid absorption and availability of carbohydrates. Maltodextrin (glucose + glucose as a polymer) is used in endurance formulas and is marketed as having slower absorption. Lactose (glucose + galactose), or milk sugar, can also be used as a recovery fuel after exercise.<sup>1,2</sup>

The ADA guidelines recommend 30-60 grams of carbohydrate intake per hour of continued exercise.<sup>2</sup> This translates to 10-15 grams of carbohydrates, or 4-8 ounces of a sports drink every 15 minutes, given that most sports nutrition drinks contain 6%-8% carbohydrates for optimal absorption and gastrointestinal (GI) tolerance.<sup>1,2</sup> The amount of carbohydrates is small and should be rapidly used during continuing exercise; however, the fluid volume is relatively large. These products should be used in practice and under simulated competition so that the athlete can learn how they tolerate a product. Larger doses of carbohydrates (80 grams) in single doses are not recommended. Limited research suggests that large doses of carbohydrate may result in a larger insulin release, leading to hypoglycemic symptoms and reduced performance.<sup>15</sup> The various carbohydrate forms (i.e., drinks, gels, and bars) do not differ in their effectiveness; however, the amount of water and electrolytes and the specific sugar sources vary. Bars and gels are lighter and easier to carry than an equivalent amount of calories in the form of a sports drink; however, they require a water source for proper dissolution, absorption, and GI tolerance. In addition, compared with sports drinks, the bars tend to contain other macronutrients, such as fats, proteins, and vitamins, making them better suited for recovery after exercise than for glycogen preservation during an event.

Although the original intent of these products was to provide fuel on the go, the market has evolved to provide meal replacements for active people in a hurry. These products are misunderstood by the public as healthier than soft drinks, candy bars, or even regular meals, despite their high sugar and caloric content. The health care provider should be prepared to read and interpret the nutrition label with patients and to calculate total calories if the package offers multiple servings. These products are not required by active adults or children who exercise 60-90 minutes in any one session.<sup>2,8</sup> Recreational athletes and sedentary individuals should be discouraged from using these products before, during, or after exercise that lasts less than 90 minutes.<sup>2,8</sup> The ADA and AAP recommend eating a meal after exercise as a suitable glycogen recovery method.<sup>2,8</sup> Examples of bars, gels, and drinks are presented in [Table 24-1](#).

### Fats: Triglyceride-Containing Products

Fats are an important source of energy, fat-soluble vitamins, and essential fatty acids for athletes, and their

consumption should not be restricted.<sup>2</sup> The timing of fat intake may be important.<sup>2</sup> Long-chain triglycerides, found in typical fats and oils, should be avoided in sports nutrition products used 1-2 hours before and during exercise because they tend to slow gastric emptying and may cause discomfort, bloating, and GI intolerance during intense exercise. Medium-chain triglycerides (MCTs) are packaged into sports drinks and powders to provide an alternative fuel to glucose and to reduce muscle glycogen utilization.<sup>11</sup> The moderate length (8-12 carbons) of MCTs results in absorption from the GI tract directly into the bloodstream, allowing more rapid utilization than with long-chain triglycerides, which are absorbed through the lymphatic system. Some MCT beverages are marketed to strength and conditioning athletes on low-carbohydrate diets. Clinical data in athletes suggest that MCTs are utilized metabolically within 30 minutes of ingestion, but no data show improved performance or muscle glycogen sparing<sup>11</sup> (Table 24-1.)

### Protein Products for Muscle Mass Gain

Athletes commonly train with weights to build muscle and to develop a bigger, stronger, or more toned body. Many athletes believe they need to consume large quantities of protein to provide substrates for muscle development. The dietary source of protein can vary and may include meat and dairy; vegetarian sources such as legumes, beans, and nuts; and prepackaged protein sources, such as protein powders, amino acid supplements, and various protein-containing bars, gels, and drinks.

Most adults who are not active athletes require 0.8-1 gram of protein per kilogram of body weight per day (g/kg/day) to provide enough protein to maintain a neutral nitrogen balance, to fuel the many repair and maintenance functions throughout the body, and to maintain muscle mass.<sup>16</sup> These sedentary adults generally do not require more than 25 kcal/kg/day for weight maintenance. Compared with the general population, active athletes who exercise for 10 or more hours per week have increased protein and calorie requirements.<sup>16</sup> The ADA guidelines recommend protein intake of 1.2-1.7 g/kg/day in highly active adults who participate in endurance exercise and those who are attempting to increase body mass; this recommendation is in addition to an increased overall caloric intake to meet higher metabolic demands.<sup>2</sup> Anecdotal evidence of athletes ingesting 1.8-2.5 g/kg/day of protein has been reported despite lack of data supporting its effectiveness.<sup>2,16</sup> A large number of protein supplement products exist in the marketplace, spurred by manufacturer claims that building muscle requires increased amounts of specific amino acids, the essential amino acids or the branch-chain amino acids, and by the large market demand. However, the ISSN and the ADA guidelines indicate that simple adjustments to the athlete's diet can provide sufficient protein to meet dietary intake goals for increasing muscle mass.<sup>1,2</sup> No evidence supports packaged protein supplements or a specific amino acid mixture as more effective at increasing body mass than eating whole foods with equal amounts of protein.<sup>1,2,16</sup> Free amino acids result in a higher osmotic effect, which can cause GI distress and diarrhea, and specific amino acid supplements can be deficient in one or more of the essential amino acids, which may adversely affect growth and development.<sup>1,2</sup>

**TABLE 24-1 Sports Nutrition Products<sup>a</sup>**

	<b>Serving Size</b>	<b>Energy (kCal)</b>	<b>Carbohydrate (gram)</b>	<b>Sugars (gram)</b>	<b>Protein (gram)</b>	<b>Fat (gram)</b>	<b>Sodium (mg)</b>	<b>Potassium (mg)</b>
<b>Electrolyte Drinks and Wafers (low calorie)<sup>b</sup></b>

**Fat (MCT)-Containing Products<sup>g</sup>**

MCT Fuel (Twin Lab)	30 mL	130	12	0	0	9	0	0
------------------------	-------	-----	----	---	---	---	---	---

- <sup>a</sup> Composition per serving. Slight differences exist within products with multiple flavors or formulations. Please refer to the product nutrition label or the manufacturer's Web site for the most current information.
- <sup>b</sup> Intended as a healthy, low-calorie alternative to carbohydrate sports drinks. For rehydration and electrolyte replacement following exercise time of an hour or less when glycogen depletion is not a concern. Performance benefits are unproven.
- <sup>c</sup> Intended for use during exercise to provide carbohydrates for energy and glycogen sparing, as well as electrolytes and water for rehydration.
- <sup>d</sup> Intended for use after exercise of prolonged duration when glycogen depletion is expected.
- <sup>e</sup> Intended for use during exercise to provide electrolytes as well as carbohydrates for energy and glycogen sparing. Require a water source for proper dissolution and absorption. Not intended for rehydration.
- <sup>f</sup> Intended for postexercise recovery after exercise of prolonged duration when glycogen depletion is expected. Can serve as a meal replacement product. Often contain added vitamins and minerals.
- <sup>g</sup> Intended as fuel for recovery in athletes who choose a low-carbohydrate diet.

Athletes attempting to gain muscle mass may require an increased total calorie intake of 30-35 kcal/kg/day to balance their increased energy needs from exercise and to provide protein for muscle building.<sup>2</sup> Muscle-building athletes should be educated to not exceed reasonable total calorie goals. Any excessive calories, including any additional protein, will be converted to fats for storage, defeating the athlete's goal of a lean physical appearance.

### **Clinical Evidence of Protein Needs for Muscle Building**

Muscle protein is in a constant state of synthesis and breakdown. Resistance exercise induces changes in muscle that effectively stimulate muscle remodeling and growth, provided the diet offers an adequate quality and timing of protein for that growth.<sup>16</sup> The process is slow and requires repeated exercise stimulus, optimal nutrition, and several months to observe weight gain. A net positive protein balance is thought to be evidence of an increase in muscle fiber diameter and in the muscle proteins actin and myosin.<sup>16</sup> Muscle weight gain relies equally on the quality of the protein, the amino acid profile of the protein source, the timing of protein intake relative to exercise, and the exercise experienced by the athlete; quantity of protein consumed has a minimal influence. The athlete must also consider the total calorie consumption per day required to meet the intensity of training and, accordingly, consume adequate calories to allow the protein to be used for building muscle.<sup>2,16</sup> Data from inexperienced athletes beginning a weight-training program suggest that 1.4 g/kg/day of protein provides neutral protein balance, and 1.7 g/kg/day is recommended for muscle accumulation.<sup>16</sup> Well-designed studies of protein intake at 2 g/kg/day and greater have not resulted in consistent increases in lean body mass compared with the control group and indicate only increased protein oxidation for energy.<sup>16</sup> Protein intake up to 2.6 g/kg/day did not influence further lean body mass accumulation or total body weight gain in inexperienced athletes. Similar results have been found in experienced strength-training athletes; therefore, the ADA recommends that strength-training athletes target 1.4-1.7 g/kg/day of protein for muscle accumulation.

### **Adverse Effects of Diets with High Protein Intake (2 g/kg/day)**

Little is known regarding nephrotoxicity risk from high-protein diets, defined here as 2 g/kg/day or greater. In theory, elimination of the amine group, or the nitrogenous waste, from protein intake may affect glomerular filtration. Unfortunately, available data are either anecdotal or retrospective. One retrospective observation used diet and exercise histories to compare groups of experienced athletes claiming to have followed a regular diet or a high-protein diet for up to 3 years.<sup>17</sup> Diet logs indicated average protein intake of 1.4 g/kg/day for the regular-diet group and 2.0 g/kg/day in the high-protein group. No difference was observed between the groups for serum creatinine measurement or estimated creatinine clearance from a 24-hour urine collection. Nitrogen clearance was not measured. Reliability of this study is questionable because a diet high in red meat may increase measured serum creatinine and urine creatinine levels, thereby affecting the accuracy of a calculated creatinine clearance. The available data are not sufficient to prove that high-protein diets over many years are either safe or unsafe. High dietary protein intake may affect hydration status or increase the risk of dehydration from the increased nitrogenous waste that must be eliminated. Adequate hydration is required to optimize elimination of the waste. A

frequent method for predicting dehydration risk is to evaluate urine color, with pale or light yellow urine considered a good sign of adequate hydration. A second method to monitor dehydration is for athletes to weigh themselves every morning, after voiding, for several days to obtain a reliable baseline weight.<sup>18</sup> Subsequently, the athletes can measure body weight before and after exercise. Any significant weight loss from short-duration exercise is likely to reflect dehydration. A similar method could be used before introduction of high-protein intake. Methods to calculate the rate of sweat production are discussed elsewhere.<sup>18</sup> Objective measures of hydration require laboratory analysis of serum and urine osmolality and electrolyte levels. A urine test to measure specific gravity is available to consumers, but further laboratory testing and validation are required to determine hydration status.<sup>18</sup>

## Water and Electrolytes

Water and electrolytes are essential to performance. A 2% decrease in total body weight can affect physical and mental performance.<sup>18</sup> Dehydration results in increased physical strain, as measured by elevations in core body temperature, heart rate, and perceived exertion. The greater the body water deficit, the greater is the strain for a given task. Dehydration can also affect cognitive performance such as mental concentration and focus on skilled tasks. Dehydration (3%-5% body weight) does not appear to affect anaerobic performance or muscle strength. Readers are referred to the position statement of the American College of Sports Medicine for guidelines and detailed discussion of this topic.<sup>18</sup>

Dehydration involves both water loss and electrolyte concentrations as separate issues. Athletes generate heat from exercise-related muscle contractions in proportion to the intensity and duration of exercise. This heat generation is transferred to the blood and then to the body core. Blood circulation through peripheral blood vessels and the skin allows radiant heat exchange with the environment. Fluid and electrolyte loss as sweat onto the skin surface facilitates evaporative cooling. Environmental conditions such as temperature, humidity, air motion, helmets, and layers of clothing influence the success of evaporative cooling. If sweat-related water and electrolyte losses are not replaced, the athlete experiences dehydration.

The significance of dehydration depends on environmental conditions, exercise intensity, and its duration. For example, compared with a recreational runner, an elite marathon runner may demonstrate a higher sweat rate, as measured by sweat loss per hour, but both athletes will have similar total sweat losses for the event owing to the prolonged time that the recreational athlete needs to complete the event. By comparison, American football players have significantly greater sweat rates than soccer players practicing in identical conditions owing to the football players' layers of clothing and equipment, which contribute to the greater heat accumulation and greater sweat and electrolyte losses, while preventing evaporative cooling. The risk of dehydration in football players is further influenced by twice-daily practice sessions, which may not allow adequate time between sessions for water replacement.

## Health Conditions Related to Dehydration

Hydration can affect health through water loss or water gain (overdrinking) and can affect serum sodium levels sufficiently to endanger health. In general, dehydration is more common, but overhydration resulting in hyponatremia can be equally life threatening. Signs of dehydration include fatigue, confusion, irritability, and increased risk of heat illness with symptoms of muscle cramps, heat exhaustion, heat stroke, and exertional rhabdomyolysis.<sup>18</sup> Rhabdomyolysis has been reported as a result of dehydration, heat stress, and novel training. Novel training involves the introduction of new exercise patterns in athletes who have not been acclimated to the new exercise, such as military recruits at boot camp or high school students attending preseason football camps.

## Prevention of Dehydration

Meal consumption is the most important aspect of maintaining optimal hydration status.<sup>2,18</sup> Eating promotes fluid intake and retention. Meals generally contain sufficient electrolytes to replace sweat losses. Consuming a meal and allowing 4-24 hours between workouts is sufficient to return to baseline water status. As mentioned previously, athletes can obtain a first-morning body weight, after voiding, to track day-to-day changes in weight. Sports drinks can provide water and electrolytes after exercise, but when assessed 24 hours after a workout, the drinks have not proven superior to the consumption of a meal.<sup>1,2,18</sup> Water alone is sufficient for rehydration during events lasting 60 minutes or less.<sup>2,8</sup> No evidence supports requiring an electrolyte sports drink to prevent dehydration in recreational events of this duration.

## Hyponatremia Risk from Drinking Excessive Free Water

Most laboratory-based studies of dehydration have occurred on stationary treadmills in climate-controlled rooms with little-to-no convective airflow to help sweat evaporation.<sup>18</sup> Because of such studies, athletes have been taught to

drink as much water as possible to prevent dehydration. However, liberal water intake has been called into question following clinical observations of weight gain, severe hyponatremia, cerebral edema, and death in athletes who consumed water without added electrolytes during athletic events lasting longer than 4 hours.<sup>18,19,20</sup> Improved water availability to athletes competing in marathons has not resulted in fewer athletes seeking medical care after races.<sup>19,20</sup> The original research was directed at elite-level athletes competing for 60-150 minutes who consumed small sips of water while running very fast and generating significant body heat and high sweat rates. Unfortunately, this description does not apply to average athletes, who complete the same marathon races at a much slower pace, generate less heat accumulation, and have lower sweat rates.

Observations under more realistic conditions resulted in an advisory statement from the International Marathon Medical Directors Association (IMMDA).<sup>20</sup> This advisory statement suggests that heat production by athletes is significantly affected by their effort (the combination of duration and intensity or speed of the exercise); therefore, a 10-kilometer race effort will generate more heat than a marathon effort (42.2 kilometers). Average athletes run slower than elite athletes; therefore, average athletes are at less risk of heat illness than elite athletes and have more time to consume water at aid stations. The result is that clinical hyponatremia occurs more frequently in nonelite athletes, particularly women who require more than 4 hours to finish a marathon, and in long-course triathletes who require 13-17 hours to complete their events.<sup>18,19,20</sup> The IMMDA recommendations suggest that fluid consumption in athletes' drinks be based on the trigger of actual thirst, rather than on a set volume of fluid intake. As the athletes' thirst increases, they can increase fluid intake from sips of water to a calculated sweat rate. The IMMDA strongly recommends that the athlete choose an electrolyte replacement drink instead of free water to avoid the risk of hyponatremia when competing in events that last 4 hours or longer.<sup>20</sup>

Athletes competing for 2 or more hours can determine their individual sweat rates by observing their total body weight before and after prolonged exercise. For example, an athlete who takes a 2-hour run on a hot afternoon may drop 2 kilograms in body weight. Each kilogram change in body weight would be associated with a 1000-mL water deficit, suggesting that the athlete has lost 2000 mL of water. This athlete can target a drinking rate of 1000 mL per hour, or 240 mL (8 ounces) every 15 minutes during prolonged exercise.

Providing athlete education before the event and electrolyte-containing sports drinks during the event reduces hyponatremia cases in triathletes<sup>21</sup> but not in experienced marathon runners.<sup>18,19,20</sup> Other factors are likely involved. For example, clinical observations indicate exercise-induced hyponatremia may increase with concurrent use of nonsteroidal anti-inflammatory agents (NSAIDs) in marathon runners<sup>20</sup> and long-course triathletes.<sup>21</sup> An exact mechanism is unknown; however, NSAIDs may interfere with normal prostaglandin-mediated regulation of glomerular filtration and renal blood flow. Triathletes with significant hyponatremia were observed to have elevated nitrogen and potassium levels, suggestive of reduced glomerular filtration.<sup>21</sup> Postural hypotension, rather than heat-related illness or dehydration, has been recognized as a health risk in endurance running that is not directly related to fluid intake. When athletes cross the finish line, the sudden decrease in leg muscle contractions allows pooling of blood in the legs and decreased venous return. The resulting decrease in cardiac output may leave the brain underperfused with oxygenated blood, causing the athlete to black out.<sup>20</sup> Athletes should continue walking past the finish line to prevent this reaction. Only athletes demonstrating a rectal temperature higher than 104°F (40°C) should be treated for heat illness.<sup>20</sup>

### Carbonated and Oxygen-Enhanced Water

Carbonation of water is not beneficial to athletes and may be detrimental. Dissolved gases can accumulate and cause GI distress and bloating, resulting in decreased total fluid consumption.<sup>18</sup> Oxygenated water claims to have 30% or higher dissolved oxygen; however, when packed in plastic bottles, it may contain no more dissolved oxygen than tap water, and 12 ounces of oxygenated water in glass bottles contains less oxygen than a single breath of room air.<sup>22</sup> Available research does not substantiate a performance benefit of oxygenated water in humans.<sup>22</sup>

### Electrolytes and Water Without Added Carbohydrates

Several sports nutrition drinks have been developed that offer water, electrolytes, and vitamins, often using artificial sweetener to replace the flavoring and calories from carbohydrates. These electrolyte waters have not been evaluated for sports performance. No evidence indicates they are effective at preventing hyponatremia, and they have minimal or no calories for sustained effort. These artificially sweetened electrolyte drinks can be chosen as an alternative to carbohydrate-containing sports drinks but are no different than water, other than the observation that a small amount of added sodium improves the absorption rate of water and the volume of fluid consumed.<sup>2,18</sup>

### Electrolytes, Carbohydrates, and Water

Addition of carbohydrates to sports drinks benefits athletes competing longer than an hour by replacing muscle

glycogen lost during periods of intense or prolonged effort. Carbohydrate supplementation during exercise provides exercising muscles with fuel for energy while allowing muscles to conserve stored carbohydrate energy as glycogen. This strategy of providing fuel during exercise at a rate of 30-60 grams per hour for events lasting longer than 60 minutes has been shown to prolong the time to exhaustion in football and soccer players, as well as in long-distance endurance athletes such as runners and cyclists.<sup>2</sup> Using a 6%-7% carbohydrate sports drink would require the athlete to drink 500-1000 mL per hour to meet this targeted carbohydrate provision. The fluid volume is large and can cause GI side effects that affect performance. Many triathletes and runners use a carbohydrate gel during the event and drink smaller amounts of water to assist in dissolution and absorption of the carbohydrate.

Low-calorie carbohydrate-containing sports drinks provide as little as 3 grams of carbohydrates per 8-ounce serving, or just 10 kilocalories, contrasting with 11-18 grams of carbohydrates and 50-80 kilocalories per 8-ounce serving of most carbohydrate-containing sports drinks. These low-calorie electrolyte waters have not been evaluated for performance benefits.

### Electrolytes, Carbohydrates, Protein, and Water

Several sports nutrition drinks combine an electrolyte- carbohydrate solution with added protein. The protein is added to provide an additional metabolic fuel for ATP production.<sup>25</sup> These products are marketed to endurance athletes competing at aerobic intensities for long durations, including marathon runners (2.5-5 hours), long-distance triathletes (2-17 hours), and adventure racers (12 hours to 5 days). The initial studies compared a control group drinking a 6%-8% carbohydrate-electrolyte solution to a second group drinking the same sports drink with the addition of calories from protein. These initial studies showed modest improvements in exercise duration in cyclists; however, these studies could not determine if the improvements were related to the additional calories or to the protein itself. The second round of studies was better designed. These follow-up studies provided equal calories to both groups and resulted in no differences in cycle exercise duration.<sup>23,24</sup> An interesting observation from these studies was a lower rate of muscle soreness the day after the cycle exercise, as reported by the athletes who received protein calories. In theory, muscle soreness could impact performance measurements on subsequent days of exercise. Unfortunately, these studies did not measure cycling performance on subsequent days and can't show an association between performance and the observed muscle soreness.

Although ready-to-drink options exist, some protein-containing drinks are powders that require reconstitution and can release significant amounts of gas when mixed with water. Bubbles and foam appear from the hydrated powder, which can influence GI tolerance in athletes. Protein-containing sports drinks should be introduced as part of the training regimen so that athletes can determine their tolerance and the impact on performance before the drinks are used during an event. Because hydrolysis can affect stability of some proteins once mixed with water, athletes should not hydrate protein-containing dry powder drinks the night before an event. Optimal protein potency and effect may require athletes to carry unmixed powder and add water during the event, a potentially unsafe practice. For example, athletes could lose control of their bicycle when reconstituting powder in triathlon events. Once mixed, all sports drinks should be consumed or stored in the refrigerator within 2 hours to prevent bacterial growth.

### Preexercise Nutrition and Hydration

The ADA guidelines recommend that a prehydration fluid of 5-7 mL/kg of body weight be consumed at least 4 hours before exercise. For example, a 59-kilogram athlete would consume 295-413 mL of fluid prior to exercise. This allows excretion of excess fluid in the urine before exercise begins. Hyperhydration with glycerol increases the risk of needing to void during competition, provides no performance advantage, and is discouraged.<sup>18,26</sup> Carbohydrate loads of 200-300 grams (from food and/or fluids) consumed 3 hours or more before exercise may enhance performance. However, the ADA guidelines state that optimal performance depends on individually determined distribution of macronutrient intake prior to exercise because of variations in athlete size, the energy demands of different sports, overall daily calorie needs, and the timing of macronutrient intake prior to the practice or event. Individual athletes should consider nutrition a part of their training regimen and should practice the timing, quality, and quantity of intake to become familiar with their own tolerance and timing. All athletes are discouraged from experimenting with new foods prior to important competitions.

### Nutrition and Hydration during Exercise

For competitions lasting longer than an hour, athletes are recommended to determine a sweat rate by measuring their pre- and postexercise body weights. A reasonable goal is to drink 16-24 fluid ounces of a sports drink for every 0.5 kilogram of body weight loss during exercise.<sup>2</sup> The ADA guidelines recommend consuming 30-60 grams of carbohydrate (from food and/or fluids) per hour during exercise to maintain blood glucose levels.<sup>2</sup> These rates are adjustable according to an athlete's tolerance. A carbohydrate drink concentration of 6%-8% is recommended because concentrations greater than 8% are associated with adverse GI effects.<sup>2</sup>

## Postexercise Nutrition and Recovery Drinks

Goals of postexercise recovery nutrition are to rehydrate, restore muscle glycogen, and provide protein to repair muscle damage and synthesize new muscle tissue, thereby preparing the athlete for another period of activity. The choice of recovery nutrition is dependent upon how much time is available until the next session of intense activity. Most active adults will exercise once daily and do not require specific sports nutrition supplements for recovery. When recovery time is 4 hours or greater, the ADA recommends that an athlete consume a balanced meal for glycogen restoration, optimal rehydration, and correction of electrolyte imbalances.<sup>2</sup> Several studies have compared a carbohydrate-only sports nutrition drink with consuming a glass of low-fat milk containing an equal number of calories from low concentrations of fat, carbohydrate, and protein. Consumption of low-fat milk was associated with greater hydration, lower urine output, and improved weight replacement after exercise.<sup>27</sup> In addition, low-fat milk was associated with a longer time to exhaustion in subsequent exercise sessions.<sup>28,29</sup> Drinking milk more accurately reflected a postexercise meal and is better for recovery after exercise than a carbohydrate-only sports drink. When recovery time is less than 4 hours, drinking a carbohydrate sports drink improves muscle glycogen recovery when compared to drinking water. The sooner the carbohydrate is consumed after exercise, the sooner muscle glycogen is replaced. The ADA guidelines recommend carbohydrate consumption of 1.5 grams per kilogram within 30 minutes after exercise.<sup>2</sup> This dose may be repeated at 2 and 4 hours postexercise when total muscle glycogen depletion is suspected.<sup>2</sup> The ADA guidelines state that protein intake may be beneficial for muscle recovery and that this need is optimally met with a balanced meal.<sup>2</sup>

## Safety and Efficacy of Specific Ergogenic Supplements

This section discusses the safety and efficacy of specific nutritional supplements and micronutrients for sports performance. Unlike the macronutrients discussed previously, here the evidence supporting the use of herbs, plant extracts, antioxidants, and other supplements purported to improve sports performance is discussed. These nutritional supplements are marketed as “foods” and are not regulated as drugs by the FDA. These foods are not required to provide safety and efficacy data in humans to prove their effectiveness on the playing field, nor do they require testing to prove their labeled contents. Readers are reminded of previous evidence of misbranding and the frequency of substances banned by antidoping agencies appearing in these products.<sup>4,5</sup> They are also referred to [Table 24-2](#) for a list of substances for which evidence is available that does not support claimed effectiveness. Athletes should take extreme caution regarding the use of nutritional supplements and sports performance, as indicated by misbranding that may lead to doping infractions as well as case reports of serious adverse effects and deaths reported from supplement use. Athletes should focus on training and proper nutrition, and not rely on nutritional supplements or other artificial means for reaching their best performance.

## Caffeine and Caffeine-Supplemented Energy Drinks

Several studies suggest an ergogenic benefit from caffeine supplementation.<sup>1,2,30,31</sup> Ordinarily, this effect would result in a no-tolerance testing policy. However, caffeine appears in nutritional products that are unrelated to exercise or performance benefit. Incidental exposure is common, and complete avoidance is unrealistic. The World Anti-Doping Agency does not list caffeine as a problematic substance. Caffeine intake at doses of 2-6 mg/kg, given 1 hour before exercise testing, appears to produce improvement in time to exhaustion on a cycle ergometer and in resistance (weight) training.<sup>30</sup> The addition of caffeine can also improve mental acuity and alertness. This is particularly beneficial in long-duration endurance sports such as 24-hour bicycle races where caffeine counteracts some of the effects of sleep deprivation. The exact mechanism for caffeine’s ergogenic effect is unknown, and benefits appear to occur at doses that are common from drinking several cups of coffee or tea. Many questions remain regarding the effective use of caffeine for ergogenic benefit.

The class of products labeled as providing “energy” is broad and increasingly popular, although the vast majority of consumption is recreational and unrelated to sports.<sup>3,31</sup> Energy drinks (EDs) and energy shots (ESs) are similar to sports drinks, but they contain caffeine in addition to water and electrolytes. EDs may contain carbohydrates or be labeled as calorie free. They usually contain a blend of other nutrients and herbal additives such as taurine or guarana that are proposed to effect exercise performance or mental performance during exercise. Most of these additives have not been proven to affect sports performance or weight loss. Readers are referred to an ISSN position paper on EDs for a more detailed assessment.<sup>31</sup> In general, EDs should prolong exercise in a manner consistent with their carbohydrate component, although many contain more carbohydrate than the typical 6%-8% seen in sports drinks and may not be tolerated as well.

EDs are not without a risk for unintended side effects. The additional caloric load may affect blood sugar and insulin levels and promote weight gain.<sup>31</sup> The amount of caffeine present in EDs is not enforced within the United States at this time and may range from 100-286 mg per drink, whereas Canada has limited EDs to 180 mg per drink.<sup>31</sup> The

quantity of caffeine is similar to a 16-ounce serving of coffee. Users are cautioned to consider the possible side effects from cumulative daily doses of caffeine. Side effects include insomnia, nervousness, tachycardia, tremors, and anxiety in addition to GI intolerance. A recent clinical observation in healthy college-age adults showed that a single dose of an ES can increase systolic and diastolic blood pressure by 5 mm Hg from baseline.<sup>32</sup> None of the healthy subjects were reported to have reached a level of prehypertension. More severe adverse effects from EDs are prompting emergency department visits and are related to indiscriminate use of EDs, often with other illicit drugs or alcohol.<sup>33</sup> The AAP has concluded that children and school-age athletes should not consume EDs or ESs and that they have no place in sports competition.<sup>8</sup> The ISSN further states that diabetics and individuals with preexisting cardiovascular, neurologic, or metabolic disorders should avoid these products.<sup>31</sup> Avoiding the use of EDs and ESs for sports performance is generally appropriate advice for any age group.

**TABLE 24-2 Selected Products Marketed as Ergogenic Supplements**

<i>Ingredient</i>	<i>Marketed Claim</i>	<i>Conclusion/Evidence</i>
Antioxidants <sup>1,2,44</sup>	Antioxidants claim to be able to reduce oxidative stress from exercise and/or to speed recovery following exercise. Many antioxidants have been included in sports nutrition supplements, including alpha-lipoic acid, carotenoids, glutathione, n-acetylcysteine, ubiquinones (coenzyme Q10), vitamin B complex, vitamin C, and vitamin E.	Evidence does not support an effect on reducing oxidative damage or enhancing performance. Frequent exercise is associated with an enhanced antioxidant system.
Arginine <sup>45</sup>	Arginine has been promoted to improve muscle building and cardiovascular functioning through the production of nitrous oxide, which causes cardiac vasodilatation and increased oxygen delivery to the heart.	Evidence does not support an effect on performance enhancement.
BCAAs <sup>1,2,46</sup> (branch-chain amino acids)	BCAAs are isoleucine, leucine, and valine. Skeletal muscle cells use BCAAs to supply energy during exercise. Supplementation may reduce fatigue and increase exercise time to exhaustion by reducing serum levels of L-tryptophan and its effect on serotonin levels in the brain.	Evidence does not consistently support an effect on endurance performance.
Carnitine <sup>2</sup>	Carnitine is an essential cofactor for the transport of long-chain fatty acids into the mitochondria. Product is proposed to improve fatty acid oxidation, fat burning, and oxygen absorption as well as to reduce lactic acid accumulation.	Evidence does not support an effect on performance.
Chromium <sup>2</sup>	Chromium is marketed to enhance carbohydrate utilization in the body, promoting fat burning and dietary protein sparing for muscle building. Product is marketed to improve endurance and strength.	Evidence does not support an effect on performance.
Citrulline <sup>2</sup>	L-Citrulline is a metabolic precursor to arginine. Citrulline is not affected by first-pass hepatic metabolism and is converted by the kidneys to arginine. Product is proposed to improve oxygen consumption and time to exhaustion in treadmill running.	Evidence does not support an effect on performance.
Conjugated linoleic acid <sup>2</sup> (CLA)	CLA is promoted to endurance athletes as	Evidence does not

	a thermogenic aid, body fat reducer, and ergogenic aid that enhances fat metabolism. CLA may increase cardiac risk by lowering high-density lipoprotein and increasing lipoprotein(a) concentrations.	support an effect on performance or body composition.
<i>Cordyceps sinensis</i> <sup>47,48</sup> <i>Cordyceps sinensis</i> is used in Chinese medicine to treat lung disease and fatigue. Products claim that this mushroom can decrease oxygen consumption and improve endurance. Product is frequently combined with <i>Rhodiola</i> . Available research published in English is limited and does not show a performance benefit.	Evidence does not consistently support an effect on performance.	
Eleuthero <sup>49</sup>	Extracts of Siberian ginseng have been reported to affect cardiorespiratory performance, fat metabolism, and improved endurance.	Evidence does not support an effect on performance.
Ginseng <sup>50</sup>	Extracts of <i>Panax ginseng</i> have been reported to improve lactate clearance and delay the onset of fatigue.	Evidence does not support an effect on performance.
Glycerol <sup>2,51</sup>	Glycerol is reported to act as an osmotic agent to promote hyperhydration prior to exercise, therefore reducing the risk of dehydration from intensive exercise in the heat.	Evidence does not support an effect on performance.
Hydroxy-methylbutyrate <sup>2,45</sup> (HMB)	Beta-HMB is a metabolite of leucine metabolism, purported to decrease muscle protein breakdown after a workout and to increase muscle mass. HMB has also been proposed to improve aerobic performance.	Evidence does not consistently support an effect on performance.
Lecithin <sup>52</sup>	Lecithin is a source of choline and a precursor to acetylcholine. Decreased plasma choline and acetylcholine levels have been reported in marathon runners. Supplementation of lecithin before a marathon does prevent the decline in serum acetylcholine levels but does not affect finishing times.	Evidence does not support an effect on performance.
<i>Rhodiola rosea</i> <sup>48,53,54</sup>	<i>Rhodiola rosea</i> is a Chinese herb used to stimulate the nervous system, improve aerobic work performance, and reduce fatigue. <i>Rhodiola</i> is reported to improve oxygenation at high altitudes and is thought to be helpful for endurance athletes. Available research published in English is limited and does not show performance benefit.	Evidence does not consistently support an effect on performance.

## Creatine

Creatine is the most widely used ergogenic aid among athletes, and it has the most consistent data.<sup>14,34</sup> Creatine, a naturally occurring substance, is synthesized in the body by the combining of arginine and glycine, or it is absorbed intact after ingestion of red meats and fish.<sup>14,34</sup> Creatine is found in all skeletal muscle as free creatine or high-energy phosphorylated creatine (PCr). PCr functions as an energy buffer, transferring a phosphate group to ADP,

thereby rapidly regenerating ATP during periods of exercise. Skeletal muscle contains limited amounts of energy stored as ATP at rest; exercise depletes this stored ATP energy quickly. The body must oxidize macronutrients through the Krebs cycle to restore ADP to the high-energy ATP state for continuous or repeated efforts. PCr transfers its energy to ADP in seconds, acting as a secondary fuel. However, the total amount of PCr energy in muscles lasts for only 20-30 seconds.<sup>14,34</sup>

Performance gains with creatine are limited to laboratory-based studies of short bursts of anaerobic activity lasting 30 seconds or less. Creatine supplementation attenuates normal decreases in the force associated with repeated work applications.<sup>14,34</sup> For example, a weight lifter performs three sets of a bench press, with a goal of 10 lifts, or repetitions, per set. The lifter takes 30 seconds of rest between each set. Ordinarily, the lifter may be able to move a planned amount of weight for 10 repetitions in the first set, 8 repetitions in the second set, and only 6 repetitions in the third set. The decreasing number of lifts is called attenuation and is related to decreased energy (ATP) in the muscles. Creatine can improve the amount of ATP energy available to lift the weight; the same athlete may complete more repetitions in each subsequent set (e.g., 10, 10, and 8 repetitions rather than 10, 8, and 6).<sup>14,34</sup> Similar improvements in maximum weight lifted in a single lift have also been reported.<sup>14,34</sup> Creatine is useful for athletic events that require repeated, short, explosive bursts of power such as sprinting and jumping seen in American football, soccer, and track and field events. By comparison, creatine does not benefit athletes in sports that require more than 20-30 seconds of high-intensity activity. Aerobic activities as short as 800-meter (2-minute) and 1600-meter (5-minute) runs on a track have not shown performance benefits.<sup>34</sup>

Current evidence does not support that creatine can induce structural changes in muscle fibers. The muscles may be larger and weigh more, owing to the presence of creatine and water in complex with creatine. The athlete may gain mass and appear stronger in the gym, but this change is dependent upon maintenance supplementation. Short-term studies show a return to normal muscle creatine concentrations and depletion of the extra PCr energy upon cessation of creatine supplementation. Creatine itself does not appear to cause permanent alteration of muscle fiber types.<sup>35,36</sup> Poor study design and inappropriate statistical analysis affect interpretation of existing studies. An observation of increased satellite cells after 8 weeks of supplementation was not validated after 12 weeks or confirmed after stopping the supplement.<sup>35</sup> A similar observation of increased myosin heavy chain expression and increased type IIx muscle fibers were not properly compared between groups or confirmed after stopping the supplement.<sup>36</sup>

Loading doses are not required if performance benefits are not desired within 10-14 days.<sup>34,35</sup> A maintenance dose of 5-6 grams daily is adequate to boost muscle creatine levels and is associated with fewer GI side effects. If an immediate improvement in strength is required, benefits can be detected in 5 days following a loading dose of creatine at 20 g/day (or 0.3 g/kg/day).<sup>34</sup> This loading dose is usually divided into 4 doses to reduce GI side effects of stomach upset and nausea. Nausea may be related to osmotic effects or to malabsorption. Other adverse effects reported with creatine include weight gain and muscle cramping. Weight gain may be related to an osmotic gain in water within muscles. Muscle cramping raises concerns of increasing risk of heat-related illness with creatine supplementation. Two reports followed college football players who took creatine supplements for as long as 3 years and compared them with teammates who did not take the supplements.<sup>37,38</sup> The athletes were followed for reports of muscle cramping, heat illness, dehydration, muscle strains, total injury reports, and missed practices. The occurrence of adverse effects did not differ between the groups. Creatine supplements have also been reported to be misbranded and to contain substances banned by antidoping agencies.<sup>4</sup>

All athletes should be discouraged from using creatine supplements until regulated testing is required. They should be encouraged to seek natural creatine sources from food sources rather than supplements. When the athlete insists on using creatine, providers can assist the athlete by recommending that creatine be used only as long as necessary, such as maintaining supplementation only during the competitive season. No reason exists to continue the supplements during the off season. Providers should also recommend appropriate additional hydration during creatine exposure because creatine is a protein that is filtered through the kidneys. If an athlete becomes significantly dehydrated, it is best to temporarily hold creatine until proper fluid balance is restored.

#### Dimethylamylamine (DMAA), Geranium Seeds, and Extracts

Dimethylamylamine (DMAA) is also known as methylhexanamine and was previously marketed as a sympathomimetic to treat nasal congestion. It has recently appeared in nutritional supplements claiming to increase muscle mass and reduce body weight, implying that the chemical was derived from a natural source such as geranium stems or extract. These products are associated with multiple cases of cardiac toxicity, acute hepatic failure, liver transplant, and death.<sup>39</sup> One report indicated 29 cases of hepatic failure with 40% of cases requiring hospitalization. Twenty-four of these individuals reported use of a DMAA-containing supplement in the 60 days prior to hepatic injury. Twelve of these individuals reported no other supplement intake besides the DMAA-containing supplement.<sup>39</sup>

## Ephedra and Pseudoephedrine

Pseudoephedrine is available without a prescription and may be troublesome for elite athletes even when used temporarily for appropriate medical reasons because of random drug testing. Urine concentrations of pseudoephedrine greater than 150 mcg/mL are flagged as inappropriate use as a stimulant. No evidence supports performance enhancement with pseudoephedrine at nonprescription doses.<sup>40</sup> However, at 2.5 mg/kg, a dose roughly five times the recommended nonprescription dose, one study of seven runners showed an average 6-second improvement in 1500-meter time.<sup>41</sup> Reports that ephedra was associated with hypertension, cardiac arrhythmias, and seizures in otherwise healthy young adults were used to determine that ephedra was unsafe for human consumption, and it was removed from U.S. markets in 2004.<sup>42</sup> No data support ephedra as useful for athletic performance.<sup>40</sup> The data are included here because plant alkaloids related to ephedra may appear in nutritional supplements and because ephedra is available in foreign markets and through Internet sales.

## Steroidal Precursors and Aromatization Inhibitors

The Anabolic Steroid Control Act of 2004 defined hormone substances that are pharmacologically related to testosterone as legend, or prescription-only, drugs. Dehydroepiandrosterone (DHEA) and androstenedione, prohormone precursors to testosterone, were sold as nutritional supplements prior to the act, but they have been identified as misbranded ingredients in nutritional supplements sold in the United States after the act. Well-designed studies demonstrate significant elevations in estradiol and estrone in men who take the supplements but no elevations in serum testosterone.<sup>43</sup> Aromatase inhibitors prevent the conversion of testosterone to estrone, and their use is specifically prohibited by the antidoping agencies. Many body-building supplements claim to include substances, such as *Tribulus terrestris*, that act as aromatase inhibitors. No data support these claims. Products that suggest that they boost testosterone or provide aromatase inhibition should not be recommended as performance-enhancing supplements.

## Stacking

Sports nutrition products often combine several agents into a single product, a process known as “stacking.” Many products include individual vitamins, minerals, metabolites, amino acids, or herbal supplements. They claim to improve endurance and muscle strength or to reduce oxidative stress related to exercise. Products with insufficient data for a clear positive effect on performance are reviewed in [Table 24-2](#).<sup>44,45,46,47,48,49,50,51,52,53,54</sup>

## Assessment of Performance-Enhancing Nutrients: A Case-Based Approach

Performance enhancers run the gamut from electrolyte solutions to energy bars to herbal supplements. To help someone select a product, the provider should determine the type of exercise or physical activity in which the individual engages, the intensity and duration of activity, and any products previously tried. The individual should also be asked about any ill effects experienced after physical activity or after using a performance enhancer. Cases 24-1 and 24-2 illustrate assessment of individuals who wish to use a performance-enhancing product. Sales of sports nutrition products designed to enhance or improve performance are increasing every year. The most common self-treatments are creatine to improve muscle power and carbohydrate administration during exercise to preserve muscle glycogen and prolong time to fatigue across all sports. Several herbal supplements claim to enhance performance, but evidence to support these claims is currently lacking. Although these natural herbal products are touted as safe, evidence suggests that some may have detrimental effects on long-term health by altering cardiovascular risk, high-density lipoprotein levels, and natural, sex-determined hormone levels.

## Patient Counseling for Performance-Enhancing Nutrients

The quest for enhanced physical performance has resulted in serious health consequences for some athletes. Clinical studies of many botanical and hormonal dietary supplements touted as performance-enhancing products reveal significant adverse effects and little or no enhancement in physical performance. Providers should discourage use of performance-enhancing products because none except creatine has been found to be effective. The box Patient Education for Performance-Enhancing Nutrients lists specific information to provide individuals. Registered dietitians with national board certification as Certified Specialist in Sports Dietetics are uniquely qualified to assist athletes of all levels in evaluating their nutritional needs and to work with them on their hydration, and the quality, quantity, and timing of foods and supplements for optimal performance. Sports dietitians can be found at the Sports, Cardiovascular and Wellness Nutrition Web site ([www.scandpg.org](http://www.scandpg.org)).

## Key Points for Sports Nutrition and Performance-Enhancing Nutrients

- Training regularly and eating a well-balanced diet are consistently shown to benefit sports performance and

activity. Most athletes do not require sports nutrition products.

- Despite marketing claims, the benefits of most performance-enhancing nutritional products and ergogenic aids are unproven, and several may be unsafe.
- Misbranding of nutritional supplements has occurred and can lead to positive screens from antidoping agencies as well as lead to unintentional safety risks.
- Most sports nutrition drinks, gels, and bars are significant sources of carbohydrate calories. The AAP has developed a position that these carbohydrate and energy drinks should not be used in adolescents and children. They should similarly be avoided in adults.
- Dehydration can significantly affect performance. However, no evidence supports sports nutrition drinks as beneficial when used during events lasting 60 minutes or less. For activity over 60 minutes, electrolytes in sports drinks are encouraged and may enhance fluid absorption.
- Sports nutrition drinks containing carbohydrates and electrolytes can prolong the time to fatigue (glycogen depletion) in events or practice lasting 60–90 minutes or longer and, therefore, may be considered when exercise duration is anticipated to exceed this duration.
- To minimize the risk of dehydration or hyponatremia caused by the intake of salt-free fluids, athletes exercising for very long periods of time should use sports drinks that contain electrolytes and carbohydrates rather than plain water.
- Creatine supplementation can increase muscle phosphocreatine concentrations, thus increasing the amount of stored energy in muscles. Phosphocreatine can lend its high-energy phosphate bond to ADP to rapidly restore ATP, allowing increased power for single and repeated activities for 30 seconds or less.
- Pseudoephedrine is monitored by the U.S. Anti-Doping Agency, and athletes subject to testing for banned substances should be warned of any product containing pseudoephedrine. A similar warning should be given for any cough and cold product that includes a sympathomimetic amine as a decongestant, such as oxymetazoline nasal spray.

#### Case 24-1

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The individual reports that he competes in the shot put and discus field events in high school. Last year he qualified for the regional meet but not the state meet, and he hopes to improve his chances of qualifying in his senior track season that starts in 3 months. Participation in the shot put and discus events can require up to six attempts, three each in the preliminary and final rounds. He feels that improving his muscle mass will result in a stronger performance and longer distances in his events.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	His performance in these events can be affected by the number of attempts that he needs to qualify for the final round and to make his best effort in the final round. In his six attempts, he often fouls one or two attempts, particularly in the discus. He may require multiple attempts to reach his goal distances of a 50-foot shot put and a 155-foot discus throw.
c. description of the patient's efforts to relieve the symptoms	He has made no specific adjustments to his diet to maintain optimal glycogen levels before or during the track season. He does drink up to 12 ounces of a 5% CHO sports drink during the meet as a taste preference over drinking water. He plans to initiate training by lifting weights in September and participating in indoor track events during the winter season.

d. patient's identity	Michael Longtree
e. age, sex, height, and weight	17 years old, male, 6 ft 1 in., 205 lb
f. patient's occupation	High school student
g. patient's dietary habits	Michael has been eating a diet consistent with the <i>MyPlate</i> servings shown in <a href="#">Chapter 22</a> .
h. patient's sleep habits	Michael sleeps 7-8 hours on school nights.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	A preseason medical examination identified no issues. Michael's blood pressure and fasting glucose levels are normal, and he takes no medications or supplements.
j. allergies	NKA
k. history of other adverse reactions to medications	None
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Michael's performance in the meet is not significantly affected by the duration of effort. Each activity lasts for only a few seconds, and the total duration of activity for up to 12 attempts is less than 60 seconds of anaerobic energy utilization; therefore, muscle glycogen depletion is not a cause. Michael may be experiencing a decline in muscle energy from the phosphagen system that is associated with repeated high-intensity activities.
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Michael can choose to take no action other than optimization of training. Regular, intensity-specific exercise can improve oxygen uptake and optimize muscle ATP production during periods of rest. Training to improve his throwing technique can result in improved distances and eliminate the need for multiple attempts in the qualification round. (2) Michael can consider increasing his muscle mass naturally by optimizing his dietary intake of protein with healthy food choices rather than a nutrition supplement.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into	Michael will adjust his dietary selections to optimize his dietary protein intake.

account patient preferences.	
6. Describe the recommended therapeutic approach to the patient or caregiver.	“You can adjust your food consumption to optimize protein intake and build muscle strength naturally, without having to rely on a packaged nutrition supplement. Keep a record of your protein intake for review and recommendations.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“A diet that is high in protein will provide protein for muscle building and recovery after intensive workouts. It will also provide a natural source of creatine and the amino acids arginine and glutamine from which the body can build creatine. The dietary boost to creatine will provide an increase in the quantity of energy stored in PCr bonds. Although each physical attempt or throw will reduce muscle ATP energy, the energy available in PCr can transfer to muscle ADP and return the ADP to ATP status in seconds, thus restoring your muscle energy.”
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	“The ADA recommends an intake of 1.4-1.7 g/kg/day of protein to optimize muscle building. Michael weighs 93 kg, making his target intake 130-160 grams per day.”
b. maximum number of days the therapy should be employed	“An athlete starting a new training program can benefit from an increase in protein intake to help establish a positive nitrogen balance and to build muscle. It is reasonable to boost protein intake to 1.5-1.7 g/kg/day (160 grams/day) for 3-4 months and then reduce to a maintenance level. Athletes who have been training for several months can maintain their muscle mass and a neutral nitrogen balance with 1.4 g/kg/day of protein intake during maintenance training.”
c. product administration procedures	“The ADA recommends that the athlete consume a small amount of protein (30 grams) within 30 minutes after the completion of intense physical exercise because protein has been associated with improved muscle building. A simple snack such as 8-12 ounces of skim milk with a 4-ounce serving of chicken or tuna would meet this requirement. Michael should consider maintaining a diet journal of his meals and snacks. This information can be assessed later to determine an estimated protein intake and make further recommendations.”
d. expected time to onset of relief	“Performance benefits from intense training can be measured in as little as 2-3 weeks. By comparison, measuring an increase in total body weight may require 2 months or more. The best way for Michael to assess the gains from his dietary plan is to follow his muscle strength gains from training.”
e. degree of relief that can be reasonably expected	“How much a gain in muscle mass will help your performance is difficult to measure. Individual performance gains vary and still require good technique to avoid fouling on early attempts.”
f. most common side effects	“The side effects from small increases in dietary protein intake are minimal. Gastrointestinal discomfort such bloating, cramping, and diarrhea have been

	reported. Be sure to drink plenty of fluids to allow the nitrogen waste from the protein to be eliminated through your kidneys.”
g. side effects that warrant medical intervention should they occur	“During any period of increased training, you should always tell your coach if you are not feeling well. Any signs of heat illness, muscle cramping, or pain on urination should be reported immediately.”
h. patient options in the event that condition worsens or persists	NA
i. product storage requirements	“Most food sources of protein require refrigeration to avoid spoiling and possible bacterial growth on the food. Store your lunches or protein snacks in a cooler or refrigerator if you will not be using it all within 2 hours.”
Solicit follow-up questions from the patient or caregiver.	“Why isn’t a creatine supplement recommended for me when many of my friends are using it?”
Answer the patient’s or caregiver’s questions.	“The protein available from dietary meat sources will contain a sufficient amount of creatine to meet your needs. As an athlete, you should be aware that many dietary supplements have been misbranded and actually contain performance-enhancing chemicals that are on banned substances lists. It is important, particularly for the high school athlete, to prepare for competition with appropriate training and experience to reach their personal best effort. Using an artificial substance to enhance athletic potential is not as great a victory as reaching it on your own.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact the patient within 2-3 weeks to review his diet intake to ensure that he has adjusted his diet appropriately.

Key: ADP = Adenosine diphosphate; ATP = adenosine triphosphate; CHO = carbohydrate; PCr = phosphocreatine; NA = not applicable; NKA = no known allergies.

### Case 24-2

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient’s symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient is an enthusiastic weight lifter who enjoys the camaraderie of the gym but does not participate in competitions. He has been lifting for 25 years and has reached a plateau in weight lifting. He has been unable to improve his lifted weight and for the last several years has started to lower the maximum weight he lifts. He does not want to increase his body mass but has been taking supplements that claim he will be stronger to prevent this perceived loss of strength. He has asked for a review of his supplements

	for safe use, following a recent adverse drug effect that may have been related to interacting medications.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	He spends 8 hours a week in the gym, splitting time between upper body and lower body exercise. He reports increasing symptoms of muscle soreness and decreased recoverability between workouts.
c. description of the patient's efforts to relieve the symptoms	He has been taking a number of oral supplements at the recommendation of other gym members and the sales clerks at the nutrition store. He has needed to take ibuprofen 200 mg every afternoon because of muscle soreness that he associates with sitting at a desk during the day.
d. patient's identity	Craig Johnson
e. age, sex, height, and weight	52 years old, male, 5 ft 9 in., 235 lb
f. patient's occupation	Logistics manager for a trucking company
g. patient's dietary habits	Eats well at home and prepares healthy meals for his lunch breaks.
h. patient's sleep habits	Works the day shift and spends his late afternoon in the gym. Generally asleep by 10 pm. Awakens daily at 6 am to go to work.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Amlodipine 10 mg daily for hypertension; simvastatin 40 mg daily for elevated LDL and low HDL; L-arginine 2 grams daily; creatine 5 grams daily; conjugated linoleic acid 9 grams daily
j. allergies	NKA
k. history of other adverse reactions to medications	None reported. His HTN is controlled.
l. other (describe) _____	None
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Craig has symptoms of myopathic pain that may be the result of statin use or a drug interaction between the simvastatin and amlodipine. Craig is taking a number of supplements that he is not certain are helpful to his hobby of weight lifting. He wants to be assured that they are not adversely affecting his medical condition.
3. Identify exclusions for self-treatment.	Craig should not take supplements that might affect his LDL and HDL cholesterol.
4. Formulate a	Options include:

comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	<p>(1) Refer patient to his PCP to review the use of simvastatin and amlodipine. The combination may be contributing to the myopathy that he sees as a performance limitation. A change in his prescription medications may be appropriate.</p> <p>(2) Craig should stop taking conjugated linoleic acid because this supplement has been associated with lower HDL levels and has no proven performance benefits.</p> <p>(3) Craig could consider discontinuation of all of his supplements because he does not require performance benefits for competition and any benefits from these unproven supplements do not outweigh the risk from adverse effects or misbranding.</p>
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The patient should consult his PCP regarding the myopathic pain. He should discontinue conjugated linoleic acid immediately and consider discontinuing the other supplements that have not been proven to affect weight-lifting performance. Craig would prefer to continue taking creatine for strength benefits.
6. Describe the recommended therapeutic approach to the patient or caregiver.	<p>(1) "You are feeling muscle soreness after workouts. This soreness could be related to the hard workouts or may be related to a known medication adverse effect. A change in prescription medication may reduce the amount of myopathic discomfort that you are feeling."</p> <p>(2) "You may choose to continue taking the supplement creatine because it has good evidence for improved strength and has not been associated with affecting HDL or LDL levels."</p>
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"A known drug interaction exists between simvastatin and amlodipine. A reduction in the dose of simvastatin, or changing to a non-interacting statin, may improve the muscle soreness."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	"Creatine maintenance doses are taken as 5 grams per day. These maintenance doses will increase the quantity of high-energy phosphocreatine (PCr). PCr will transfer its available energy to ADP, restoring ATP. There does not appear to be a benefit from taking more than 5 grams per day. Taking creatine for years has not been prospectively studied; however, short-term studies have consistently been associated with modest gains in many weight-lifting measurements."
b. maximum number of days the therapy should be employed	"Creatine has been taken for years by young football players. However, the effects of long-term supplementation in patients your age have not been determined."
c. product administration	"Creatine is usually taken as a powder and mixed into a smoothie or shake. Taking the

procedures	creatine supplement within 30 minutes after exercise may improve muscle building.”
d. expected time to onset of relief	NA
e. degree of relief that can be reasonably expected	“You should have some mental relief that your medications and creatine have no significant interactions. You should not expect any changes to your weight-lifting abilities from stopping these supplements. Repeat your serum lipid levels on your usual schedule. Your HDL changes will be minimal.”
f. most common side effects	“Large doses of creatine can cause gastrointestinal distress and cramping; however, your years of experience indicate that you can tolerate this 5 gram dose without difficulty. Some concern exists that long-term protein loading can affect kidney function, so you should continue your regular physician visits and laboratory monitoring. Be aware that misbranding of creatine supplements can result in an inadvertent exposure to chemicals that are regulated by antidoping agencies.”
g. side effects that warrant medical intervention should they occur	“If you observe a urine color that is significantly darker than usual or includes a new foul smell, first assess your hydration status. If the urine changes are persistent with proper hydration, you will want to follow up with your primary care provider.”
h. patient options in the event that condition worsens or persists	“Stopping creatine is always a consideration because you are not seeking competition-related performance benefits. Stopping the supplement has little effect other than a small reduction in weight-lifting measures.”
i. product storage requirements	“Unmixed creatine powder can be stored at room temperature, but mixed creatine shakes should be refrigerated or consumed within 2 hours.”
Solicit follow-up questions from the patient or caregiver.	“Could you provide more information on the other side effects I might experience from the simvastatin-amlodipine interaction. Should I stop these medications before seeing my physician?”
Answer the patient’s or caregiver’s questions.	“The interaction results in higher-than-normal serum levels of simvastatin. You should call your physician immediately because you are already experiencing muscle pain, tenderness, and weakness. Other symptoms of a more severe reaction include fever, joint swelling, joint pain, unusual bruising and/or yellowing of the skin or eyes. You should not stop taking your medications until you discusses these possible adverse effects with your physician.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact the patient within 1 week to determine if he has made an appointment with his physician.

Key: ADP = Adenosine diphosphate; ATP = adenosine triphosphate; HDL = high-density lipoprotein; HTN = hypertension; LDL= low-density lipoprotein; NA= not applicable; NKA = no known allergies; PCP = primary care provider.

#### Patient Education for Performance-Enhancing Nutrients

The objective in selecting a performance enhancer is to choose a product that is safe and appropriate for the type, intensity, and duration of the physical activity. Following the recommendations of a primary care provider (PCP) and other health care providers, as well as carefully following product instructions and the self-care measures listed here, will help ensure optimal therapeutic outcomes.

## Muscle Glycogen Preservation

- Carbohydrate-containing sports drinks contain one or more forms of sugar and the electrolytes sodium and potassium. These drinks are optimal for intermediate sprint activities, such as soccer and football, and for endurance events and practice or training sessions that last longer than 60 minutes. Small doses repeated every 15-20 minutes may be necessary for sustained energy over longer events to maintain glucose levels for performance energy, thereby delaying the time to fatigue.
- Athletes with diabetes should seek the advice of a PCP or sports dietitian before beginning an exercise program to ensure that they are prepared to avoid hypoglycemia while exercising.
- Note that sports bars often contain other macronutrients, such as fats and proteins. Many of these bars are more appropriate for after-exercise recovery than for use during athletic events. If a well-balanced meal is unavailable within 2 hours of exercise, many of these bars may be an appropriate after-exercise fuel replenishment source. (Table 24-1 lists specific products.)
- Long-chain triglycerides can cause discomfort and bloating during intense exercise; therefore, avoid consuming meals that contain large amounts of fat at least 2 hours before exercise.

## Enhancement of Muscle Mass

- Athletes do not need to exceed the recommended daily intake of 1.7 grams of protein per kilogram of body weight to increase body mass. Available data indicate that higher intakes do not produce additional muscle mass or strength.
- Athletes who ingest high amounts of protein, either through their foods or protein supplements, should discuss this practice with their PCP or sports dietitian. Blood urea nitrogen and serum creatinine levels may be monitored to ascertain whether high protein intake is affecting kidney function.

## Hydration and Electrolytes

- For athletes exercising less than 60 minutes, water intake alone is usually sufficient to complete the exercise.
- Athletes exercising longer than 60 minutes may consider incorporating a carbohydrate- and electrolyte-containing sports drink into the exercise program for optimal performance.
- Endurance athletes exercising for 4 hours and longer are discouraged from drinking only free (regular) water owing to the risk of dilutional hyponatremia. Exercise of this duration (e.g., marathon running and long-distance triathlons) will require electrolyte and carbohydrate replacement for optimal performance.
- Athletes should not target a set quantity of water to consume during exercise; rather, athletes should drink according to the trigger of thirst. Slower runners and walkers exercising in cool conditions can consume water at a lower rate (sips), whereas faster and heavier athletes and those exercising in heat and humidity should be prepared to drink more. Individual calculations of sweat rate for fluid needs during exercise and an additional calculation for recovery fluids can be made to better meet the athlete's needs.
- Athletes should consume 6-12 ounces of plain water if exercise lasts less than 60 minutes. If exercise lasts longer than 60 minutes, consider a carbohydrate- and electrolyte-containing sports drink. (See Fluid Tips for Training and Competition, available at: [www.extension.arizona.edu/sites/extension.arizona.edu/files/pubs/az1387.pdf](http://www.extension.arizona.edu/sites/extension.arizona.edu/files/pubs/az1387.pdf))
- Carbonated water may cause GI distress and bloating; avoid drinking carbonated water before or during an athletic event.

## Ergogenic Supplements

- Little or no clinical evidence supports the performance-enhancing claims of most herbal supplements.
- Creatine may help increase muscle strength and power in events that require short bursts of power, but GI discomfort may occur. To avoid this problem, do not take loading doses. The same benefits occur within 7-14 days of taking a daily maintenance dose of 5 g/day. Maintain proper hydration to assist in the elimination of metabolic waste and to avoid dehydration.
- Long-term use of creatine has no known benefit. The strength improvements of creatine are not maintained and will "wash out" to baseline when the supplement is stopped. Athletes should consider optimizing their nutritional intake rather than using creatine.

## Handbook of Nonprescription Drugs &gt; Chapter 25. Infant Nutrition and Special Nutritional Needs of Children

**Infant Nutrition and Special Nutritional Needs of Children: Introduction**

Human milk is most physiologically suited to infants and is the optimal milk source for feeding infants until 12 months of age. The American Academy of Pediatrics (AAP) recommends that human milk be used as the sole source of nutrition for infants during the first 6 months of life. For infants whose mothers choose not to breast-feed, the nutritional quality, safety, and convenience of infant formulas make them an appropriate alternative. Variations among formulas allow for product selection that will meet a specific infant's nutritional needs while offering differences in palatability, digestibility, nutrient sources, convenience, and cost.

A health care provider should be able to provide information to parents or other caregivers to encourage successful breast-feeding. In addition, in consultation with the child's parents and primary care provider, the health care provider should be able to evaluate indications, advise on formula selection, and help ensure its appropriate use. This service requires knowledge of infant and child nutrition needs, breast-feeding, and commercially prepared infant and pediatric formulas, including differences in formula composition and specific uses for therapeutic formulas.

Some children will require enteral formulas after the age of 1 year because of various disease states and conditions. The health care provider needs to be knowledgeable about these products and their appropriate use to be able to answer caregiver questions about them, facilitate their procurement, and do triage for complications associated with these products.

**Organ Maturation and Infant Growth**

Knowledge of the development of the gastrointestinal (GI) tract and the kidney is crucial to understanding infant nutrition. Monitoring the infant's growth and growth rate using the World Health Organization (WHO) growth charts is important for assessing possible abnormal or unhealthy growth. The WHO growth charts are recommended for children less than 24 months of age, and the Centers for Disease Control and Prevention (CDC) growth charts are recommended for children over the age of 24 months.<sup>1</sup>

**Gastrointestinal Maturation**

By the end of the second trimester of pregnancy, all segments of the fetus's GI tract are formed and display some physiologic function. The third trimester, however, is the period of maximal GI tract growth and differentiation. Therefore, premature infants (those born before 37 weeks gestation) often have reduced GI tract function, especially those born prior to 32 weeks gestation. Transition from intrauterine nutrition through the maternal-fetal unit (i.e., the placenta) to extrauterine nutrition through milk requires the maturation of many physiologic processes. These processes include effective sucking, swallowing, gastric emptying, intestinal peristalsis, and defecation; salivary, gastric, pancreatic, and hepatobiliary secretions; and intestinal brush border enzymes and transport systems (Table 25-1).<sup>2</sup>

**TABLE 25-1 Gastrointestinal Maturation**

<i>Function</i>	<i>Weeks of Gestation When First Detectable</i>	<i>Comments</i>
Sucking and swallowing	16	16 weeks: swallowing of amniotic fluid 26 weeks: sucking 33-35 weeks: mature, coordinated sucking, swallowing, and breathing
Gastric motility and secretion	20	Gastric emptying delayed in first few days of life; affected by caloric density, carbohydrate concentration, pathologic conditions
Intestinal motility	20	26-30 weeks: disorganized contractile activity 30-34 weeks: repetitive groups of contractions 34-35 weeks: more mature migrating motor complexes
<b>Digestion and Absorption</b>		
<b>Examples of Factors Important in Digestion and Absorption</b>	<b>Weeks of Gestation When First Detectable</b>	<b>Proportion of Adult Values</b>
<b>Protein</b>		
Enterokinase	24-26	20% at 30 weeks 10%-25% at term
Hydrochloric acid	At birth	<20% at 30 weeks <30% at term, 50% for first 3 months
Peptidases	<12	15% at 30 weeks Nearly 100% at term
Trypsinogen/chymotrypsinogen	20	10%-60% at term
Amino acid transport	ND	Nearly 100% at term
Macromolecule absorption	ND	Nearly 100% at term
<b>Fat</b>		
Lingual lipase	30	Nearly 100% at term
Pancreatic lipase	16-20	5%-10% at term
Bile acids	22	25% at 32 weeks 50% at term
Medium-chain triglyceride uptake	ND	100% (absorption occurs in the stomach)
Long-chain triglyceride uptake	ND	10%-90% at term
<b>Carbohydrate</b>		

Pancreatic alpha-amylase	22-30	0% at term Secretion begins at 6 months of age
Salivary alpha-amylase	16	0% at 30 weeks 10%-20% at term
Lactase	10	30% at 28-34 weeks Nearly 100% at term
Monosaccharide absorption	11-19	Glucose absorption: 50%-60% at term

Key: ND = Not determined.

Source: Reference 2, and Kleinman RE, Kamin DS. Gastrointestinal development. In: Baker SS, Baker RD, Davis AM, eds. *Pediatric Nutrition Support*. Sudbury, MA: Jones and Bartlett; 2007:15-27.

Nutritive sucking develops at approximately 33-34 weeks gestation. In term infants, a mature, efficient pattern of sucking is seen within a few days after birth. In premature infants, an immature, inefficient pattern may persist for a month or more. Infants born before 34 weeks gestation cannot coordinate sucking, swallowing, and breathing; therefore, they may require tube feedings for several weeks to months until these reflexes mature. Liquid nutrition is appropriate for all infants until complex tongue movements and swallowing reflexes mature. Maturation of these reflexes typically occurs at 4-6 months of age, and it is at this time that solid foods can be safely added to an infant's diet.<sup>2</sup>

Early in life, frequent feedings (every 2-3 hours) are necessary, because the stomach capacity of a term newborn with a birth weight greater than 2500 grams (5 pounds 8 ounces) is only 20-90 mL. Gastric capacity increases to 90-150 mL by 1 month of age, at which time longer periods between feedings are possible. Human milk empties more rapidly from the stomach than infant formula; therefore, human milk-fed infants will typically eat more often than their formula-fed peers.

In term infants, gastric acid and pepsin secretion peak in the first 10 days of life, decrease between 10 and 30 days of life, and then increase to adult levels by 3 months of age. In premature infants, basal acid output is lower than that of a term infant but increases with postnatal age. Milk in the infant's stomach causes a sharp increase in the pH of the gastric contents and a slower return to lower pH values than in older children and adults. Gastric acidity in the newborn is unsuitable for optimal pepsin action. Therefore, little protein digestion occurs in the stomach because of low pepsin activity. The extent of protein absorption, however, is similar to that seen in children and adults. Amino acids and peptides produced by protein digestion are absorbed passively or by active transport mechanisms that reach adult capacity by the age of 14 weeks.

Premature and full-term infants can digest most carbohydrates, because the production of intestinal enzymes such as sucrase, maltase, isomaltase, and glucoamylase is sufficiently mature at birth. Lactase activity increases relatively late in fetal life and begins to decline after the age of 3 years, especially in African American and Asian children. By adulthood, approximately 15% of Caucasians, 40% of Asians, and 85% of African Americans are deficient in intestinal lactase.<sup>3</sup> Pancreatic amylase secretion does not reach adult levels until approximately 1 year of age. Salivary amylase may help compensate for this relative lactase and amylase deficiency in early infancy. Despite this relative lactase deficiency, most term and preterm infants tolerate lactose-containing formulas with negligible unabsorbed carbohydrate output in their stools. Unabsorbed lactose that enters the colon undergoes bacterial fermentation (colonic salvage) to short-chain fatty acids, which creates an acidic environment that favors growth of acidophilic bacterial flora (lactobacilli) and suppresses growth of more pathogenic organisms. This acidity also promotes water absorption and prevents osmotic diarrhea. Because of the relative abundance of glucoamylase, compared with lactase, in the premature infant's intestine, glucose polymers are digested and absorbed better than lactose.<sup>2</sup>

Newborns exhibit low pancreatic lipase concentrations and slow rates of bile acid synthesis, both of which are important for fat absorption. The rate of bile acid synthesis increases throughout gestation and with increasing postnatal age. The bile acid pool in a premature infant is one-fourth that of an adult, whereas a term infant's is one-half that of an adult. However, fat malabsorption is not a major problem in preterm or term infants, given that lingual and gastric lipases are present. Infants born earlier than 34 weeks gestation, however, may exhibit steatorrhea.

Intestinal length may also affect nutrient absorption. At birth, a term infant's small intestine is approximately 270 cm (106 inches) long. During the third trimester the intestinal length approximately doubles. Therefore, infants born prematurely will have less small intestine and, subsequently, decreased surface area for absorption. Adult intestinal length of 4-5 meters (13-16.5 feet) is reached by about 4 years of age.

#### Kidney Maturation

Maturation of the kidney is also important in nutrition, because it determines the ability of the kidney to excrete a solute load. Glomerular filtration begins around the ninth week of fetal life; however, kidney function does not appear to be necessary for normal intrauterine homeostasis, given that the placenta serves as the major excretory organ. After birth, the rate of glomerular filtration increases until growth stops, toward the end of the second decade of life. Even after correction for body surface area, the glomerular filtration rate of a child does not approximate adult values until the third year of life.

#### Growth

Birth weight is determined primarily by maternal prepregnancy weight and pregnancy weight changes. The average birth weight of a term infant is approximately 3500 grams (7 pounds 8 ounces). Premature infants are categorized on the basis of birth weight: low-birth-weight infants weigh less than 2500 grams (5 pounds 8 ounces); very low-birth-weight infants weigh less than 1500 grams (3 pounds 4 ounces); extremely low-birth-weight infants weigh less than 1000 grams (2 pounds 3 ounces); and micropreemies weigh less than 750 grams (1 pound 10 ounces).

Water weight loss (6%-10% of body weight) occurs immediately after birth over a period of 1-2 weeks and is followed by an average weight gain of 1%-2% of birth weight daily (25-35 g/day in term infants) during the first 4 months, and 15 g/day over the next 8 months. Most term infants double their birth weight by 4 months of age and triple it by 12 months. Premature infants may reach these milestones sooner. From 2 years to approximately 10 years of age, the growth rate is fairly constant at about 2.3 kg (5 pounds) each year. Growth velocity increases and a major growth spurt occurs during adolescence. Height shows a growth pattern similar to that of weight; most infants increase their length by 50% in the first year, 100% in the first 4 years, and 300% by 13 years of age. Changes in body composition accompany height and weight changes. Most notably, total body water decreases as adipose tissue increases. Total body water accounts for approximately 90% of total body weight at 24 weeks gestation, 70% at term, and 60% by 1 year of age.

Normal values of weight, length/height, and head circumference (until 3 years of age) for infants and children are generally expressed in terms of percentile-for-age; the reference standards most commonly used are the WHO growth standards for infants and children less than 2 years of age and the CDC growth charts developed by the National Center for Health Statistics (NCHS) for children greater than 2 years of age. In 2006, the CDC, National Institutes of Health (NIH), and AAP met to discuss the use of the recently released WHO growth standards in the United States. Three primary benefits of the WHO growth standards for infants and children less than 2 years of age were cited as the reason for their use in the United States. These benefits include establishing growth of the breast-fed infant as the norm for growth, providing a better description of physiologic growth in infancy, and basing information on a high-quality study designed explicitly for creating growth charts. For children greater than 2 years of age, the CDC growth charts should still be used, because the methods used to create both the CDC and WHO growth charts were similar for 2- to 5-year-olds, and the WHO growth charts only represent children up to 5 years of age.<sup>1</sup> Charts can be downloaded free of charge at [www.cdc.gov/growthcharts](http://www.cdc.gov/growthcharts). The infant charts are intended for use in term infants. Once premature infants reach 40 weeks gestational age, their growth parameters can be plotted on these charts, but their age must be corrected for gestational age (i.e., chronological age in weeks minus number of weeks premature) until 24 months of age for weight and 36 months for length/height and head circumference. Charts for premature infants less than 40 weeks gestation and children with specific conditions (e.g., cerebral palsy or Turner syndrome) are available and should be used when appropriate. These specialized growth charts can be found on various Web sites, including the Kennedy Krieger Institute for children with disorders of the brain and spinal cord, such as cerebral palsy ([www.kennedykrieger.org](http://www.kennedykrieger.org)), and the Turner Syndrome Society of the United States ([www.turnersyndrome.org](http://www.turnersyndrome.org)). Specialized growth

charts are no longer recommended by AAP for children with Down syndrome ([www.ndss.org](http://www.ndss.org)), and standard charts for age should be used.<sup>4</sup> The most commonly used charts for premature infants are the Babson and Benda charts (charts can be accessed at [www.biomedcentral.com/1471-2431/3/13](http://www.biomedcentral.com/1471-2431/3/13)). Most infants' growth parameters will fall between the 2nd and 98th percentiles on the gender-specific weight-for-age, length/height-for-age, weight-for-length, and head circumference-for-age charts. Most children grow along a percentile established shortly after birth, but spurts and plateaus are common. Failure to thrive is defined as a fall of two or more growth percentiles from a previously established percentile in 6 months or less. If growth is not progressing as expected, particularly in the first year of life when growth should be rapid, the infant's diet and other potential contributory factors (e.g., environment, diseases, or syndromes) should be evaluated. Satisfactory growth is the most sensitive indicator of whether nutritional needs are being met.

For children older than 2 years, body mass index (BMI)-for-age charts can be useful in assessing obesity risk. BMI, a measure of body weight adjusted for height, is a useful tool to assess body fat. BMI is calculated as weight in kilograms divided by height in meters squared. According to current CDC guidelines, a child with a BMI at or above the 85th percentile on the gender-specific, BMI-for-age NCHS chart is considered "at risk of overweight," and a child with a BMI at or above the 95th percentile is "overweight." However, in 2005, the American Medical Association, in collaboration with the Health Resources and Services Administration and the CDC, convened an expert committee charged with revising these recommendations. The committee's nomenclature changes were intended to make it easier to discuss children's weight issues with parents and children and to transition to adult assessments. These new recommendations state that a child whose BMI is at or above the 85th percentile but below the 95th percentile or 30 kg/m<sup>2</sup>, whichever is smaller, should be classified as "overweight." A child whose BMI is at or above the 95th percentile or 30 kg/m<sup>2</sup>, whichever is smaller, should be classified as "obese."<sup>5</sup> In 2009-2010, 12.3% of children and adolescents 2-19 years of age were greater than or equal to the 97th percentile, 16.9% were greater than or equal to the 95th percentile, and 31.8% were greater than or equal to the 85th percentile for BMI-for-age growth.<sup>6</sup> The prevalence of obesity in children has not changed since 2007-2008. However, between 1999-2000 and 2009-2010, a significant increase in the prevalence of obesity was observed in males 2-19 years of age but not in females. Also, a significant increase in BMI was observed in males 12-19 years of age but not in females. A BMI below the 5th percentile is indicative of underweight. The health care provider should realize that, because of the way the growth charts were developed, 5% of normally growing and healthy children will fall below the 5th percentile and 5% will fall above the 95th percentile on the weight-for-age or height-for-age charts. These children should not be branded as "malnourished" or "obese."

### Energy Requirements and Growth

Acceptable growth is achievable only with adequate intake; absorption; and utilization of energy, protein, carbohydrates, minerals, and vitamins. The Food and Nutrition Board of the National Research Council has established dietary reference intakes (DRIs), as reference values for nutrient intake sufficiency and safety. The DRIs for micronutrients are discussed in detail in [Chapter 22](#), and tables in that chapter list the current established recommended dietary allowances (RDAs) and adequate intakes (AIs) for healthy infants and children. [Table 25-2](#) provides the DRIs of macronutrients for healthy infants and children.<sup>7</sup> Children with various diseases and syndromes may have different needs. One example is the need for "catch-up" calories in infants and children recovering from failure to thrive. Calorie requirements for catch-up growth are often 1.25 times those of age-matched peers, depending on the degree of catch-up growth needed. In patients with fat malabsorption (e.g., patients with cystic fibrosis or other cause of pancreatic insufficiency, bile acid deficiency, and short-bowel syndrome), calories for catch-up growth may be 1.5 times or more those of age-matched peers.

**TABLE 25-2 Dietary Reference Intakes of Macronutrients for Full-Term Infants and Children<sup>a,b</sup>**

Nutrient	0-6 Months	7-12 Months	1-3 Years	4-8 Years	9-13 Years
Energy <sup>c</sup> (kcal/day)	M: 570 F: 520	M: 743 F: 676	M: 1046 F: 992	M: 1742 F: 1642	M: 2279 F: 2071
Protein <sup>c</sup> (g/kg/day)	1.5	1.5 <sup>d</sup>	1.1 <sup>d</sup>	0.95 <sup>d</sup>	0.95 <sup>d</sup>
(g/day)	9.1	13.5 <sup>d</sup>	13 <sup>d</sup>	19 <sup>d</sup>	34 <sup>d</sup>
Carbohydrate (g/day)	60	95	130 <sup>d</sup>	130 <sup>d</sup>	130 <sup>d</sup>
Water (L/day) <sup>e</sup>	0.7	0.8	1.3	1.7	M: 2.4 F: 2.1
Fat (g/day)	31	30	ND	ND	ND
Alpha-linolenic acid (g/day)	0.5	0.5	0.7	0.9	M: 1.2 F: 1
Linoleic acid (g/day)	4.4	4.6	7	10	M: 12 F: 10
Fiber (g/day)	ND	ND	19	25	M: 31 F: 26

Key: AI = Adequate intake; DRI = dietary reference intake; F = female; M = male; ND = not determined; RDA = recommended dietary allowance.

<sup>a</sup> Expressed as AIs unless noted otherwise.

<sup>b</sup> DRIs have not been established for premature infants.

<sup>c</sup> Estimated requirements; include needs associated with growth (i.e., energy expenditure plus energy deposition). The assumed normal body weight and length used for the DRIs are 0-6 months: 6 kg, 62 cm; 7-12 months: 9 kg, 71 cm; 1-3 years: 12 kg, 86 cm; 4-8 years: 20 kg, 115 cm; and 9-13 years: 36 kg, 144 cm for males, 37 kg, 144 cm for females.

<sup>d</sup> Expressed as RDA.

<sup>e</sup> Water from all sources including formula, human milk, foods, beverages, and drinking water.

Source: Reference 7.

Energy requirements vary with age and clinical condition. Total energy expenditure is a combination of basal energy needs, the energy required to digest food (thermic effect of feeding, also called "specific dynamic action of food"), thermoregulation, and activity. Estimates of energy requirements for infants and children are based on meeting total energy expenditure plus promoting growth. An infant's energy requirement is higher in relation to body mass than that of an adult or older child because of the rapid growth experienced during infancy. Estimated energy requirements for term infants and children are shown in [Table 25-2](#).<sup>7</sup> Although no RDA has been established, premature infants require as much as 120-150 kcal/kg/day or more for adequate growth.

### Infant Nutritional Standards

An amendment to the Federal Food, Drug, and Cosmetic Act (Infant Formula Act of 1980; amended 1986) gives the Food and Drug Administration (FDA) the authority to revise nutrient levels for infant formulas, establish quality control, and require adequate labeling. FDA sets specifications for minimum amounts of 29 nutrients and maximum amounts of 9 of those nutrients. All formulas marketed in the United States must meet these requirements. Parents should be cautioned against using any infant formula not manufactured in the United States. FDA alerts have warned of the dangers of using infant formulas from China whose contents fall well below FDA standards. Formulas granted exemption from FDA-established nutrient specifications must be labeled for use by infants who have inborn errors of metabolism, had a low birth weight, or otherwise have unusual medical problems or dietary needs. A list of exempt formulas can be obtained at the FDA Web site ([www.fda.gov](http://www.fda.gov)).

### Components of a Healthy Diet

Infants require the same dietary components as adults: fluid, carbohydrates, proteins, fats, and micronutrients. However, the desired proportion of these components in the infant diet differs.

#### Fluid

Water is an important part of an infant's diet, given that it makes up a larger proportion of the infant's body weight than in older children or adults. The Holliday-Segar method is most often used to estimate maintenance water needs: 100 mL/kg/day for the first 10 kg of body weight, plus 50 mL/kg/day for each kilogram between 10 and 20 kg, and 20 mL/kg/day for each kilogram over 20 kg. Body surface area may also be used to estimate daily fluid requirements; fluid requirements are approximately 1500 mL/m<sup>2</sup>/day. These methods will underestimate the needs of premature infants, whose requirements are, in general, much higher (i.e., 120-170 mL/kg/day or more). Adequate water intake in the first 6 months of life can be derived from human milk or formula. Both contain sufficient amounts of water, so the normal, healthy infant does not need supplemental water. From 6-12 months of age, when solid foods are introduced, water intake remains high, because most infant foods contain at least 60%-70% more water than other foods, and formula or human milk intake should still be high. Renal excretion, evaporation from the skin and lungs, and, to a lesser extent, feces are the major routes of fluid loss. Increased water loss caused by diarrhea, fever, or unusually rapid breathing, particularly in concert with decreased water intake, may result in significant dehydration and electrolyte imbalance, and must be offset by fluid intake in excess of maintenance needs.

#### Carbohydrates

An AI for carbohydrates has been established for infants ([Table 25-2](#)).<sup>7</sup> Under normal circumstances, an infant can efficiently use a diet with 40%-50% of total calories from a carbohydrate source. Carbohydrate intake should be balanced with adequate fat intake to allow proper neurologic development. A carbohydrate-free diet is generally undesirable, because it may lead to metabolic modifications favoring fatty acid breakdown, dehydration, and tissue protein and cation loss. However, children with seizures may receive an essentially carbohydrate-free diet, the ketogenic diet, because these metabolic effects may facilitate seizure control. Use of a ketogenic diet should be under the direct, strict supervision of a physician along with a registered dietitian or other qualified health care provider. Lactose, the primary carbohydrate source in human milk and most milk-based formulas, is hydrolyzed to its monosaccharide components, glucose and galactose, by gastric acid and lactase. Congenital lactase deficiency is a rare type of lactose intolerance resulting from an inborn error of metabolism. Infants born prematurely, prior to the maturation of significant lactase activity (before approximately 36 weeks gestation), are relatively lactase deficient. Secondary lactase deficiency is a temporary reduction in intestinal lactase caused by gastroenteritis or significant malnutrition. Because of low lactase activity, infants with congenital lactase deficiency, premature infants, and infants recovering from diarrhea or severe malnutrition may be unable to completely metabolize the quantity of lactose found in human milk or milk-based infant formulas, and may develop lactose intolerance resulting in diarrhea, abdominal pain or distention, bloating, gas, and cramping.

Fiber intake is of considerable interest because, in adults, high-fiber diets have been associated with the prevention of diverticular disease, colon cancer, and coronary heart disease. (See [Chapter 23](#) for further discussion of fiber.) The American Health Foundation has recommended a daily fiber intake calculated by using the following equation: fiber (grams/day) = age (in years) plus 5. Age-plus-10 g/day is also felt to be a safe intake.<sup>8</sup> An AI for fiber for infants 0-12 months of age has not been established. Infants rarely require fiber to maintain normal bowel function. However, from age 6-12 months, whole cereals, green vegetables, and legumes provide a source of fiber in the infant's diet. The fiber AI for older children is shown in [Table 25-2](#). Adult values are reached by the teenage years.

#### Protein and Amino Acids

The most recent revision of the DRIs established new AIs for protein in term infants and children ([Table 25-2](#)).<sup>7</sup> Total body protein increases by an average of 3.5 g/day in the first 4 months of life and by 3.1 g/day over the next 8 months, representing an overall increase in body protein composition from 11%-15% of total body weight.

The protein's amino acid composition (i.e., chemical value) is also important. Amino acids are classified as essential (or indispensable), nonessential, or conditionally essential. The amino acids cysteine, histidine, isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan, tyrosine, and valine are considered essential for infants because the human body cannot synthesize them from other amino acid and carbohydrate precursors. In the neonate and young infant, immature biochemical pathways for synthesis or conversion of amino acids may prevent adequate synthesis for normal growth and development. Taurine is an especially important amino acid in infancy. Quantities in human milk are high, and all infant formulas are supplemented during the manufacturing process to provide the same margin of physiologic safety as that provided by human milk.<sup>9</sup> Taurine is not an energy source and is not used for protein synthesis, but it serves as a cell membrane protector by attenuating toxic substances (e.g., oxidants, secondary bile acids, and excess retinoids) and acting as an osmoregulator. Taurine deficiency can result in retinal dysfunction, slow development of auditory brain stem-evoked response in preterm infants, and poor fat absorption in preterm infants and children with cystic fibrosis. These conditions can be improved with taurine supplements.

Despite similar amino acid densities and milk intakes in formula-fed compared with human milk-fed infants, serum concentrations of some amino acids measured in formula-fed infants tend to exceed those measured in human milk-fed infants; however, the growth of these infants is equivalent. The protein content of human milk adjusts to a growing infant's needs, but the high protein needs of preterm infants are not completely met by early human milk. Fortification with commercially available powders or liquids is required for the preterm infant to achieve reasonable amino acid profiles and to meet expected growth rates. In evaluating the adequacy of an infant's protein intake, one must consider not only the absolute amount of protein ingested but also the growth rate, the quantity of nonprotein calories and other nutrients necessary for protein synthesis, and the quality of the protein itself.

#### Fat and Essential Fatty Acids

Fat is the most calorically dense component in the diet, providing 9 kcal/g compared with 4 kcal/g for both protein and carbohydrates. Fat accounts for approximately 50% of the nonprotein energy in both human milk and infant formula. Infant feeding practices, especially fat and calorie intake, are increasingly being linked to obesity and other diseases (e.g., diabetes and cardiovascular disease) in adulthood. Despite these concerns, children younger than 2 years (the time of most rapid growth and development requiring high-energy intakes) should not receive a fat- or cholesterol-restricted diet unless medically prescribed. Children between 12 months and 2 years who are at increased risk for cardiovascular disease (CVD) because of a family history of obesity, dyslipidemia, or CVD may be candidates for reduced-fat milk products.<sup>10</sup> AAP supports this position because of the need for adequate fatty acid intake for normal neurologic development and adequate calories for growth.<sup>10</sup> Parents of children between 2 and 5 years of age should be encouraged to adopt a diet that contains 20%-30% of total calories from fat, with less than 10% of calories from saturated fats and less than 1% from trans fatty acids.<sup>10</sup> The diet must also contain small amounts of the two essential polyunsaturated fatty acids (PUFAs): linoleic acid, an omega-6 (n-6) fatty acid, and linolenic acid, an omega-3 (n-3) fatty acid. These fatty acids are precursors for the n-3 and n-6 long-chain PUFAs: docosahexaenoic acid (DHA) and arachidonic acid (ARA), respectively. Essential fatty acid deficiency, rarely seen in the United States, can manifest as increased metabolic rate, failure to thrive, hair loss, dry flaky skin, thrombocytopenia, and impaired wound healing. Because of substantial fat stores, overt clinical manifestations of essential fatty acid deficiency are generally

delayed for weeks to months in older children and adults; however, rapid onset (within days to weeks) may occur in premature infants with inadequate linoleic acid in their diets. Linoleic acid represents the bulk of PUFAs in infant formulas. Generally, an intake of linoleic acid equal to 1%-2% of total dietary calories is adequate to prevent essential fatty acid deficiency; 3%-7% is the amount found in human milk. The AI for the essential PUFAs is shown in [Table 25-2](#).<sup>7</sup> Historically, infant formulas contained only the precursor PUFAs: linoleic and linolenic acid. Now, most infant formulas are supplemented during manufacturing with DHA and ARA. In fact, more than 60 countries permit the addition of these fatty acids to infant formulas. AAP has not taken an official stand on whether infant formulas should be supplemented with DHA and ARA. These long-chain PUFAs, which are abundant in human milk but not in cow milk, are not considered essential but are thought to provide extra benefits. Increased amounts of DHA beyond what is currently being added to term infant formulas to mimic term human milk levels are being recommended for some preterm infants.<sup>11</sup> DHA is important in both brain and eye development; the direct role of ARA is less clear. However, supplementation of DHA without ARA may lead to ARA deficiency and possible growth suppression. Whether the addition of DHA and ARA to infant formulas improves visual and cognitive function remains controversial. Some studies have shown benefits to an infant's visual function, cognitive and behavioral development, and growth with DHA and ARA supplementation; other studies have shown no differences in supplemented versus control infants.<sup>12,13,14,15,16,17,18,19</sup> Benefits such as decreasing allergies and the incidence of common respiratory illnesses have also been suggested, but studies have had mixed results.<sup>20,21</sup> No adverse effects have been noted in infants receiving DHA- and ARA-supplemented formulas; however, two studies in which the formula was supplemented with only DHA reported growth suppression, stressing the importance of supplementation with both DHA and ARA.<sup>15</sup> More recent studies have examined the long-term benefits, particularly cognitive, of DHA supplementation and have not found sustained benefits.<sup>22,23,24,25</sup> FDA has issued a "generally recognized as safe" (GRAS) notification to Martek Biosciences Corporation for its patented plant-based fatty acid blends DHASCO and ARASCO, which are currently used to supplement infant formulas during manufacturing. There is also evidence that maternal diet can affect fatty acid concentrations in the infant, both in utero and during lactation for human milk-fed infants.<sup>26,27</sup> Many prenatal vitamins, both prescription (e.g., Nexa Plus, Duet DHA Balanced) and over-the-counter (e.g., Similac Prenatal, various store brands), currently are available with an additional softgel capsule containing either DHA or DHA with eicosapentaenoic acid (EPA). The sources of DHA and EPA range from fish-based products to plant-derived sources. Enfamil Expecta Prenatal, softgel capsules containing 200 mg DHA, is marketed as a non-fish-based supplement for pregnant and lactating women to increase maternal dietary DHA and potentially increase DHA concentrations in their infants. These capsules may have less aftertaste than other sources of DHA and ARA. Routine supplementation during pregnancy and lactation remains controversial and should be discussed with a health care provider.

#### Micronutrients

DRIs for term infants (given as AIs, if defined, or as RDAs, if AIs are not defined) for vitamins and minerals, including trace elements, are shown in [Tables 22-3](#) and [22-4](#) in [Chapter 22](#). Precise needs are difficult to define and depend on energy, protein, and fat intakes as well as absorption and nutrient stores. Infant formulas are supplemented with adequate amounts of vitamins and minerals to meet the needs of most term and premature infants when the appropriate formula is chosen. As with protein, human milk must be fortified to meet the micronutrient needs of most premature infants. Appropriate supplementation is included in the discussion of specific milks and formulas.

#### Infant Food Sources

Human milk- and cow milk-based formulas are the primary food sources for most infants in the United States. Soy protein-based formulas and goat milk are alternatives. A variety of formulas are available to feed infants with special nutritional needs, including those unable to consume a regular oral diet, those with inborn errors of metabolism, and those with various malabsorptive conditions. Most infants and children receive either human milk or an enteral formula orally; however, some children will receive these through feeding tubes such as naso- or orogastric, gastrostomy, or jejunostomy tubes. A discussion of these feeding techniques is beyond the scope of this chapter.

#### Human Milk

Both WHO and AAP recommend that infants be breast-fed without supplemental foods or liquids for approximately the first 6 months (i.e., exclusive breast-feeding).<sup>28-30</sup> Breast-feeding initiation rates worldwide have increased steadily since 1990, with the rate at hospital discharge increasing from a low of 24.7% in 1971 to 77% in 2010 (provisional rates with final values to be reported in August 2014). However, in 2013, the reported rate of any breast-feeding at 6 and 12 months of age was only 49% and 27%, respectively. Sociodemographic factors affect breast-feeding rates. Black women are less likely than white, Hispanic, and Asian women to breast-feed. For infants born in 2007, approximately 60% of black women ever breast-fed and 30% breast-fed when their infants were 6 months of age, compared with 78% and 45% for white women, 81% and 46% for Hispanic women, and 86% and 59% for Asian women, respectively. At 1 year of age, rates continue to differ, although less so, with 24% of white women, 25% of Hispanic women, and 35% of Asian women still breast-feeding at that time, compared with 13% of black women.<sup>31,32,33</sup> Poor, unmarried, and poorly educated women are also less likely to breast-feed their infants. Because breast-feeding is a major public health concern, breast-feeding goals were included in *Healthy People 2020: National Health Promotion and Disease Prevention Objectives*, the national plan to improve the health of the American people.<sup>34</sup> One objective of *Healthy People 2020* is to have 82% of all infants in the United States breast-fed at birth, with 61% receiving human milk at 6 months of age and 34% receiving human milk at 1 year of age. As of 2008 (the last official reporting of information), the levels of achievement for these three goals were 75% at birth, 44% at 6 months, and 23% at 1 year. *Healthy People 2020* also includes targets for breast-feeding exclusivity, such as a target of 46% for exclusive breast-feeding through 3 months and 25% through 6 months, as well as a decrease in formula supplementation within the first 2 days of life to 14%. As of 2008, the breast-feeding exclusivity goals had current baseline levels of 34% at 3 months, 15% at 6 months, and formula supplementation within the first 2 days of life at 25%. All values showed improvement from the 2006 baseline levels except for formula supplementation within the first 2 days of life, which was previously 24% ([www.healthypeople.gov](http://www.healthypeople.gov)). AAP recommends support for breast-feeding through the first year of life. The AAP policy statement on breast-feeding and the use of human milk was updated in 2012 and includes reinforcement of breast-feeding and human milk as the reference normative standards for infant feeding and nutrition and reaffirmation of the recommendation to exclusively breast-feed for 6 months, followed by continued breast-feeding for 1 year or longer as mutually desired by mother and infant. AAP cautions that medical contraindications to breast-feeding are rare in the United States. Moreover, AAP recommends (1) the use of the WHO growth charts to avoid mislabeling of underweight and failure-to-thrive infants, (2) hospital initiatives to encourage and support the initiation and sustaining of exclusive breast-feeding, (3) support by pediatricians as advocates of breast-feeding, and (4) acknowledgment of the economic benefits to society of breast-feeding.<sup>29</sup> Breast-feeding not only offers an optimal source of nutrition for the infant, but also provides other benefits, such as improved mother-child bonding, and advantages to the infant's general health, growth, and development. Strong evidence indicates human milk decreases the incidence and severity of various infections (e.g., nonspecific gastrointestinal tract infections, respiratory tract infections, otitis media) in infants, and necrotizing enterocolitis in premature infants.<sup>29</sup> Other proposed benefits of human milk include decreased rates of sudden infant death syndrome, types 1 and 2 diabetes mellitus, leukemia, overweight, obesity, hypercholesterolemia, asthma, atopic dermatitis, eczema, celiac disease, and childhood inflammatory bowel disease. Breast-feeding has also been associated with slightly enhanced performance on tests of cognitive development; however, the effect of genetic and socioenvironmental factors on intelligence is difficult to measure separately from breast-feeding.<sup>29</sup> For premature infants, improvement is also seen in clinical feeding tolerance, quicker attainment of full enteral feeding, and improved neurodevelopmental outcomes. With these benefits in mind, AAP recommends the use of human milk for all preterm infants. If the mother's own milk cannot be provided, pasteurized donor milk should be used.<sup>29</sup> Besides enhanced mother-child bonding, maternal benefits of breast-feeding include decreased postpartum bleeding, more rapid uterine involution, decreased menstrual blood loss, increased spacing between children, earlier return to prepregnancy weight, decreased risk of breast and ovarian cancer, decreased risk of rheumatoid arthritis, and decreased hip fracture and osteoporosis in the postmenopausal period. A savings of \$13 billion per year (\$3.7 billion in direct and indirect pediatric health costs with \$10.1 billion in premature death from pediatric diseases) could be saved if 90% of mothers in the United States would exclusively breast-feed for 6 months.<sup>35</sup> For businesses, the case for breast-feeding is an economic one. For every \$1 businesses spend on creating and supporting lactation support programs at the business site, they have a \$2-\$3 return on their investment.<sup>36</sup> An

economic analysis of estimated direct health care costs for diarrhea, lower respiratory tract infections, and otitis media in the first year of life found that costs for infants who were never breast-fed were \$300 more than for infants exclusively breast-fed for at least 3 months.<sup>37</sup>

Many unanswered questions exist regarding the protective effects of breast-feeding. What is the duration of protection after breast-feeding has been discontinued? What influence does maternal age have on the protective effect? How great is the interactive effect of social and demographic variables? How does the addition of solid foods (complementary feeding) to the diet of a human milk-fed infant influence the protective effect? What consequence does partial formula feeding have on the protective effect? Well-designed studies are needed to answer these questions.

The impact of the use of breast pumps also should be considered. The 2005-2007 Infant Feeding Practices Study II (IFPS II) assessed the use of expressed human milk among breast-feeding mothers of infants between the ages of 1.5 and 4.5 months.<sup>38</sup> Of these mothers, 85% had expressed human milk sometime during the life of their infant, and 5.6% of mothers had exclusively fed their infants expressed human milk. As with breast-feeding rates in general, the use of expressed human milk is more common among women with a higher level of education and a higher household income. The primary reason reported in IFPS II for the use of expressed human milk is the ability to have someone else feed the infant, allowing many mothers to continue to provide breast milk while working outside of the home.

Although this process can provide many of the same benefits to the infant and mother, some concerns should be noted. If an electric breast pump is used improperly, a mother can have mastitis, pain, trauma, and nipple wounds. For the infant, expressed human milk can become contaminated with bacteria if it is stored improperly. Storing human milk in nonglass containers can destroy some key milk components, and storing milk at either refrigeration or freezer temperatures can reduce levels of key milk components (i.e., vitamin C, lipids, and immunologic cells). Finally, the composition of human milk changes throughout a single feeding and with the infant's age. For example, most mothers who express human milk feed the infant and then express the remainder for later use. This method separates the foremilk, which is high in carbohydrate content, from the hindmilk, which is high in fat content. This feeding separation of the macronutrient components within the mother's milk can lead to adverse gastrointestinal effects such as diarrhea. Well-designed research is needed in this area to assess the true impact of the use of breast pumps on maternal health and infant nutrition.<sup>38</sup>

Very few contraindications to the use of human breast milk exist. In developed countries, such as the United States, one reason for women not breast-feeding is the maternal diagnosis of human immunodeficiency virus (HIV) infection, which can be transmitted through human milk. Women with HIV in underdeveloped countries, however, are encouraged to breast-feed, because the risk of infant morbidity and mortality with formula use (from inadequate sanitation, refrigeration, and illiteracy) is greater than the risk of HIV transmission.<sup>29</sup> Other reasons women in developed countries may not be able to breast-feed, either temporarily or permanently, are classic galactosemia; active, untreated tuberculosis; human T-cell lymphotropic virus types I or II; herpes simplex lesion on the breast (may use other breast); and the use of contraindicated drugs (Table 25-3). Several excellent texts provide information regarding the use of drugs during lactation and pregnancy<sup>39,40</sup> (see also Appendix I of this book). In addition, a comprehensive database of available information regarding drugs in lactation (LactMed) is maintained by the US National Library of Medicine (<http://toxnet.nlm.nih.gov/cgi-bin/sis/htmlgen?LACT>). Further questions can be directed to the poison control center (800-222-1222) or the National Breastfeeding Helpline at 800-994-9662 (<http://www.womenshealth.gov/breastfeeding/>). The overall risk of a drug to a breast-fed infant depends on the concentration in the infant's blood and the effects of the drug on the infant. Feeding immediately before the mother's dose may help minimize exposure, because the concentration in milk is likely to be lowest toward the end of the dosing interval. This may not be true for lipid-soluble drugs. Alternating breast- and bottle-feeds or pumping and discarding breast milk is an option, if the need for a particular drug is short term.

**TABLE 25-3 Selected Drugs Contraindicated or to Be Used Cautiously While Breast-Feeding**

Prescription Drugs	Drugs of Abuse	Radiopharmaceuticals (time to wait after exposure)
<b>Contraindicated Drugs</b>		
Ciprofloxacin	Amphetamine	Copper 64 (50 hours)
Cyclophosphamide	Cocaine	Gallium 67 (2 weeks)
Cyclosporine	Heroin	Indium 111 (20 hours)
Doxepin	Marijuana	Iodine 123 (36 hours)
Doxorubicin	Phencyclidine	Iodine 125 (12 days)
Ergotamine		Iodine 131 (2-14 days)
Leflunomide		Radioactive sodium (96 hours)
Methotrexate		Technetium 99m (15 hours to 3 days)
<b>Drugs to Be Used Cautiously Because of Significant Potential Adverse Effects</b>		
Acebutolol	Clemastine	Primidone
Amiodarone	Chloramphenicol	Sulfasalazine
5-Aminosalicylic acid	Gold salts	Tetracyclines (long-term)
Atenolol	Lithium	Vitamin D (high-dose)
Aspirin	Phenobarbital	
Bromocriptine	Phenytoin

Contains manufacturers' prescribing information and information from the U.K. Drugs in Lactation Advisory Service. Accessed at <http://pediatrics.aappublications.org/content/108/3/776.full.pdf+html>, June 2, 2013.

In the United States and other countries, human milk donor banks have been established, with 13 member banks in the Human Milk Banking Association of North America (HMBANA) and 7 sites in various stages of development. Human milk donations are taken from carefully screened, unpaid donors; then the milk undergoes Holder pasteurization to eliminate potential viral and bacterial contaminants while maintaining most of the milk's unique immunologic factors.<sup>41</sup> It is estimated that about 50% of the immunoglobulin A (IgA) is lost in processing; however, because cow milk contains no IgA, infants who receive donor human milk still benefit from its presence. The cost is approximately \$4 per ounce plus shipping and handling. More information about donor milk banks, including how to be a donor or receive donor milk, can be obtained at HMBANA's Web site ([www.hmbana.org](http://www.hmbana.org)).

#### Cow Milk

Cow milk is the primary nutrient source for commercially prepared milk-based infant formulas. Both human and cow milk contain more than 200 ingredients in the fat- and water-soluble fractions. Estimates of the major nutrients contained in pooled mature human milk and whole cow milk are listed in Table 25-4.

**TABLE 25-4 Average Composition of Mature Human Milk and Whole Cow Milk**

Component	Mature Human Milk <sup>a</sup>	Whole Cow Milk
-----------	--------------------------------	----------------

Water (mL/100 mL)	87.1	87.2
Energy

#### Whole Cow Milk

Whole cow milk is not suitable for providing nutrition to infants younger than 1 year. Because of the low concentration and poor bioavailability of iron, whole cow milk has been associated with iron-deficiency anemia.<sup>42,43</sup> Sensitivity to dietary proteins, most commonly cow or soy milk proteins, can manifest as occult GI bleeding, further increasing the risk of anemia. In the past decade, convincing evidence has accumulated to indicate that iron deficiency impairs psychomotor development and cognitive function in infants, even with relatively mild anemia. Milk-protein intolerance and/or allergy can also result in rash, wheezing, diarrhea, vomiting, colic, and anaphylaxis when whole cow milk is used. When whole cow milk is fed with solid food, infants receive unnecessarily high intakes of protein and electrolytes, resulting in a high renal solute load (RSL; [Table 25-5](#)).<sup>44,45</sup> The implications of a high RSL will be discussed later in this chapter. The current position of AAP's Committee on Nutrition (CON) is that iron-fortified infant formula is the only acceptable alternative to human milk. The use of cow milk is not recommended during the first year of life.<sup>42</sup>

#### Reduced-Fat Cow Milk

Reduced-fat cow milk, such as skim milk (0.1% fat), low-fat milk (1% fat), and reduced-fat milk (2% fat), has been advocated to prevent obesity and atherosclerosis as part of a "healthy diet." However, when the low-fat diet recommended for adults is imposed on children younger than 2 years, it puts them at risk for failure to thrive and impaired neurologic development. Infants who receive a major percentage of their caloric intake from reduced-fat milk may receive an exceedingly high protein intake and an inadequate intake of essential fatty acids. The maximum protein concentration allowed by FDA in infant formulas is 4.5 g/100 kcal, but skim milk and 2% milk provide approximately 8-10 g/100 kcal and 7-10 g/100 kcal, respectively. Therefore, using reduced-fat cow milk for infant nutrition provides an unbalanced percentage of calories supplied from protein, fat, and carbohydrates.

Per unit volume, skim milk has a slightly higher potential RSL (PRSL) than does whole cow milk ([Table 25-5](#)). The solute concentration is further increased by water loss during processing. Reduced-fat milk is not recommended during episodes of diarrhea because of the possibility of hypertonic dehydration. As stated earlier, AAP does not recommend the use of low-fat diets during the first 2 years of life, except for children between 12 months and 2 years with a family history of CVD.

**TABLE 25-5 Potential Renal Solute Load of Selected Milks and Infant Formulas**

	PRSL	
	mOsm/L	mOsm/100 kcal
Human milk	93	14
Milk-based formula	135-260	20-39
Soy protein-based formula	160	24
Whole cow milk	308	46
Skim cow milk	326	93
FDA upper limit	277	41
Beikost <sup>a</sup>	153	23

Key: FDA = Food and Drug Administration; PRSL = potential renal solute load.

<sup>a</sup> Beikost is foods other than milk or formula.

Source: References 44 and 45.

#### Evaporated Milk

Evaporated milk is a sterile, convenient source of cow milk with standardized concentrations of protein, fat, and carbohydrate. However, it is not recommended for infant feeding.

#### Goat Milk

Although goat milk is the primary milk source for more than 50% of the world's population, it is rarely used in the United States for infants intolerant to cow milk. Goat milk is commercially available in powdered and evaporated forms. It contains primarily medium- and short-chain fatty acids; therefore, the fat is more readily digested than the fat in cow milk. Unfortified goat milk is not recommended during infancy because it is deficient in folate and low in iron and vitamin D. The evaporated form of Meyenberg goat milk, however, is supplemented with vitamin D and folic acid. Powdered Meyenberg goat milk is supplemented with only folic acid; therefore, it is recommended only for children older than 1 year. Because the powder formulation is not a complete formula, vitamin supplementation is required if it is used for infant nutrition.

#### Commercial Infant Formulas

When provision of human milk to an infant is not possible or not desired by the mother, then commercially supplied infant formulas are an acceptable alternative ([Table 25-6](#)). Differences in palatability, digestibility, sources of nutrients, convenience of administration, and cost among these formulas allow for individualization to the infant's special nutrient needs and the family's resources.

Similac Go & Grow Soy-based Formula [P] (A)	20	18.9	Soy protein isolate, L-methionine, taurine	69.6	Corn syrup solids, sugar, fructooligosaccharides	37	High oleic safflower, soy, and coconut oils; DHA, ARA	—	13.5
<b>Children's Formulas</b>									
PediaSure/PediaSure Enteral Formula <sup>g</sup> [R] (A)	30	30	Milk protein concentrate	139	Corn maltodextrin, sugar	38	High oleic safflower, soy, and MCT oils; soy lecithin	16	11
PediaSure 1.5 [R] (A), vanilla	45	59	Milk protein concentrate	160	Corn maltodextrin	68	High oleic safflower, soy, and MCT oils; soy lecithin, DHA	15	11
PediaSure with Fiber <sup>h</sup> /PediaSure Enteral Formula with Fiber <sup>h</sup> [R] (A)	30	30	Milk protein concentrate	143 (13 grams/L of dietary fiber with 6.5 grams/L of scFOS <sup>h</sup> )	Corn maltodextrin, sugar	38	High oleic safflower, soy, and MCT oils; soy lecithin	16	11
PediaSure 1.5 with Fiber <sup>h</sup> [R] (A), vanilla	45	59	Milk protein concentrate	165 (13 g/L of dietary fiber with 6.5 g/L of scFOS <sup>h</sup> )	Corn maltodextrin	68	High oleic safflower, soy, and MCT oils; soy lecithin, DHA	15	11
Nutren Junior [R]/Nutren Junior with Fiber <sup>i</sup> [R] (Nes)	30	30 (50:50)	Milk protein concentrate, 50% whey protein concentrate	110 (3.8 g/L of insoluble fiber and 2.2 g/L of soluble fiber as PreBio <sup>j</sup> )	Maltodextrin, sugar; fiber product also contains pea fiber, fructooligosaccharides, inulin	50	Soybean, canola, and MCT oils (coconut and/or palm kernel oils); soy lecithin	20	14
Boost Kid Essentials [R] (Nes)	30	28	Sodium and calcium caseinates, whey protein concentrate	134	Sugar, maltodextrin	38	High oleic sunflower, soybean, MCT (coconut and/or palm kernel oil), and soy oils; soy lecithin	20	13.9
Boost Kid Essentials 1.5 [R]/Boost Kid Essentials 1.5 with Fiber [R] (Nes)	45	42	Sodium and calcium caseinates, whey protein concentrate	165 (8 g/L of fiber)	Maltodextrin, sugar	75	MCT, soy, and sunflower oils; soy lecithin	10	13.9
Compleat Pediatric [R] (Nes)	30	37.6	Chicken, sodium caseinate, and pea puree	132 (6.8 g/L of Nutrisource Fiber)	Corn syrup, green pea and green bean puree, peach and cranberry juice, maltodextrin	39	Canola and MCT oils (coconut and/or palm kernel); hydroxylated soy lecithin	20	14
Carnation Breakfast Essentials [P,R] (Nes)	24	35	Powder = nonfat milk; liquid = calcium caseinate	103	Sugar, maltodextrin; powder also has lactose; liquid also has sucralose	35	Powder = trace butterfat; liquid = corn oil	—	13.6
<b>Other Therapeutic Formulas—Older Infants, Toddler, and Pediatric</b>									
E028 Splash [R] (Nut), flavored	30	25	Free L-amino acids	146	Maltodextrin, sugar	35	Fractionated coconut, canola, and high oleic sunflower	35	7.7

							oils		
EleCare Jr [P] (A), flavored or unflavored	30	31	Free amino acids	107	Corn syrup solids	49	High oleic safflower, MCT, and soy oils	33	14.9
Neocate Junior [P] (Nut), flavored or unflavored	30	33	Free L-amino acids	104	Corn syrup solids	50	MCT, refined vegetable oils (palm kernel and/or coconut, canola, and high oleic safflower oils)	35	16
Pepdite Junior [P] (Nut), flavored or unflavored	30	31	Hydrolyzed pork and soy proteins	106	Corn syrup solids	50	MCT, fractionated coconut, canola, and high oleic safflower oils	35	14
Peptamen Junior [R] (Nes)	30	30 (0:100)	Enzymatically, hydrolyzed whey protein (milk)	136	Maltodextrin, sugar, corn starch, guar gum, sucralose	38	MCT (coconut and/or palm kernel oil), soybean, and canola oils; soy lecithin	60	14
Peptamen Junior 1.5 with PreBio <sup>i</sup> [R] (Nes), flavored or unflavored	45	45	Enzymatically, hydrolyzed whey protein (milk)	180	Maltodextrin, corn starch, fructooligosaccharides, inulin, guar gum	68	MCT (coconut and/or palm kernel oils), soybean, and canola oils; soy lecithin	60	20.8
Peptamen Junior Fiber with PreBio <sup>i</sup> [R] (Nes)	30	30 (0:100)	Enzymatically, hydrolyzed whey protein (milk)	136 (7.4 g/L of fiber <sup>d</sup> )	Maltodextrin, sugar, corn starch, pea fiber, fructooligosaccharides, inulin	38.4	MCT (coconut and/or palm kernel oils), soybean, and canola oils; soy lecithin	60	14
Vivonex Pediatric [P] (Nes)	24	24	100% free L-amino acids	130	Maltodextrin, modified corn starch	23	MCT (coconut and/or palm kernel oil), soybean oils	70	10
Portagen [P] (MJ)	30	35	Sodium caseinate	115	75% corn syrup solids, 25% sugar	48	MCT and corn oils, soy lecithin	87	18.8

Key: A = Abbott Nutrition; ARA = arachidonic acid; C = concentrate; C:W = casein:whey ratio; DHA = docosahexaenoic acid; G = Gerber; MCTs = medium-chain triglycerides; mfr = manufacturer; MJ = Mead Johnson Nutritionals; Nes = Nestlé Nutrition; Nut = Nutricia North America; P = powder; R = ready-to-feed; scFOS = short-chain fructooligosaccharides.

*Note:* Federal regulations require nutrient values to be reported as intakes per 100 kcal. These intakes can be found on the manufacturers' Web sites. Values per liter of formula are provided for ease of calculation. Changes occur periodically in formula composition; for the most up-to-date information, refer to the Web sites.

<sup>a</sup> When powder is prepared to the stated caloric density.

<sup>b</sup> Available as newborn formulation [R,P] with C:W ratio of 20:80. Provides sufficient vitamin D (400 international units) in minimum volume of 27 fl oz.

<sup>c</sup> Has  $\frac{1}{5}$  of the lactose content of standard milk-based formula.

<sup>d</sup> Powder form available as Nutramigen with Enflora LGG.

<sup>e</sup> When carbohydrate is added as directed to make a 20 kcal/oz concentration. For RCF, 54 grams of carbohydrate + 12 fl oz water + 13 fl oz of RCF to yield 26 fl oz. For 3232A, 81 grams of 3232A + 59 grams carbohydrate per quart prepared.

<sup>f</sup> Contains *Bifidus* BL, *Bifidobacterium lactis*, which is similar to probiotics found in human milk.

<sup>g</sup> Enteral formula contains less sucrose and has a lower osmolality.

<sup>h</sup> Prebiotic Nutraflora scFOS are short-chain fructooligosaccharides that provide fuel for beneficial bacteria in the digestive tract to help support a healthy immune system.

<sup>i</sup> PreBio is a unique blend of fructooligosaccharides and inulin. These compounds may increase colonic mucosal integrity and permeability, promote potentially beneficial bacteria, and improve colonic absorption of water and electrolytes.

#### Formula Properties

The International Formula Council is a voluntary, nonprofit trade association composed of the five companies that manufacture and market infant formulas and adult nutritionals: Abbott Nutrition, Mead Johnson Nutritionals, Nestlé Infant Nutrition, Perrigo Nutritionals, and Pfizer Nutrition. The association has established guidelines requiring liquid formulations to be free of all viable pathogens, their spores, and other organisms that may cause product degradation. In addition, infant formula constituents must meet certain concentrations to ensure optimum nutrition. Guidelines have been established to ensure safety and efficacy of infant formulas.

#### Microbiologic Safety

Manufacturers sterilize liquid formulas using heat treatment, and the product is free of microbes as long as the container remains intact. Powdered formulas are not required or guaranteed to be sterile; however, coliforms and other pathogens are absent, and contamination with other microorganisms is below acceptable

government standards. If clinically significant microbiologic contamination occurs, an infant ingesting the formula could develop diarrhea with subsequent fluid and electrolyte losses. In 2002, FDA issued an alert after the death of an infant in a neonatal intensive care unit because of contamination of powdered formula with *Enterobacter sakazakii* at the manufacturing site.<sup>46</sup>

Risk for infection after exposure to contaminated formula likely depends on a number of factors, including immune status. For that reason, to minimize risk for premature and immunocompromised infants, ready-to-feed or liquid concentrates are recommended unless no suitable alternative to a powdered formula exists.

### Physical Characteristics

Infant formulas are emulsions of edible oils in aqueous solutions, but fat separation rarely occurs. If it does, shaking the container will usually redisperse the fat. Redispersion may not happen if stabilizers are lacking or if the formula was stored beyond its shelf life. Liquid infant formulas may contain thickening agents, stabilizers, and emulsifiers to provide uniform consistency and prolong stability. Protein agglomeration may occur, however, if storage time is excessive. This agglomeration ranges from a slight, grainy development through increased viscosity and gel formation to eventual protein precipitation. Agglomeration and separation do not affect a formula's safety or nutritional value; however, the formula's appearance may deter caregivers from using it.

### Caloric Density

The standard caloric density for infant formulas is 20 kcal/oz or approximately 67 kcal/100 mL, which mimics the average caloric density of human milk. One recent exception is selected standard infant formulas manufactured by Abbott Nutrition, which, if prepared according to standard preparation instructions, provide 19 kcal/oz or approximately 65 kcal/100 mL (Table 25-6). A healthy, term infant should have no difficulty consuming enough formula to meet both calorie and fluid needs with this caloric density. Premature, malnourished, volume-restricted (i.e., cardiac or liver disease, or poor oral feeding), or severely ill infants may require more calories (130-150 kcal/kg/day or higher) or formulas with higher caloric densities (e.g., 22, 24, or 27 kcal/oz) to meet their calorie needs. Infant formulas with caloric densities significantly lower or higher than 20 kcal/oz are regarded as therapeutic formulas to be used in managing special clinical conditions (Tables 25-6 and 25-7). Concentrated formulas should be used only under close medical supervision, especially with monitoring for dehydration caused by the reduction in free water consumed.

**TABLE 25-7 Indications for Therapeutic Infant Formulas<sup>a</sup>**

<b>Problem</b>	<b>Suggested Therapeutic Formula</b>	<b>Comments</b>
Allergy or sensitivity to cow milk or soy protein	EleCare DHA/ARA, Neocate Infant DHA & ARA, Nutramigen, PurAmino, Pregestimil, Similac Expert Care Alimentum	Protein hydrolysate or free amino acid formula is best. Up to 50% cross-sensitivity between cow milk and soy protein allergies. Powder form of Similac Expert Care Alimentum contains corn, whereas the ready-to-feed form does not.
Biliary atresia, cholestatic liver disease	EleCare DHA/ARA, Enfaport, Pregestimil, Similac Expert Care Alimentum	Impaired digestion and absorption of long-chain fats; higher percentage of MCTs may improve absorption.
Carbohydrate intolerance (severe)	3232A, RCF	Carbohydrate-free; a patient-tolerated carbohydrate source is added gradually (e.g., dextrose, glucose, sucrose, fructose).
Cardiac disease	No therapeutic formula generally necessary	Low electrolyte content (Similac PM 60/40), if renal insufficiency. Electrolyte supplementation may be needed in patients receiving diuretics. Calorically dense, standard formulas often used due to failure to thrive and volume restriction.
Celiac disease	EleCare DHA/ARA, Neocate Infant DHA & ARA, Nutramigen, PurAmino, Pregestimil, Similac Expert Care for Diarrhea	Advance to standard formulas as intestinal epithelium returns to normal; diet must be gluten free.
Chylothorax or chylous ascites	Enfaport	High MCT intake decreases flow through the lymphatic system.
Constipation	No therapeutic formula necessary	Continue routine formula; increase water; refer severe constipation.
Cystic fibrosis	EleCare DHA/ARA, Pregestimil, Similac Expert Care Alimentum	Impaired digestion and absorption of long-chain fats; cow milk-based formula or human milk may be used with appropriate pancreatic enzyme supplementation. Enzyme supplementation may be required even with predigested therapeutic formulas; soy protein-based formulas contraindicated.
Diarrhea, chronic nonspecific	Enfamil ProSobee, Nutramigen, Similac Sensitive, Similac Soy Isomil, Gerber Good Start Soy	Trial of lactose-free cow milk or soy protein-based formula may be needed; avoid fruit juices.
Diarrhea, intractable	3232 A, EleCare DHA/ARA, PurAmino, Pregestimil, RCF, Similac Expert Care Alimentum	Hydrolyzed protein needed because of impaired digestion of intact protein, long-chain fats, and disaccharides. Similac Expert Care Alimentum contains sucrose and may not be appropriate for all cases.
Diarrhea, antibiotic-associated	Similac Expert Care for Diarrhea	Contains added dietary fiber from soy and was specifically formulated for infants with diarrhea secondary to antibiotics; use short term until diarrhea resolves.
Failure to thrive	No therapeutic formula generally necessary; EleCare DHA/ARA, Pregestimil, Similac Expert Care Alimentum	Most cases related to inadequate intake. Start with standard formula; may need more calorically dense formula for catch-up growth; change to predigested formula only if malabsorption present.
Galactosemia	Enfamil ProSobee, Nutramigen, Pregestimil	Formulas without lactose or sucrose; cow and human milk contraindicated.
Gastroesophageal reflux	Enfamil A.R., Similac Sensitive For Spit-Up	In otherwise healthy children, may start with standard formula thickened with rice cereal. (Start with 1-2 teaspoons per ounce of formula and increase to a maximum of 1 tablespoon per ounce as tolerated.) Thickening formula with rice cereal increases the caloric density, may cause constipation, results in delivery of less volume, and usually requires enlarging the nipple. Some infants may have an allergic-type reaction to rice cereal; oatmeal may be used in these cases.

		Attempt small, frequent feedings; avoid using products like Thick-It and SimplyThick to thicken formula (products are intended for patients with dysphagia or swallowing difficulties); use more calorically dense formula if decreased volume or catch-up growth needed.
Hepatitis without liver failure	No therapeutic formula necessary	Impaired digestion or absorption of long-chain fats is uncommon.
Hepatitis with liver failure	EleCare DHA/ARA, Enfaport, Pregestimil, Similac Expert Care Alimentum	Impaired digestion or absorption of long-chain fats may occur.
Increased ostomy output	Similac Expert Care for Diarrhea	Improve consistency in term infants without malabsorption (e.g., Hirschsprung's disease, imperforate anus, necrotizing enterocolitis, or intestinal atresias).
Lactose intolerance (primary or secondary)	Enfamil ProSobee, Similac Sensitive, Similac Soy Isomil, Gerber Good Start Soy	Remove lactose from diet; use lactose-free formula.
Necrotizing enterocolitis (during recovery or postresection)	EleCare DHA/ARA, Neocate Infant DHA & ARA, Pregestimil, Similac Expert Care Alimentum	Impaired digestion or absorption requires a hydrolysate or free amino acid formula.
Prematurity	Fortified human milk (preferred); Enfamil Premature 20 Cal, Similac Special Care 20 with Iron, Gerber Good Start Premature 20, or transition infant formula (Enfamil EnfaCare, Similac Expert Care NeoSure, or Gerber Good Start Nourish)	Human milk fortifier needed; transition formula (see formula column) can be added to human milk to increase caloric density after discharge (1 tsp/90 mL milk makes 24 kcal/oz).
Renal insufficiency	Similac PM 60/40	Formula is low phosphate, low PRSL.

Key: MCT = Medium-chain triglyceride; PRSL = potential renal solute load.

<sup>a</sup> Products are listed alphabetically; list is not all-inclusive; other products may be acceptable.

### Osmolality and Osmolarity

Osmolality is the preferred term for reporting the osmotic activities of infant formulas. Osmolality represents the number of osmoles of solute per kilogram of solvent (Osm/kg). Any dietary component soluble in water contributes to osmolality. Osmolality is directly related to the concentration of molecular or ionic particles in the solution (i.e., amino acids, small peptides, electrolytes, and simple sugars) and inversely proportional to the concentration of water in the formula. The osmolality of human milk is approximately 295 mOsm/kg; osmolality of standard caloric density formulas is 200-300 mOsm/kg.

The osmolality of an infant formula may be expressed as the concentration of solute per unit of total volume of solution or as the number of osmoles of solute per liter of solution (Osm/L). The osmolality of human milk is approximately 273 mOsm/L. Formulas for infants should have osmolalities no higher than 400 mOsm/L. Unless the formula is very concentrated, there is no meaningful difference between osmolality and osmolarity of infant formulas.

The osmolality of a formula increases with increasing caloric density. The relationship between osmolality and caloric density is reasonably linear within the range of caloric concentrations usually fed to infants. Therefore, if the osmolality of a 20 kcal/oz formula is known, the same formula with any other caloric density can be calculated, assuming a direct proportion between osmolality and caloric density. For example, if a 20 kcal/oz formula has an osmolality of 283 mOsm/kg, then the same formula concentrated to 24 kcal/oz would have an osmolality of approximately 340 mOsm/kg.

No clinically meaningful difference exists in the osmolalities of the commonly used 20 kcal/oz, ready-to-use formulas. In addition, when concentrated products are diluted to provide a formula with 20 kcal/oz, there are no meaningful differences in osmolalities compared with the similar ready-to-use product. However, directions for diluting concentrated and powdered formulas must be followed exactly. Soy protein-based formulas have somewhat lower osmolalities than milk-based formulas because of the difference in carbohydrate source.

### Potential Renal Solute Load

The PRSL is the solute load derived from the diet that must be excreted by the kidney if the amino acids from protein digestion are not used for growth or eliminated by nonrenal routes. The PRSL of an infant formula can be calculated with the following equation:  $PRSL (mOsm) = N/28 + \text{sodium} + \text{chloride} + \text{potassium} + \text{phosphorus}_{(available)}$ , where N is the total nitrogen in milligrams, and sodium, chloride, potassium, and phosphorus<sub>(available)</sub> ( $P_a$ ) are expressed as millimoles (or milliosmoles). The  $P_a$  is assumed to be the total phosphorus content except in soy-based formulas, in which it is only two-thirds of the total

phosphorus. Table 25-5 lists PRSLs for various milks and infant formulas compared with the FDA-recommended upper PRSL limit.<sup>44,45</sup> Excretion of 1 mOsm of ingested solute requires 1 mL of water intake. Standard 20 kcal/oz infant formulas supply approximately 1.5 mL of water per kilocalorie ingested, an adequate amount of water to provide usual needs. Therefore, when the infant is healthy the PRSL is generally not a factor; however, during illnesses associated with water loss, such as vomiting, diarrhea, and fever, or in infants with compromised renal function or diabetes insipidus, the PRSL of the infant's formula becomes a factor in maintaining fluid balance. Feeding a formula with a high PRSL (i.e., high protein content or concentrated to more than 24 kcal/oz) may produce a hypertonic urine, leading to increased renal water losses and dehydration.

### Types, Uses, and Selection of Commercial Infant Formulas

Standard formulas for term infants are milk based or milk based with added whey protein (whey-predominant). Other formulas are available for infants and children with specific dietary needs and should be used only under medical supervision.

#### Milk-Based Formulas

Milk-based formulas (Table 25-6) are prepared from nonfat cow milk, vegetable oils, and added carbohydrate (lactose). The added carbohydrate is necessary, because the ratio of carbohydrate to protein in nonfat cow milk solids is less than desirable for infant formulas. The most widely used vegetable oils are corn, coconut, safflower, sunflower, palm olein, and soy. Replacement of the butterfat with vegetable oils allows for better fat absorption. Although Similac Sensitive is a milk-based formula, it contains sucrose with corn maltodextrin, rather than lactose, as the carbohydrate source and may be used for infants with lactose intolerance. Enfamil Gentlease and Gerber Good Start Soothe contain decreased lactose amounts (20% and 50%, respectively) when compared with their product-line's standard milk-based formulas, and both are marketed for infant colic.

#### Therapeutic Formulas

Therapeutic infant formulas are used for infants with conditions requiring dietary adjustment and should be used with medical supervision, rather than being self-selected by parents. Table 25-7 lists indications for various therapeutic formulas, including soy protein-based, casein-based, casein hydrolysate-based or whey hydrolysate-based, and low-electrolyte and low-mineral formulas. Formulas intended for use by premature infants and those formulated specifically for children from 1-10 years of age are also considered therapeutic formulas.

**Prethickened Milk-Based Formulas.** Enfamil A.R. and Similac Sensitive For Spit-Up were developed specifically for infants with gastroesophageal reflux. These iron-fortified formulas contain rice starch. Before ingestion, the viscosity of Enfamil A.R. or Similac Sensitive For Spit-Up is much lower than a standard infant formula thickened with rice cereal. Therefore, these formulas flow better through a nipple than standard infant formula thickened with rice cereal. Once ingested, however, the viscosity increases dramatically in the stomach's acidic pH, reaching a viscosity equal to the combination of standard infant formula plus rice cereal. This effect may be minimized in infants receiving a histamine<sub>2</sub>-receptor antagonist (e.g., ranitidine or famotidine) or proton pump inhibitor (e.g., omeprazole, lansoprazole, or esomeprazole) for treatment of their gastroesophageal reflux, if the gastric pH is greater than 5.4. Also, Similac Sensitive For Spit-Up is a lactose-free formula. Neither Enfamil A.R. nor Similac Sensitive For Spit-Up is recommended for use in premature infants because neither will adequately meet their needs, especially for protein, calcium, and phosphorus. In May 2011, the FDA cautioned parents against using thickening agents such as SimplyThick and Thick-It in premature infants because of reports of necrotizing enterocolitis. This cautionary statement was expanded to infants of all ages in September 2012.<sup>47</sup>

**Soy Protein-Based Formulas.** Despite relatively few true indications for soy protein-based formulas, approximately 20% of formulas sold in the United States are soy protein based, suggesting that these formulas are being selected by parents rather than being prescribed by health care providers.<sup>34,37</sup> Soy protein-based formulas (Table 25-6) contain a soy isolate fortified with L-methionine; none contain lactose. Soy formulas are a safe and nutritionally sound alternative for normal growth and development in infants who are not fed human milk, who do not tolerate cow milk-based formula, or whose parents choose them for other reasons (e.g., vegetarians). However, because soy formulas have insufficient amounts of calcium, phosphorus, and vitamin D in relationship to some infants' increased needs, they are not recommended for patients weighing less than 1800 grams.<sup>48</sup>

Food allergy occurs in infants because the immature digestive and metabolic processes may not be completely effective in converting dietary proteins into nonallergenic amino acids. Cow milk protein allergy occurs in 2%-3% of infants and is defined as symptomatology involving the respiratory tract (wheezing), skin (rash), or GI tract (diarrhea and bloody stools) disappearing when cow milk is removed from the diet and reappearing on two separate challenges when cow milk is reintroduced during a symptom-free period. Symptoms of cow milk protein intolerance generally regress within 3-4 years in most children. Soy protein-based formulas are appropriate for infants with lactose intolerance resulting from lactase deficiency and with documented immunoglobulin E (IgE)-mediated allergy to cow milk protein. However, infants with cow milk protein-induced enteropathy or enterocolitis are also frequently sensitive to soy protein (up to 50% cross-sensitivity); therefore, AAP/CON recommends protein hydrolysate formulas for these infants.<sup>48</sup> Most infants suspected of having adverse reactions to milk-based formulas have not experienced life-threatening manifestations. These infants appear to tolerate soy protein-based formulas that are less expensive and better tasting than the protein hydrolysate formulas. Routine use of soy protein-based formulas has no proven value in prevention of atopic disease.<sup>49</sup> Some infants with moderate-severe gastroenteritis develop intolerance to lactose and sucrose because of a temporary lactase and sucrose deficiency. However, after rehydration, most infants with diarrhea can be managed by continuing their usual nutrition regimen whether milk based or soy protein based.

RCF is a soy protein-based formula that contains no carbohydrates. Use of this formula is limited to infants unable to tolerate the type or amount of carbohydrates in human milk or infant formulas. A carbohydrate source (sucrose, dextrose, fructose, or glucose polymers) is added gradually in increasing amounts to slowly improve carbohydrate tolerance.

In addition, soy protein-based formulas are not recommended for infants with cystic fibrosis, because these children do not use soy protein adequately, will lose substantial nitrogen in their stools, and will develop hypoproteinemia or even anasarca (generalized infiltration of fluid into subcutaneous connective tissue). Formula-fed infants with cystic fibrosis do well nutritionally when given an easily digested formula that contains semi-elemental protein and medium-chain triglycerides (MCTs) (e.g., a casein hydrolysate-based formula). However, studies have shown that infants with cystic fibrosis grow equally well on a regular cow milk-based formula or human milk as long as adequate pancreatic enzyme supplementation is given.<sup>50</sup>

**Casein Hydrolysate-Based Formulas.** Protein is supplied by enzymatically hydrolyzed, charcoal-treated casein rather than by whole protein in casein hydrolysate-based formulas, which include Pregestimil, Nutramigen, and Similac Expert Care Alimentum (Table 25-6). These formulas are classified as semi-elemental and contain nonantigenic polypeptides with molecular weights less than 1200 daltons; therefore, they can be fed to infants who are sensitive to intact milk protein. Casein hydrolysate-based formulas are supplemented with L-cysteine, L-tyrosine, and L-tryptophan, because the concentrations of these amino acids are reduced during the charcoal treatment.

Carbohydrate sources in casein hydrolysate-based formulas vary and include corn syrup solids, modified corn and tapioca starch, corn maltodextrin, and sucrose (Table 25-6). Glucose polymers found in corn syrup solids, modified corn starch, or corn maltodextrin are particularly useful in infants who have malabsorption disorders and are frequently intolerant to high concentrations of lactose, sucrose, and glucose. In addition, glucose polymers contribute little to the total osmolar load. Low osmolality is an advantage in intestinal disorders in which the osmolar load of disaccharide- or glucose-containing elemental diets may not be tolerated. The formula 3232 A is an extensively hydrolyzed casein-based formula with added amino acids that is intended, like RCF, to be used with small amounts of carbohydrate to gradually improve tolerance. This product contains modified tapioca starch and fat, 85% of which is MCTs.

Hydrolysate formulas usually contain modified fat sources. MCTs are typically included since they do not require emulsification with bile and are more easily digested and absorbed than long-chain fats. Shorter-chain fatty acids and MCTs are directly absorbed into the portal system, not into the lacteals of the lymphatic system. In addition, MCTs enhance the absorption of long-chain triglycerides and do not require carnitine for transport into the mitochondria, where oxidation and energy production occur. However, MCTs cannot be the sole source of dietary fat, given that they do not provide essential fatty acids, increasing the risk of essential fatty acid deficiency. Pregestimil, Nutramigen, and Similac Expert Care Alimentum contain DHA and ARA as long-chain fatty acids. Diarrhea can result from MCT malabsorption caused by overfeeding or intestinal mucosal disease.

Use of casein hydrolysate-based formulas for allergy prophylaxis is controversial. AAP's policy statement on hypoallergenic formulas states that infants with a high risk for developing allergy identified by a strong family history (both parents or one parent and a sibling) may benefit from a hypoallergenic formula, but studies are not conclusive.<sup>48</sup> Currently, no evidence exists to support the use of hydrolysate formulas for treating colic, irritability, or gastroesophageal reflux. Although these symptoms are common in infants, they are rarely a result of an IgE-mediated allergic reaction to cow milk protein.

Extensively hydrolyzed casein formulas are less palatable than standard formulas. If the formula is rejected by the infant when first offered, it should be tried again after a few hours. These products are designed to provide a sole source of nutrition for infants up to 4-6 months of age and a primary source of nutrition through 12 months of age, when indicated. Extended use of hydrolysate formulas as a sole source of nutrition in children older than 6 months requires close medical supervision and monitoring.

**Whey Hydrolysate-Based Formulas.** Enzymatically hydrolyzed whey protein is another protein source used in infant formulas (Gerber Good Start Gentle). Infants who have GI intolerance to cow milk but are not allergic to it often tolerate whey hydrolysate-based formula. This product is promoted as having a pleasant taste, smell, and appearance. It may be better accepted than casein hydrolysate-based formulas, which parents and infants find differ noticeably from cow milk- and soy protein-based formulas in both appearance and taste. There are no specific indications for these products, so they may be chosen according to parent/patient or program preference.

**Amino Acid-Based Formulas.** Occasionally, infants are intolerant to even hydrolyzed casein and require a free amino acid-based formula. Neocate Infant DHA & ARA, EleCare DHA/ARA, and PurAmino contain 100% free amino acids and are considered hypoallergenic. They are used for infants with cow milk protein allergy, multiple food protein allergies, or intolerance to casein hydrolysate formulas.

**High MCT Formulas.** Enfaport and Portagen are unique formulas because of their high MCT content (i.e., 84% and 87% of the fat, respectively). They also contain higher concentrations of both lipid- and water-soluble vitamins than are found in casein hydrolysate-based formulas. The higher concentrations of MCTs and vitamins in these formulas help compensate for the impaired digestion and absorption of long-chain fats in patients with pancreatic insufficiency (e.g., cystic fibrosis), bile acid deficiency (e.g., biliary atresia or cholestatic jaundice), and intestinal resection. Another use is to decrease lymphatic flow in patients with lymphatic anomalies such as chylothorax and chylous ascites. Enfaport can be used as the sole dietary source for infants, whereas Portagen can be used as the sole dietary source for children and adults or as a beverage to be consumed with each meal as a supplement. Children with fat malabsorption who receive Portagen can develop essential fatty acid deficiency. Linoleic acid (e.g., corn or safflower oil, or Microlipid) can be given in the diet, either by mixing with the formula or by syringe through a feeding tube, to prevent essential fatty acid deficiency.

**Low PRSL Formulas.** Similac PM 60/40 is an infant formula with lower mineral (potassium and phosphorus) and protein (1.5 g/100 mL) content, and therefore lower PRSL than standard infant formulas. It is most appropriately used for infants with renal insufficiency. Similac PM 60/40 also contains less calcium and iron than standard infant formulas; supplementation of these minerals may be necessary.

**Premature Infant Formulas.** AAP's current recommendation is for all premature infants to receive maternal human milk or donor human milk.<sup>29</sup> However, inadequate nutrient intake can occur in human milk-fed premature infants because unfortified human milk does not meet the needs of this population. Because of their increased nutrient needs and somewhat decreased ability to consume an adequate volume, premature infants (especially those less than 34 weeks gestation) often need feedings providing a higher caloric density, as well as increased protein, calcium, phosphorus, and other nutrients. The nutritional goal for a preterm infant is to achieve a postnatal growth rate approximating the intrauterine growth rate of a normal fetus of the same postconceptional age.

No commercially available formula is completely satisfactory for premature infants. Formulas for premature infants (Table 25-6) share features such as whey-predominant proteins, carbohydrate mixtures of lactose and corn syrup solids, and fat mixtures containing both MCTs and long-chain triglycerides. They differ in electrolyte, vitamin, mineral, protein, and caloric content. When given in sufficient volume, these formulas promote adequate growth in preterm infants. An isotonic osmolality (approximately 300 mOsm/kg of water) is maintained at a caloric density of 24 kcal/oz or 80 kcal/100 mL.

Calcium and phosphorus are crucial to the development and maintenance of the human skeleton. In addition, calcium and phosphorus are integral components of many biochemical reactions. Calcium requirements are affected by protein and phosphorus intake in that these nutrients interact with the renal tubular reabsorption of calcium. Calcium-to-phosphorus weight ratios vary significantly for human milk (2:1) and cow milk (1.2:1). This ratio also varies in commercial infant formulas. Formulas designed for term infants will not meet the calcium and phosphorus needs of premature infants. For these infants, the additional calcium and phosphorus found in premature infant formulas is necessary for normal bone growth and mineralization. Typical amounts of calcium and phosphorus found in 20 kcal/oz infant formulas are 111-121 mg calcium/100 mL and 56-68 mg phosphorus/100 mL for preterm formulas versus 45-53 mg calcium/100 mL and 25-29 mg phosphorus/100 mL for term formulas. Human milk fed to premature infants requires calcium and phosphorus fortification with either a human milk fortifier or a transitional premature formula, which is discussed later in this chapter.

Nutrient-enriched transition or postdischarge formulas are designed specifically to provide for continued catch-up growth in premature infants after hospital discharge. Similac Expert Care NeoSure, Enfamil EnfaCare, and Gerber Good Start Nourish (all milk-based formulas) contain MCTs as part of the fat source. The caloric (22 kcal/oz), protein, vitamin, and mineral content of these formulas exceed those of standard term formulas but are less than those of 24 kcal/oz premature infant formulas. Use of these formulas in preterm infants until 9 months postnatal age results in greater linear growth, weight gain, and bone mineral content than are seen with the use of standard, term infant formulas.<sup>51</sup>

**Human Milk Fortifiers.** Mothers who deliver prematurely produce milk that is higher in protein, sodium, potassium, and possibly other nutrients than the milk of mothers who deliver at full term. However, these nutrients decline to the amounts found in mature human milk by 4-8 weeks after delivery. During the third trimester, the fetus receives 125-150 mg of calcium and 65-80 mg of phosphorus daily, most of which are deposited in bone. Without supplementation, human milk, whether preterm or mature, cannot supply that amount of calcium and phosphorus, which are needed to prevent osteopenia of prematurity. Therefore, human milk must be fortified for premature infants to achieve adequate growth.<sup>52</sup>

Commercial products have been developed to supplement the nutrient content of human milk so that it meets the needs of most preterm infants. Enfamil Human Milk Fortifier Acidified Liquid, Similac Special Care 30 with Iron, and Prolact+ H<sup>2</sup>MF are all liquids that add nutrients to human milk without displacing a significant amount of volume. Enfamil Human Milk Fortifier Acidified Liquid and Similac Special Care 30 with Iron are made from cow milk supplemented with whey protein to provide a casein:whey ratio of 40:60 and a fat mixture to provide MCTs. When added to human milk, fortifiers increase the osmolality by only 10-36 mOsm/kg. Prolact+ H<sup>2</sup>MF is made from concentrated 100% human milk. It provides extra protein, calories, vitamins, and minerals and is specifically indicated for preterm infants weighing less than 1250 grams. Table 25-8 lists the composition of the human milk fortifiers. Studies support adequate weight gain and nutrient retention in infants when either fortified human milk or commercial preterm formulas are ingested.<sup>53,54</sup> However, human milk has been shown to provide various immunologic benefits, as well as improve the IQ of infants born small for gestational age and very low-birth-weight infants.<sup>55</sup> The use of these products will result in weight gain equivalent to intrauterine growth rates in most premature infants. Product selection will therefore be dictated by cost and clinical preference. These products are expensive. Enfamil Human Milk Fortifier Acidified Liquid costs approximately \$2.60 per vial, and one vial is generally added to each 25 mL of human milk to yield a 24 kcal/oz concentration. Moreover, this product comes only in cartons of 100-200 vials. Similac Special Care 30 with Iron costs as much as \$0.83 per ounce and, when added in equal parts (2 ounces of human milk to 2 ounces of Similac Special Care 30 with Iron), yields a 25 kcal/oz concentration. Prolact+ H<sup>2</sup>MF is the most expensive, costing approximately \$6.25 per milliliter, and requiring the addition of 20 mL of Prolact+4 H<sup>2</sup>MF with 80 mL of human milk to yield a 24 kcal/oz concentration. The greatest evidence supporting the financial benefit of human milk as a sole source of nutrition is in relation to decreased incidence of necrotizing enterocolitis (NEC).<sup>56,57</sup> Once the infant is ready for discharge from the hospital or has reached a weight of 2.5 kg, one of the transition or postdischarge formulas can be added to human milk to increase the caloric density (1 teaspoon of powder added to 90 mL of formula yields 24 kcal/oz) and delivery of other nutrients.

**TABLE 25-8 Human Milk Fortifiers**

<i>Component</i>	<i>Enfamil Human Milk Fortifier Acidified Liquid<sup>a</sup></i>	<i>Similac Special Care with Iron 30<sup>b</sup></i>	<i>Prolact+4 H<sup>2</sup>MF<sup>c</sup></i>

**Metabolic Formulas.** Infants with various inherited inborn errors of metabolism require specific formulas tailored to their particular condition and must be under the care of a specialist, usually a pediatric endocrinologist or geneticist. Information about these formulas is available on the various manufacturers' Web sites. These formulas, as well as formulas intended for use in low-birth-weight infants or in patients with specific medical conditions or dietary needs, are classified by FDA as "exempt formulas," which means they are exempt from FDA nutrient content and labeling requirements.<sup>58</sup>

**Concentrated Formulas.** A child with caloric needs exceeding normal requirements may be given concentrated formula under medical supervision. A few ready-to-use formulas made from cow milk are available in a caloric density of 22 or 24 kcal/oz (Table 25-6). Various concentrations can be prepared from liquid concentrates or powders by varying the amount of water added (Tables 25-9 and 25-10). Increasing caloric density by adding less water also increases delivery of all nutrients, including protein and electrolytes, and decreases free water delivery. Increased concentration of protein and electrolytes (i.e., PRSL) in conjunction with decreased fluid intake may result in dehydration and electrolyte imbalances. Careful monitoring of the infant's fluid intake and output, weight, serum electrolytes, blood urea nitrogen, serum creatinine, and urine specific gravity and osmolality is recommended, especially on initiation of the concentrated formula.

**TABLE 25-9 Dilution of Concentrated Liquid Infant Formulas<sup>a</sup>**

Caloric Concentration Desired (kcal/oz)	Liquid Formula Concentrate (ounce)	Added Water (ounce)
20	1	1
22 (actual 21.8)	3	2.5
24	3	2
26-27 (actual 26.7)	3	1.5
28-29 (actual 28.6)	5	2

<sup>a</sup> Commercial concentrates of infant formula contain 40 kcal/oz before dilution with water.

**TABLE 25-10 Dilution of Powdered Term Infant Formulas<sup>a</sup>**

Caloric Concentration Desired (kcal/oz)	Formula Powder (scoop) <sup>b</sup>	Added Water (ounce)
20	1	2
24	3	5
28	4	5.5
28	7	10

<sup>a</sup> Powdered infant formulas generally contain 44 kcal per level, packed scoop before dilution. If a large volume of formula is to be prepared, add powder necessary to supply desired calories; then add water to the final volume desired. Directions for preparation may vary; check manufacturer's information.

<sup>b</sup> Historically, the conversion of 1 scoop = 1 tablespoon of powder has been used. However, this measurement varies between powders. For improved accuracy, parents and caregivers should be instructed to use the manufacturer's provided scoop for all measurements.

Modular macronutrient components (Table 25-11) can be added to either human milk or infant formula and are available as alternatives to concentrating formulas. Adding carbohydrates as glucose can result in diarrhea. Protein supplementation may increase the PRSL. Fat may be added as MCTs (MCT Oil; Nestlé Nutrition) or Microlipid (Nestlé Nutrition) for infants with fat malabsorption or intolerance. Microlipid is an emulsion made from safflower oil that provides long-chain fatty acids and mixes well with formula. Addition of fat can lead to diarrhea, steatorrhea, delayed gastric emptying, vomiting, and gastroesophageal reflux. Adding modular components is more expensive and time-consuming than simply concentrating the formula; these components should be reserved for situations in which a single nutrient is needed or further concentration of the formula is not appropriate.

**TABLE 25-11 Modular Additives**

Additive <sup>a</sup> (Mfr)	Nutrient(s) Provided	Amount of Nutrient(s)	Calories
Beneprotein (Nes)	Whey protein isolate (milk)	Per 7 gram scoop or packet: protein 6 grams	25.2 kcal/scoop

Polycose (A)	Carbohydrate (glucose polymers derived from controlled hydrolysis cornstarch)	Per tablespoon (6 grams): carbohydrate 5.6 grams	23 kcal/tablespoon
Microlipid (Nes) (liquid)	Long-chain fats (safflower oil)	Per mL: fat 0.5 gram	4.5 kcal/mL
MCT Oil (Nes) (liquid)	MCTs (coconut/palm kernel oil)	Per mL: fat 0.93 gram	7.7 kcal/mL
Super Soluble Duocal (Nut)	Carbohydrate, fat (MCT 35%)	Per tablespoon: carbohydrate 6.3 grams; fat 1.9 grams	25 kcal/scoop 42 kcal/tablespoon
Benecalorie (Nes) (liquid)	Calcium caseinate (milk); high oleic sunflower oil	Per 1.5 ounces: protein 7.2 grams; fat 33.75 grams	7.5 kcal/mL
ProMod Liquid Protein (A) (liquid)	Hydrolyzed beef collagen	0.33 grams protein/mL	3.3 kcal/mL
Liquid Protein Fortifier (A) (liquid)	Casein hydrolysate	0.17 grams protein/mL	0.67 kcal/mL

Key: A = Abbott Nutrition; MCT = medium-chain triglycerides; Nes = Nestlé Nutrition; Nut = Nutricia North America.

**Toddler Formulas.** Toddler formulas (second part of [Table 25-6](#); e.g., Gerber Graduates Gentle, Similac Go & Grow Milk-based Formula, Enfagrow Premium Next Step) are designed for infants and children 9-24 months of age. AAP/CON, however, has stated that these formulas offer no nutritional advantages; standard formulas are appropriate for infants up to 12 months of age.<sup>42</sup>

**Formulas for Children 1-13 Years of Age.** Nutritionally complete, isotonic, virtually lactose-free enteral formulas designed for young children who cannot tolerate a normal diet or eat solid food are available (second part of [Table 25-6](#); e.g., PediaSure, Nutren Junior, Boost Kid Essentials). Flavored products contain sucrose, have a pleasant taste, and can be used as oral supplements. These formulas are also appropriate to use as tube feedings regardless of tube tip placement. They contain adequate amounts of calcium, phosphorus, iron, and vitamin D for this age group; the amounts contained in adult enteral products are typically inadequate.

Several therapeutic formulas have also been developed for children 1-13 years of age ([Table 25-6](#)). Peptamen Junior is a peptide-based, semi-elemental formula. Vivonex Pediatric, Neocate Junior, E028 Splash (a flavored, nutritionally complete drink), and EleCare Jr are amino acid-based elemental formulas, whereas Peptide Junior is a peptide-based, amino acid-based elemental formula. These products are intended for use in children with altered digestive or absorptive capabilities caused by a number of conditions, including severe protein allergy and eosinophilic esophagitis ([Table 25-7](#)).

#### Nutritional Problems in Infancy

GI problems, especially diarrhea, can occur with the use of infant formulas, as well as with human milk or any food. Tooth decay and nutritional deficiencies are other potential problems.

##### Diarrhea

Diarrhea can lead to failure to thrive (chronic) and dehydration (acute). Infants are particularly susceptible to dehydration because of their high metabolic rate and ratio of surface area to weight and height. Fluid depletion by diarrhea or vomiting may quickly (within 24 hours) produce severe dehydration with fluid and electrolyte imbalances, shock, and possible death. A potential formula-related cause of diarrhea and vomiting is the improper dilution of a concentrated liquid or powdered formula or the incorrect addition of a modular product.

If diarrhea develops, the health care provider should ascertain the severity and duration, stool frequency, and formula preparation method. If the diarrhea appears severe (i.e., many more stools per day than normal) or has continued for more than 72 hours, or if the infant is clinically ill (fever, lethargy, anorexia, irritability, dry mucous membranes, or decreased urine output), the infant should be referred for medical attention. (Diarrhea is discussed in [Chapter 16](#).)

Mild diarrhea will usually resolve without the need for medical intervention, but the infant should be observed closely for signs of dehydration. Temporarily discontinuing usual dietary intake is not recommended except during a 4- to 6-hour period of oral rehydration if the infant is dehydrated. Oral electrolyte replacement solutions manufactured especially for infants (e.g., Pedialyte, Enfalyte) may be used for short-term replacement of fluid and electrolyte losses in mild-to-moderate dehydration to augment fluid intake, but these solutions should not replace formula or human milk intake.<sup>59</sup> Prevention of dehydration by replacement of ongoing losses with a glucose/electrolyte solution in liquid or frozen form is the best intervention for diarrhea in infants and children. Lactose-free formulas or a lactose-free diet may be considered for infants and children with moderate-severe diarrheal illness, but full-strength lactose-containing formulas, human milk, or a regular diet can be used in most infants. Parents should be advised that diarrhea is likely to continue for 3-7 days regardless of the type of formula, and seeking medical consultation is advised if a sudden increase in stool output occurs with resumption of feeding.<sup>59</sup>

##### Other GI Issues

Adverse GI effects of formula include mechanical obstruction ( inspissated milk curds) and hypersensitivity to specific milk protein. Cow milk intolerance is associated most often with an inability to digest lactose or milk proteins. Hyperosmolar formulas may adversely affect premature infants during the early neonatal period and may be a contributing factor in the development of necrotizing enterocolitis, a severe inflammation of the intestinal mucous membranes. For this reason, initiation of feedings in these infants is most often done with unfortified human milk or a 20 kcal/oz premature infant formula. Only after the infant has reached 100 mL/kg/day of enteral feedings is the caloric density advanced.<sup>60</sup> Initiation and advancement of formula for premature infants should occur under medical supervision and are not appropriate for self-care.

##### Tooth Decay

Baby bottle tooth decay can occur in children who are bottle-fed beyond the typical weaning period (1 year) and who go to sleep with their bottles. It can also occur if the infant is allowed to sip on a bottle or training cup frequently during the day. Caries can be seen in children younger than 2 years and may involve the maxillary incisors, maxillary and mandibular first molars, or maxillary and mandibular canines. Restorative dentistry is often required, leading to the potential for difficulty in speech development. Methods for prevention once teeth start to erupt include substituting plain water for carbohydrate-containing formula or other drinks given in a bottle until the infant is weaned from the bottle, encouraging the use of a cup for high-sugar drinks such as juice, using either infant juices that contain a higher portion of water or standard juices diluted with additional water, ensuring adequate fluoride intake, cleaning the baby's mouth at least once daily, and weaning from breast or bottle by 10-12 months of age.<sup>61</sup> Going to sleep with a bottle should be actively discouraged for all infants.

##### Nutritional Deficiencies or Toxicities

Generally, age- and condition-appropriate commercial infant formulas are nutritionally adequate and safe for most infants and children. Nutritional deficiencies reported historically with commercial infant formulas are unlikely today with appropriate supplementation procedures and technological advances in processing. Because of a concern about possible aluminum contamination of infant formulas, the Food and Agriculture Organization of the United Nations has set a provisional tolerable aluminum intake of 1 mg/kg/day. Aluminum toxicity can interfere with cellular and metabolic processes in the nervous system as well as negatively affect bone and liver tissues.<sup>62</sup> Aluminum toxicity is primarily a concern in patients with decreased or immature renal function, such as premature infants. If an infant were to ingest as much as 200 mL/kg/day of a formula known to have the highest aluminum content, the amount of aluminum received per day would still be less than 0.5 mg/kg/day. The highest aluminum concentrations in infant formulas (500-2400 mg/L) have been reported in soy protein-based

formulas, because plants readily absorb aluminum from soil.

#### Infant Formula Preparation

Most formulas are available as a ready-to-use liquid or as a liquid concentrate or powder for reconstitution mixed with water. Ready-to-use formulas should *never be diluted*. They are convenient but usually more expensive. In contrast, concentrated liquids *must be diluted*, typically by mixing equal amounts of water and concentrated liquid (e.g., 13-ounce can of formula with 13-ounce can of water) to prepare a 20 kcal/oz formula (Table 25-10). Powdered term and preterm transition or postdischarge formulas provide a measuring scoop in the can and require addition of 1 packed level scoop of powder to each 2 ounces of water for a 20 kcal/oz term formula and a 22 kcal/oz preterm postdischarge formula. Directions for preparation may vary and should always be compared with the manufacturer's or health care professional's directions. If the family is given alternative directions from those printed on the can, these should be given in writing and explained thoroughly to the caregiver. Directions should be provided in the appropriate language for non-English-speaking patients. Before use, infant formula containers should be inspected for the expiration date and damage. Unopened formula containers, cans, or bottles can be stored at room temperature but must not be subjected to extreme temperature changes.

#### Preparation Techniques

Each infant formula has specific instructions for preparation, and most formulas have symbols on the containers that can be used as guidelines in preparing formula. Because infants may be more susceptible to infection, various sterilization methods have been recommended for infant formula preparation. Table 25-12 reviews sterilization methods for different types of formulas. Studies have shown that the clean method of preparing formula (i.e., not boiling the water) is as safe as terminal sterilization (i.e., boiling the water); therefore, some providers do not recommend boiling water. WHO and AAP currently recommend that all water for formula preparation be boiled because of reports of municipal water supply contamination in some areas. If well or pond water is used or if the area is prone to flooding, the water must be boiled.<sup>63,64</sup> If tap water is used, cold water should be run for at least 2 minutes before use to clear any lead that might be in the pipes and decrease lead exposure. If bottled water is used in infant formula preparation, it should be treated the same as tap or well water (i.e., boil and cool it prior to use) unless the water is labeled as sterile.

**TABLE 25-12 Sterilization Method for Infant Formula Preparation**

<b>General Preparation</b>
<ul style="list-style-type: none"> <li>• Always wash hands before preparing formula or handling bottles and nipples; repeat washing if interrupted.</li> </ul>
<ul style="list-style-type: none"> <li>• Sterilize bottles and other equipment (e.g., glass measuring cup, spoons, nipples, rings, and disks) separately from the formula.<sup>a</sup> Many pediatricians and other primary care providers now consider the use of a dishwasher with a heated drying cycle as adequate for sterilization of infant feeding supplies.</li> </ul>
<ul style="list-style-type: none"> <li>• Using tongs, place all equipment in a deep pan or sterilizer, cover all equipment with cold tap water, bring to a boil, and continue boiling for 5 minutes.</li> </ul>
<ul style="list-style-type: none"> <li>• Tap and bottled water should be heated until it reaches a rolling boil, allowed to continue to boil for 1-2 minutes, and then allowed to cool to room temperature. Boiling for a longer period of time may concentrate impurities (e.g., lead) in the water.</li> </ul>
<ul style="list-style-type: none"> <li>• Using tongs, remove all items from the pan or sterilizer and place on a clean towel. Place bottles and nipples on the towel with their open ends facing down.</li> </ul>
<b>Concentrated Liquid Formula</b>
<ul style="list-style-type: none"> <li>• For cans, wash top of can with hot water and detergent, rinse in hot running water, and dry. Shake can well and open it with a clean punch-type can opener.</li> </ul>
<ul style="list-style-type: none"> <li>• For bottles, the protective cap must be removed. Shake bottle well and open.</li> </ul>
<ul style="list-style-type: none"> <li>• Mix appropriate amounts of concentrated liquid and sterilized water (according to product label or health care provider instructions). For accuracy, use a measuring cup for all measurements of formula and water.</li> </ul>
<ul style="list-style-type: none"> <li>• Pour formula into sterilized bottles; place nipples, rings, and disks on bottles.</li> </ul>
<ul style="list-style-type: none"> <li>• Tightly cover any unused formula and store in refrigerator. Use formula within 48 hours of preparation or discard.</li> </ul>
<b>Powdered Formula</b>
<ul style="list-style-type: none"> <li>• Wash top of can with hot water and detergent, rinse in hot running water, and dry.</li> </ul>
<ul style="list-style-type: none"> <li>• Open can and mix appropriate amounts of powder and sterilized water (according to product label or health care provider instructions). For accuracy, use the scoop provided or a dry measuring cup for all measurements.</li> </ul>
<ul style="list-style-type: none"> <li>• Pour formula into sterilized bottles; place nipples, rings, and disks on the bottles.</li> </ul>
<ul style="list-style-type: none"> <li>• Tightly cover any unused formula and store in the refrigerator. Use formula within 48 hours of preparation.</li> </ul>
<ul style="list-style-type: none"> <li>• Cover any formula remaining in the can with the plastic top. Write the date on the opened can. Store in a cool, dry place for up to 1 month.</li> </ul>
<b>Ready-to-Use Formula</b>
<b>Ready-to-Use Cans</b>
<ul style="list-style-type: none"> <li>• Wash top of can with hot water and detergent, rinse in hot running water, and dry.</li> </ul>
<ul style="list-style-type: none"> <li>• Shake can well, and open it with a clean punch-type can opener.</li> </ul>
<ul style="list-style-type: none"> <li>• Add the amount of formula needed for a single feeding to one sterilized bottle or to the number of bottles needed for a full day's feedings.</li> </ul>
<ul style="list-style-type: none"> <li>• <i>Do not add water.</i></li> </ul>
<ul style="list-style-type: none"> <li>• Prepared bottles and any formula left in the can should be tightly covered and refrigerated for up to 48 hours after the can was opened.</li> </ul>
<b>Ready-to-Use Bottles</b>
<ul style="list-style-type: none"> <li>• The protective cap must be removed, and a sterile nipple must be screwed onto the bottle before feeding.</li> </ul>
<ul style="list-style-type: none"> <li>• Shake each bottle well to ensure mixing of formula.</li> </ul>
<b>All Types of Formulas</b>
<ul style="list-style-type: none"> <li>• Warm bottle to desired temperature by immersing in hot water bath or running under hot water.</li> </ul>
<ul style="list-style-type: none"> <li>• Heating bottles in the microwave is not recommended.</li> </ul>
<ul style="list-style-type: none"> <li>• Never boil or overheat formula.</li> </ul>

- Shake each bottle well before feeding infant.
- Test formula temperature before feeding infant.
- After feeding, discard any formula left in bottle, and immediately rinse bottle and nipple in cool water.

<sup>a</sup> If disposable bottle liners are used, only nipples, rings, and screw tops of bottles need to be sterilized; the manufacturer has sterilized the bottle liners.

Table 25-12 provides handling instructions and recommendations for storage of infant formulas once the original container has been opened. Expressed human milk should be stored in glass or plastic airtight containers, refrigerated, and used within 24-48 hours. Human milk can be frozen, preferably in the rear of the freezer compartment, for up to 2 weeks if the freezer compartment is inside the refrigerator, up to 3-4 months when the freezer has a separate door from the refrigerator, and up to 6 months if in a 0°F (-17.8°C) freezer. Frozen milk should be rapidly thawed by holding the container under tepid running water or placing it in a tepid water bath. Thawed human milk should always be used within 24 hours of thawing and never refrozen.

#### Adverse Effects of Improperly Prepared and/or Administered Formulas

As stated previously, the failure to properly dilute a concentrated infant formula can result in a hypertonic solution that could result in diarrhea and dehydration. In extreme cases, the ingestion of an overly concentrated formula can lead to hypernatremic dehydration (induced by water deficit), metabolic acidosis, and renal failure. Excessive formula dilution can lead to water intoxication that can result in irritability, hyponatremia, coma, brain damage, or death. Such a situation may occur when a caregiver misunderstands the instructions for preparing a concentrated formula, dilutes a ready-to-use formula, or tries to make the baby's formula last longer by diluting it.

Parents or other caregivers may have questions about how much infant formula their child should receive. Typically, a health care provider at the hospital will have given parents feeding instructions prior to discharge. However, when a formula change is made after hospital discharge, adequate information may not be provided in some health care settings. Generally, the required daily formula intake depends on an infant's age, weight, and individual considerations such as the need for catch-up growth (Table 25-13). During the first year of life, a normal healthy formula-fed term infant usually eats every 3-5 hours (average of 4 hours). Small or weak infants may eat every 2-3 hours, because they have smaller stomach capacities or shorter gastric emptying times, or tire easily during feedings. Breast-fed infants or those receiving human milk from a bottle also will nurse or eat more often, given that human milk empties from the stomach more rapidly than formula. Most term infants will lengthen the interval between feedings to 4 hours by the age of 3-4 weeks. Premature infants may continue to require frequent feedings past 6-8 weeks of age, depending on the infant's birth weight and growth. Some infants begin to stop nighttime feedings after 1-2 months of age, whereas others take as long as 4-6 months. The process is highly variable and may depend more on the weight of the infant than on his or her age; most infants are able to sleep through the night when they reach approximately 11 pounds.

**TABLE 25-13 Average Age-Appropriate Number of Daily Feedings and Volume per Feeding**

Age	Average Number of Daily Feedings	Average Volume per Feeding (ounce)
Birth-2 weeks	6-10	2-3
2 weeks-1 month	6-8	4-5
1-3 months	5-6	5-6
3-4 months	4-5	6-7
4-12 months	3-4	7-8

The amount of formula offered to a bottle-fed infant should be consistent with the DRI for energy according to age and weight (Table 25-2). Table 25-13 lists typical quantities of feedings for various age groups. The infant should be fed on demand and not forced to take more formula than is desired at any one feeding. If the infant finishes a bottle and still seems hungry, more formula should be offered. Parents should also be aware that an infant typically loses weight (mostly water) during the first week of life, but by 2 weeks of age, the child should be gaining weight. Appropriate weight gain usually indicates that an infant is receiving an appropriate amount of formula. The WHO standardized growth charts are used to determine whether an infant is growing appropriately. Weight, length/height, and head circumference should be plotted at each medical visit.

Both underfeeding and overfeeding are potential problems. Infants who like to "graze" all day can take in too much milk and gain too much weight. However, this can also be a sign of inadequate intake in breast-fed infants and lead to failure to thrive. Other problems associated with overfeeding are regurgitation, gastroesophageal reflux, vomiting, loose stools, constipation, and colic. Spitting up a small amount of formula, even if it is after every feeding, is usually not a cause for concern. If an infant is regurgitating or vomiting significant amounts, a primary care provider should be consulted. Biliary (green) emesis is always a reason to immediately consult the child's primary care provider.

Loose stools are normal for some infants, especially those receiving human milk or hydrolyzed formulas. They may also be caused by an improperly concentrated formula, overfeeding, or administration of contaminated formula. Human milk-fed infants may have only 1 stool every 1-3 days; however, some infants will have 10-12 stools each day. Formula-fed infants usually have 1-3 stools per day. Diarrhea, defined as increased stool volume and frequency that differ from the usual volume and frequency, warrants medical attention when it persists for more than 3 days or when the infant appears dehydrated. Constipation is rare in human milk- or formula-fed infants; it most often results from inadequate formula intake. Severe or prolonged constipation with straining and blood streaks on the stool warrant a visit to the primary care provider.

#### Product Selection Guidelines

For healthy, term infants, a milk-based formula with or without added whey protein is indicated, except for those who require a therapeutic formula. Recommendations for a formula should be based on the preparation methods, the parents' or caregiver's ability to follow directions, the parents' attitudes and preferences, sanitary conditions and availability of refrigeration facilities, and cost. Before assisting parents in selecting a therapeutic formula, the health care provider should determine whether a primary care provider recommended the formula. For many parents, cost may be a critical factor in formula selection. Concentrated liquids and powders are typically less expensive than ready-to-use products. Convenience is also a consideration. The preparation of powdered and concentrated liquid formulas requires more manipulative functions and more attention to clean technique. The formula selected should be one that is well tolerated by the infant, convenient for the parents, and priced to fit the family's budget. To simplify formula preparation away from home, parents can select products available in unit-of-use packaging for ready-to-use liquids, or they can place powder packets or powder in an empty bottle and add water whenever needed.

The federal grant program Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) helps ensure that all infants; children (up to 5 years of age); and pregnant, postpartum, and breast-feeding women have access to adequate nutrition. State health departments and other agencies regulate and allocate funds in the federal grant program (i.e., \$6.6 billion in FY2012). Formula and preventive services are free to eligible participants. More than 9 million people received WIC benefits each month in 2011, most of them infants and children.<sup>65</sup>

#### Vitamin and Mineral Supplementation

Routine multivitamin and mineral supplementation is generally unnecessary for most formula- or human milk-fed term infants. However, some infants may be at risk for deficiency and require supplementation. Cases of vitamin D-deficiency rickets continue to be reported in the United States, and the prevalence of iron-deficiency anemia in children ages 1-3 years is 2.1% in the general population.<sup>43,66</sup> Therefore, particular care should be taken to ensure that children in this age group get adequate dietary iron. AAP does not, however, endorse routine iron supplementation in children ages 1-3 years, unless the child's diet is low in iron-containing foods.<sup>43</sup>

Vitamin and mineral supplementation may be needed for preterm and human milk-fed infants whose nutrition is inadequate (Table 25-14).<sup>67</sup> These infants and

those with other nutritional deficiencies, malabsorptive and other chronic diseases, rare vitamin-dependent conditions, inborn errors of vitamin or mineral metabolism, or deficiencies related to the intake of certain medications will need medically supervised vitamin and mineral supplementation.

**TABLE 25-14 Guidelines for Use of Vitamin and Mineral Supplements in Healthy Infants<sup>a</sup>**

	Multivitamin/Mineral	Vitamin D <sup>b</sup>	Vitamin E	Folate	Iron <sup>c</sup>
<b>Full-Term Infants</b>					
Human milk-fed	0	+	0	0	±
Formula-fed	0	± <sup>d</sup>	0	0	0
<b>Preterm Infants</b>					
Human milk-fed <sup>e</sup>	+	+	0	0	+
Formula-fed <sup>e</sup>	+	+	0	0	+
<b>Older Infants (≥6 Months)</b>					
Normal	0	0	0	0	±
High-risk <sup>f</sup>	+	0	0	0	±

Key: + = Supplement usually indicated; ± = supplement sometimes indicated; 0 = supplement not usually indicated.

<sup>a</sup> Not shown is vitamin K for newborn infants and fluoride in areas where there is insufficient fluoride in the water (Table 25-15).

<sup>b</sup> All infants should have a minimal intake of 400 international units of vitamin D per day beginning during the first few days of life; this intake should be continued throughout childhood and adolescence.

<sup>c</sup> Iron-fortified formula and infant cereals are more convenient and reliable sources of iron than a supplement.

<sup>d</sup> Supplement typically indicated if receiving less than 1000 mL/day of infant formula. Exception is Enfamil Premium Newborn, which is indicated from birth to 3 months of age and provides 400 international units of vitamin D in 810 mL (27 fl oz).

<sup>e</sup> Multivitamin supplements (plus added folate) are needed primarily when calorie intake is below approximately 300 kcal/day or when the infant weighs less than 2.5 kg; vitamin D should be supplied at least until 6 months of age in human milk-fed infants. Iron should be started by 2 months of age.

<sup>f</sup> Multivitamin/mineral preparations including iron are preferred to supplements containing iron alone.

Source: References 7 and 67.

#### Human Milk-Fed, Full-Term Infants

The healthy, full-term, human milk-fed infant requires little to no special supplementation for the first 4-6 months of life except for vitamin D and iron. AAP recommends vitamin D supplementation (400 international units per day) for all human milk-fed infants unless they are weaned to at least 1000 mL/day of vitamin D-fortified formula. Risk factors for vitamin D deficiency include higher birth order (third child or later), dark skin, cultural factors that minimize maternal skin exposure to sunlight, and delayed intake of dairy products in the infant or mother because of intolerance or other factors.<sup>68</sup> Mothers should be encouraged to maintain a balanced diet and to drink three to five 8-ounce glasses of milk each day while breast-feeding. If the mother cannot tolerate milk because of lactose intolerance, lactose digestion aids (e.g., Lactaid and Dairy Ease) or lactose-free milk are available. Mothers who do not drink milk should be encouraged to increase vitamin D and calcium intake through other dietary sources or by taking supplements. Furthermore, if the infant is showing signs or symptoms of being excessively colicky, the primary care provider should consider a milk sensitivity. If sensitivity is confirmed, the breast-feeding mother should decrease her dairy consumption and seek nondairy sources of calcium and vitamin D.

Human milk-fed infants rarely develop iron-deficiency anemia before 4-6 months of age.<sup>43</sup> Although the iron concentration in human milk averages only 0.3-0.5 mg/L, the form of iron is well absorbed. At 4-6 months of age and beyond, the iron stores in infants fed human milk exclusively may become exhausted, requiring a supplemental source. The addition of iron-enriched foods such as fortified infant cereals will usually meet needs, or alternatively, an iron supplement (elemental iron 2 mg/kg/day) can be given. However, a more recent study indicates an association between increased duration of breast-feeding and decreased iron stores in the body.<sup>69</sup> Term infants who are small for gestational age are likely to have higher requirements, but the necessity of supplementation in this population is unclear.<sup>70</sup>

The first iron-enriched food introduced into the infant's diet is typically infant cereal. Bioavailability of the large-particle, electrolytic iron powder used to fortify dry infant cereals is substantially less than ferrous sulfate iron used in milk- or soy protein-based formulas. Cereals also contain potent inhibitors of iron absorption and are unreliable in preventing iron deficiency when infants receive minimal iron from other sources. Iron-fortified, wet-packed cereal and fruit combinations marketed in jars offer no exposure of the iron sulfate to oxygen until the jar is opened; therefore, iron absorption is improved. Consuming fruit juices and other products containing ascorbic acid along with iron-fortified cereals has been shown to enhance iron absorption.<sup>71</sup>

#### Formula-Fed, Full-Term Infants

Full-term infants who consume adequate amounts of an iron-fortified, milk-based formula do not need vitamin and mineral supplementation in the first 6 months of life. An iron-fortified formula is preferred to ensure adequate iron stores for growing infants. Infants fed iron-fortified formulas do not demonstrate a difference in stool consistency, fussiness, colic, or regurgitation compared with infants fed low-iron formulas. Vitamin and mineral supplements are not needed for infants older than 6 months who receive a diet consisting of formula and increasing amounts of infant and table foods. A multivitamin with minerals may be needed, however, if the infant is at special nutritional risk.

#### Preterm Infants

Preterm infants fed with either human milk or formula need vitamin and mineral supplementation. Their nutrient needs are greater than those of full-term infants because of their more rapid growth rate, inability to ingest an adequate volume of formula or human milk, decreased intestinal absorption, and decreased body stores. Until these infants can consume about 300 kcal/day or until they reach a body weight of 2.5 kg, a multivitamin supplement should be administered to provide the equivalent of the recommended intakes for full-term infants.

Premature infants are especially susceptible to iron-deficiency anemia because of marginal iron stores at birth. Without supplementation (e.g., blood

transfusions), iron stores will be depleted by 2 months of age, in contrast to depletion at 4-6 months of age in full-term infants. Original AAP/CON recommendations included iron supplementation at a dosage of 2 mg elemental iron per kilogram daily for premature infants with birth weights between 1500 and 2500 grams once they are 2 months old or have doubled their birth weight.<sup>43,51</sup> AAP now recommends that preterm infants who receive human milk should receive elemental iron supplementation (2 mg/kg/day) earlier, within 1 month through 12 months of age. If these preterm infants are transitioned to formula, they will most likely not require iron supplementation once they are consuming 150 mL/kg/day. However, recent reports have shown that approximately 14% of preterm infants receiving appropriate formula will still need a supplement at 4-8 months of age because of decreased iron stores.<sup>43</sup> To prevent such diminished stores, some advocate even earlier initiation of iron supplementation in preterm infants less than 30 weeks gestational age by starting supplementation as early as 2 weeks of age with elemental iron doses of 2-4 mg/kg/day.<sup>72</sup> Infants receiving erythropoietin should receive 6 mg of elemental iron per kilogram daily. To minimize the possibility of hemolytic anemia in infants with insufficient vitamin E absorption, iron supplements should be withheld until the preterm infant is several weeks old. However, with adequate vitamin E supplementation in the formula, the risk of hemolytic anemia is minimal. Supplementation of calcium, phosphorus, and vitamin D in preterm infant formulas is necessary to ensure adequate bone mineralization and to prevent osteopenia and rickets. The prevention of severe bone disease in preterm infants appears to depend on both high oral intakes of calcium and phosphorus and the intake of at least 400 international units (12.5 mg) of vitamin D per day.<sup>51</sup> Therefore, preterm infants should receive a special preterm infant formula containing appropriate amounts of calcium, phosphorus, and vitamin D. Depending on the volume of formula consumed, vitamin D supplementation may be necessary along with a premature formula to provide 400- 800 international units per day.

#### Fluoride Supplementation

When used appropriately, fluoride is both safe and effective in preventing and controlling dental caries. Fluoride reduces dental decay by reducing the solubility of enamel, reducing the ability of bacteria to produce acid, and promoting remineralization. Systemic fluoride, such as that obtained from fluoridated water, primarily provides a topical benefit to teeth, given that fluoride is secreted from the salivary glands.<sup>73</sup> In 2010, the CDC reported 74% of the U.S. population who receive their water supply from a community water system receive adequate fluoride.<sup>74</sup>

Fluoride supplementation is currently not recommended from birth to 6 months of age. Furthermore, the recommended supplementation for children 6 months to 6 years of age whose drinking water is inadequately fluoridated and who do not receive adequate fluoride from other sources has been decreased from previous recommendations because of an increased incidence of fluorosis.<sup>75</sup> Fluorosis, which affects approximately 22% of children, is a change in the appearance of the teeth, ranging from minor white lines running across the teeth to a very chalky appearance resulting from too much fluoride. Infants who are being fed powdered or concentrated formula should be given fluoride supplements only if the community's drinking water, or bottled water used for making formula, contains less than 0.3 ppm of fluoride. Bottled water is often free of fluoride and supplementation should be administered. [Table 25-15](#) can be used to determine the proper fluoride supplementation for a child, depending on the fluoride level in the drinking water. Ready-to-use formulas are manufactured with defluoridated water and contain less than 0.3 ppm of fluoride. The primary care provider may recommend a fluoride supplement for infants not receiving adequate fluoride.

**TABLE 25-15 Recommended Fluoride Supplementation (mg/day)<sup>a</sup>**

Age	Fluoride Concentration of Drinking Water (ppm)		
	<0.3	0.3-0.6	≥0.6
<b>Recommended Supplementation</b>			
Birth-6 months	0	0	0
6 months-3 years	0.25	0	0
3-6 years	0.50	0.25	0
6-16 years	1.00	0.50	0

<sup>a</sup> Sodium fluoride 2.2 mg contains fluoride 1 mg.

Source: References 73 and 75.

#### Assessment of Infant Nutrition: A Case-Based Approach

Body weight, length, and head circumference are the growth standards for determining whether infants are receiving the appropriate nutrients, are digesting and absorbing ingested nutrients, or both. If an infant appears to be underweight or underdeveloped, the health care provider should advise the parent to take the infant to a primary care provider for evaluation.

The provider's primary role is to provide information about breast-feeding and infant formula products, including assistance with product selection and preparation instructions.

Cases 25-1 and 25-2 are examples of assessment of infant nutrition.

#### Case 25-1

Relevant Evaluation Criteria	Scenario/Model Outcome
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Emma Miller's mother is worried about Emma spitting up formula after every feeding, almost always with a little force. Although some emesis has occurred since birth, the amount and frequency have increased over the last week. Emma's mother thinks Emma appears to have more gas, often crying from "gas pains." Emma has always been a "good burper" so her mother feels her "gas pains" are not related to too much air in her stomach. The infant girl appears well hydrated and according to her mother, she has no temperature.
b. description of any	Emesis occurs only after feedings. Emma appears to be more comfortable after each episode of emesis. Irritability associated with

factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	gas pains appears to be relieved by simethicone.
c. description of the patient's efforts to relieve the symptoms	Emma's mother has been giving simethicone for gas. Nothing specific has been done for the emesis.
d. patient's identity	Emma Miller
e. patient's age, sex, height, and weight	8 weeks old, girl, 23 in., 11 lb 7 oz (5.2 kg)
f. patient's dietary habits	Emma was receiving breast milk exclusively until 1 week ago when her mother stopped breast-feeding. The infant was changed to Similac Advance. Per the mother's report, the formula is being mixed to a standard 20 kcal/ounce concentration according to the instructions on the container. The infant takes approximately 120 mL (4 ounces) every 3 hours. No extra water or juice is given during the day.
g. patient's sleep habits	Emma has not started sleeping through the night yet.
h. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Emma is a healthy, term infant without any significant medical conditions or past medical history. Her mother is currently giving her simethicone 20 mg four times a day as needed for gas pain. Emma's mother reports she usually gives about 2-3 doses per day.
i. allergies	NKA
j. history of other adverse reactions to medications	None
k. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Primary problem: emesis with feedings Secondary problem: increased intestinal gas
3. Identify exclusions for self-treatment.	Bloody or bilious emesis Signs of dehydration: sunken fontanelle, dry mucous membranes, decreased wet diapers, dark urine, decreased oral intake
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Emma to immediate medical attention/PCP. (2) Review preparation of infant formula with Emma's mother. (3) Monitor Emma's symptoms and recommend nondrug measures only. (4) Recommend a medication alone or combined with nondrug measures. (5) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Emma's current feeding schedule, 120 mL of 20 kcal/oz formula every 3 hours, provides 185 mL/kg/day and 123 kcal/kg/day. Both are within the usual recommended intakes for a healthy, term infant (Tables 25-2 and 25-13). Because the emesis and gas pain have increased since Emma was transitioned from breast-feeding to infant formula, Emma most likely does not tolerate the bovine milk proteins found within Similac Advance, but she needs to be seen by her PCP for further assessment. Explain the correlation between the increased emesis and gas pain and the transition to milk protein-containing formula. Recommend Emma see her PCP to discuss changing to either a soy-based formula such as Similac Soy Isomil or to a partially hydrolyzed formula such as Similac Expert Care Alimentum. If Emma continues to have problems after a change in formula, she should follow up with her PCP for further management.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"The increased emesis and gas pain are caused by the transition from breast-feeding to a formula containing cow milk protein. A change in the infant formula type such as soy formula or a partially hydrolyzed formula should improve Emma's symptoms. If the symptoms persist after the change in formulations, Emma should be seen again by her PCP."
7. Explain to the patient	"Because the symptoms started (or acutely worsened) with the change from breast milk to infant formula, and both the colic

7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	Because the symptoms started (or acutely worsened) with the change from breast milk to infant formula, and both the caloric density and the volume of the infant formula are appropriate for a healthy, term infant, intolerance to cow milk protein is the most likely cause of Emma's emesis and irritability. If cow milk protein intolerance is the major issue, changing the formula should produce relief of symptoms within several days."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. product storage requirements	"Infant formula should be used soon after mixing or kept tightly covered in the refrigerator and used within 24 hours of preparation. See product information for any specific storage requirements."
b. specific nondrug measures	NA
Solicit follow-up questions from the patient or caregiver.	"What if Emma continues to have emesis and gas pain after seeing the PCP and changing formulas?"
Answer the patient's or caregiver's questions.	"From the history, it sounds like Emma might have a cow milk protein intolerance. If she receives a soy or partially hydrolyzed formula, she should have improvement in her emesis and gas pains. If a change in formula does not improve her symptoms, her PCP will further assess her GI intolerance."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Ask the patient's mothers to call in 2-3 days to update you on Emma's response to your recommendations; or you could call her in 2-3 days to evaluate the response. If no improvement has been made, ensure that the mother has made an appointment with Emma's PCP to further management.

Key: GI = Gastrointestinal; NA = not applicable; NKA = no known allergies; PCP = primary care provider.

#### Case 25-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Stephen Shultz is a healthy-appearing 4-month-old, term infant. His mother comes to the pharmacy today because she is wondering if she should start to give Stephen vitamins because he is exclusively breast-fed. Her pediatrician suggested this at his recent well child checkup.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	None
c. description of the patient's efforts to relieve the symptoms	NA
d. patient's identity	Stephen Schultz
e. age, sex, length, and weight	4 months old, boy born at 38 weeks gestational age, 25 in., birth weight 15 lb 2 oz (6.9 kg)
f. patient's occupation	NA
g. patient's dietary habits	Stephen's mother is still on maternity leave. Stephen is exclusively breast-fed, eating approximately every 3-4 hours during the day.
h. patient's sleep habits	He sleeps from 10 pm to 6 am.

i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Stephen is a healthy, term infant with no preexisting medical conditions. He currently takes no prescription or nonprescription medications and no dietary supplements.
j. allergies	NKA
k. history of other adverse reactions to medications	None
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Potential for vitamin D and iron deficiency due to age and exclusive breast-fed diet.
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer to the PCP. (2) Recommend an over-the-counter multivitamin with iron. (3) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Recommend a standard infant multivitamin containing ferrous sulfate.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Your PCP suggested a multivitamin since Stephen is now 4 months of age and is exclusively breast-fed. I would recommend a standard infant multivitamin containing ferrous sulfate."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Term infants have approximately a 4- to 6-month store of iron reserves in their bodies. Human milk is very low in iron but meets most infants' needs for the first 4-6 months. Moreover, Stephen's need for adequate vitamin D currently exceeds the amount provided in breast milk. For these reasons, your PCP suggested you start giving a daily multivitamin containing iron."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	"Infant multivitamin with iron (e.g., Enfamil Poly-Vi-Sol with Iron Drops) 1 mL by mouth daily."
b. maximum number of days the therapy should be employed	"Until recommended to discontinue per Stephen's PCP."
c. product administration procedures	"Measure liquid using the dropper that comes with the medication and have Stephen swallow the liquid."
d. expected time to onset of relief	NA
e. degree of relief that can be reasonably expected	NA
f. Most common side effects	"Side effects are rare but gastrointestinal effects are possible. Give the iron drops with food if these effects occur."
g. Side effects that warrant medical attention	"Contact a health care provider if signs of an allergic reaction, such as a rash or trouble breathing, occur after a dose is given."
h. Patient's options in the event that condition worsens or persists	NA
i. Product storage requirements	"Keep medication in a tightly secured container away from any extreme temperature and out of children's reach."
j. Specific nondrug measures	NA

Solicit follow-up questions from the patient or caregiver.	"What do I do if Stephen spits out a dose of the multivitamin product?"
Answer the patient's or caregiver's questions.	"If Stephen spits out a dose of the multivitamin product, do not try to give the dose again. The medication is not so vital that it must be given each day for a medical condition, and Stephen could potentially receive too much iron if given multiple doses. Be cautious of the potential for the multivitamin product to stain clothing."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Ask Stephen's mother to call to update you on his response to your recommendations; or you could call her in a week to evaluate his response.

Key: NA = Not applicable; NKA = no known allergies; PCP = primary care provider.

### Patient Counseling for Infant Nutrition

The number and variety of infant formulas available may bewilder some parents. Once the formula type recommended or prescribed by the baby's primary care provider is known, the parents can be directed to the appropriate product. If the parents need further assistance with product selection, a product to match the parents' preferences can be recommended. At these encounters, the parents should be questioned to make sure they know how to properly prepare their baby's formula and how much formula to give at each feeding. The box Patient Education for Infant Nutrition lists specific information to provide parents. In addition, families who may qualify for WIC but are not enrolled can be advised of its availability and benefits.

#### Patient Education for Infant Nutrition

Optimal nutrition is critical in infants and children to ensure normal growth and development. Parents who carefully follow product instructions and the measures listed here will help ensure optimal nutrition-related outcomes.

- Check unopened formula containers for damage. Do not use products if they are significantly dented or if the expiration date has passed.
- When preparing formula from powder or liquid concentrate, carefully follow instructions for diluting the formula to the desired caloric density (Tables 25-9 and 25-10). If the formula is too concentrated, the baby may have diarrhea or become dehydrated. If it is too dilute, the baby can become water intoxicated, which might lead to irritability, seizures, coma, or brain damage.
- When preparing formula from powder or liquid concentrate, follow the technique for aseptic sterilization. Be sure to sterilize the bottles (or use sterile liners) and other equipment, and boil the water used to make the formula (Table 25-12).
- When preparing ready-to-use formulas, do not add water to the formula. Follow the instructions in Table 25-12. Be sure to sterilize the bottles (or use sterile liners) and other equipment.
- Use prepared or opened ready-to-use formula within 48 hours. Keep refrigerated.
- Feed your baby according to the frequency and quantities listed in Table 25-13 unless instructed otherwise by the baby's primary care provider. Paying careful attention to your infant's hunger and fullness cues is important to avoid over- and underfeeding. Discuss any concerns with your infant's primary care provider.
- Heating formula in a microwave is not recommended. However, if formula or human milk is warmed in a microwave, follow the instructions below to prevent exploding containers, scalds, or burns to the baby's mouth:
  - Remove the bottle's lid to allow heat to escape.
  - Heat only 4 ounces or more of refrigerated milk; do not thaw frozen human milk in a microwave. Place frozen human milk in a tepid water bath to thaw.
  - Heat 4 ounces of refrigerated formula on full power for no longer than 30 seconds; heat 8 ounces of refrigerated formula for 45 seconds.
  - After heating the formula, replace the nipple assembly and invert the bottle a minimum of 10 times.
  - Test the formula's temperature by putting a few drops on your tongue or the top part of your hand or the back of the wrist. Do not feed the baby the formula unless it feels cool to the touch.

### When to Seek Medical Attention

- Seek medical attention if:
  - Your baby is regurgitating or vomiting significant amounts of formula. A small amount of spitting up is normal. Projectile vomiting or bilious vomiting (i.e., green) always requires immediate medical attention.
  - Your baby has severe diarrhea or diarrhea that persists for more than 3 days.
  - Your baby appears dehydrated (e.g., decreased number of wet diapers, dark urine, limp, no tears, or lethargic).
  - Your baby's stools have blood in them.

### Key Points for Infant Nutrition and Special Nutritional Needs of Children

- Human milk is the optimal food for infants under 12 months of age, and its use should be encouraged for nearly all infants. When breast-feeding or provision of human milk is not possible or desired, commercial infant formulas provide a safe, nutritionally adequate substitute.
- Commercial formulas are available in a variety of types to meet the needs of most infants, as well as children with special nutritional needs, such as those with a feeding tube.
- Therapeutic formulas designed for infants and children with alterations in requirements caused by disease or other conditions, including prematurity, vary in content and are not generically equivalent. These formulas should be used under medical supervision and are not self-selected.
- Accurate preparation of formula is critical to ensure optimal nutrition outcomes. Parents should be counseled on proper preparation techniques.
- Some infants will require vitamin and/or mineral supplementation when their needs are not adequately met by their formula intake.
- Parents should be referred to their child's primary care provider if their infant or child has persistent vomiting or if at any time the emesis is bilious (green).
- Parents should be referred to their child's primary care provider if their infant or child has diarrhea lasting more than 3 days, especially if dehydration develops, if the child looks clinically ill, or if there is blood in the stool.

## Handbook of Nonprescription Drugs &gt; Chapter 26. Overweight and Obesity

**Overweight and Obesity: Introduction**

Obesity rates have increased at an alarming rate since the mid-1970s. Overweight and obesity are significant because they are associated with increased morbidity and mortality from various conditions, including cardiovascular diseases (CVD), type 2 diabetes mellitus (type 2 DM), gallbladder disease, osteoarthritis, obstructive sleep apnea, nonalcoholic steatohepatitis, and several cancers.<sup>1</sup> In the United States, increasing concern centers on overweight and obesity in children and adolescents.

The National Health and Nutrition Examination Surveys (NHANES) of the U.S. population have tracked prevalence of overweight and obesity in adults from 1960 to the present. These surveys have demonstrated a marked increase in obesity in both men and women across all age and ethnic groups. More than one-third of U.S. adults are currently obese (Figure 26-1).<sup>2</sup> Increases in obesity prevalence appear to have slowed for both females and males between 1999 and 2010, but the percentage of morbidly obese adults continues to rise.<sup>3</sup> Figure 26-1 also illustrates the changes in prevalence of the overweight population across recent NHANES surveys. These have remained fairly stable at 32%-34%.<sup>2</sup>

Notes: Overweight but not obese is BMI greater than or equal to 25 but less than 30; grade 1 obesity is BMI greater than or equal to 30 but less than 35; grade 2 obesity is BMI greater than or equal to 35 but less than 40; grade 3 obesity is BMI greater than or equal to 40.

Overweight and obesity among adults 20 years of age and over. Key: BMI = Body mass index; CDC = Centers for Disease Control and Prevention; NCHS = National Center for Health Statistics. (Source: Reference 2.)

Prevalence of obesity during childhood and adolescence, as tracked by the NHANES data, has risen considerably, as shown in Figure 26-2.<sup>2</sup> These increases also appear to have slowed over the period 1999-2010.<sup>4</sup>

The economic impact of overweight and obesity is substantial. The estimated direct medical costs of obesity are as high as \$147 billion annually.<sup>5</sup> The Institute of Medicine recently estimated that obesity-related illness costs about \$190 billion, accounting for more than 20% of annual health spending in the United States.<sup>6</sup> Quantification of costs that are directly due to obesity is difficult, given that many comorbidities of obesity have other etiologies.

Americans spend billions of dollars on weight-control products and services annually. Use of nonprescription or dietary supplement weight-loss products is very common. Health care providers should be knowledgeable in discussing benefits as well as limitations and potential harm of weight-loss products and should be comfortable in recommending effective nonpharmacologic lifestyle changes such as diet and exercise. If patients need additional strategies, the provider may then refer them for consideration of prescription weight-loss therapies.

**Clinical Indicators of Overweight and Obesity**

The 2013 American Heart Association/American College of Cardiology/The Obesity Society (AHA/ACC/TOS) "Guideline for

the Management of Overweight and Obesity in Adults” defines overweight and obesity in adults by body mass index (BMI), a parameter that takes into account both height and weight.<sup>7</sup> The U.S. Preventive Services Task Force (USPSTF) on screening for and management of obesity also recommends BMI for screening of obesity.<sup>8</sup> Table 26-1 illustrates BMI values for persons of various heights and weights and gives equations for calculation of the BMI. Overweight is defined in adults as a BMI of 25-29.9 (kg/m<sup>2</sup>) and obesity as a BMI of 30 or greater.

There are limitations to the exclusive use of BMI as an indicator of overweight and obesity, as it does not take into account extreme variation in body composition. Very muscular persons, for example, may be classified by BMI as overweight or obese when, in fact, they are not carrying excessive adipose tissue. Alternatively, some people with BMI in the desirable range may have less than optimal muscle mass and high body fat. Some of these persons may be classified as “metabolically obese normal weight,” with increased insulin resistance, hypertriglyceridemia, and a predisposition to type 2 DM and CVD.<sup>9</sup> Finally, ethnic groups may differ in what BMI range is optimal for minimizing the risk of obesity-related CVD. The importance of the distribution of body fat to risk of morbidity and mortality has long been recognized. Central fat around the waist and deep visceral adipose surrounding internal organs are associated with greater health risk than inert subcutaneous adipose in regions such as the buttock or thigh. Fat cells in the viscera of the abdomen are associated with chronic inflammation, which in turn can contribute to chronic diseases such as CVD, type 2DM, and cancer.<sup>10</sup> Men with waist circumference greater than 40 inches and women with waist circumference greater than 35 inches are often considered at increased relative risk of type 2 DM and CVD. The USPSTF recommendations suggest that waist circumference may be an alternative to BMI in some populations.<sup>8</sup> In an effort to better identify and address obesity and its related risks, providers are strongly encouraged to take measurements of height, weight, and waist circumference; these physical assessment techniques can be realistically accomplished even in a busy clinical setting.

Metabolic syndrome is characterized by the presence of certain metabolic risk factors and has been associated with increased risk of coronary artery disease, other vascular diseases, and type 2 DM. Patients with three or more of the following are said to have metabolic syndrome:

- Waist circumference greater than 40 inches in men or 35 inches in women (numbers may vary in differing ethnicities)
- Serum triglycerides of 150 mg/dL or greater
- High-density lipoprotein (HDL) cholesterol less than 40 mg/dL in men or less than 50 mg/dL in women
- Blood pressure level of 130/85 mm Hg or higher
- Fasting serum glucose of 100 mg/dL or greater

Individuals with metabolic syndrome are likely to demonstrate insulin resistance and may benefit more from weight loss for reduced morbidity and mortality compared to overweight or obese persons without the syndrome. In addition, increased muscle mass is associated with improved insulin sensitivity. Therefore, physical activity resulting in increased muscle mass may result in improved insulin sensitivity even in the absence of weight loss.

Notes: Obesity is BMI at or above the sex- and age-specific 95th percentile BMI cutoff points from the 2000 CDC Growth Charts.

Key: BMI = Body mass index.

<sup>a</sup> To determine BMI, find the height in the left-hand column; then move across the row to a given weight. The number above the weight column is the BMI for that height and weight.

<sup>b</sup> BMI calculations: weight (kg)/height (m<sup>2</sup>) or (weight [lb]/height [in.<sup>2</sup>]) × 703.

<sup>c</sup> BMI 30-34.9 known as Class I obesity; BMI 35-39.9 known as Class II obesity; BMI ≥ 40 known as Class III obesity.

Recent data have challenged the concept that a “normal” BMI of 18.5-25 confers a mortality advantage. A 2013 meta-analysis indicates that although obesity is associated with higher all-cause mortality, overweight is associated with lower all-cause mortality compared with normal weight.<sup>11</sup> Whether these results are related to overweight patients receiving earlier or better health care, reflect some protection by metabolic reserves, or are due to some other mechanism is speculative at this time, and controversy over the results continues. These seemingly puzzling findings emphasize that factors such as blood pressure, lipid levels, fasting blood sugars, and waist circumference as well as BMI are important risk factors.

Some evidence suggests that the correlation between obesity and CVD is not as strong as it once was, perhaps because of improvements in medical care for CVD and its risk factors. However, this reduction in obesity-related CVD mortality has been accompanied by an increase in obesity-associated disability, perhaps because of people becoming overweight or obese at earlier ages or because of their living longer. Some evidence supports cardiorespiratory fitness as an independent determinant of mortality in overweight and obese persons (i.e., the concept that being fat but fit carries significantly lower risk than being fat and unfit).<sup>9</sup>

The Endocrine Society has published guidelines for obesity in children.<sup>12</sup> These guidelines define children and adolescents with a BMI “percentile for age” between the 85th and 95th percentiles as overweight and 95th percentile or greater as obese, based on Centers for Disease Control and Prevention growth charts.

### Pathophysiology of Overweight and Obesity

Weight gain is a reflection of energy intake exceeding energy expenditure. A pound of adipose tissue represents about 3500 calories (kcal) of energy. An excessive intake of only 10 kcal/day over the level of energy expenditure could result in a gain of approximately 1 pound of fat in a year’s time. The physiology of energy intake and expenditure is complex and involves numerous body systems, including the hypothalamic-pituitary axis, autonomic nervous system, central nervous system, endocrine system, gastrointestinal (GI) tract, and adipose tissue.

Both genetic and environmental factors are important in the etiology of overweight and obesity, and there is a complex interplay between these factors. The rapid increase in obesity over the past few decades argues for a strong environmental role. Increased portion sizes and caloric intakes are undoubtedly contributing to recent trends in obesity rates. Today’s lifestyle and environment are likely modulating genetic expression of obesity in many individuals. For example, one recent study showed that persons with higher intakes of sugar-sweetened beverages were likely to express more alleles known to be associated with obesity compared to patients consuming fewer sugar-sweetened beverages.<sup>13</sup> However, consumers should be cautioned about commercial weight management programs offering genetic analysis as part of their packages; such programs may be beneficial, but currently marketing trumps the underlying science.

Researchers studying obesity have identified several different hormones and proteins potentially involved in energy balance.<sup>14</sup> Studies are ongoing to determine whether excesses, deficiencies, or resistance to specific substances are related to weight homeostasis. Leptin is an example of a hormone secreted by adipose tissues where resistance to the hormone may be a factor. Other compounds of research interest include neuropeptide Y, ghrelin, and melanocortins. An in-depth discussion of this topic is beyond the scope of this chapter.

Environmental factors contributing to recent increases in obesity include decreased physical activity coupled with increased food availability and consumption, especially calorie-dense foods. Guidelines for regular moderate physical activity are met by one-half to two-thirds of Americans.<sup>15</sup> Initiation of even modest amounts of exercise by sedentary persons can have multiple health benefits including maintenance of current weight instead of continued weight gain.

Significant increases in portion sizes of food and increased sedentary working hours may be environmental factors contributing to excessive energy intake. Twenty years ago, the typical muffin contained about 200 calories, whereas today it contains closer to 500 calories. Similarly, a typical chocolate chip cookie contained less than 100 calories, whereas today a single serving cookie often contains more than 250 calories. See [Chapter 22](#) for a discussion of a healthy diet and *MyPlate*.

Another factor receiving attention as a possible etiology of overweight and obesity is sleep duration.<sup>16</sup> Several epidemiologic studies have associated high BMI values with shorter sleep duration.

Still another concept in the etiology of obesity relates to the gut microbiome.<sup>17</sup> Obese persons have been found to have different proportions of certain bacteria compared with lean persons. Furthermore, these proportions have been shown to change with weight loss. These findings may lead to investigation of prebiotics, probiotics, and antibiotics as tools for weight maintenance and weight loss.

Some medications can lead to weight gain.<sup>18</sup> There is clear evidence that the majority of the second-generation antipsychotics contribute to significant weight gain and related metabolic disorders. Older antidepressants (tricyclics and monoamine oxidase inhibitors) are associated with modest weight gain. Although some of the selective serotonin reuptake inhibitor antidepressants have been touted as producing weight loss, this loss is usually short lived, and weight gain can eventually occur. Other important groups of medications contributing to significant weight gain are hormonal contraceptives, systemic corticosteroids, certain anticonvulsants, certain sulfonylureas, thiazolidinediones, and insulins. The latter three groups are noteworthy because patients with type 2 DM placed on these medications frequently are already overweight.

### Complications of Obesity

Overweight and obesity are associated with myriad chronic health problems.<sup>1</sup> Many of these problems improve with even modest weight loss. Obese persons experience more difficulties in performing activities of daily living such as walking several flights of stairs or bending and kneeling.

Obesity is associated with coronary heart disease (CHD) through its impact on risk factors such as hypertension, dyslipidemia, and type 2 DM. Overweight and obesity have been linked to increased risk for heart failure, arrhythmias, and stroke. Prevalence of hypertension begins to increase at relatively low levels of overweight. Weight loss in obese persons is associated with significant reductions in blood pressure.<sup>19</sup>

The relationship between CHD and obesity is confounded by other risk factors such as blood lipid levels, blood pressure, type 2 DM, and smoking. Despite this, several studies that carefully controlled for confounders have shown BMI and abdominal fat to be independent risk factors for the development of CHD in both genders.<sup>19</sup> As noted previously, central visceral adiposity is more closely associated with cardiovascular disease than is subcutaneous adiposity.

Data from the Physicians’ Health Study showed approximately a twofold increase in risk of either ischemic or hemorrhagic stroke in subjects with a BMI of 30 or higher compared with those with a BMI of 23 or lower.<sup>19</sup> This effect appeared to be independent of the presence of hypertension, type 2 DM, or dyslipidemia. BMI may affect stroke risk through an increase in prothrombotic and proinflammatory factors found in obese persons. Venous thromboembolism risk is also increased in

obese persons.<sup>19</sup>

There is a correlation between increasing BMI and increasing triglyceride and low-density lipoprotein (LDL) cholesterol levels. Beneficial HDL cholesterol levels tend to be lower in both men and women with higher BMI values. However, it is important to recognize that these correlations do not prove causation. Even modest weight loss of 3-8 kg can have a beneficial effect on blood lipid levels.<sup>7</sup>

The relationship between overweight and obesity and type 2 DM is well documented (see [Chapter 45](#)). Visceral adiposity (high waist circumference) has been shown to be a risk factor for development of type 2 DM. Persons who are initially insulin resistant, typically evidenced by high plasma triglycerides and low HDL cholesterol, are most likely to benefit from weight loss for reduced morbidity and mortality. Modest weight loss is effective in improving blood glucose control in patients with type 2 DM and preventing development of type 2 DM in those at risk.<sup>7</sup>

Negative attitudes exist toward obese people, leading to social stigmatization and discrimination. Overweight children may develop psychosocial difficulties stemming from compromised peer relationships.<sup>20</sup>

Obesity appears to increase the risk for a number of other diseases, including gallbladder disease, nonalcoholic fatty liver disease, osteoarthritis, sleep apnea, asthma, certain types of cancer, and disorders of female reproduction.<sup>1</sup> Obesity is a risk factor for hyperuricemia and gout.<sup>1</sup> Overweight is believed to contribute to a significant proportion of certain cancers and increased mortality from cancer.<sup>1</sup> Of particular concern are cancers with a hormonal basis such as cancers of the breast, prostate, or endometrium, as well as cancers of the colon, rectum, and gallbladder. Hypertension and gestational diabetes are more likely in obese women who become pregnant.

## Management of Overweight and Obesity

### Management Goals and General Management Approach

For many individuals, losing weight or maintaining weight loss is a lifelong challenge. Lifestyle changes, including dietary modification and increased exercise, are cornerstones of management. Successful weight loss and maintenance of loss require significant behavioral modification. Pharmacologic therapy using nonprescription agents should be only a short-term measure unless a primary care provider (PCP) supervises therapy. Long-term use of prescription therapies under the care of a PCP may be an option for patients with a BMI of 30 or higher or a BMI of 27 or higher with comorbid conditions.<sup>7</sup> However, pharmacologic interventions often result in only modest weight loss that is regained after drug discontinuation. Bariatric surgery may be considered for patients with a BMI of 40 or higher or a BMI of 35 or higher with comorbid conditions, including hypertension, hyperlipidemia, and type 2 DM.<sup>7</sup> This surgery is effective for helping achieve weight loss for many patients, although success following surgery also requires lifestyle changes. The procedures carry their own significant risks. Many chronic diseases and conditions improve with weight loss. However, weight-loss goals set by many individuals are unrealistic and based on cosmetic rather than health benefit. Weight loss (and maintenance of that loss) of 5%-10% of initial weight can have positive benefits in individuals with hypertension and type 2 DM. The AHA/ACC/TOS guidelines state that the initial goal of weight loss is to reduce body weight by about 5%-10% over 6 months.<sup>7</sup> If this goal is achieved and further weight loss is indicated, it can be attempted. The first 10% loss carries the greatest health benefits and is easiest to attain, given that weight loss often plateaus after 6 months because of decreased basal metabolic rate. It is more important to maintain the 10% weight loss than to pursue further weight loss in many patients, and most patients find the weight maintenance to be harder than the initial modest weight loss. An approach often overlooked may be to prevent further weight gain in persons who have slowly but steadily gained weight over a period of years. [Figure 26-3](#) is a guide for the health care provider in recommending weight-loss measures.

### Nonpharmacologic Therapy (Lifestyle Intervention)

Dietary modification or restriction is the mainstay of weight-loss therapy. Physical activity is less effective in producing weight loss initially, but becomes extremely important in maintaining weight loss and improving overall fitness. The term *lifestyle intervention* describes a strategy of dietary change, physical activity, and behavior therapy. One major key to weight loss and maintenance of that loss is employment of lifestyle interventions that are sustained over a long period of time. Lifestyle intervention programs should be included in pharmaceutical care services.<sup>21</sup>

### Dietary Change

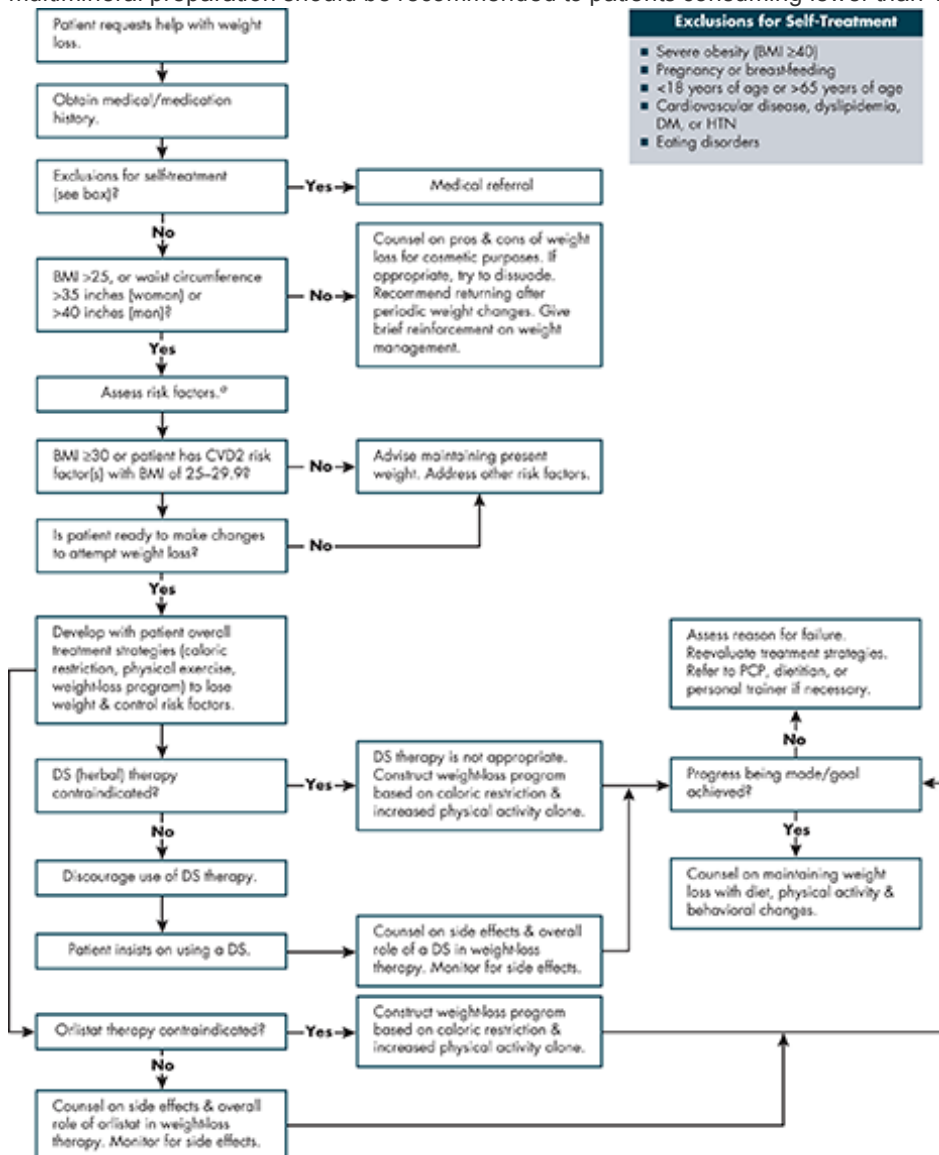

Dietary change is the most commonly used weight-loss strategy. Diet strategies include caloric restriction; changes in dietary proportions of fat, protein, and carbohydrate; use of macronutrient substitutes (i.e., sugar and fat substitutes); and changes in timing or frequency of meals. Short-term success for many methods has been documented; however, data on longer-term effectiveness and safety are limited. Weight loss at the end of relatively short-term programs can exceed 10% of initial body weight. However, there is a strong tendency to regain this weight. A relatively small portion of participants do maintain weight loss over more extended periods, although the actual percentage of these successful participants varies. The National Weight Control Registry tracks individuals who have maintained weight loss of at least 30 pounds for at least 1 year.<sup>22</sup> To initially lose weight, persons in this registry used a variety of methods; about half were self-directed and half used some type of program. Most individuals reported maintaining weight loss through a combination of a low-calorie, low-fat diet and exercise, most commonly walking.

Even small changes in dietary patterns can have a positive effect. Cutting portion sizes, switching to water or diet soda rather than sugar-sweetened beverages, using smaller plates for meals, and keeping healthy snacks such as fruits and vegetables on hand are useful, sustainable strategies. Trying to emphasize foods in the diet with low energy density (i.e., low calories per weight of food) may be helpful because these foods tend to promote satiety. Because these are long-term lifestyle changes, patients should be encouraged to make these realistic, smaller changes rather than opt for the more radical fad diets that are difficult to adhere to long term. (See [Chapter 22](#) for more details about healthy diets.)

### Caloric Restriction

Daily caloric allowances for moderately active individuals vary with age, gender, and body weight. The U.S. population suffers from “portion distortion” and needs to relearn appropriate food portion sizes based on age and activity levels. Daily caloric intake allowances for an average 30-year-old man (BMI, 18.5-25; height, 5 ft 11 in.) in a temperate climate range from 2200-3000 kcal/day, depending on activity level. Corresponding figures for an average 30-year-old woman (BMI, 18.5-25; height, 5 ft 5 in.) are 1800-2800 kcal/day.<sup>23</sup> These figures are lower for older persons and higher for younger adults. Caloric requirements for women increase during pregnancy and lactation (see [Chapter 22](#)).<sup>23</sup> Self-initiated weight loss during pregnancy is not recommended.

A diet that is individually planned and seeks to create a deficit of  $\geq 500$  kcal/day should be an integral part of any weight-loss program.<sup>7</sup> Two levels of caloric restriction are commonly used. A low-calorie diet (LCD) of about 1200-1800 kcal/day may involve a structured commercial program, or it may involve guidelines for selecting conventional foods, including careful attention to portion sizes. Weight loss on an LCD is typically 1-2 pounds per week. A very-low-calorie diet (VLCD) of 800 or fewer calories per day should be conducted and monitored under medical supervision and accompanied by high-intensity lifestyle intervention. VLCDs are frequently administered as liquid formulas given several times a day. Although weight loss with VLCDs over 12-16 weeks is typically double that of LCDs, long-term results are generally no better. A multivitamin and multimineral preparation should be recommended to patients consuming fewer than 1200 kcal/day for prolonged periods.

Self-care of overweight and obesity. Key: ACC = American College of Cardiology; AHA = American Heart Association; BMI = body mass index; CVD = cardiovascular disease; DM = diabetes mellitus; DS = dietary supplement; HTN = hypertension; PCP = primary care provider; TOS = The Obesity Society.

Total fasting or semistarvation is sometimes proposed as a means of weight reduction in severely obese persons. However, starvation depletes the body of lean tissue (protein) and essential electrolytes in addition to fat. If total fasting is undertaken, hospitalization and medical supervision are recommended.

#### Altered Proportions of Food Groups

The most commonly recommended diets for weight loss are reduced-calorie diets emphasizing decreased fat intake, particularly decreased saturated fat. The 2010 Dietary Guidelines for Americans recommends a diet supplying no more than 35% of total calories from fat, of which no more than 10% of total calories come from saturated fat.<sup>24</sup> Future guidelines will probably place less emphasis on restricting fat calories and more emphasis on including monounsaturated and polyunsaturated fat while minimizing saturated fat. A low-fat diet alone is inadequate for weight loss; the diet must also reduce total calories.

Very-low-fat vegetarian diets in the context of other lifestyle changes have been advocated. Although such programs can result in regression of coronary atherosclerosis in some patients with moderate-severe CHD, applicability to larger populations remains questionable with regard to compliance.<sup>25</sup> Dietary fat must be carefully chosen when consuming a very-low-fat diet to prevent essential fatty acid deficiency. Such diets increase triglyceride levels and lower HDL cholesterol in the short term because of high carbohydrate content.

There is a spectrum of popular high-protein, higher-fat, low-carbohydrate diets. Some contain very low amounts of carbohydrates (about 5% to 15% of total calories; e.g., Atkins diet) and are ketogenic, whereas others are considered moderate-carbohydrate diets (about 35% to 50% of calories from carbohydrate; e.g., Zone diet). People often start out on the ultralow form of the diet and transition to a more moderate form. Part of the success of low carbohydrate diets may lie in the fact that they simplify food choices, thus facilitating dietary adherence.

The theory behind very low carbohydrate diets is that they prevent elevated insulin levels that promote storage of body fat. Much of the weight loss seen with these diets is a result of decreased caloric intake from avoiding high-carbohydrate foods. Initial weight-loss results partially from a diuretic effect and glycogen depletion. Low carbohydrate diets result in significant weight loss over 6-24 months. Concerns about long-term safety of these diets still exist. Most studies have indicated that serum lipid levels, overall, are not affected deleteriously over the short term in most dieters, mainly because of weight loss. Triglycerides and HDL cholesterol levels are generally affected more favorably with low-carbohydrate diets, whereas low-fat diets have more favorable effects on LDL and total cholesterol.<sup>26</sup> Potential adverse effects include lack of essential nutrients such as potassium, calcium, and magnesium. High-protein foods consumed in large quantities on these diets could increase uric acid levels and precipitate gout, although this problem has not been common in studies with up to a year of follow-up. High animal protein content promotes calcium excretion in the urine that could be deleterious to bone health. Restriction of fruits, vegetables, whole grains, and milk products could increase a person's risk of various cancers by depleting essential vitamins, minerals, and fiber and could also lead to constipation. A high-protein, low-carbohydrate (HPLC) diet has been shown to alter metabolic profiles in the colon of obese men after as little as four weeks of consumption.<sup>27</sup> Decreases in protective short chain fatty acids and increases in potentially carcinogenic N-nitroso compounds in a HPLC diet could be risk factors for colonic disease if this diet is followed for long periods. Attention to the type of fiber content included in HPLC diets could help offset these effects, but this benefit has not yet been proven.

High-protein content may predispose people to dehydration and hyperfiltration by the kidneys, leading to eventual kidney damage, particularly in diabetic patients. Headache, muscle weakness, and fatigue are other adverse events reported by some persons on low-carbohydrate diets. Several published randomized trials of such diets demonstrated relative safety of the low-carbohydrate, higher-fat, high-protein diets for 6-24 months, with greatest weight loss seen in the first 6 months.<sup>26</sup> In the Women's Health Initiative trial, reduction of total fat intake for 8 years did not reduce risk for CVD.<sup>28</sup> This finding may be related to the observation that carbohydrate-restricted diets have more favorable effects, when compared with fat-restricted diets, not only on triglyceride and HDL cholesterol levels, but also on small dense LDL cholesterol mass.<sup>28</sup>

Low-glycemic-index food products are promoted commercially. Glycemic index refers to the amount of blood glucose rise seen over a set period of time after ingestion of a standardized amount of a food. Many high-carbohydrate, low-fat diets exhibit a high glycemic index. By making carbohydrate choices carefully, a lower glycemic response can be obtained. Low-glycemic-index diets would promote satiety, prevent large fluctuations in insulin concentrations, and might help maintain insulin sensitivity. Studies have not consistently supported the usefulness of low-glycemic-index diets in weight control, and the methods used to classify foods with this system are controversial.

#### Use of Food Additives

Some patients may use food additives such as artificial sweeteners and fat substitutes to reduce caloric intake. Although theoretically the use of these agents should help decrease caloric intake, the existing data are conflicted as to beneficial effects these products may produce. [Table 26-2](#) outlines information related to sugar and fat substitutes.

#### Meal Replacement Therapy

Diets that use meal replacements typically involve replacing up to two meals a day with a liquid drink, snack bar, or measured frozen meal, with the dieter encouraged to eat a “reasonable” third meal each day. The main advantage to this approach is portion control. Products typically contain about 200-300 kcal per serving and are low fat, although low-carbohydrate options are also available. The challenge with this approach is that dieters enter their third meal extremely hungry and may consume excessive calories by overeating at this time. Early weight loss with these products, part of which may be a result of low sodium content leading to water loss, can give a psychological boost to adhere to the program. Meal replacement products are discussed further in [Chapter 23](#).

**TABLE 26-2 Sugar and Fat Substitutes**

<i>Substitute (sample trade name)</i>	<i>Comments</i>
<b>Sugar Substitutes</b>	
Monk fruit extract <sup>a</sup> (Nectresse)	Products may contain very small amounts of other natural sweeteners such as erythritol, molasses, and sugar
Saccharin (Sweet 'n Low) <sup>a</sup>	Has bitter taste; has been replaced largely by newer sweeteners
Aspartame (Nutra Sweet) <sup>a</sup>	Contains phenylalanine; therefore, contraindicated in patients with phenylketonuria; not for use in cooking or baking as heat breaks it down into free amino acids, which impart a bitter taste
Fructose	Nutritive sweetener and should not be viewed as sugar free; insulin not required for fructose utilization in the body; contains approximately 10 calories when supplied in an amount providing the equivalent of about 1 teaspoon of sucrose
Sorbitol	Nutritive sweetener and should not be viewed as sugar free; does not cause tooth decay, but can cause osmotic diarrhea when ingested in large quantities; contains approximately 10 calories when supplied in an amount providing the equivalent of about 1 teaspoon of sucrose
Xylitol	Nutritive sweetener and should not be viewed as sugar free; does not cause tooth decay; contains approximately 10 calories when supplied in an amount providing the equivalent of about 1 teaspoon of sucrose
Acesulfame potassium (Sweet One) <sup>a</sup>	May be substituted for sucrose in cooking; may be combined with aspartame, because some people detect a metallic aftertaste with acesulfame potassium alone
Sucralose (Splenda) <sup>a</sup>	May be used in cooking
Neotame <sup>a</sup>	Chemically similar to aspartame; may be used in cooking
Cyclamates <sup>a</sup>	Banned by FDA in 1969 because of association with cancer in animals; applicability of this finding to humans has been challenged; remains available in many countries
Stevia <sup>a</sup>	Approved in United States as of 2008 as a food additive in a specific purified form
<b>Fat Substitutes<sup>b</sup></b>	
Microparticulated protein (Simplese)	Used in frozen desserts, salad dressing; unstable to heat
Soluble fiber (Oatrim)	Derived from oats and designed to replace fat in meats, cheeses, baked goods, and frozen desserts
Sucrose polyester (Olean)	Also known as olestra; is not absorbed; can cause malabsorption of fat-soluble vitamins; GI side effects can be seen with ingestion of large quantities; can be used for cooking and frying

Key: FDA = Food and Drug Administration; GI = gastrointestinal.

<sup>a</sup> Can be labeled as noncaloric based on FDA labeling regulations; cyclamates no longer approved by FDA for use as sugar substitute.

<sup>b</sup> Use of these fat substitutes in food products in place of fat typically decreases caloric content of the foods by about half unless extra sugars are added into the products.

### Commercial Weight-Loss Programs

Structured commercial weight-loss programs such as Weight Watchers, Jenny Craig, and Take Off Pounds Sensibly (TOPS) are very popular in the United States. Women tend to gravitate to these programs more than men. Participation in structured commercial programs may be expensive, because participants are required to purchase program-specific tools as well as specially packaged snacks or meals. The success seen with these programs is likely at least partially due to the social support that develops with periodic meetings. Online tools such as diet and exercise diaries and support groups are increasingly available; these resources may be less expensive than community-based structured commercial programs.

### Physical Activity

Encouragement of physical activity for preventing overweight and obesity is an important public health strategy for all age groups, including children. The U.S. Department of Health and Human Services outlines physical activity recommendations as shown in [Table 26-3](#).<sup>29</sup> For older adults, regular exercise can reduce functional declines that occur with aging. Increased physical activity is an important component of weight-loss therapy and is even more important in weight maintenance after weight loss. Patients who regularly exercise may, in general, be more committed to a healthy lifestyle. Exercise builds muscle, which has a higher metabolic rate than a corresponding amount of fat. Weight loss that can be achieved by an exercise program is modest; combining a reduced-calorie diet with increased physical activity produces greater weight loss and reduction in abdominal fat than either approach alone. Some patients may have medical conditions restricting the types of exercise in which they should participate. These patients should have a medical evaluation before starting an exercise regimen. Regardless of concomitant diseases, current recommendations call for men older than age 40 and women older than age 50 to undergo a medical evaluation before starting an exercise program.

For sedentary patients, a walking program is often a good place to begin. A pedometer may be an inexpensive aid to increasing activity in some individuals. Patients can start by walking 30 minutes each day for 3 days a week, building up to at least 60 minutes of moderate-intensity physical activity most days of the week. The 60-minute activity periods can be accrued in multiple smaller increments throughout the day with similar benefit. Patients should be encouraged to participate in activities that they enjoy and are therefore more likely to continue.

### Behavioral Therapy

Behavioral therapy can improve the outcome of weight-loss programs when used in combination with other strategies such as diet, exercise, and medications. Behavioral interventions are most effective when patients participate in sessions at least once or twice a month.<sup>8</sup> Behavioral therapy may be administered in either an individual or group setting by professionals or lay leaders. Remote coaching and mobile technologies are increasingly being explored as less expensive methods for encouraging adherence to lifestyle modifications.

Behavioral techniques include the following:

- Environmental modification: Do not have high-calorie foods readily available and thus avoid problem foods altogether.
- Thought-pattern modification: Set reasonable, specific, proximate goals; identify and plan for potential obstacles.
- Self-efficacy: Maintain an optimistic and positive approach.
- Social support: Rely on family, friends, and health care providers.<sup>30</sup>

**TABLE 26-3 Physical Activity Recommendations<sup>a</sup>**

<b>Children and Adolescents</b>
Aerobic: ≥60 minutes of moderate or vigorous aerobic activity a day, including vigorous activity at least 3 days a week
Muscle and bone: strengthening physical activity should occur at least 3 times a week
<b>Adults</b>
Aerobic: 150 minutes of moderate aerobic activity or 75 minutes of vigorous physical activity a week, performed in ≥10-minute episodes <sup>b</sup>
Muscle: strengthening activities involving major muscle groups should occur at least twice a week

<sup>a</sup> As proposed by the U.S. Department of Health and Human Services, "2008 Physical Activity Guidelines for Americans."<sup>25</sup>

<sup>b</sup> More activity than is outlined here is necessary to promote weight loss in most persons. Exercise should be used in

combination with dietary restriction to promote weight loss.

### Public Health Initiatives

In an era when federal and state governments bear an increasing percentage of the cost of health care in the United States, interest in public health initiatives to decrease overweight and obesity has increased. Efforts by all levels of government to require dietary information in restaurant menus, to limit portion sizes of sugar-sweetened beverages, to limit trans-fat content in commercial foods, and to levy taxes on certain unhealthy foods are just a few examples of initiatives that have been considered or actually implemented. Many schools have banned the sale of sugar-sweetened beverages and high-fat snacks on their premises. These measures are controversial, and positive benefits on public health are not consistently shown at this time.

### Pharmacologic Therapy

Pharmacologic therapy is generally not recommended for weight loss, as exemplified by the fact that more weight-loss products have been removed from the market than approved in recent years because of safety concerns. The ideal drug, which would provide fast and permanent weight loss with no adverse effects, simply does not exist despite the billions of research and consumer dollars spent on weight-loss products every year.

The most current guidelines for weight loss recommend that prescription weight-loss medications approved by the Food and Drug Administration (FDA) for long-term use be reserved as an adjunct to diet and physical activity for patients with BMI of 30 or higher or for patients with BMI of 27 or higher with concomitant diseases or risk factors.<sup>7</sup> The drugs can be used singly and at the lowest effective dose to reduce the likelihood of adverse events. The same guidelines should apply to all weight-loss products, whether prescription or nonprescription drugs or dietary supplements, although nonprescription orlistat (Alli) is recommended for BMI greater than 25 as outlined in the following section. Any of these medications or supplements should be used with concomitant lifestyle intervention and continuous assessment for efficacy, safety, and tolerance.

### Status of Nonprescription Weight-Loss Products

Because of the lack of safety and efficacy data, FDA banned 111 weight-control ingredients in nonprescription drug products in 1991.<sup>31</sup> In 2000, FDA requested that all drug companies discontinue marketing phenylpropanolamine-containing products because of safety issues.<sup>32</sup> In addition, nonprescription drugs containing ephedrine and related alkaloids in combination with a stimulant or analgesic could no longer be marketed as of 2001,<sup>33</sup> and the stimulant laxative ingredients aloe and cascara sagrada were banned as ingredients in nonprescription drugs in 2002.<sup>34</sup> In 2004, FDA banned dietary supplements containing ephedrine alkaloids, declaring these supplements adulterated because they present an unreasonable risk of illness or injury.<sup>35</sup> This ban was upheld in 2007.<sup>36</sup> Common names used for the various botanicals that contain ephedrine alkaloids include sea grape, yellow horse, joint fir, popotillo, ma huang, and country mallow. Whereas these products are banned from sale in the United States, similar substances that may pose similar risks are still included in dietary supplements and are often found as components of weight-loss products.

Dietary supplements are distinct entities from nonprescription drugs. They include herbal and other products meant to supplement the diet and are regulated under the Dietary Supplement Health and Education Act of 1994 (see [Chapters 50 and 51](#)). They are generally recognized as safe unless proven otherwise by FDA. Nonprescription drugs, conversely, are regulated as drugs by FDA and must adhere to more stringent regulations of safety, efficacy, and quality.

The majority of drugs currently considered safe and efficacious for weight loss are restricted to prescription-only status and include benzphetamine (Didrex), diethylpropion (Tenuate), mazindol (Sanorex), methamphetamine (Desoxyn), orlistat (Xenical), phendimetrazine (Bontril), phentermine (Ionamin), phentermine/topiramate (Qsymia), and lorcaserin (Belviq). Sibutramine (Meridia) was removed from the U.S. market in October 2010. Of note, both phentermine/topiramate and lorcaserin were only recently approved by FDA in an effort to provide practitioners with some additional prescription options to promote weight loss. The reader is directed to standard references for more information about these drugs.

Orlistat was approved by FDA as a prescription weight-loss medication (Xenical) in 1999 and as a nonprescription weight-loss medication (Alli) in 2007.<sup>37</sup> The prescription strength of orlistat is approved for use in patients ages 12 years and older, whereas the nonprescription medication is approved for those ages 18 years and older.

GlaxoSmithKline Consumer Healthcare provides free support to those using Alli through an individually tailored online plan called myalliplan ([www.myalli.com](http://www.myalli.com)). The Alli starter pack provides reference guides to help patients follow the program as well as information for joining the online plan. FDA issued a public warning in 2012 about a counterfeit version of Alli being sold on the Internet that was illegal and unsafe. Tips on how to recognize the counterfeit product and further information can be found at the FDA Web site.<sup>38</sup>

Orlistat aids in weight loss by decreasing absorption of dietary fats. It inhibits gastric and pancreatic lipases and specifically reduces absorption of fat by inhibiting hydrolysis of triglycerides.<sup>39</sup> It is recommended for use along with a reduced-calorie, low-fat diet and exercise program. The labeling for the prescription product states that the drug is indicated for obese patients with a BMI of 30 or higher or for patients with a BMI of 27 or higher who also demonstrate risk factors such as diabetes, hypertension, or dyslipidemia. The labeling for the nonprescription product simply states that the drug is indicated for use in overweight adults, which by the standard definition would be persons with a BMI of 25 or higher.<sup>39</sup>

The recommended dosage of prescription-strength orlistat is 120 mg three times a day before meals containing fat; at this dosage, it inhibits dietary fat absorption by about 30%.<sup>39</sup> The nonprescription form of the drug is recommended at a dosage of 60 mg three times a day before meals containing fat; its inhibition of fat absorption may be less. With either dosage of orlistat, there is increased risk of greasy diarrhea as the amount of fat increases in a meal. Because of its mechanism of action, there is no need to give the drug with a fat-free meal.

Most studies have used the 120 mg dosage in combination with a reduced-calorie diet and have reported modest weight losses, especially during the first 6 months of therapy. This dosage may also be useful for weight-loss maintenance following initial weight loss. In one of the few full-text studies published with the 60 mg nonprescription dose, weight loss after 16 weeks in the active drug group was significantly greater than in patients receiving placebo (3.05 kg versus 1.90 kg;  $p < .001$ ).<sup>40</sup> The nonprescription product labeling notes that most patients lost 5-10 pounds (about 2-5 kg) over 6 months in clinical trials. Patients receiving orlistat have had significantly greater reductions in LDL cholesterol and blood pressure compared with placebo. Effects on lipid levels may be independent of weight loss, whereas the changes in blood pressure are probably largely due to weight loss. Orlistat in the 120 mg dosage has been shown to be effective in preventing and delaying development of type 2 DM over a 4-year period in patients with impaired glucose tolerance,<sup>41</sup> and it resulted in significant weight loss and weight-loss maintenance in obese patients with chronic kidney disease.<sup>42</sup>

Orlistat may decrease absorption of fat-soluble vitamins (A, D, E, and K). It is recommended that patients taking this medication take a multivitamin once daily at bedtime or separated by at least 2 hours from an orlistat dose. Orlistat is minimally absorbed and therefore exhibits little systemic toxicity. Common GI side effects are caused by the increased fat present in the GI tract and include flatulence with oily spotting, loose and frequent stools, fatty stools, and fecal urgency and incontinence. Decreasing the amount of ingested fat can minimize these effects. These side effects are expected to be less common with the nonprescription dosage compared to the prescription dosage, and they generally improve within a few weeks of initiating therapy.

Drug interactions with orlistat are unlikely because of the drug's limited absorption. A theoretical concern exists when a patient is taking both orlistat and warfarin because of the potential for orlistat to decrease vitamin K absorption; close monitoring of the international normalized ratio (INR) is recommended with concomitant use of these medications. Orlistat should be avoided in patients receiving cyclosporine; reductions in cyclosporine plasma concentrations have been noted. Patients with malabsorption disorders should avoid taking orlistat, and patients with a history of thyroid disease, cholelithiasis, nephrolithiasis, or pancreatitis should consult their primary care provider before taking orlistat. In addition, the package label advises patients taking medications to treat diabetes to consult a doctor or pharmacist before using orlistat. In May 2010, FDA required labeling changes of both the prescription and nonprescription strengths of orlistat because of rare cases of severe liver injury. The following statement was added to the package inserts: "Patients should stop use of orlistat and contact their healthcare professional if they develop the signs and symptoms of liver injury, including itching, yellow eyes or skin, dark urine, light-colored stools, or loss of appetite."<sup>43</sup> This action by FDA was based on 13 reported cases of severe liver injury with orlistat, including one case in the United States associated with the nonprescription strength. There has been concern about potential associations between orlistat and development of breast and colon cancers. However, FDA concluded there was not a causal relationship between orlistat and cancer.<sup>44</sup>

Nonprescription orlistat may be useful as an adjunct to lifestyle changes in helping patients lose modest amounts of weight. Results will be more favorable when this agent is combined with a reduced-calorie, low-fat diet and increased physical activity. Orlistat has the ability to help change people's eating habits. Rather than suppressing the appetite, an effect that goes away once the drug is discontinued, orlistat helps people choose food with less fat content, resulting in fewer side effects. Once the drug is discontinued, these people should be able to continue to make these healthier food choices. Patients should be aware that the GI side effects of the medication are likely to be exacerbated by concomitant ingestion of a low-carbohydrate, high-fat diet. There is some concern that this nonprescription agent may be misused, particularly by adolescents; it would be prudent for health care providers to watch for adolescents purchasing this medication. Orlistat is rated pregnancy category X and is contraindicated in pregnancy because weight loss offers no potential benefit to a pregnant woman and may result in fetal harm. It is not known if orlistat crosses into human milk. Caution should be exercised when orlistat is administered to a nursing mother. The safety and effectiveness of the nonprescription orlistat product have not been established for patients younger than age 12. Clinical studies of orlistat did not include sufficient numbers of patients ages 65 years and older to determine whether they respond differently from younger patients. No dosage adjustment is recommended in patients with renal or hepatic dysfunction.

#### Use of Inappropriate Medications for Weight Loss

Individuals seeking to lose weight will sometimes turn to inappropriate, potentially dangerous methods to induce loss, such as using laxatives or diuretics. The risks associated with laxatives and diuretics are discussed in [Chapters 15 and 9](#), respectively.

#### Reformulated Weight-Loss Products

Since FDA ruling on ephedra-containing dietary supplements, many manufacturers are including bitter orange (*Citrus aurantium*) in weight-loss medications, often in combination with sources of caffeine such as cola nut (*Cola acuminata* or *Cola nitida*), guarana (*Paullinia cupana* or *Paullinia sorbilis*), or maté (*Ilex paraguariensis*). Bitter orange contains synephrine, which is structurally similar to epinephrine, and octopamine, which is similar to norepinephrine. Bitter orange is being touted as a safe alternative to ephedra in many herbal weight-loss products. Although adrenergic effects of synephrine

and octopamine have the potential for appetite suppression and lipolysis, these products also carry the same potential health risks as ephedra. A randomized, double-blind, placebo-controlled study of single doses of *C. aurantium* in healthy adults reported significant increases in heart rate and blood pressure compared with placebo. The authors state that the effects likely are due to a combination of *C. aurantium*, caffeine, and other stimulants contained in the multicomponent preparation.<sup>45</sup> Clinical trials of *C. aurantium* for weight loss have failed to support efficacy for this indication. Numerous nonprescription weight-loss products list multiple ingredients, many of which are herbal extracts with varying active ingredients, together with vitamins and minerals. Many of these ingredients lack any scientific evidence for usefulness in weight loss. To confuse matters even more, many of the herbal extracts are listed by their common or not-so-common names (e.g., bitter orange, Seville orange, and sour orange are all common names for *C. aurantium*), and many do not list the botanical name, making it difficult to determine exactly what the herbal product contains. The majority of these products have not been clearly demonstrated to be effective or safe, and many have been associated with serious adverse effects. Health care providers are advised to carefully review the labels of all dietary supplement weight-loss products to determine the risk for adverse reactions and drug-supplement interactions.

### Herbal Products

A summary of botanicals commonly used in weight-loss supplements is provided in [Table 26-4](#).<sup>46,47,48,49</sup> Many of these supplements also contain vitamins and minerals, presumably to ensure adequate intake of these essential nutrients by patients on low-caloric diets. In addition, the majority of these supplements contain multiple ingredients with several purported actions, although the advertising claims frequently focus on one solitary ingredient or action or both. To further complicate the problem, many of the supplements contain “proprietary blends.” Ingredients of proprietary blends must be listed, but their amounts do not have to be specified. It is important to note, however, that none of these ingredients have sufficient scientific evidence to support their usefulness in weight loss. Broadly speaking, the ingredients of weight-loss supplements can be categorized as follows:

- Stimulants and energy boosters and thermogenic aids claim to increase basal metabolism, increase energy, and counteract fatigue (e.g., caffeine and bitter orange).
- Fat and carbohydrate modulators claim to alter fat or carbohydrate metabolism or both, resulting in decreased body fat mass and increased lean muscle mass (e.g., green tea, chromium, and garcinia).
- Appetite suppressants and satiety promoters claim to decrease caloric intake by suppressing appetite or promoting satiety (e.g., guar gum, glucomannan, and psyllium).
- Fat absorption blockers claim to block intestinal absorption of dietary fat (e.g., chitosan).
- Carbohydrate absorption blockers claim to block intestinal absorption of dietary carbohydrates (e.g., kidney bean extract and mung bean extract).
- Cortisol blockers claim to block stress-induced release of cortisol, which is claimed to cause increased appetite and fat storage (e.g., beta-sitosterol, phosphatidylserine, and theanine).
- Laxatives (e.g., cascara sagrada and psyllium) claim to promote weight loss by increasing fecal loss.
- Diuretics (e.g., dandelion and caffeine) claim to promote weight loss by increasing urination.

Herbal laxatives and diuretics are often included in multiple-ingredient dietary supplements marketed for weight loss. For example, “dieter’s” or “slimming” teas contain a variety of botanical laxatives and diuretics. Diuretics, whether herbal or drug, may result in an initial transient weight loss, but this effect lasts only a few days. Herbal or drug laxatives typically act in the colon and, therefore, will not decrease caloric absorption in the small intestine, which is the primary site of food absorption. Many of these botanicals are stimulant laxatives that should be used for only 1-2 weeks at a time. Prolonged use may lead to electrolyte imbalances and dependence on the laxative for regular bowel movements (cathartic colon), as discussed in [Chapter 15](#).

**TABLE 26-4 Complementary Therapies Commonly Used for Weight Loss**

<b>Agent</b>	<b>Risks</b>
<b>Stimulants, Energy Boosters, and Thermogenic Aids</b>	
Bitter orange ( <i>Citrus aurantium</i> )	Synephrine may cause hypertension, cardiovascular toxicity, myocardial infarction, stroke, and seizure.
Caffeine: Cola nut ( <i>Cola acuminata</i> , <i>Cola nitida</i> ), green tea ( <i>Camellia sinensis</i> ), guarana ( <i>Paullinia cupana</i> , <i>Paullinia sorbilis</i> ), maté ( <i>Ilex paraguariensis</i> )	Caffeine may cause GI distress, nausea, dehydration, headaches, insomnia, nervousness, anxiety, muscle tension, heart palpitations, hypertension, addiction, decreased appetite, vertigo, and possible genetic damage; avoid in patients with gastric ulcers. Use with caution in patients with renal disease, panic disorder, hyperthyroidism, anxiety, or susceptibility to spasm; use only under medical supervision in patients with peptic ulcers, cardiovascular disease, or blood-clotting abnormalities; discontinue use at least 24 hours before surgery; may alter effects of anticoagulant medications.
<b>Fat and Carbohydrate Modulators</b>	

Chromium	Chromium is generally well tolerated at low doses. Rhabdomyolysis and renal failure may occur with large doses. May cause mood and sleep changes, headaches, and cognitive and perception dysfunction. Evidence of benefit of chromium picolinate is inconsistent and controversial.
Conjugated linoleic acid (CLA)	CLA causes GI upset.
Garcinia or brindleberry ( <i>Garcinia cambogia</i> )	Hydroxycitric acid may cause GI distress with high doses; not recommended in patients with diabetes mellitus or dementia.
Green coffee	Green coffee is generally well tolerated. Green coffee extract contains caffeine (see Caffeine, listed above). No long-term, high-quality studies have been published, and available evidence of benefit is conflicting.
Green tea ( <i>Camellia sinensis</i> )	See Caffeine, listed above.
Licorice ( <i>Glycyrrhiza glabra</i> )	Pseudoaldosteronism, hypertension, and hypokalemia may occur.
Pyruvate	GI upset may occur.
<b>Appetite Suppressants and Satiety Promoters</b>	
Glucomanan ( <i>Amorphophallus konjac</i> )	Risks are similar to those of plantain. No large, well-designed studies have been published, and available evidence of benefit is conflicting.
Guar gum ( <i>Cyamopsis tetragonolobus</i> )	Risks are similar to those of plantain.
Hoodia ( <i>Hoodia gordonii</i> )	No risks are reported. Although unpublished trials suggest a reduced caloric intake in patients taking hoodia, there is a general lack of well-conducted clinical evidence to support the use of hoodia for weight loss.
Plantain or psyllium ( <i>Plantago lanceolata</i> , <i>Plantago major</i> , <i>Plantago psyllium</i> , <i>Plantago arenaria</i> )	Flatulence, GI distress, nausea, and vomiting may occur; plantain may interact with lithium or carbamazepine.
<b>Fat Absorption Blockers</b>	
Chitosan	Chitosan is generally well tolerated; may cause GI upset, flatulence, nausea, increased stool bulk, constipation; may exhibit cross-sensitivity in patients with shellfish allergies.
Green coffee	See comments under Fat and Carbohydrate Modulators.
Raspberry ketones extract ( <i>Rubus idaeus</i> )	No reliable information about adverse effects of raspberry extract is available. The active ingredient is structurally similar to phenylephrine; see Bitter Orange, listed above.
<b>Carbohydrate Absorption Blockers</b>	
Ginseng ( <i>Panax</i> sp.)	Ginseng may cause nervousness, excitation, inability to concentrate, estrogenic effects, Stevens-Johnson syndrome, allergy, and hypoglycemic effects; may interact with several drugs including warfarin, digoxin, alcohol, and phenelzine.
<b>Laxatives and Diuretics</b>	
Cascara sagrada ( <i>Rhamnus purshiana</i> )	Abdominal pain, cramps, and diarrhea may occur; chronic use can lead to potassium depletion, disturbed heart function, and muscle weakness; avoid in patients taking digoxin or potassium-depleting diuretics.
Dandelion ( <i>Taraxacum officinale</i> )	Avoid use in patients with allergies to ragweed, marigolds, etc. (Asteraceae/Compositae family); contraindicated in patients with gallbladder or bile-duct obstruction, or with bowel obstruction or pus in the pleural cavity.
<b>Miscellaneous</b>	
Calcium	Constipation, nausea, and vomiting may occur; possibly effective when ingested as naturally occurring calcium in foods, but not when used as a dietary supplement.
Guggul ( <i>Commiphora mukul</i> )	GI distress, diarrhea, nausea, and skin rash may occur; use only under medical supervision in patients with hyperthyroidism; may alter effects of thyroid

	medications, cholesterol-lowering medications, anticoagulants, antiplatelet medications, propranolol, and diltiazem.
Pyruvate	No risks are reported.
Willow bark ( <i>Salix alba</i> )	Willow bark is a salicin source; no risks reported when taken orally.

Key: GI = Gastrointestinal.

Source: References 46-49. Also see [Chapter 51](#) for additional related information.

Herbal sources of caffeine have often been used in combination with ephedra and willow bark (as a source of salicin) for weight loss because of purported synergistic effects. This combination is often referred to as a “fat-burning stack” or “ECA” (ephedrine-caffeine-aspirin), with claims of additive thermogenic or heat-producing effects.<sup>48,49</sup> However, adverse reactions to these products, either alone or in combination, range from relatively mild symptoms, such as headache, nervousness, and hypertension, to more severe reactions, such as stroke, myocardial infarction, and sudden death. In several cases, significant adverse events occurred in otherwise healthy young or middle-aged adults, and many occurred following consumption of relatively low doses for short periods.<sup>48,49</sup>

#### Economically Motivated Adulteration

Although adulteration of medications is not a new concept, it is of increasing concern in the dietary supplement industry. A working definition of economically motivated adulteration proposed by FDA is the “fraudulent, intentional substitution or addition of a substance in a product for the purpose of increasing the apparent value of the product or reducing the cost of its production, i.e., for economic gain.”<sup>50</sup> For example, a recent examination of a hoodia weight-loss product determined the material was actually derived from cacti and contained no hoodia.<sup>51</sup> FDA tracks tainted supplements; the most common issue related to weight-loss supplements is the undisclosed inclusion of sibutramine, a prescription weight-loss medication that was voluntarily withdrawn from the U.S. and Canadian markets because of an increased risk of heart attack and stroke in patients with concomitant CVD.<sup>52</sup> Economic adulteration, whether intentional or unintentional, is of particular concern in the weight-loss dietary supplement industry because increasing numbers of cases with the potential for causing serious adverse events are appearing in the literature.

#### Assessment of Overweight and Obesity: A Case-Based Approach

When health care providers are asked to recommend a weight-loss method or product, they should determine the patient’s motivation for weight loss. The reason may be immediately obvious for some patients; others may want to lose a few pounds to improve their appearance or to enhance their perception of good health. The provider should perform a waist circumference test and calculate the BMI to assess the patient. The provider should review current prescription and nonprescription drugs and ask about use of herbal products and other dietary supplements.

The provider should assess what weight-loss strategies were used previously and whether the attempts were successful. Part of this assessment also includes any dietary counseling or physical activity training the patient may have received in the past. The patient’s support system should be taken into consideration; support from family and friends is a critical component for success. Likewise, cultural backgrounds should be considered, as cultural and social factors have a strong effect on food decisions. Such factors should not be seen as insurmountable obstacles. The provider can serve an important role to motivate and encourage the patient in weight loss.

Using all information obtained during the assessment, the provider can decide whether weight loss is appropriate and, if warranted, can help select the type, intensity, and length of a weight-loss program. Patients with significant comorbid conditions in addition to obesity should be discouraged from using dietary supplements. Individuals within the normal height and weight range who want to lose weight for other reasons (e.g., improved appearance or sense of well-being) should be advised about the difficulty of the task and the potential adverse physical and psychological effects; often these individuals can be refocused to engage in healthy exercise activities that will attain the results they are seeking.

Cases 26-1 and 26-2 illustrate assessment of patients who seek assistance with weight control.

#### Case 26-1

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient’s symptoms and medical history, including:	

a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient has been overweight since childhood. She has never been severely obese but typically gains a few pounds each year. Her obese status does not significantly affect her ability to perform her activities of daily living.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient eats when stressed. She snacks while watching television at night as well as at her desk at work.
c. description of the patient's efforts to relieve the symptoms	Patient has tried various diet and exercise programs over the past 20 years. These usually result in a 5- to 10-pound weight loss; she then typically gains weight back when she gets bored with the regimen or gets stressed by work.
d. patient's identity	Rhonda Price
e. age, sex, height, and weight	42 years old, female, 5 ft. 5 in., 185 lb.
f. patient's occupation	Secretary
g. patient's dietary habits	Usually eats a bagel for breakfast. Sometimes takes leftovers for lunch and sometimes eats out with coworkers. Typically fixes a well-balanced meal for her family for dinner; fixes a rich dessert once or twice a week. Patient states that she has a "weakness" for chips, which she frequently eats while watching television at night.
h. patient's sleep habits	Goes to bed late and gets up early; averages about 5.5 hours of sleep per night during the week and 7-8 hours on the weekends.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	No current prescription medications. Takes ibuprofen occasionally for aches and pains and famotidine for heartburn.
j. allergies	NKA
k. history of other adverse reactions to medications	None
l. other (describe) _____	Does not engage in regular exercise. When she goes on a diet, she may make an effort to walk a mile at lunchtime during the work week.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Patient's BMI is 31, placing her in the obese category (Table 26-1). Poor dietary habits, inadequate sleep, and lack of exercise probably contribute.
3. Identify exclusions for self-treatment (Figure 26-3).	None identified.
4. Formulate a	Options include:

comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	<p>(1) Refer Rhonda to a dietitian and personal trainer for diet and exercise advice, respectively.</p> <p>(2) Refer Rhonda to reputable Web sites such as <a href="http://choosemyplate.gov">choosemyplate.gov</a> for tracking food intake and exercise and for advice on these.</p> <p>(3) Refer Rhonda to a support group such as Weight Watchers.</p> <p>(4) Counsel Rhonda on diet and exercise.</p> <p>(5) Recommend a dietary supplement for weight loss.</p> <p>(6) Recommend orlistat.</p> <p>(7) Take no action.</p>
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The patient chooses to try nonprescription orlistat while also trying to lower her caloric intake, mostly by cutting back on bread, pasta, chips, and desserts. She agrees to try to get exercise in sustainable ways throughout the day, such as parking farther away from work and taking a short walk during lunch or after work most days of the week. During inclement weather, she identifies that she could climb the five stories of steps a couple of times a day for exercise. She is encouraged to enlist fellow coworkers or friends who need to lose weight to join her in an informal or formal weight-loss support group.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Take orlistat up to 3 times a day before meals that contain fat. Skip the dose if a meal contains no fat."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Orlistat should not be used as the sole method for weight loss but should be combined with a lower-calorie diet and increased physical activity."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. appropriate dose and frequency of duration	"Take 60 mg up to 3 times a day."
b. maximum number of days the therapy should be employed	"The biggest weight loss is usually seen within the first 6 months of therapy. Decreased serum cholesterol and blood pressure may accompany weight loss."
c. product administration procedures	"Take before meals that contain fatty foods. Spreading dietary fat among 3 meals a day, plus minimizing the amount of dietary fat should help minimize gastrointestinal side effects, such as oily discharge and gas. Taking a multivitamin supplement at bedtime (separated from orlistat) is recommended, as orlistat can cause malabsorption of fat-soluble vitamins."
d. expected time to onset of relief	"Some weight loss should occur within 2 weeks of initiating orlistat therapy, especially if diet and exercise regimens are being followed."
e. degree of relief that can be reasonably expected	"Loss of 5-10 pounds during the first 6 months of therapy is a common outcome."

f. most common side effects	“Flatulence, oily spotting, loose and frequent stools, fatty stools, fecal urgency, and fecal incontinence may be experienced. These can be minimized by decreasing dietary fat and also tend to decrease with time.”
g. side effects that warrant medical intervention should they occur	“Because of rare reports of liver toxicity, you should contact your primary care provider immediately if itching, yellow eyes or skin, dark urine, or loss of appetite occurs.”
h. patient options in the event that condition worsens or persists	“Consult a dietitian or personal trainer for diet and exercise advice. Consult with primary care provider about prescription therapy for weight loss.”
i. product storage requirements	None
j. specific nondrug requirements	“Dietary caloric restriction and exercise are of paramount importance. Find exercise that is enjoyable and sustainable. Try to spend more time standing rather than sitting throughout the day and especially in the evening. Attempt to reduce stress and thus stress eating. Keep healthy snacks such as fruits and vegetables in the house for nighttime snacking instead of eating chips. Consider cutting down on making desserts and serve fresh fruit instead. Too little sleep has been associated with increased body weight, so sleep hygiene measure may be helpful.” (See <a href="#">Chapter 46</a> .)
Solicit follow-up questions from the patient or caregiver.	“Can I double the dose of medication if weight loss slows?”
Answer the patient’s or caregiver’s questions.	“Dosage above 60 mg up to 3 times a day should be attempted only under the supervision of a primary care provider.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Ask Rhonda to weigh herself twice a week and record these values. She should return to you in a month to show you her progress and to discuss her diet and exercise regimen. A weight loss of a few pounds over the first month should be considered a success.

Key: BMI = Body mass index; NKA = no known allergies.

### Case 26-2

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient’s symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient is concerned about her weight and overall appearance. She has been considered overweight since kindergarten. She wants to lose around 30 pounds by the time of her eighth-grade semiformal dance, which is in 6 months.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient’s symptom(s)	Patient mimics her brothers when it comes to foods: she likes potato chips, nachos, soda, and pizza. She also eats a lot of rice and beans.

c. description of the patient's efforts to relieve the symptoms	Patient has not tried to lose weight in the past because her parents have thought her to be a healthy weight.
d. patient's identity	Angel Marquez
e. age, sex, height, and weight	13 years old, female, 5 ft 3 in., 185 lb
f. patient's occupation	Eighth-grade student
g. patient's dietary habits	She typically eats a hot breakfast with her family, which often includes beans, tortillas, and eggs or burritos with chorizo and beans. She usually eats lunch at the lunch cafeteria. She often gets potato chips and a soda from a snack machine in the afternoon. She has a big dinner every night with her family, often including dessert.
h. patient's sleep habits	Averages about 7-8 hours a night
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Multivitamin once daily
j. allergies	NKA
k. history of other adverse reactions to medications	None
l. other (describe) _____	Patient participates in physical education classes at school twice a week. She has no other regular exercise activity. Patient is Hispanic, and both of her parents are overweight.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Patient's BMI is 32.8 k, placing her in the obesity category ( <a href="#">Table 26-1</a> ). This places her at increased risk for type 2 DM, high cholesterol, hypertension, sleep apnea, and orthopedic problems during adolescence and adulthood if her weight is not normalized. Having daily sodas, regularly consuming fatty and salty snacks, and eating heavy breakfasts and dinners, together with minimal physical activity, are contributing to her weight problem. Her cafeteria lunches may also be a contributing factor.
3. Identify exclusions for self-treatment ( <a href="#">Figure 26-3</a> ).	Age younger than 18 years is an exclusion for self-treatment.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Angel to a PCP for a health screen. (2) Refer to a dietitian and personal trainer for diet and exercise advice, respectively. (3) Recommend nonprescription orlistat. (4) Recommend a dietary supplement weight-loss product. (5) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the	Refer the patient to a PCP for a health screen.

patient's problem, taking into account patient preferences.	
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Your primary care provider may refer you for a health screen, or the provider could also offer prescription-strength orlistat."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"You need to see your provider to determine if a diet and exercise program is appropriate. Healthy eating habits and exercise are the mainstays of successful weight loss, and these should be a lifelong goal."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"Is there an OTC medication that might work?"
Answer the patient's or caregiver's questions.	"No OTC medications are approved or appropriate to recommend in a patient younger than age 18 without referral from a primary care provider."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact the patient in a day or two to ensure she made an appointment and sought medical care.

Key: BMI = Body mass index; DM = diabetes mellitus; N/A = not applicable; NKA = no known allergies; OTC = over-the-counter; PCP = primary care provider.

### Patient Counseling for Overweight and Obesity

The objectives for counseling patients who want to lose weight are to foster realistic goals for weight loss together with promoting a healthy restricted-calorie diet and increased physical activity. The ultimate goal is to achieve a healthy weight and maintain that weight over the long term. For patients unable to lose weight, the objective is to prevent further weight gain. The box Patient Education for Overweight and Obesity lists specific information for patients.

### Evaluation of Patient Outcomes for Overweight and Obesity

Successful weight loss generally requires a lifelong approach that combines healthy eating and exercise patterns. Realistic weight-loss goals of 5-10% of the initial weight over 6 months, or 1-2 pounds per week, should be encouraged. During any weight-loss program, the patient should be monitored for healthy eating and exercise patterns, and, at a minimum, blood pressure should be routinely measured. More extensive physical examinations and laboratory measures may be indicated, particularly in patients with comorbid conditions such as hypertension or type 2 DM. Follow-up with patients attempting weight loss should be encouraged, preferably monthly or quarterly. In addition to measuring weight at follow-up visits, the health care provider should explore eating habits and exercise patterns with the patient, especially if weight loss is not being achieved. Goals that were set should be reexamined and followed up by the provider, with new goals or modifications set as appropriate. Referral to a dietitian or personal trainer may be helpful. Following weight loss, emphasis should be placed on the importance of maintaining the weight loss by continuing healthful dietary and exercise habits. Referral for pharmacologic therapy or consideration of bariatric surgery may be an option for patients with more significant obesity who fail to lose weight through lifestyle interventions.

### Key Points for Overweight and Obesity

- A reasonable goal for weight loss in most overweight and obese subjects is a 5-10% loss over 6 months.

- Although this amount of weight loss may not result in the cosmetic effect desired by the dieter, it is associated with a reduction in risk for chronic disease.
- The safest approach to losing weight entails combining a reduced-calorie diet with increased physical activity.
- Physical activity typically needs to be something the person enjoys if it is to be sustained over long periods of time.
- A key to sustained weight loss is modification of behavior related to eating and exercise.
- If nonprescription or dietary supplement products for weight loss are used, they should be continuously assessed for efficacy, safety, and tolerance. All health care providers should be informed of the product(s) used. Labels of nonprescription or dietary supplement weight-loss products should be carefully reviewed to determine the risk for adverse reactions and drug-supplement interactions.

#### Patient Education for Overweight and Obesity

The objectives of self-treatment are to (1) foster realistic weight-loss and exercise goals, (2) maintain a healthy weight, and (3) prevent further weight gain. Carefully following the self-care measures listed here, together with continued adherence to a safe and effective weight-loss program, will help ensure optimal therapeutic outcomes.

#### Health Risks of Obesity

- Health risks related to overweight and obesity include the following:
  - Coronary heart disease
  - Type 2 diabetes mellitus
  - Sleep apnea
  - Elevated serum triglycerides and dyslipidemia
  - Hypertension
  - Stroke
  - Gallbladder disease
  - Osteoarthritis
  - Certain types of cancers

#### Nondrug Treatment Guidelines

- Focus on small, gradual changes in eating and exercise patterns.
- Maintain realistic goals for weight loss and increased activity levels.
- Eat a low-calorie balanced diet.
- Eat meals at the table, and do nothing else while eating (no television, etc.).
- Set a regular eating schedule, and avoid skipping meals.
- Eat slowly and enjoy the food.
- Put down your fork or spoon between bites.
- Try to leave some food on your plate each time you eat.
- Wait 5 minutes before going back for extra helpings of food.
- Remove serving dishes from the table after the first servings have been made.
- Leave the table or at least clear food from the table after eating.
- Use smaller plates so moderate servings do not appear too small.
- Start a meal with a broth-based soup (low salt) to help you feel fuller.
- Strive to consume at least five servings a day of fruits and vegetables.
- Keep on hand healthful snacks such as fruits and vegetables, low-fat cheese and yogurt, and frozen fruit juice bars.
- Drink at least eight glasses of noncaloric beverages each day to help you feel full.
- When you experience a craving, try doing something else, such as going for a walk; cravings generally pass within minutes.
- Shop for food immediately after a meal, and use a prepared list.
- Gradually increase your activity level, with the goal of engaging in 60 minutes of moderate-intensity physical activity most days of the week.
- Increase your lifestyle activity: walk and stand more, climb stairs, and park farther from your destination.
- Limit the amount of time spent watching television, playing video games, or using the Internet.
- Keep a diary of your weight, physical activity, and caloric intake so you can see your progress and success.

#### Drug Management Guidelines

- Avoid taking nonprescription drugs and supplements marketed for weight loss, with the exception of orlistat. They are not proven to work, and they can cause significant side effects.
- If you do decide to take one of these products, make sure to notify your primary care provider and pharmacist so you can be adequately followed for potential side effects and interactions with drugs.

**Handbook of Nonprescription Drugs > Chapter 27. Ophthalmic Disorders****Ophthalmic Disorders: Introduction**

The nonprescription ophthalmic market consists of products that treat a wide range of disorders. Little population-based data are available on the epidemiology of these disorders. People with ocular conditions are commonly seen in the primary care provider's office, the emergency department, the eye care provider's office, or the pharmacy. Ocular discomfort associated with dry eye disease may be the most common condition for which nonprescription ophthalmic products can be used. Dry eye disease may affect as many as 5 million people in the United States ages 50 years and older.<sup>1</sup>

Many common conditions that cause ocular discomfort are minor and self-limiting. In some instances, however, relatively minor symptoms may be associated with severe, potentially vision-threatening conditions. Health care providers should be well versed in eye anatomy and physiology (as well as in common ocular conditions) so they can provide the best possible guidance for patients who want help choosing between self-treatment and professional medical care.

Self-treatable ophthalmic disorders occur primarily on the eyelids; however, a few disorders of the eye surface may be responsive to self-treatment. The latter include dry eyes, allergic conjunctivitis, diagnosed corneal edema, presence of loose foreign debris, minor ocular irritation, and the cleaning or lubricating of artificial eyes. *Careful assessment is important*, especially with ongoing symptoms, to rule out more complicated manifestations that may require referral to an eye care specialist.

**Role of Eye Anatomy in Ocular Drug Pharmacokinetics**

The external location and exposure of the eye make it susceptible to environmental and microbiologic contamination. The eye has many natural defense mechanisms to protect it against contamination, however, and the eyelid is one of its major protective elements (Figure 27-1).

The eyelids are a multilayer tissue covered externally by the skin and internally by a thin, mucocutaneous epithelial layer called the palpebral conjunctiva. The middle portion of the eyelid contains glandular tissue and muscles for lid movement. The glandular tissue found within the eyelid, along with conjunctival goblet cells, secretes the bulk of nonstimulated tears.

The eyelids primarily protect the anterior surface of the eye and spread the tears produced by the glandular tissue over the ocular surface. The lids force the flow of tears toward the nose and into the drainage canals located in the upper and lower eyelids. The drainage canals converge, forming the lacrimal sac between the inner eyelid and nose. The lacrimal sac is drained by a canal opening just below the inferior turbinate of the nasal cavity. A highly vascularized epithelium lines the lacrimal drainage system, and absorption into the systemic circulation along this pathway gives rise to the potential systemic effects of topically administered eye medications.<sup>2</sup>

The tear layer keeps the ocular surface lubricated, provides a mechanism for removing debris that touches the ocular surface, and has potent antimicrobial action provided by specific enzymes and a number of immunoglobulins (including the most prevalent, immunoglobulin A). The tear layer is a complex, multilayer film. The outer lipid layer maintains the eyes' optical properties and reduces evaporation. The middle aqueous layer is largely responsible for the wetting properties of the tear film. The inner mucinous layer allows the outer lipid and middle aqueous layers to maintain constant adhesion across the cornea and conjunctiva. Abnormalities within any one of the tear layers can result in ocular discomfort.

Tears are produced at a rate of 1-2  $\mu\text{L}$  per minute, with a turnover of approximately 16% of the total volume per minute.<sup>3,4</sup> As much as 25% of the total tear volume is lost to evaporation.<sup>3</sup> An ambient tear volume of approximately 7-10  $\mu\text{L}$  is found on the ocular surface at any point in time.<sup>3</sup> During episodes of ocular irritation, reflex tearing is stimulated by the lacrimal gland found underneath the outer portion of the upper eyelid, and tear production increases to greater than 300% of the nonstimulated production rate.<sup>5</sup> Reflex tearing occurs immediately on instillation of a drug into the eye, diluting the drug's concentration. Drug penetration into the eye is reduced because of increased lacrimal drainage and tearing that falls down the cheek. Studies have shown that as much as 90% of an instilled dose of a drug administered to the eye may be lost.<sup>6</sup>

The visible external portion of the eye is composed of the noninnervated sclera and the innervated cornea. The sclera is a tough, collagenous layer that gives the eye rigidity and encases the internal eye structures. The visible sclera is covered by two epithelial layers: the episclera and the bulbar conjunctiva. The bulbar conjunctiva is contiguous with the palpebral conjunctiva at the junction between the eyelid and the ocular surface (the fornix). The episcleral and bulbar conjunctival layers (which contain the vascular and lymphatic systems of the anterior eye

surface) are the sources of visible eye redness in ocular irritation or inflammation.

Anatomy of the eyelid and eye surface.

The cornea is an aspherical, vascular tissue that is the principal refractive element of the eye. The cornea is approximately 12 mm wide and 0.5 mm thick and consists of five distinct layers. Of the five corneal layers, the pharmacokinetics of ocularly administered drugs is affected by the outermost epithelium layer, the middle and most abundant stromal layer, and the innermost endothelial layer. The corneal epithelium is lipophilic and facilitates the passage of fat-soluble drugs. However, if a drug is too lipophilic, it may become trapped in the corneal epithelium. The epithelium is often the rate-limiting step in absorption of medication into the anterior chamber. The corneal stroma is hydrophilic and allows the passage of water-soluble drugs.

Damage to the corneal epithelium may often increase drug absorption rates. Comparative studies with intact and compromised epithelium have shown that drug penetration into the aqueous humor may be increased as much as threefold in corneas with compromised epithelium.<sup>7</sup> Corneal epithelium can be compromised by trauma, routine contact lens wear, topical ocular anesthetics, and thermal or ultraviolet (UV) light exposure.

Directly behind the cornea is the anterior chamber, a cavity filled with aqueous humor. The aqueous humor maintains the normal intraocular pressure (IOP) and provides nutritional support for the cornea and crystalline lens. The aqueous humor is produced by the ciliary body and is drained from the anterior chamber through the uveoscleral tract and the trabecular meshwork. The trabecular meshwork, which is located at the junction of the cornea and iris, accounts for approximately 80%-90% of aqueous drainage from the anterior chamber. The uveoscleral tract (located posterior to the iris and comprising the sclera, ciliary body, and choroid areas) accounts for approximately 10%-20% of aqueous drainage, although this percentage may vary with age and disease state.

During episodes of internal eye inflammation, inflammatory cells may block the drainage system, causing the IOP to rise. Increased IOP is one of the most significant risk factors for primary open-angle glaucoma. Similarly, during episodes of closed-angle glaucoma, the iris physically blocks the trabecular meshwork, which also results in an increase in IOP. Dilating the pupil with mydriatic drugs may precipitate an angle-closure attack. These attacks often occur as the pupil is returning to its normal state several hours after the mydriatic drug has been instilled. Any agent with anticholinergic or dilating effects has the potential to cause angle closure. The most common symptoms are brow ache or headache, often accompanied by nausea and vomiting. These symptoms are severe enough to cause individuals to visit their eye care providers.

The visible, colored portion of the eye, the iris, is located in the anterior segment of the eye, behind the cornea. It functions in much the same way as an aperture on a camera by regulating the amount of light striking the retina. The central opening in the iris is the pupil. The pupillary diameter is controlled by two opposing muscles within the iris: the sphincter and the dilator. The sphincter muscle runs along circular arcs parallel to the pupillary border and causes a miotic (closing) effect through parasympathetic stimulation. The dilator muscles are radial from the pupillary border and cause a mydriatic (opening) effect through sympathetic stimulation. Prostaglandins released by the iris during episodes of inflammation may affect the sphincter muscle, resulting in constriction of the pupil.

The ciliary body is bordered anteriorly by the iris and is continuous posteriorly with the choroid. In addition to producing aqueous humor, the ciliary body participates in focusing the optical mechanism (lens) for near viewing (a process known as accommodation). During episodes of ocular inflammation, the ciliary muscle may go into spasm, resulting in fluctuating vision and pain. Therefore, inhibition of the ciliary muscle (cycloplegia) with anticholinergic agents is a frequent treatment for internal ocular inflammation.

The vitreous cavity, located in the posterior segment of the eye, is the largest portion of the eye and is filled with vitreous humor. Floating spots in the visual field ("floaters") are related to this area. Floaters are deposits of various shapes, sizes, and motility in the vitreous humor; they may be related to degenerative changes in gel that is normally transparent. Problems in this area are not amenable to self-treatment and require professional evaluation because of the possibility of concurrent retinal problems.

The retina is responsible for the initial processing and transmission of light signals. A number of inflammatory conditions of the retina can occur, and most have prominent symptoms. Some, however, have relatively mild symptoms, mimicking common irritative conditions. Trauma, even minor, may cause the retina to separate from its underlying layer (the pigment epithelium), resulting in retinal detachment. The retinal pigment epithelium provides vital "electrical" support to the retina. Macular degeneration, the leading cause of blindness in the United States, is directly related to atrophy in the pigment epithelium. Diabetic retinopathy also is a major cause of vision loss.

## Dry Eye Disease

### Pathophysiology and Clinical Presentation of Dry Eye

Dry eye disease is among the most common disorders affecting the anterior eye.<sup>1</sup> Most often associated with the aging process (especially with postmenopausal women), dry eye also can be caused by lid defects, corneal defects, loss of lid tissue turgor, Sjögren's syndrome, Bell's palsy, thyroid eye disease, various collagen diseases (e.g., rheumatoid arthritis), and systemic medications. Refractive surgery patients may complain of transient dry eyes for weeks to months after the procedure. This effect is usually mild if it does occur, but it can be more pronounced in some patients. Drugs with anticholinergic properties (e.g., antihistamines and antidepressants), decongestants, diuretics, and beta-blockers are some of the more common pharmacologic causes of dry eye. The condition may be exacerbated by allergens or other environmental conditions (e.g., dry, dusty working situations), or by heating and air conditioning systems that reduce relative humidity, thereby increasing the evaporation of tears.

Dry eye disease is characterized by a white or mildly red eye; patients may complain of a sandy, gritty feeling or a sensation that something is in the eye. Contrary to what the name suggests, dry eye disease often may present with excessive tearing initially. Abnormalities in the tear layer cause less-than-optimal lubrication of the ocular surface, thus producing more inadequate tears and beginning a vicious cycle. Failure to properly diagnose and treat dry eye diseases can result in severe damage to eye tissue, particularly to the corneal surface (see Color Plates, photograph 3). Recent evidence demonstrates that dry eye disease can be linked to a T-cell-mediated inflammatory process, which can respond to immunomodulatory agents (e.g., cyclosporine).<sup>8</sup>

### Treatment of Dry Eye Disease

#### Treatment Goals

The goal in treating dry eye disease is to alleviate and control the dryness of the ocular surface, thereby relieving the symptoms of irritation and preventing possible tissue and corneal damage. Although dry eye disease also has been referred to as "dysfunctional tear syndrome," "keratoconjunctivitis sicca," and "dry eye disease," a recent published report of the International Dry Eye Workshop (DEWS) accepted "dry eye disease" as the most appropriate term.<sup>1,9</sup> The DEWS report, in conjunction with a Delphi panel paper and the recently published preferred practice patterns

from the American Academy of Ophthalmology, has introduced a severity scale and an accompanying set of guidelines for treatment of dry eye disease.<sup>9,10,11</sup>

### General Treatment Approach

The primary self-treatment for dry eye disease is the use of ocular lubricants. However, treatment of mild and moderate dry eye disease also includes other pharmacologic and nonpharmacologic recommendations, including education, environmental modifications, eyelid therapy, elimination of offending topical or systemic medications, and use of systemic omega-3 fatty acid supplements (e.g., flax seed oil; [Table 27-1](#)). The availability of synthetic chemicals suitable for topical application to the eye has resulted in the development of various solutions (artificial tears) to help alleviate dryness of the ocular surface. Artificial tear products vary by viscosity according to the ingredients used in their preparation. Increasing the viscosity of a product results in a more prolonged ocular contact time and greater resistance to tear dilution. Mild cases of dry eye disease may be treated with less viscous products, whereas more severe cases may require more viscous products. Bland (i.e., nonmedicated) ophthalmic ointment (e.g., petrolatum) is another type of ocular lubricant. Because ointment preparations tend to cause blurred vision, they are typically reserved for use only at bedtime or for severe cases of dry eye. As with ointments, the more viscous the tear drops are, the greater their blurring effect becomes. Vitamin A preparations are also available for treating dry eye disease.

Nonpharmacologic measures (e.g., warm compresses; discontinuing any offending agents; eyelid therapy, consisting of warm compresses and eyelid hygiene) may also increase eye comfort for patients with this disorder. The use of omega-3 oils or flax seed oil in the normal doses recommended by the manufacturer is thought to improve lid function, possibly because the products have some anti-inflammatory properties.<sup>9,10,11</sup>

**TABLE 27-1 Treatment Recommendations for Dry Eye Disease by Disease Severity Level**

<b>Mild</b>
Education, environmental modifications
Elimination of offending topical or systemic medications
Aqueous enhancement using artificial tear substitutes, gels/ointments
Eyelid therapy (warm compresses and eyelid hygiene)
Treatment of contributing ocular factors such as blepharitis or meibomianitis
<b>Moderate</b>
Same treatments listed for mild disease plus the following treatments:
Anti-inflammatory agents (topical cyclosporine and corticosteroids, systemic omega-3 fatty acid supplements)
Punctal plugs
Spectacle side shields and moisture chambers
<b>Severe</b>
Same treatments listed for mild and moderate disease plus the following treatments:
Systemic cholinergic agonists
Systemic anti-inflammatory agents
Mucolytic agents
Autologous serum tears
Contact lenses
Correction of eyelid abnormalities
Permanent punctal occlusion
Tarsorrhaphy

Source: Adapted from the American Academy of Ophthalmology Preferred Practice Guidelines at [www.AAO.org](http://www.AAO.org).

Eye care providers treat the most severe cases of dry eye disease with punctal plugs, which occlude the lacrimal drainage system to increase the available tear pool. New understanding of the underlying pathophysiology of dry eye disease suggest that patients may benefit from treatment with topical cyclosporine.<sup>8</sup> However, patients with mild dry eye disease may require relief of only ocular surface dryness, whereas patients with more moderate and severe dry eye disease may benefit from a combined approach of immunomodulating agents (e.g., topical cyclosporine in conjunction with ocular surface lubrication); such patients must be referred to an eye care specialist.

#### Nonpharmacologic Therapy

The primary nondrug measure is avoiding environments that increase evaporation of the tear film. If possible, patients should avoid dry or dusty places. Using humidifiers or repositioning workstations away from heating and air conditioning vents may help alleviate dry eyes. In addition, avoiding prolonged use of computer screens and wearing eye protection (e.g., sunglasses or goggles) in windy, outdoor environments may further help alleviate dry eye problems.

#### Pharmacologic Therapy

Nonmedicated ointments are commonly used in treating minor ophthalmic disorders, including dry eye. Because ointments can cause blurred vision (resulting in severe vision limitations), combination therapy using artificial tears and nonmedicated ointments is usually recommended. Gels offer some advantage to patients because they disturb vision less compared to ointments and are tolerated better. The effectiveness of retinol solutions for treating dry eye remains speculative.

#### Artificial Tear Solutions

Although many advances have been made in understanding the mechanisms involved in tear film formation, the role of tears in maintaining a normal conjunctival and corneal surface is still not completely understood. Lubricants that are formulated as artificial tear solutions consist of preservatives, inorganic electrolytes to achieve tonicity and maintain pH, and water-soluble polymeric systems. The lubricating agents in artificial tear products are similar, but buffering agents, preservatives, pH, and other formulation components may vary (Table 27-2). The newer artificial tear substitutes have important properties, including their ability to stabilize the tear film, protect the corneal and conjunctival cells, reduce tear evaporation with the combination of lipids, and enhance wound healing and lubrication of the ocular surface.<sup>1</sup>

**TABLE 27-2 Commonly Used Nonprescription Ophthalmic Lubricants**

<i>Trade Name</i>	<i>Primary Ingredients</i>
<b>Artificial Tear Solutions</b>	
Bion Tears <sup>a</sup>	Hydroxypropyl methylcellulose 0.3%; dextran 70, 0.1%
Clear Eyes Contact Lens Relief Drops	Sorbic acid 0.25%; EDTA 0.1%; NaCl; hypromellose; glycerin
Dry Eyes	PVA 1.4%; sodium phosphate; NaCl; BAK 0.01%; EDTA
Eye-Lube-A	Glycerin 0.25%; EDTA; NaCl; BAK
GenTeal Lubricant Eye Drops, Mild and Mild to Moderate	Hydroxypropyl methylcellulose; boric acid; phosphonic acid; NaCl; sodium perborate
HypoTears <sup>b</sup>	PVA 1%; PEG 400; BAK 0.01%
LubriTears	Hydroxypropyl methylcellulose 2906, 0.3%; dextran 70, 0.1%; EDTA; KCl; NaCl; BAK 0.01%
Moisture Eyes <sup>b</sup>	Propylene glycol 1%; glycerin 0.3%; BAK 0.01%
Murine Tears Lubricant	Povidone 0.6%; PVA 0.5%; BAK
Nature's Tears	Hydroxypropyl methylcellulose 2906, 0.4%; KCl; NaCl; sodium phosphate; BAK 0.01%; EDTA

Ocucoat Lubricating <sup>b</sup>	Hydroxypropyl methylcellulose 0.8%; dextran 70, 0.1%; BAK 0.01%
Preservative-Free Moisture Eyes <sup>a</sup>	Propylene glycol 0.95%; boric acid; NaCl; KCl; sodium borate; EDTA
Refresh	PVA 1.4%; povidone 0.6%
Refresh Dry Eye Therapy	Glycerin 1.0%; polysorbate 80, 1.0% (polymer matrix; emulsifying agent; carbomer; castor oil)
Refresh Optive	CMC 0.5%; glycerin 0.9%; Purite <sup>c</sup> ; boric acid; calcium chloride; magnesium chloride; KCl; levocarnitine; erythritol
Refresh Optive Sensitive PF	CMC sodium 0.5%; glycerin 0.9%; boric acid, calcium chloride, erythritol, levocarnitine Magnesium chloride, KCL, water (purified), sodium borate, NaCl
Refresh Optive Sensitive PF Advanced	CMC sodium 0.5%, glycerin 1%, polysorbate 80, 0.5%, boric acid, castor oil, erythritol, levocarnitine, carbomer copolymer type A, purified water, Purite; may also contain hydrochloric acid, sodium hydroxide
Refresh Plus <sup>a</sup>	CMC sodium 0.5%
Refresh Tears	CMC sodium 0.5%; Purite <sup>c</sup>
Soothe	Restoryl (Drakeol-15 1.0% and Drakeol-35 4.5%); polysorbate 80, 0.4%; octoxynol 40; NaCl; sodium phosphate; EDTA; polyhexamethylene biguanide preservative
Systane	PEG-400, 0.4%; propylene glycol 0.3%; boric acid; calcium chloride; hydroxypropyl guar; magnesium chloride; polyquaternium preservative; KCl; NaCl; zinc chloride; water
Teargen	BAK 0.01%; EDTA; NaCl; PVA
Teargen II	Hydroxypropyl methylcellulose 2910, 4 mg; dextran 70, 0.1%; NaCl; KCl; sodium borate
Tears Naturale	Hydroxypropyl methylcellulose 0.3%; dextran 70, 0.1%; BAK 0.01%
Tears Naturale Forte	Dextran 70, 0.1%; hydroxypropyl methylcellulose 0.3%; glycerin 0.2%; polyquaternium 1, 0.001%; NaCl; KCl; sodium borate
Tears Naturale Free <sup>a</sup>	Hydroxypropyl methylcellulose 0.3%; dextran 70, 0.1%
Tears Naturale II	Hydroxypropyl methylcellulose 0.3%; dextran 70, 0.1%; Polyquad 0.001%
Tears Plus	PVA 1.4%; povidone 0.6%; chlorobutanol 0.5%
Tears Renewed	BAK 0.01%; EDTA; dextran 70, 0.1%; NaCl; hydroxypropyl methylcellulose 2906, 0.3%
Theratears PF <sup>a</sup>	CMC 0.25%
Visine Pure Tears Drops <sup>b</sup>	Glycerin 0.2%; hypromellose 0.2%; PEG 400, 1%
<b>Nonmedicated Ointments</b>	
Artificial Tears PF <sup>a</sup>	White petrolatum; anhydrous liquid lanolin; mineral oil
Dry Eyes	White petrolatum; mineral oil; lanolin
DuraTears Naturale <sup>a</sup>	Petrolatum; mineral oil; lanolin
HypoTears	White petrolatum; light mineral oil
Lacri-Lube N.P. <sup>a</sup>	White petrolatum 57.3%; mineral oil 42.5%; lanolin alcohols
Lacri-Lube S.O.P.	White petrolatum 56.8%; mineral oil 42.5%; lanolin alcohols; chlorobutanol 0.5%
Preservative Free	White petrolatum 80%; mineral oil 20%

Moisture Eyes PM	
Refresh P.M. <sup>a</sup>	White petrolatum 56.8%; mineral oil 41.5%; lanolin alcohols
Tears Renewed <sup>a</sup>	White petrolatum; light mineral oil
<b>Nonmedicated Gels</b>	
GenTeal Lubricant Eye Gel	Hydroxypropyl methylcellulose 0.3%; sodium perborate 0.028%; carbopol 980; phosphoric acid; sorbitol
Theratears Gel	CMC 1%; KCl; sodium bicarbonate; NaCl; sodium phosphate

Key: BAK = Benzalkonium chloride; CMC = carboxymethylcellulose; EDTA = ethylenediamine tetraacetic acid; KCl = potassium chloride; NaCl = sodium chloride; PEG = polyethylene glycol; PVA = polyvinyl alcohol.

<sup>a</sup> Preservative-free product.

<sup>b</sup> Preservative-free formulation available.

<sup>c</sup> Stabilized oxychloro complex.

One class of ophthalmic vehicles or ocular lubricants, in their commonly used ophthalmic formulation concentrations, is the substituted cellulose ethers, which include hydroxypropyl methylcellulose 0.3%-0.8% and carboxymethylcellulose (CMC) 0.5% and 1.0%. These solutions are colorless and vary in viscosity depending on the grade and concentration of the cellulose ether. Polyvinyl alcohol (PVA) 1.4% and povidone 0.6% are two other vehicles commonly used as ocular lubricants.<sup>12,13,14,15</sup>

Combining drugs with these vehicles increases the vehicles' viscosity, thereby enhancing the drugs' action. The increased viscosity retards drainage of the active ingredient from the eye, thus increasing the retention time of the active drug and enhancing bioavailability at the external ocular tissues. These effects generally occur without irritation or toxicity to the ocular tissues. Similar to the cellulose ethers, PVA also enhances stability of the tear film without causing ocular irritation or toxicity.

Povidone has surface-active properties similar to those of cellulose ethers. This compound is believed to form a hydrophilic layer on the corneal surface, mimicking natural conjunctival mucin. This mucomimetic property has firmly established the role of povidone as an artificial tear formulation. Because this agent promotes wetting of the ocular surface, mucin- and aqueous-deficient dry eyes appear to benefit from its use.

One example of the most commonly recommended and newer products on the market is Refresh Optive Advanced Lubricant Eye Drops, which contains glycerin (0.9%), polysorbate 80 (0.5%), CMC 0.5%, boric acid, castor oil, erythritol, levocarnitine, and carbomer copolymer type A. This product is reported to be a lipid-based, triple action preparation that helps lubricate and hydrate dry eyes and protects against evaporation of natural tears. Soothe is an artificial tear solution that contains a lipid restorative layer, which provides a barrier to prevent loss of the aqueous component of the tears.

Systane is a lubricant eyedrop that contains a gelling and polymer system. Hydroxypropyl guar binds to the hydrophobic corneal surface, forming a glycocalyx or gel-like environment that stays in contact with the ocular surface for a longer period of time. Systane is said to create an ocular shield, allowing epithelial repair that promotes patient comfort and relief of symptoms. Optive, a combination of CMC and glycerin, is believed to help protect the corneal epithelium through an osmotic protective effect.

Studies have shown that formulations of artificial tear products without preservatives are less likely than those with preservatives to irritate the ocular surface.<sup>10</sup> Providers and patients should be aware, however, that nonpreserved products should be discarded immediately after being opened and used.

Most patients with mild cases of dry eye disease instill drops of artificial tears once or twice per day, typically on arising in the morning and/or before retiring at night (Table 27-3).<sup>11</sup> Recommending drops at least twice per day is a good starting point. The viscosity of the drops and amount used can then be adjusted according to the patient's response. For more severe cases, the dosage can be increased to 3-4 times daily. If the patient's clinical needs and response to therapy indicate more frequent use, these solutions may be given as often as hourly. In many cases, artificial tears may be continued indefinitely, depending on patient response. Preservative-free products or those with less toxic preservatives (e.g., Purite or sodium perborate; see Ophthalmic Preservatives) are preferred in patients with moderate-severe dry eye disease.

Use of ocular lubricants requires balancing the number of drops per day with the viscosity of the recommended solution and the presence of a preservative; as the number of drops per day increases, toxicity from preservatives

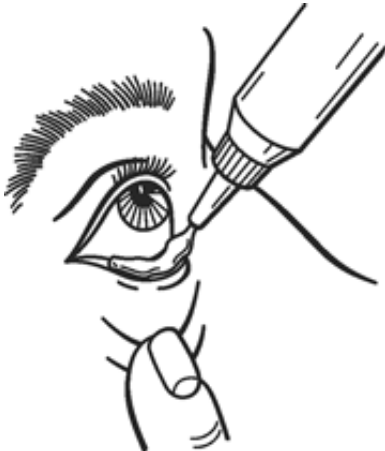

becomes more likely.<sup>16</sup>

Although PVA is compatible with many commonly used drugs and preservatives, certain compounds (e.g., sodium bicarbonate, sodium borate, the sulfates of sodium, potassium, and zinc) can thicken or gel solutions containing PVA. For example, sodium borate is found in some extraocular irrigating solutions or irrigants and may react with contact lens wetting solutions that contain PVA.<sup>17</sup> Therefore, health care providers must be cautious when recommending solutions containing PVA.

### Nonmedicated Ophthalmic Ointments

The primary ingredients in commercial nonprescription ophthalmic ointments (Table 27-2) are white petrolatum 60% (which contains a lubricant and an ointment base), mineral oil 40% (which helps the ointment melt at body temperature), and lanolin (which facilitates incorporation of water-soluble medications and also prevents evaporation).

**TABLE 27-3 Administration Guidelines for Eyedrops**

<ol style="list-style-type: none"> <li>1. If you have difficulty determining whether eyedrops have touched your eye surface, refrigerate the solution before instilling it. Do not refrigerate suspensions. Always check the expiration date.</li> <li>2. Wash hands thoroughly. Wash areas of the face around the eyes. Contact lenses should be removed unless the product is designed specifically for use with contact lenses.</li> <li>3. Tilt head back. When administering drops to children, have them lie down before placing drops in their eyes.</li> <li>4. Gently grasp lower outer eyelid below lashes, and pull eyelid away from eye to create a pouch.</li> <li>5. Place dropper over eye by looking directly at it, as shown in the drawing.</li> </ol>		<ol style="list-style-type: none"> <li>6. Just before applying a single drop, look up.</li> <li>7. As soon as the drop is applied, release the eyelid slowly. Close eyes gently for 3 minutes by placing your head down as though looking at the floor (using gravity to pull the drop onto the cornea). Minimize blinking or squeezing of the eyelid.</li> <li>8. Use a finger to put gentle pressure over the opening of the tear duct.</li> <li>9. Blot excessive solution from around the eye.</li> <li>10. If multiple medications are indicated, wait at least 5 minutes before instilling the next drop. This pause helps ensure that the first drop is not flushed away by the second and that the second drop is not diluted by the first.</li> <li>11. If using a suspension, shake well before instilling. If using the suspension with another dosage form, place the suspension drop last, because it has prolonged retention time in the tear film.</li> <li>12. If both drop and ointment therapy are indicated, instill the drops at least 10 minutes before the ointment so that the ointment does not become a barrier to the drops' penetration of the tear film or cornea.</li> </ol>
--	---	---

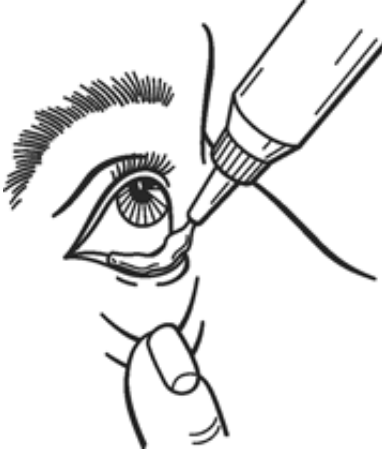

The principal advantage of nonmedicated (bland) ointments is their enhanced retention time in the eye, which appears to enhance the integrity of the tear film. Therefore, mucin- and aqueous-deficient eyes can benefit from the application of lubricating ointments.

Ointment formulations are usually administered twice daily (Table 27-4). However, depending on the patient's clinical needs and therapeutic response, ointments may be administered as often as every few hours or only occasionally, as needed. Many patients prefer to instill the ointment at bedtime to keep the eyes moist during sleep and improve

morning symptoms of dry eye.

Because of the viscosity of the melted ointment base in the tear film, many patients complain of blurred vision when using ointments. This problem can usually be managed by decreasing the amount of ointment instilled or by administering the ointment at bedtime. Providers should routinely counsel patients about the blurred vision associated with eye ointments.

**TABLE 27-4 Administration Guidelines for Eye Ointments**

<ol style="list-style-type: none"> <li>1. Wash hands thoroughly. Wash areas of the face around the eyes.</li> <li>2. If both drop and ointment therapy are indicated, instill the drops at least 10 minutes before the ointment so that the ointment does not become a barrier to the drops' penetration of the tear film or cornea.</li> <li>3. Tilt head back.</li> <li>4. Gently grasp lower outer eyelid below lashes, and pull eyelid away from eye as shown in the drawing.</li> </ol>		<ol style="list-style-type: none"> <li>5. Place ointment tube over eye by looking directly at it.</li> <li>6. With a sweeping motion, place a one-fourth- to one-half-inch strip of ointment inside the lower eyelid by gently squeezing the tube, but avoid touching the tube tip to any tissue surface.</li> <li>7. Release the eyelid slowly.</li> <li>8. Close eyes gently for 1-2 minutes.</li> <li>9. Blot excessive ointment from around the eye.</li> <li>10. Vision may be blurred temporarily. Avoid activities that require good visual ability until vision clears.</li> </ol>
--	--	--

Ointment preparations are generally nonirritating, but preservatives can be toxic to ocular tissues. Some patients develop hypersensitivity reactions, which may prompt them to discontinue therapy. Changing to a single-use, preservative-free formulation (e.g., Duratears Naturale, HypoTears, Lacri-Lube N.P., or Refresh PM) may eliminate symptoms associated with preservative-containing ointments. Preservative-free products are particularly helpful in long-term treatment. As a rule, pharmacists should recommend preservative-free, nonmedicated ointments for the treatment of dry eye to avoid the potential problems associated with preservatives.

### Formulation Considerations for Ocular Lubricants and Other Ophthalmic Products

Ocular lubricants and other nonprescription ophthalmic drugs are formulated to reduce the stinging, burning, and other side effects commonly associated with some ophthalmic drugs. These products are comfortable to use because their pH is carefully controlled, and because they use buffers, tonicity adjusters, and preservative systems; therefore, they encourage patients to adhere to self-treatment. Drug vehicle and preservative systems are among the most important inactive ingredients of these products. Other commonly used vehicles are dextran 70, gelatin, glycerin, hydroxyethylcellulose, methylcellulose, polyethylene glycol, and propylene glycol. Various other ingredients often are included as excipients.

#### Ophthalmic Preservatives

Preservatives are incorporated into multidose ophthalmic products. These components are intended to destroy or limit the growth of microorganisms inadvertently introduced into the product. Surfactants, one of two distinct groups of preservatives, are usually bactericidal, meaning they disrupt the bacterial plasma membrane. Of the quaternary surfactants, benzalkonium chloride (BAK) and benzethonium chloride are preferred by many manufacturers because of their stability, excellent antimicrobial activity, and long shelf-lives. Unfortunately, these agents can have toxic effects on both the tear film and the corneal epithelium.<sup>18,19</sup> Long-term use of topical products containing BAK can damage conjunctival and corneal epithelial cells. Complications associated with BAK include allergy, fibrosis, dry eye disease, and increased risk of failure of glaucoma surgery.<sup>20</sup> Although only a small percentage of patients with

dry eye disease experience BAK toxicity, it may become quite problematic for those exhibiting symptoms. Polyquad, a large-molecular-weight quaternary compound, does not bind to contact lenses and is less toxic than BAK.

Chlorhexidine is useful as an antimicrobial agent in the same range of concentrations as BAK, yet it is used at lower concentrations in commercial ophthalmic formulations. Because it does not alter corneal permeability to the same extent as BAK, chlorhexidine is not as toxic to the eye.

The second distinct group of preservatives includes the metals mercury and iodine, their derivatives, and alcohols. Of the mercurial preservatives, patients who become sensitized to thimerosal develop contact blepharitis or conjunctivitis after several weeks of exposure and must discontinue the use of products that contain it. These products are rapidly disappearing from the marketplace.

Chlorobutanol is less effective than BAK as an antimicrobial preservative and, in fact, tends to disappear from bottles during prolonged storage.<sup>12</sup> However, prolonged use of chlorobutanol does not appear to produce allergic reactions. This preservative is often used in 0.5% concentrations and has both antifungal and antibacterial properties.

Methylparaben and propylparaben, both p-hydroxybenzoic acid derivatives, have a long history of use in some ophthalmic medications (especially in artificial tears and nonmedicated ointments). However, these preservatives are unstable at high pH and can sometimes induce allergic reactions.

Ethylenediamine tetraacetic acid (EDTA) is a chelating agent that preferentially binds and sequesters divalent cations. EDTA assists the action of thimerosal, BAK, and other agents. EDTA can sometimes induce contact allergic reactions.<sup>21</sup>

Sodium perborate, which has been used extensively as a tooth-bleaching agent, has found a new use as an ophthalmic preservative. The first of two so-called “disappearing preservatives,” sodium perborate dissociates on contact with the eye to form hydrogen peroxide, which in turn rapidly dissociates to oxygen and water. The amount of hydrogen peroxide formed is so small that it does not produce eye irritation. The second, Purite (oxychloro complex), also is designed to dissociate on contact with the eye. After exposure to long-wavelength UV light, Purite breaks down quickly to water and sodium chloride. These disappearing preservatives have the advantage of microbial protection while potentially limiting preservative toxicity.

Other less common ophthalmic preservatives include cetylpyridinium chloride, phenylethyl alcohol, sodium propionate, and sorbic acid.

### Ophthalmic Excipients

Other useful excipients are antioxidants, wetting agents, buffers, and tonicity adjusters. Antioxidants prevent or delay deterioration of products that are exposed to oxygen. Wetting agents reduce surface tension, allowing the drug solution to spread more easily over the ocular surface. Buffers are added to help maintain a pH range of 6.0-8.0, thereby preventing ocular discomfort on product instillation. Tonicity adjusters allow the medication to be isotonic with the physiologic tear film. Products in the sodium chloride equivalence range of 0.9%-1.2% are considered isotonic; they help reduce ocular irritation and tissue damage. Solutions in the tonicity range of 0.6%-1.8% are usually comfortable when placed on the human eye. Hypertonic solutions used for corneal edema are not well tolerated.

### Product Selection Guidelines

In recent years, artificial tear preparations have been introduced in preservative-free formulations and, more recently, in disappearing-preservative formulations. These preparations are beneficial for patients who are sensitive to preservatives such as BAK and thimerosal, those who use drops frequently, and those with compromised corneas. Four solution products (Gentel [Mild to Moderate or Moderate to Severe], Refresh Liquigel, and Refresh Tears) and three lubricant gels (Gentel Lubricant Eye Gel [Mild to Moderate or Moderate to Severe] and Tears Again Gel) are uniquely formulated to allow the preservative to rapidly dissociate into nontoxic components on the ocular surface. True preservative-free artificial tear preparations (e.g., Bion Tears, Celluvisc, HypoTears, and Refresh Plus) are available in a variety of unit-dose dispensers, and some of these products are formulated to provide electrolyte support to the damaged surface epithelium of the eye. Preservative-free formulations not only are more expensive than preserved artificial tear solutions, but also are easily contaminated by the patient during use. Therefore, patients must follow strict hygienic procedures for self-administration and should discard any unused solution immediately after opening and using it.

Clinical results and patient acceptance remain the final criteria for determining a product's efficacy in the treatment of patients with dry eye. Importantly, no single formulation has yet been identified that will universally improve clinical signs and symptoms while maintaining patient comfort and acceptance.<sup>16,17</sup> If symptoms do not improve after use of multiple artificial tear products, the patient should be encouraged to seek professional assessment and care from an eye care provider.

### Allergic Conjunctivitis

#### Pathophysiology and Clinical Presentation of Allergic Conjunctivitis

The list of antigens that can cause ocular allergy is virtually endless, but the most common allergens include pollen, animal dander, and topical eye preparations. Patients with ocular allergy will often report seasonal allergic rhinitis, as well. Allergic conjunctivitis is characterized by a red eye with watery discharge (see Color Plates, photograph 4). The hallmark symptom of ocular allergy is itching. Vision is usually not impaired but may be blurred because of excessive tearing. Contact lenses should not be used until the condition resolves.<sup>22</sup>

### Treatment of Allergic Conjunctivitis

#### Treatment Goals

The goals in treating allergic conjunctivitis are to (1) remove or avoid the allergen, (2) limit or reduce the severity of the allergic reaction, (3) provide symptomatic relief, and (4) protect the ocular surface.

#### General Treatment Approach

Questioning the patient about exposure to allergens may help identify the offending substance. Removal or avoidance of the responsible allergen is the best treatment, but nonprescription ocular lubricants, ocular decongestants, ocular decongestant/antihistamine preparations, ocular antihistamines/mast cell stabilizers, oral antihistamines, and cold compresses will help relieve symptoms.

#### Nonpharmacologic Therapy

In addition to removing and/or avoiding exposure to the offending allergen, applying cold compresses to the eyes 3-4 times per day will help reduce redness and itching. Other important measures for avoiding the allergic response include checking the pollen count, keeping doors and windows closed, running air conditioning, using air filters, and so on. If eyes are itchy, cool compresses often help relieve some symptoms.<sup>31</sup>

#### Pharmacologic Therapy

The first-line treatment of allergic conjunctivitis is to instill artificial tears as needed (see Treatment of Dry Eye). If symptoms persist, the patient should switch to an ophthalmic antihistamine/mast cell stabilizer product. The reclassification of a product from prescription to nonprescription status has been a very favorable improvement for the treatment of allergic conjunctivitis. Ketotifen fumarate 0.025% (Zaditor, Alaway) is very safe and can be used in individuals ages 3 years and older; it is dosed twice daily and is very effective in relieving the signs and symptoms of allergic conjunctivitis. Although a definite time period of treatment has not been well studied, these antihistamine/mast cell stabilizer products have been used for many years in patients, depending on symptoms. An oral antihistamine can be added to the second treatment option, if needed. Medical referral is indicated if symptoms do not resolve.

Nonprescription ophthalmic products designated specifically for treatment of allergic conjunctivitis include decongestants (often in combination with antihistamines) and, more recently, the antihistamine/mast cell stabilizer combination. (See Chapter 11 for discussion of systemic nonprescription antihistamines.)

#### Ophthalmic Decongestants/ Alpha-Adrenergic Agonists

Four decongestants are available in nonprescription strength for topical application to the eye: phenylephrine, naphazoline, tetrahydrozoline, and oxymetazoline. In nonprescription ophthalmic products, phenylephrine is available in a concentration of 0.12% or lower. Higher concentrations of phenylephrine (2.5% and 10%) are prescription products and are used for pupillary dilation. Naphazoline, tetrahydrozoline, and oxymetazoline are chemically classified as imidazoles. As Table 27-5 shows, these agents are available as solutions in a variety of concentrations.

Phenylephrine acts primarily on alpha-adrenergic receptors of the ophthalmic vasculature to constrict conjunctival vessels, thereby reducing eye redness. The higher-concentration, prescription-only products that contain this agent are generally reserved for the short-term dilation needed for eye examinations. Similar to phenylephrine, the imidazoles have greater alpha- than beta-receptor activity and, therefore, are clinically useful in constricting conjunctival blood vessels. These agents have only minimal effect on the underlying vessels of the episclera and sclera. Vasoconstrictors are effective in constricting conjunctival vessels and in reducing redness, vascular congestion, and eyelid edema, but they do not diminish the allergic response.<sup>23</sup> Table 27-6 lists dosages of ophthalmic decongestants.

**TABLE 27-5 Commonly Used Nonprescription Ophthalmic Products Containing Decongestants, Antihistamines, and/or Astringents**

<i>Trade Name</i>	<i>Primary Ingredients</i>

<b>Decongestant Eyedrop Products</b>	
All Clear	Naphazoline 0.012%; PEG 300, 0.2%; BAK 0.01%; EDTA
All Clear AR	Naphazoline 0.03%; BAK 0.01%; hydroxypropyl methylcellulose 0.5%; EDTA
Allerest	Naphazoline 0.012%; BAK; EDTA
Clear Eyes	Naphazoline HCl 0.012%; glycerin 0.2%; BAK
Clear Eyes ACR	Naphazoline 0.012%; BAK; EDTA; zinc sulfate 0.25%; glycerin 0.2%
Murine Tears Plus	Tetrahydrozoline HCl 0.05%; povidone 0.6%; PVA 0.5%; BAK
Naphcon	Naphazoline HCl 0.012%; BAK 0.01%
Opti-Clear	Tetrahydrozoline 0.05%; BAK 0.01%; boric acid; EDTA; sodium borate; NaCl
Relief <sup>a</sup>	Phenylephrine; PVA 1.4%; EDTA
Tetrasine Extra	Tetrahydrozoline 0.05%; PEG 400, 1.0%; EDTA; BAK
Visine Advanced Relief	Tetrahydrozoline HCl 0.05%; PEG 400, 1.0%; povidone 1.0%; BAK 0.01%; dextran 70, 1.0%
Visine L.R.	Oxymetazoline HCl 0.025%; BAK 0.01%
Visine Moisturizing	Tetrahydrozoline HCl 0.05%; BAK 0.01%; EDTA; hydroxypropyl methylcellulose 0.5%
Visine Original	Tetrahydrozoline HCl 0.05%; BAK 0.01%
Vision Clear	Tetrahydrozoline 0.05%; BAK 0.01%; boric acid; EDTA; sodium borate; NaCl
<b>Antihistamine/Mast Cell Stabilizer Eyedrop Products</b>	
Zaditor, Alaway	Ketotifen 0.025%; BAK 0.01%; glycerol; sodium hydroxide and/or hydrochloric acid; purified water
<b>Antihistamine/Decongestant Eyedrop Products</b>	
Naphcon A	Pheniramine maleate 0.3%; naphazoline HCl 0.025%; BAK 0.01%
Opcon-A	Pheniramine maleate 0.315%; naphazoline HCl 0.02675%; hydroxypropyl methylcellulose 0.5%; BAK 0.01%
Vasocon A	Antazoline phosphate 0.5%; naphazoline HCl 0.05%; BAK 0.01%
Visine-A	Pheniramine maleate 0.3%; naphazoline HCl 0.025%; BAK 0.01%
<b>Decongestant/Astringent Eyedrop Products</b>	
Clear Eyes ACR	Naphazoline HCl 0.012%; zinc sulfate 0.25%; glycerin 0.2%; BAK
Visine Allergy Relief	Tetrahydrozoline HCl 0.05%; zinc sulfate 0.25%; BAK 0.01%
Zincfrin	Phenylephrine HCl 0.12%; zinc sulfate 0.25%; BAK 0.01%

Key: BAK = Benzalkonium chloride; EDTA = ethylenediamine tetraacetic acid; NaCl = sodium chloride; PEG = polyethylene glycol; PVA = polyvinyl alcohol.

<sup>a</sup> Preservative-free formulation.

**TABLE 27-6 Dosage Guidelines for Nonprescription Ophthalmic Decongestants and Antihistamines**

<i>Agent</i>	<i>Nonprescription Concentration (%)</i>	<i>Dosage</i>	<i>Duration of Action (hours)</i>	<i>Duration of Use</i>
<b>Decongestant Products</b>				
Phenylephrine	0.12	1-2 drops up to 4	0.5-1.5	72 hours

Phenylephrine	0.12	1-2 drops up to 4 times/day	0.5-1.0	72 hours
Naphazoline	0.1, 0.12, 0.02, 0.03	1-2 drops up to 4 times/day	3-4	72 hours
Oxymetazoline	0.025	1-2 drops every 6 hours	4-6	72 hours
Tetrahydrozoline	0.05	1-2 drops every 4 hours	1-4	72 hours
<b>Antihistamine/Mast Cell Stabilizer</b>				
Ketotifen	0.025	1 drop every 8-12 hours	8-12	≥72 hours
<b>Decongestant/Antihistamine Products</b>				
Naphazoline/pheniramine	0.025 (naphazoline) 0.3 (pheniramine)	1-2 drops 3-4 times/day	3-4	72 hours
Naphazoline/antazoline	0.05 (naphazoline) 0.5 (antazoline)	1-2 drops 3-4 times/day		72 hours

When used as directed, ocular decongestants generally do not induce ocular or systemic side effects. However, their availability to and use in children should be monitored carefully. Ingestion of these products can result in coronary emergencies and death. When used excessively or long term, ocular decongestants have the potential to produce rebound conjunctival hyperemia (i.e., rebound conjunctival congestion), allergic conjunctivitis, and allergic blepharitis.<sup>24</sup> Thus, they should not be used for more than 72 hours. Rebound congestion appears to be less likely with topical ocular use of naphazoline or tetrahydrozoline than with oxymetazoline or phenylephrine. Rebound congestion may be experienced within a few days of initiating treatment, although a case was reported within 8 hours of use.<sup>24</sup> Patients with apparent rebound congestion should be referred to an eye care provider for differential diagnosis and management.

Indiscriminate use of decongestants in an irritated eye can induce papillary dilation and may precipitate angle-closure glaucoma in eyes that have narrow anterior chamber angles. Use of these products in angle-closure glaucoma is contraindicated, and providers should counsel patients with angle-closure glaucoma against using these products in treating allergic conjunctivitis.

Some patients may experience epithelial xerosis (abnormal dryness) from prolonged topical instillation of ocular decongestants, which may exacerbate the symptoms of irritation, pain, and dryness associated with allergic conjunctivitis.

Ocular decongestants should be used cautiously by patients with systemic hypertension, arteriosclerosis, other cardiovascular diseases, or diabetes. Adverse cardiovascular events are also possible when these agents are used in patients with hyperthyroidism.<sup>25</sup> Because of these possible adverse reactions, patients should not use phenylephrine and other ocular decongestants as ocular irrigants. During pregnancy, women should use ocular decongestants sparingly, if at all. Storing solutions at high temperatures may cause ocular reactions and severe mydriatic responses to instillation. If offending ophthalmic signs or symptoms do not resolve within 72 hours, the patient should see an eye care provider.

#### Ophthalmic Antihistamines and Ophthalmologic Antihistamines/ Mast Cell Stabilizers

Two nonprescription antihistamines are available for topical ophthalmic use: pheniramine maleate and antazoline phosphate. Although these antihistamines are effective alone, nonprescription products containing them also contain a decongestant. The two combinations are pheniramine/naphazoline and antazoline/naphazoline (Table 27-5). Pheniramine and antazoline are in different antihistamine classes, but both act as specific histamine<sub>1</sub>-receptor antagonists.<sup>26,27</sup> Topical antihistamines are used for rapid relief of symptoms associated with seasonal or atopic conjunctivitis. Using a decongestant with either topical antihistamine has been shown to be more effective than using either agent alone.<sup>28</sup>

Ketotifen fumarate is an ophthalmic antihistamine and mast cell stabilizer. It produces very potent H<sub>1</sub>-receptor-antagonist activity, thereby preventing acute histamine-mediated allergy symptoms. The mast cell stabilization activity inhibits mast cell degranulation, preventing the release of inflammatory mediators, including histamine. Ketotifen also inhibits eosinophils, thereby inhibiting the release of late-phase mediators. Ketotifen provides relief within minutes, its

effects may last up to 12 hours from a single dose, and it does not contain a vasoconstrictor;<sup>23</sup> therefore, it is a very safe product with no concerns for vasoconstrictor overuse.

Table 27-6 provides dosages of the antihistamine combination products. Burning, stinging, and discomfort on instillation are the most common side effects of ophthalmic antihistamines.<sup>29,30</sup>

Ophthalmic antihistamines have anticholinergic properties and may cause pupil dilation. This effect is seen most commonly in people with light-colored irises or compromised corneas (e.g., contact lens wearers).<sup>26</sup> In susceptible patients, pupil dilation can lead to angle-closure glaucoma. Therefore, these drugs are contraindicated in people with a known risk of angle-closure glaucoma.<sup>26</sup> Sensitivity to one of the components is another contraindication.

#### Product Selection Guidelines

Ketotifen is the safest and most effective product for the treatment of allergic conjunctivitis. It is the greatest improvement in the nonprescription treatment of allergic eye disease in many years. The twice-daily dosing and the safety of this product for children ages 3 years and older make it the primary therapy for patients with signs and symptoms of allergic conjunctivitis.

Although product-to-product comparisons are available for decongestant and antihistamine ophthalmic products, reaching definitive conclusions regarding clinical comparisons of the available nonprescription ocular decongestants is difficult. Naphazoline 0.02%, however, is an excellent choice for nonprescription therapy of mild-moderate conjunctivitis of environmental, viral, or noninfectious origin.

Because rebound congestion appears to be less likely after topical ocular use of naphazoline or tetrahydrozoline, these agents should generally be recommended over phenylephrine or oxymetazoline.

#### Complementary Therapies

The homeopathic product known as Similasan Eye Drops #2 is indicated for relief from itching and burning caused by allergic reactions. The active homeopathic ingredients are Apis, Euphrasia, and Sabadilla. The efficacy of this formulation has not been established in controlled clinical trials.

### Corneal Edema

#### Pathophysiology and Clinical Presentation of Corneal Edema

Corneal edema may occur from a variety of conditions, including overwear of contact lenses, surgical damage to the cornea, and inherited corneal dystrophies. The edematous area of the cornea is often confined to the epithelium. Because fluid accumulation distorts the optical properties of the cornea, halos or starbursts around lights (with or without reduced vision) are a hallmark symptom of corneal edema. An eye care provider must diagnose this disorder.

#### Treatment of Corneal Edema

##### Treatment Goals

The goal in treating corneal edema is to draw fluid from the cornea, thereby relieving the associated symptoms.

##### General Treatment Approach

Once the initial diagnosis is established, patients can use topical hyperosmotic formulations to treat corneal edema. Of the topical ophthalmic hyperosmotic agents available, only sodium chloride can be obtained without a prescription in both solution and ointment formulations (Table 27-7). Sodium chloride is available as a 2% or 5% solution and as a 5% ointment. First-line treatment is instillation of a 2% solution 4 times per day. If symptoms persist, nighttime use of a 5% hyperosmotic ointment should be added to the regimen.<sup>31</sup> If symptoms do not respond to the augmented treatment, the patient should switch to a 5% hyperosmotic solution and continue nighttime use of the ointment. If symptoms still persist, medical referral is necessary.<sup>31</sup>

##### Pharmacologic Therapy

###### Hyperosmotics

Hyperosmotic agents increase the tonicity of the tear film, promoting movement of fluid from the cornea to the more highly osmotic tear film. Normal tear flow mechanisms then eliminate the excessive fluid. Many patients with mild-moderate corneal epithelial edema may experience improved subjective comfort and vision after appropriate use of these medications.

Usually, the patient instills 1 or 2 drops of the solution every 3-4 hours (Table 27-3). The ointment formulation, however, requires less frequent instillation and is usually reserved for use at bedtime to minimize symptoms of

blurred vision (Table 27-4). Because vision associated with edematous corneas is often worse upon awakening, several instillations of the solution during the first few waking hours may be helpful.

In general, sodium chloride 5% in ointment form is the most effective in reducing corneal edema and improving vision, but it tends to cause stinging and burning. For that reason, patients often prefer the 2% solution for long-term therapy. Hypertonic saline is nontoxic to the external ocular tissues, and allergic reactions are rare.<sup>31</sup>

The most important contraindication to topical hyperosmotic sodium chloride is its use to clear edematous corneas in patients with traumatized epithelium. The intact corneal epithelium permits only limited permeability to inorganic ions; therefore, an absent or compromised corneal epithelium will result in increased corneal penetration of the hyperosmotic product, reducing its osmotic effect.<sup>31</sup> Patients whose history or physical appearance suggests a damaged corneal epithelium should be referred to an eye care provider immediately. Patients must be directed never to prepare homemade saline solutions for use in the eye because of the risk of infection.

### Loose Foreign Substances in the Eye

#### Pathophysiology and Clinical Presentation of Loose Foreign Substances in the Eye

Despite the protective effect of the eyelids, foreign substances often contact the ocular surface. The immediate response of the eye is watering (tearing). If the substance causes only minor irritation and does not abrade the eye surface, self-treatment is appropriate.<sup>32</sup>

**TABLE 27-7 More Commonly Used Miscellaneous Nonprescription Ophthalmic Products**

<i>Trade Name</i>	<i>Primary Ingredients</i>
<b>Hyperosmotics</b>	
AK-NaCl Solution	NaCl 5%; methylparaben 0.023%; propylparaben 0.017%
AK-NaCl Ointment <sup>a</sup>	NaCl 5%; lanolin oil; mineral oil; white petrolatum
Muro 128 Solution 2%	NaCl 2%; hydroxypropyl methylcellulose 2906; methylparaben 0.046%; propylparaben 0.02%; propylene glycol; boric acid
Muro 128 Solution 5%	NaCl 5%; boric acid; hydroxypropyl methylcellulose 2910; propylene glycol; methylparaben 0.023%; propylparaben 0.01%
Muro 128 Ointment <sup>a</sup>	Mineral oil; white petrolatum; lanolin
<b>Irrigant Solutions</b>	
Blinx	NaCl; KCl; sodium phosphate; BAK 0.005%; EDTA 0.02%
Collyrium for Fresh Eyes	Boric acid; sodium borate; BAK
Bausch and Lomb Eye Wash	Sodium borate; boric acid; NaCl; sorbic acid 0.1%; EDTA 0.025%
Eye Stream	Sodium acetate 0.39%; sodium citrate 0.17%; sodium hydroxide and/or hydrochloric acid; BAK
Eye Wash	NaCl; sodium phosphate dibasic; sodium phosphate monobasic; EDTA; preserved with benzalkonium chloride in purified water
Irrigate Eye Wash	NaCl; mono- and dibasic sodium phosphate; EDTA; BAK
Optigene	NaCl; mono- and dibasic sodium phosphate; EDTA; BAK
Visual-Eyes	NaCl; mono- and dibasic sodium phosphate; BAK; EDTA
<b>Prosthesis Lubricant/Cleaner</b>	
Enuclene Solution	Tyloxapol 0.25%; hydroxypropyl methylcellulose 0.85%; BAK 0.02%
SteriLid Eyelid Cleanser	Water; PEG-80; sorbitan laurate; sodium trideceth sulfate

Key: BAK = Benzalkonium chloride; EDTA = ethylenediamine tetraacetic acid; KCl = potassium chloride; NaCl = sodium chloride; PEG = polyethylene glycol.

<sup>a</sup> Preservative-free formulation.

## Treatment of Loose Foreign Substances in the Eye

### Treatment Goals

The goal in treating loose foreign substances in the eye is to remove the irritant by irrigating the eye. If a known foreign substance is a fragment of wood or metal, it should be treated promptly by an eye care provider because of the potential for penetrating injuries.

### General Treatment Approach

If reflex tearing does not remove the foreign substance, the eye may need to be flushed. Lint, dust, and similar materials can usually be removed by rinsing the eye with sterile saline or specific eyewash preparations (irrigants). Outside of a medical setting, treat eyes exposed to loose particles by flushing the eyes with copious amounts of water from a sink faucet or garden hose. If needed, eye ointment can be applied at bedtime.<sup>32</sup>

### Pharmacologic Therapy

#### Ocular Irrigants

An ocular irrigant is used to cleanse ocular tissues while maintaining their moisture; these solutions must be physiologically balanced with respect to pH and osmolality. Because the tissues that the irrigant contacts obtain nutrients elsewhere, the role of irrigants is primarily to clear away unwanted materials or debris from the ocular surface. To reduce risk of contamination, patients should use ocular irrigants only on a short-term basis, and they should be sure that no other ocular pathology is being missed. All ophthalmic irrigating solutions are available without a prescription (Table 27-7).

In the eye care provider's office, irrigating solutions come in handy after certain clinical procedures, and they are often used to wash away mucous or purulent exudates from the eye. They are also administered in the hospital to clean out eyes between changes of ocular dressings.

Ocular irrigants should not be used for open wounds in or near the eyes. Although irrigating solutions may be used to wash out the eyes after contact lens wear, they have no particular value as contact lens wetting, cleansing, or cushioning solutions.

If the patient experiences continuous eye pain, changes in vision, or continued redness or irritation of the eye, or if the ocular condition persists or worsens, evaluation by an eye care provider should be strongly encouraged. Irrigants may be packaged with an eyecup; however, because contamination of the eyecup is possible, it should not be used to rinse the eye.

## Minor Eye Irritation

### Pathophysiology and Clinical Presentation of Minor Eye Irritation

Nonallergic, minor eye irritation can be caused by a loose foreign substance in the eye; contact lens wear; or exposure of the eye to wind, sun (e.g., snow skiing without protective eye goggles), smog, chemical fumes, or chlorine. Redness of the eye is a common sign of minor irritation. In cases of snow blindness, other burns from UV light, or arc welder's burns, common additional symptoms include pain and the feeling of "sand in the eyes."

### Treatment of Minor Eye Irritation

Minor irritation often responds well to artificial tear solutions or nonmedicated ointments (see Treatment of Dry Eye Disease).

Zinc sulfate, a mild astringent, may be recommended for temporary relief of minor ocular irritation. The dosage is 1-2 drops up to 4 times daily.

The homeopathic product known as Similasan Eye Drops #1 is marketed to relieve dryness and redness caused by smog, contact lenses, and other causes. The active homeopathic ingredients are Belladonna, Euphrasia, and Mercurius sublimatus. Controlled clinical trials have not demonstrated the efficacy of this formulation in the treatment of this condition.

## Chemical Burn

## Pathophysiology and Clinical Presentation of Chemical Burn

Chemical burns may occur from exposure to alkali (e.g., oven cleaners, cement, or lye); acids (e.g., battery acid or vinegar); detergents; and various solvents and irritants (e.g., tear gas or mace). Burns may range from mild to severe, depending on the inciting agent and/or exposure time. Patients complain of pain, irritation, photophobia, and tearing. Signs will vary according to the severity. Less severe signs include superficial punctate keratitis (small pinpoint loss of epithelial cells in the cornea), perilimbal ischemia, chemosis, hyperemia, eyelid edema, hemorrhages, and first- or second-degree burns of the lid and outer skin. More severe signs include corneal edema and opacification, anterior chamber inflammation, increased IOP, and retinal toxicity from scleral penetration. Alkali burns are more penetrating and potentially more damaging to eye tissues than acid burns. Alkali burns often are more resistant to irrigation and have greater tissue destruction when they penetrate into the deeper (stromal) layers of the cornea. If the burns are more superficial and only several layers of the corneal epithelium have been affected, the cells should be replenished within approximately 24 hours.<sup>32</sup>

### Emergent Treatment of Chemical Burn

Emergent treatment includes immediate copious irrigation with sterile saline (Table 27-7) or even tap water, if nothing else is available. Irrigation must be continued until an eye care provider can be seen; if irrigation is stopped prematurely, residual material that may still be under the lid or in the inferior cul-de-sac may cause the pH of the tear film to revert to either acidic or alkaline.<sup>32</sup> Further treatment after irrigation may include the use of cycloplegic agents, topical antibiotics, and analgesics. In more severe cases, if significant inflammation of the anterior chamber or cornea is present, eye care specialists may use topical steroids. Antiglaucoma medications are also used if the IOP is elevated. Follow-up by the eye care provider is required to prevent conjunctival adhesions and corneal complications. Chemical burns are considered ophthalmic emergencies and should be referred to an eye care provider or emergency department immediately.

### Artificial Eyes

Besides the obvious aesthetic benefits, clearing dried mucus or fluid secretions from the surfaces of artificial eyes eliminates a potential medium for bacterial growth. A sterile, isotonic buffered solution containing tyloxapol 0.25% and BAK 0.02% is available especially for cleaning and lubricating ophthalmic prostheses. The primary method of preventing bacterial growth is routine hygiene with mild, nonallergenic soap and water. Tyloxapol is a surfactant that softens solid matter on the prosthesis, and BAK aids tyloxapol in wetting the artificial eye. The solution is used in the same manner as ordinary artificial tears. With the artificial eye in place, 1 or 2 drops of solution should be applied 3 or 4 times daily. In addition, the solution can be used as a cleaner to remove oil or mucous deposits; in this case, the artificial eye is then rubbed between the fingers and rinsed with tap water before reinsertion.

### Contact Dermatitis

#### Pathophysiology and Clinical Presentation of Contact Dermatitis

Contact dermatitis of the eyelid can be a reaction to either an allergen or an irritant. Causes of contact dermatitis include a change in cosmetics or soap, exposure to eye medications, or contact with other foreign substances. The involvement of both eyelids suggests allergy, because both eyes are often exposed. Common symptoms include swelling, scaling, or redness of the eyelid, along with profuse itching. Sunburns of the eyelids and UV burns to the cornea (e.g., recent sun exposure from beach or ski outings without eye protection) should be ruled out.

#### Treatment of Contact Dermatitis

Questioning the patient about the use of eye medications or new products (e.g., eyeliner or eye shadow) may help identify the offending substance quickly. Discontinuing use of the suspected product is the best treatment. If swelling of the eyelid is marked, nonprescription oral antihistamines (e.g., diphenhydramine) along with cold compresses applied 3-4 times per day will help reduce the inflammation and itching.

### Assessment of Ophthalmic Disorders: A Case-Based Approach

For patients who have not seen an eye care provider, the pharmacist or primary care provider must determine whether the ophthalmic disorder is self-treatable or requires medical referral. Great care must be taken when assessing a patient with a new, acute problem. Ocular inflammation and irritation can be caused by many conditions, some of which can be treated safely and effectively with nonprescription ophthalmic products. These products are used primarily to relieve minor symptoms of burning, stinging, itching, and watering. The Food and Drug Administration has suggested that self-treatment may be indicated for tear insufficiency, corneal edema, and external

inflammation or irritation.

Cases 27-1 and 27-2 are examples of the assessment of patients with ophthalmic disorders.

[Table 27-8](#) describes the major features of disorders that require medical referral. Any self-treated condition that does not resolve within a reasonably short time should be referred to an eye care provider for care.

### Case 27-1

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient has suffered from allergies over the past couple of weeks this spring. She currently is taking a systemic, nonsedating OTC antihistamine (loratadine 10 mg), but she is still having ocular symptoms. Her ocular irritation and dry eye symptoms are definitely affecting her day-to-day activities. She is willing to do anything to cure the problem.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Symptoms appeared about the same time as last year, at the start of spring. Patient started her loratadine last year and did fine. This year, however, her eyes are itchy, red, and dry, and her eyelids are swollen, even though her systemic complaints seem under control. The dryness and ocular irritation began prior to the allergy season.
c. description of the patient's efforts to relieve the symptoms	The decongestant eyedrops to get the "red out" do not appear to give her any relief from her ocular symptoms.
d. patient's identity	May Wong
e. age, sex, height, and weight	49 years old, female; 5 ft 6 in., 125 lb
f. patient's occupation	Full-time employee; mother of two
g. patient's dietary habits	Normal healthy diet with occasional social drinking; works out on tread mill 4 times weekly.
h. patient's sleep habits	Stays up late and sleeps in as allowed by her schedule.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Seasonal allergies (spring and fall): loratadine 10 mg once daily, tetrahydrozoline eyedrops 3-4 times daily in both eyes; glucosamine capsules 2 times daily; aspirin 75 mg daily
j. allergies	Seasonal allergies (spring and fall): loratadine 10 mg once daily, tetrahydrozoline eyedrops 3-4 times daily in both eyes; glucosamine capsules 2 times daily; aspirin 75 mg daily
k. history of other adverse reactions to medications	None

I. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Patient is experiencing exacerbation of seasonal allergy symptoms. This is the first year she has experienced ocular irritation and dryness; some symptoms have occurred a little earlier than expected.
3. Identify exclusions for self-treatment (Table 27-8 and Figure 27-2).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Mrs. Wong to an eye care provider (optometrist or ophthalmologist). (2) Suggest that Mrs. Wong discontinue her topical decongestant eyedrops and switch to ketotifen topical drops twice daily. (3) Recommend that she continue with her OTC artificial tear solution. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The patient prefers to discontinue her decongestant drops and start the artificial tear product and the new ocular antihistamine:
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Instill 1 drop of the ketotifen eyedrops twice daily in both eyes as described in Table 27-3. Supplement throughout the day with the artificial tear product as much as you desire; however, wait at least 5 minutes after instilling the ketotifen eyedrops."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"You may not need to see an eye care provider if you follow the administration guidelines in Table 27-3."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	See Table 27-6.
b. maximum number of days the therapy should be employed	See Table 27-6.
c. product administration procedures	See Table 27-3.
d. expected time to onset of relief	See Table 27-6.

e. degree of relief that can be reasonably expected	“Complete symptom control should be possible. Some minor symptoms likely will appear from time to time.”
f. most common side effects	“Burning, stinging, and discomfort may occur on instillation of the drops.”
g. side effects that warrant medical intervention should they occur	“If the eye pain worsens and the redness continues, see your eye care provider.”
h. patient options in the event that condition worsens or persists	“An eye care provider should be consulted if the condition does not improve, or if irritation and pain become intolerable.”
i. product storage requirements	“Store under room temperature and away from heat and light. Observe product expiration date.”
j. specific nondrug measures	“Remove and/or avoid exposure to the offending allergen (e.g., check pollen count, keep doors and windows closed, run air conditioning, use air filters). In addition, apply cold compresses to the eyes 3-4 times per day to help reduce redness and itching.”
Solicit follow-up questions from the patient or caregiver.	(1) “If my eyes still bother me, may I use the drops that I was using previously to get the red out?” (2) “Also, my spouse has tobramycin/dexamethasone eyedrops that he used previously, and they seemed to help him very quickly. May I try his eyedrops?”
Answer the patient’s or caregiver’s questions.	(1) “No. The get-the-red-out eyedrops actually can cause more ocular redness (rebound) and eye dryness.” (2) “The tobramycin/dexamethasone drops (steroid and antibiotic) can cause significant eye complications, such as secondary infection, glaucoma, and cataract.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Inform the patient to feel free to contact you if she has any further questions.

Key: NA = Not applicable; NKA = no known allergies; OTC = over-the-counter.

### Case 27-2

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient’s symptoms and medical history, including:	

a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient explains that he burned the skin around his eyelids, and his eyes are sore and pretty red. He was working in his bathroom on a clogged sink. He bought a viscous product for clearing drains and poured it in the clogged sink, which contained some water that would not drain. He got the plunger and started plunging the water, and some of the fluid splashed into his face. It burned some of the skin around his eyelids, as well as his eyes. He thought the redness and pain would get better in a few hours, but they seem to be getting worse, especially in the right eye. If he closes his eyes, the pain abates a bit; however, because his symptoms do not seem to be getting any better, he would like assistance choosing a product that might help.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The patient mentions that his eyes hurt when he keeps them open (especially the right one). He also mentions that his vision is sensitive to light and that his eyes feel "gritty" when he leaves them open.
c. description of the patient's efforts to relieve the symptoms	He wears sunglasses to help protect from the glare, but they do not really help the pain or redness. He has taken 2 ibuprofen tablets for the pain, but they are not giving him much relief.
d. patient's identity	Jim Orwell
e. age, sex, height, and weight	35 years old, male, 6 ft 2 in., 195 lb
f. patient's occupation	Accountant
g. patient's dietary habits	Pretty healthy; fishes twice a week; diet low in fatty foods.
h. patient's sleep habits	7 hours a night
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	None; occasional upset stomach relieved by Maalox
j. allergies	None
k. history of other adverse reactions to medications	None
l. other (describe) _____	Patient is an avid runner; runs 4 times per week.
<b>Assessment and Triage</b>	

2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Mr. Orwell has a chemical burn with residual ocular involvement. He needs to be seen immediately by an eye care specialist.
3. Identify exclusions for self-treatment.	<a href="#">Table 27-8</a>
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) To prevent or reduce scarring of eyelids from chemical burns, he should continue to flush both eyes immediately and for at least 10 minutes. (2) Patient should use sterile saline or water, if possible. If neither is available, he should flush with tap water. (3) After flushing eye, he should arrange immediate transportation to an emergency facility.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Initially, the patient did not want to see an eye doctor; after briefly discussing alkali burns and learning that such burns could continue causing further damage, he said he would go right away.
6. Describe the recommended therapeutic approach to the patient or caregiver.	The patient needs to see an eye doctor right away. In the meantime, he should use an irrigating solution to irrigate his eyes.
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Seeing an eye doctor is the best option. The eye doctor can determine how much damage has been done and if continual treatment is required. The doctor can also recommend a topical treatment for your eyelids."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the	Criterion does not apply in this case.

patient or caregiver.	
Solicit follow-up questions from the patient or caregiver.	“Is there anything I should do to prevent this in the future?”
Answer the patient’s or caregiver’s questions.	“In the future, it is critical to wear protective goggles when working with liquids that may potentially cause chemical burns. Some protection of the skin and face is also suggested to protect from burns.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact the patient to find out the results of the eye doctor’s examination and treatment.

**TABLE 27-8 Differentiation of Ophthalmic Disorders That Require Medical Referral**

<i>Disorder</i>	<i>Potential Signs/Symptoms</i>	<i>Complications</i>	<i>Treatment Approach</i>
Blunt trauma	Ruptured blood vessels, bleeding into eyelid tissue space, swelling, ocular discomfort, facial drooping	Internal eye bleeding, secondary glaucoma, detached retina, periorbital bone fracture (blowout fracture)	Medical referral is appropriate.
Foreign particles trapped/embedded in the eye	Reddened eyes, profuse tearing, ocular discomfort	Corneal abrasions/scarring, chronic red eye, intraocular penetration from metal striking metal at high speeds	Medical referral for removal of particles is appropriate.
Ocular abrasions	Partial/total loss of corneal epithelium, blurred vision, profuse tearing, difficulty opening eye	Risk of bacterial/fungal infection with eye exposure to organic material, corneal scarring, anterior chamber rupture	Medical referral is appropriate.
Infections of eyelid/eye surface	Red, thickened lids, scaling	Scarring of lids, dry eye, corneal abrasion or scarring, loss of vision, hordeolum (stye), chalazion (risk of malignancy), and blepharitis (loss of lashes, corneal irritation)	Medical referral is appropriate.
Eye exposure to chemical splash, solid chemical, or chemical fumes	Reddened eyes, watering, difficulty opening eye	Scarring of eyelids and eye surface, loss of vision	To prevent/reduce scarring of eyelids from chemical burns, flush eye immediately for at least 10 minutes, preferably with sterile saline/water. If neither is available, flush with tap water. After flushing eye, arrange immediate transportation to an emergency facility. No recommendation is noted for chemical neutralization.

Thermal injury to eye (welder's arc)	Reddened eyes, pain, sensitivity to light	Corneal scarring, secondary infection	Medical referral for definitive care (including possible eye patching) is appropriate.
Bacterial conjunctivitis	Reddened eyes with purulent (mucous) discharge, ocular discomfort, eyelids stuck together on awakening	Typically self-limiting in 2 weeks	Medical referral for treatment with topical antibiotics to clear infection more quickly is appropriate; some infections require systemic antibiotic treatment.
Viral conjunctivitis	Reddened eyes with watery discharge, ocular discomfort, hyperemia	Typically self-limiting in 2 or 3 weeks	Medical provider will monitor for corneal involvement. Treatment with topical decongestants to provide comfort is appropriate; cold compresses can be applied.
Chlamydial conjunctivitis	Watery or mucous discharge, ocular discomfort, low-grade fever, possible blurred vision	Scarring	If infection with <i>Chlamydia</i> spp. is known or suspected, or if symptoms are too vague to rule out viral or allergic conjunctivitis, medical referral is mandatory.

### Patient Counseling for Ophthalmic Disorders

Before counseling a patient, the health care provider should carefully consider the nature and extent of ocular involvement. Patients with acute ocular disease must receive a prompt, definitive diagnosis (including baseline visual acuity) before the provider considers the appropriateness of nonprescription therapy. Some acute conditions (which may or may not involve ocular pain or blurred vision) can be appropriately treated with nonprescription agents, but a recent diagnosis from an eye care provider can give additional reassurance and confidence in recommending such treatment. Although the cost-effectiveness of ophthalmic care can be greatly improved through the use of nonprescription agents, severe visual impairment—including blindness—can be a serious clinical and medicolegal complication if referral for definitive diagnosis and treatment is delayed. After careful consideration of the patient's history, the primary care provider should always counsel patients on the indications for and limitations of self-treatment. The algorithms in [Figures 27-2](#) and [27-3](#) can assist providers in recommending the appropriate treatment for self-treatable disorders of the eye surface and eyelid, respectively.

Numerous nonprescription ophthalmic products for treating minor ocular irritations are available for self-administration by the patient with minimal or no supervision. These products are also adequate for treating certain clinical conditions diagnosed by primary care providers or eye care providers. First-line therapy should always include counseling on nonpharmacologic treatment. These treatments alone are frequently sufficient to relieve the ocular symptoms or are necessary as an adjunct to the ophthalmic drug therapy. Proper drug instillation technique is critical if the target tissue (the eye) is to receive the maximum benefit from the medication. Ophthalmic solutions and ointments are often used incorrectly. Carefully instructing patients in the proper self-administration procedures can help ensure maximum safety and effectiveness of these agents. Appropriate patient education and counseling must accompany dispensing of any ophthalmic product.

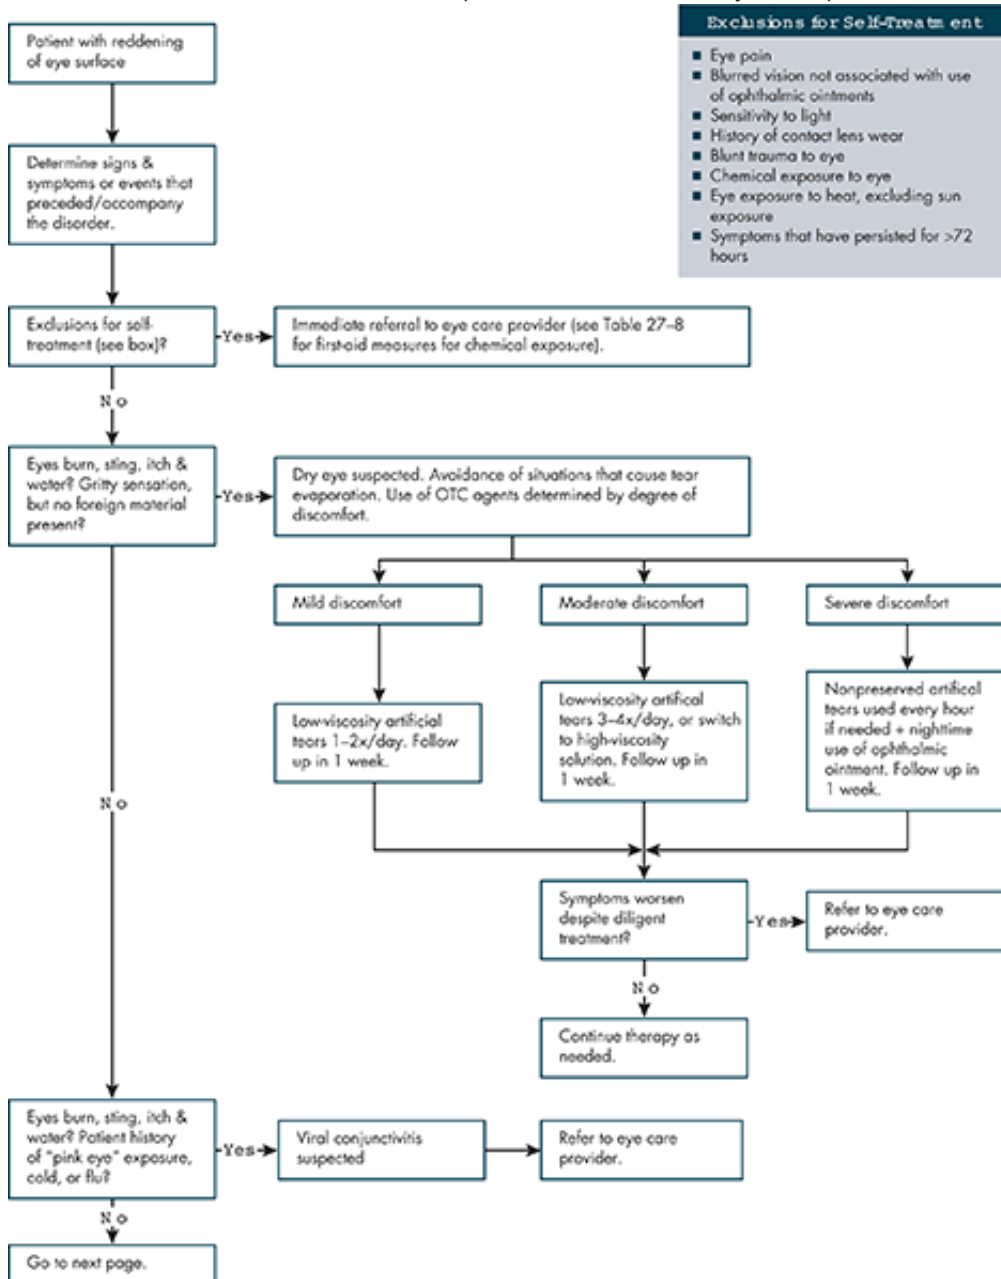

Although drug side effects and interactions are rare with topically applied ophthalmic products, the potential for such effects does exist; therefore, patients should be advised of possible adverse effects, including the clinical signs of drug toxicity or allergy.

The health care provider must actively assist patients in selecting the appropriate product, which will enhance compliance, minimize or avoid side effects, and reduce the attendant costs of therapy. The other major considerations in making therapeutic recommendations include whether the person has a sensitivity to one of the product constituents, whether the product can be used with contact lenses, and whether the product has the potential to wash out prescription ophthalmic drugs the patient may be using. With the exception of ophthalmic antihistamines and decongestants, little product-to-product comparative research has been done for nonprescription ophthalmic preparations. Therefore, therapy recommendations should be made on the basis of the patient's diagnosis and the

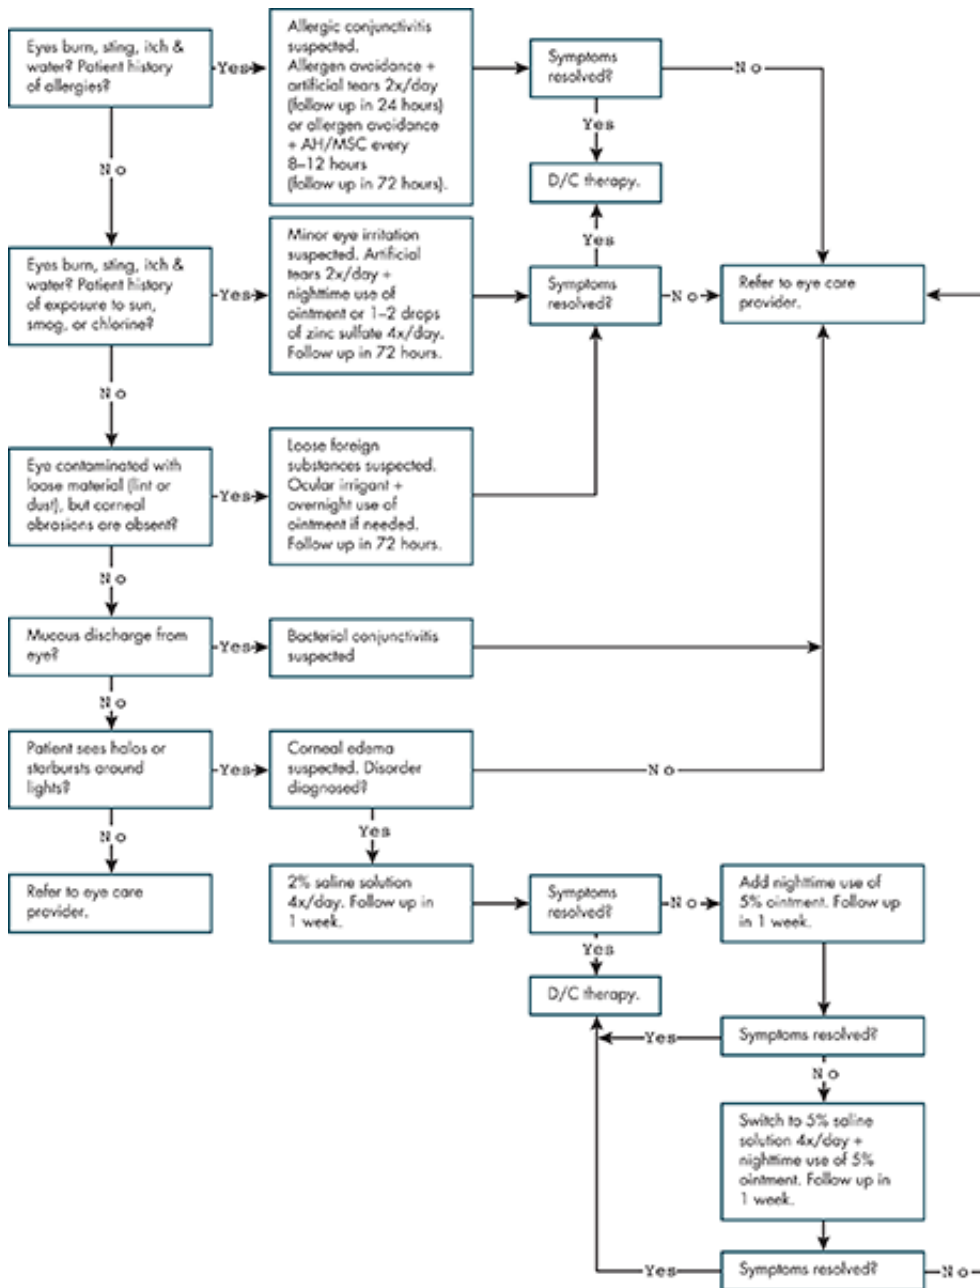

products the patient is using. The box Patient Education for Ophthalmic Disorders lists specific information to provide patients.

### Evaluation of Patient Outcomes for Ophthalmic Disorders

Patients who self-treat for allergic conjunctivitis, loose foreign substances in the eye, or minor eye irritation should see an eye care provider if symptoms persist after 72 hours of treatment. Dry eye disease is often a chronic disorder, requiring continuous treatment with ophthalmic lubricants. Patients with this disorder should be advised to seek medical care if the symptoms worsen despite diligent self-treatment. Patients with corneal edema should consult an eye care provider if the symptoms persist or worsen despite adherence to the instructions for treating the disorder. Symptoms of contact dermatitis should resolve quickly once the offending substance is removed. If symptoms persist after 72 hours of antihistamine use, the patient should see an eye care provider.

Self-care of eye surface disorders. Key: AH = Antihistamine; D/C = discontinue; MCS = mast cell stabilizer; OTC = over-the-counter.

#### Exclusions for Self-Treatment

- Signs and symptoms of infection of eyelids (e.g., red, thickened eyelids; scaling)
- Blunt trauma to eye
- Exposure of eye to chemicals
- Head lice
- Macular degeneration
- Hordeolum, chalazion, blepharitis

Copyright © American Pharmacists Association

Self-care of eyelid disorders. Key: AH = Antihistamine; D/C = discontinue.

#### Patient Education for Ophthalmic Disorders

The objectives of self-treatment are to (1) relieve the symptoms of minor ophthalmic disorders using the appropriate nonprescription products or nondrug measures and (2) use nonprescription products as adjunctive treatment of ophthalmic disorders diagnosed by an eye care provider. For most patients, carefully following product instructions and the self-care measures listed here will help ensure good outcomes.

- Remove the causative ocular agent/irritant that predisposes you to your ocular condition or disease.
- If *blunt trauma* to the eye occurs, obtain an eye examination as soon as possible.
- If you have *dry eye disease* and the first ophthalmic lubricants used to treat it are not effective, ask your eye care provider or pharmacist about the following treatment options: increasing the dosage, switching to a product with increased viscosity, and/or switching to a preservative-free product (Table 27-2).
- When treating *allergic conjunctivitis*, do not exceed the recommended dosages of ophthalmic antihistamine/mast cell stabilizer, decongestant, or antihistamine/decongestant products (Tables 27-5 and 27-6). Consult an eye care provider if symptoms persist after 72 hours of treatment.
- Discard or replace eyedrop bottles 30 days after the sterility safety seal is opened. The manufacturer's expiration date does not apply once the seal is broken.
- If *eye exposure to chemicals* occurs, irrigate the eye continuously for 10 minutes with copious amounts of water or eye irrigants (Table 27-7) and seek immediate eye care.
- If *loose foreign substances* such as lint, dust, or pollen enter the eye, flush the substance from the eye using an eye irrigant or water (Table 27-7).
- If a *foreign substance* becomes embedded in the eye or trapped under the eyelid, see an eye care provider. Failure to remove the substance could cause an eye infection or tissue damage.
- Consult an eye care provider before treating *corneal edema*. If hyperosmotic solutions (Table 27-7) are recommended, follow the recommended dosages even though the product may sting. Continual utilization of these products will depend upon the eye care professional's suggestions.
- Note that taking ophthalmic vitamin supplements for macular degeneration along with general multivitamins may result in gastrointestinal upset or vitamin toxicity.
- If *contact dermatitis of the eyelid* occurs, wash the affected areas, identify the cause of the reaction, and try to

avoid future contact with the substance. Consult an eye care provider if symptoms persist after 72 hours of use of oral antihistamines.

### Key Points for Ophthalmic Disorders

- The pharmacist is positioned in the community to treat patients with ophthalmic pathology or to recommend self-management with one or more nonprescription drugs.
- Many ophthalmic products are available to manage the symptoms of minor acute or chronic conditions of the eye and eyelid.
- By understanding the pathophysiology of certain ocular conditions and knowing how to assess a patient who presents with such conditions, pharmacists should be able to optimize the safe, appropriate, effective, and economical use of nonprescription drugs to manage selected conditions of the eye and eyelid.
- Nonprescription ophthalmic products should be used only in cases of minor pain or discomfort. If doubt exists concerning the nature of the problem, the pharmacist should refer the patient for professional care.
- Nonprescription ocular medications should not be recommended to patients who have demonstrated an allergy to any of the active ingredients, preservatives, or other excipients in the product.
- Patients who are already using a prescription ophthalmic product should use nonprescription products only after consulting with an eye care provider or pharmacist.
- Patients with narrow anterior chamber angles or narrow-angle glaucoma should not use topical ocular decongestants because of the risk of angle-closure glaucoma.
- Drug administration should be conservative in patients with hyperemic conjunctiva because of the potential for increased systemic drug absorption and the risk of adverse effects.
- The lowest concentration and conservative dosage frequencies should be used, especially for ocular decongestants; overuse should be avoided.
- Ophthalmic products frequently are used incorrectly; therefore, counseling on appropriate application of products is crucial.

**Handbook of Nonprescription Drugs** > Chapter 28. Prevention of Contact Lens-Related Disorders**Prevention of Contact Lens-Related Disorders: Introduction**

Both soft and gas permeable contact lenses are considered Class II medical devices regulated by the Food and Drug Administration (FDA).<sup>1</sup> Similar to legend drugs, contact lenses are available only by prescription in the United States. Contact lenses are made of flexible or rigid plastics that allow the passage of oxygen to the corneal surface. Designed to be easily applied, worn, and removed, with minimal disturbance to ocular physiology, contact lenses are used to correct refractive errors, alter the cosmetic appearance of the wearer, or therapeutically treat diseases of the anterior surface of the eye (i.e., the cornea). Compared with earlier rigid lenses, soft contact lenses have greatly enhanced comfort, and since their introduction in 1971, the contact lens market has significantly expanded. An estimated 125 million people use contact lenses worldwide, including as many as 38 million in the United States. For 2012, the U.S. soft contact lens market was \$2.4 billion of the worldwide contact lens market of \$7.1 billion.<sup>2</sup> The types of lenses prescribed vary markedly among countries; however, soft lenses dominate 90% of the market, with gas permeable lenses accounting for approximately 20% of prescribed contact lenses in some countries, such as Argentina, Costa Rica, Mexico, Peru, and Venezuela, but only 9% of contact lenses prescribed in the United States.<sup>3</sup> The newest soft lens material, known as silicone hydrogel, continues to dominate the soft lens market, accounting for nearly half of prescribed soft lenses worldwide and 65% in the United States.<sup>2</sup>

As many as 50% of contact lens wearers experience complications; however, this number varies widely by type of lens, wearing schedule, and compliance with care regimens.<sup>4</sup> Contact lenses, even when expertly fit, alter ocular tissues and change the corneal metabolism. The prevention of contact lens-related disorders requires that both patients and health care providers understand the proper fitting, prescribing, and care regimens associated with safe contact lens wear. Failure to do so can greatly increase the chance of corneal infection (ulcers) and other ocular conditions that may result in permanent eye damage and blindness. Preventive measures aimed at improving patient hygiene and appropriate contact lens care, as well as adherence to the recommended replacement frequency, reduce the overall risk of contact lens complications.<sup>5</sup> Fortunately, most complications from contact lens wear are reversible, if attended to promptly. Approximately 25%-33% of patients discontinue wearing their contact lenses periodically or permanently, with lens discomfort or dryness cited as the most common reason.<sup>6-8</sup> Proper care and fitting of lenses can help eliminate discomfort and encourage patients to continue wearing their lenses.

The fitting and dispensing of contact lenses, traditionally the sole domain of optometrists and ophthalmologists, have undergone dramatic changes in recent years. The Fairness to Contact Lens Consumers Act, passed by Congress in 2003, requires that contact lens prescribers release a copy of the contact lens prescription to patients at the conclusion of the fitting process, whether or not it is requested.<sup>9</sup> This act allows patients to obtain contact lens fitting services from their eye care providers and gives them the freedom to purchase contact lens materials from any legitimate source, including pharmacies.

The availability of contact lenses from nonprofessional sources such as department stores, mail-order services, or the Internet is a significant concern. In these circumstances, after presentation of a valid prescription, contact lenses can be dispensed by any individual, who only has to comply with state and local business statutes that have no stipulations for basic training in eye care or regard for professional or technical licensing in health care. Recent research has shown that individuals who purchase contact lenses from the Internet are less likely to adhere to recommended lens care,<sup>10,11</sup> which is particularly concerning because online sales of glasses and contact lenses are estimated at \$350 million for 2012, having grown more than 28% in the past decade.<sup>2</sup>

As this chapter will point out, fitting and dispensing contact lenses involve more than the parameters of the lenses. Patient compliance with care systems, wearing schedules, and replacement schedules must also be considered. Patient education on lens handling and on signs and symptoms of complications are essential parts of the fitting process. Another concern is enforcement of expiration dates for lens prescriptions.

*Editor's Note:* This chapter is based on the 17th edition chapter of the same title, written by Peter A. Russo, Bruce I. Gaynes, and Janet P. Engle.

**Use of Contact Lenses**

Most people can wear one or more types of contact lenses without problems if certain precautions are taken. In a few cases, use of contact lenses is contraindicated.

**Indications for Contact Lenses**

The primary indication for the use of contact lenses is the correction of refractive errors such as myopia (nearsightedness), hyperopia (farsightedness), astigmatism, and presbyopia. Astigmatism occurs when dissimilar curvatures of the refractive surface of the eye result in a blurred image. Gas permeable lenses or toric soft lenses can be used to correct astigmatism.

The benefits of contact lens wear are widely known and include the convenience of freedom from glasses, no obstruction from eyeglass frames, no fogging of lenses caused by sudden temperature changes, improved optics and clarity of vision, wider peripheral field of vision, equal image sizes when refractive disparity exists between eyes, and better function during sporting activities or exercise. Perhaps a significant reason for choosing contact lenses is the perceived improvement in self-image and personal appearance.<sup>12</sup>

The decision to wear contact lenses rather than eyeglasses is sometimes based on therapeutic necessity. For example, in patients with keratoconus (a corneal dystrophy causing a gradual protrusion of the central cornea), satisfactory vision is usually unattainable with ordinary eyeglasses but can be achieved with rigid contact lenses. Another example of therapeutic necessity is the use of soft contact lenses as “bandage” lenses in the case of corneal abrasions. Other, less common, indications for contact lenses include aphakia (absence of the natural lens of the eye), corneal scarring, and disfigured eyes. In these conditions, patients typically see better with contact lenses, and for patients with disfigurement, tinted prosthetic soft contact lenses may improve cosmetic appearance by rendering disfigurement from a variety of conditions virtually unnoticeable.

### Contraindications and Warnings for Contact Lenses

Without question, however, there are patients who are poor candidates for contact lens wear and cannot or should not wear contact lenses. Contraindications are often based on lifestyle as well as on medical history. The following are relative contraindications that should be considered on an individual basis before fitting contact lenses:

- Patients who are monocular. The risk of complications such as inflammation or infection that can permanently scar the cornea must be weighed against the need for optimal visual correction. Overnight wear of lenses should absolutely be avoided.
- Patients with active pathology of the lids, cornea, or conjunctiva. Such conditions include blepharitis, corneal infections (e.g., herpes keratitis), or conjunctivitis. Common colds or chronic allergic conditions such as hay fever and asthma also may make contact lens wear extremely uncomfortable or impossible.
- Patients with dry eye (keratitis sicca) unless using bandage soft contact lenses for protection. This area is controversial because some patients with severe dry eye actually benefit from the use of bandage soft contact lenses to protect the ocular surface. Cosmetic lens wearers who have insufficient tear production, a deficiency or excess of mucin, or excessive lipid production, or who need to spend time in excessively dry environments may be unable to use contact lenses successfully. Poor blink rate or incomplete blinking may also contribute to difficulty with lens wear. Postmenopausal women may experience higher rates of dry eye that preclude successful contact lens wear.
- Women who are pregnant or using oral contraceptives. The fluid-retaining properties of estrogen may lead to edema of the cornea, which will alter corneal topography and affect the fit of contact lenses.
- Patients with diabetes. Diabetic patients are advised against continuous-wear contact lenses because of retarded healing processes and reduced corneal sensitivity. This precaution is probably unnecessary for daily wear of lenses unless problems occur.
- Patients who must use eye medications frequently (e.g., treatment of glaucoma). The preservatives in multidose bottles can bind to soft contact lenses and cause toxicity to the corneal epithelium.
- Patients with a vocation or hobby that is not conducive to lens wear (e.g., smoking, chemical environment). Occupational conditions that may prohibit the wearing of contact lenses include exposure to wind, glare, molten metals, irritants, dust and particulate matter, tobacco smoke, chemicals, and chemical fumes. Certain chemical fumes may be particularly hazardous because of the potential concentration of irritants under a rigid lens or inside a soft lens. The lens theoretically prolongs contact of such substances with the cornea and can lead to corneal toxicity.
- Lens wearers who may move from low to high altitude. Moving from a low to a high altitude may cause hypoxia (causing edema of the cornea) or metabolic deficiency, resulting in irritation and corneal abrasions.
- Patients who have shown a pattern of abusing lens wear or multiple episodes of ocular complications.
- Patients who are unable to care for contact lenses appropriately. This group includes young patients who are not properly supervised or older patients who lack the cognitive skills or dexterity to handle contact lenses.

### Soft versus Rigid Contact Lenses

There are only two major categories of contact lenses: soft (hydrophilic) and rigid (gas permeable [GP]) lenses. Rigid lenses of non-gas permeable polymethylmethacrylate (PMMA) (often known as “hard” contact lenses) are rarely used owing to their lack of oxygen permeability. Soft and GP lenses are composed of single or multiple plastic monomers; soft lens materials contain water but GP lens materials do not. Soft lenses are popular because of their

excellent initial comfort on insertion. Rigid lenses have always provided the best optics and, therefore, superior visual acuity. In the contact lens field, use of the term *hard lenses* during patient counseling is no longer acceptable because it creates a stigma about optimal lens designs for individual needs. Therefore, rigid lenses should simply be referred to as gas permeable lenses. [Table 28-1](#) provides a comparison of PMMA, soft, and GP lenses. [Table 28-2](#) compares the advantages and disadvantages of soft and GP contact lenses with regard to ease of care and handling, potential complications, and other parameters.

### Hydrophilic (Soft) Contact Lenses

First introduced in 1971, soft contact lenses have become the lens of choice from the standpoint of health care providers and patients alike. In the United States alone, soft contact lenses represent almost 90% of all contact lens fits.<sup>2</sup> Once limited by poor reproducibility and limited parameter availability, soft contact lenses are now available in any spherical or cylindrical power, and they can correct for presbyopia, myopia or hyperopia, and astigmatism. The primary monomer that soft lenses are manufactured from is 2-hydroxyethyl methacrylate (HEMA). Other monomers used include methacrylic acid (MA) and n-vinylpyrrolidone (NVP).<sup>13</sup> The equilibrium point of hydration of polyHEMA soft contact lenses is 38%. As the polymer changes to contain either MA or NVP, the equilibrium water content increases to 60% or more. The hydration characteristic of soft lenses may be adversely influenced by several variables, including temperature, oxidative reactions of lens care solutions, tonicity, and pH.<sup>13</sup>

**TABLE 28-1 Comparison of Contact Lens Characteristics**

	<i>PMMA</i>	<i>Lens Type Soft</i>	<i>Gas Permeable</i>
<b>Lens Characteristics</b>			
Rigidity	+++	0	+++
Durability	+++	+	++
Oxygen transmission	0	++	+++
Chemical adsorption	0	+++	0
<b>Optical Quality</b>			
Visual acuity	+++	+	+++
Correction of astigmatism	Yes	Toric	Yes
Photophobia	++	+	++
Spectacle blur	+++	0	++
<b>Convenience</b>			
Comfort	+	+++	++
Adaptation period	Weeks	Days	Weeks
Continuous wear	No	Yes	Yes
Intermittent wear	No	Yes	No

Key: PMMA = Polymethylmethacrylate; + indicates the degree to which the characteristic is present; 0 means the characteristic is not present.

In 1986, FDA classified soft hydrogel contacts into four categories according to water content and ionic properties (low water non-ionic, high water non-ionic, low water ionic, high water ionic). Soft contact lenses with less than 50 percent water content are considered to be low water. Less reactive surfaces are called non-ionic, and more reactive materials are called ionic.<sup>2</sup> Most eye care providers fit non-ionic soft contact lenses because of the lenses' inherent chemical ability to deter the formation of charged protein and lipid deposits. Ionic lenses have a negative surface charge, which tends to attract more protein deposits compared with non-ionic lenses. Non-ionic lenses are electrically neutral and tend to be less reactive with the tear film, resulting in a more deposit-resistant lens. Originally, soft contact lenses were intended to be cleaned and disinfected daily and replaced on a yearly basis. Compliance was poor because patients opted for convenience over ocular health by not following prescribed daily care regimens, by replacing lenses after years of wear, and by sleeping overnight while wearing lenses, in some cases for weeks at a

time. Contact lens complications such as corneal edema, neovascularization, and infiltrates were observed. Oxygen deprivation, or hypoxia, was known to be a significant factor in many of these complications. The oxygen transmissibility of contact lenses is described by the term Dk/L,<sup>13</sup> where “D” represents gas diffusion, “k” solubility, and “L” the contact lens center thickness in centimeters. A higher Dk/L value allows more oxygen to pass through the lens. As the water content increases, the “k” value and oxygen permeability increase. However, permeability also depends on lens thickness.

Tighter quality control and refinement of manufacturing techniques have led to improved lens reproducibility and to the advent of disposable soft contact lenses. Disposable lenses represent the fastest-growing segment of the soft lens market. A true disposable soft contact lens is worn once and replaced without interval cleaning, implying that it is worn continuously.<sup>2</sup> The advantage of having a clean lens worn on a regular basis appealed to many patients and lessened the incidence of complications from a soiled lens, such as contact lens papillary conjunctivitis. With disposable contact lenses, the traditional yearly replacement schedule has been replaced with soft lenses, which are replaced monthly. However, some patients use soft contact lenses that are replaced biweekly or daily. Silicone hydrogel materials have contributed to the ability to have continuous wear lenses.

Health care providers were hopeful that frequent lens replacement would improve compliance and negate the negative effects of biofilm development on the surface of lenses. Many also believed that silicone hydrogel materials would effectively eliminate inflammatory and infectious complications of contact lens wear, including microbial keratitis, by removing the effects of hypoxia on the corneal epithelium. Although years of clinical use have shown that these materials do, in fact, diminish the hypoxic effect of lens wear, such as redness, limbal neovascularization, and microcystic edema, they have failed to eliminate infectious and inflammatory complications.<sup>14</sup> One study showed identical rates of microbial keratitis for overnight wear of silicone hydrogel materials and use of older HEMA materials.<sup>15</sup> FDA, however, continues to allow two continuous-wear schedules that are lens specific to remain in effect. The first is 6 continuous days and nights of wear, with the lens being discarded on day 7, as implemented during the early days of continuous wear. For some of the most permeable materials, FDA approves 30 nights of continuous wear, followed by replacement of the lens. Patients should be made aware that the continuous wear of contact lenses has clearly been shown to be the greatest risk factor for the most devastating consequences of lens wear, primarily microbial keratitis. Even though lenses are approved for 30 nights of continuous wear, some patients may not be able to tolerate wearing them for this length of time. None of the soft contact lenses on the market, including silicone hydrogel materials, can prevent or protect an individual from inflammatory and infectious complications. This statement emphasizes the importance of patient education and compliance with care regimens, wearing and replacement schedules, and awareness of adverse symptoms to ensure safe contact lens wear. Even a disposable, continuous-wear lens may be used only on a daily wear basis, and patients should replace lenses at the prescribed interval. When worn on a daily wear basis, these lenses must be cleaned and disinfected regularly. Patients looking to optimize convenience without exposing themselves to the risk of continuous wear should be directed toward daily disposable lenses. Daily disposables have the following advantages: (1) each lens is sterile prior to removal from its package for immediate insertion into the eye; (2) no cleaning regimen is necessary because the lens is discarded after wear; (3) deposit formation is minimal; and (4) lens-related problems, such as giant papillary conjunctivitis or allergic reactions to lens care solutions, occur less frequently.

**TABLE 28-2 Advantages and Disadvantages of Soft and Gas Permeable (GP) Contact Lenses**

<i>Soft Contact Lenses</i>	<i>GP Contact Lenses</i>
<b>Advantages</b>	
Excellent initial lens comfort	Excellent optics for optimal visual acuity
Rapid adaptation; well suited for intermittent lens wear	Correct nearly all forms of refractive error
Correct nearly all forms of refractive error	Improve vision for conditions with irregular corneas
Ease of fitting	Fit customized to individual patient
Ease of care	Economical
Unlikely to trap foreign material under the lens	Lower incidence of inflammatory/infectious complications
Unlikely to dislodge or fall out; well suited for sporting activities	
Can be tinted for cosmetic or prosthetic purposes (many lenses have light tints to improve visibility when handling)	

<b>Disadvantages</b>	
Not possible to achieve excellent visual acuity for all patients	Longer initial adaptation period
Fluctuations in vision because lens hydration varies with prolonged wear and changes in temperatures and humidity	Capable of trapping foreign material beneath the lens, causing discomfort
Lens fitting not customized to the patient	May dislodge from the eye
More prone to complications, especially from hypoxia	More difficult to fit
Fragility of lenses during handling	Flare around the periphery that may be noticed at night, particularly with large pupils
Lenses susceptible to preservatives in ophthalmic products	
Unable to verify correct eye for each soft lens once packaging is removed or to mark identification (i.e., L or R) on lens surface	

### Hydrophilic Lens Fitting

Unlike rigid contact lenses, which are typically custom designed, the parameters of the most commonly used soft contact lenses are predetermined by the manufacturer and are proprietary in nature. Often, the lens diameter and base curve are limited to one or two choices at most, providing little flexibility for adjusting fit. In addition, if a lens does not fit correctly or causes some other complication, another lens design must be tried. There are exceptions, and custom soft lenses with a specified diameter, base curve, and power can be ordered.

### Hydrophilic Contact Lenses as Therapeutic Devices

Aside from the cosmetic use of contact lenses, hydrophilic lenses have found wide application in the treatment of ocular disease and are being examined for potential use as ocular drug delivery devices. Notably, hydrophilic lenses are employed as an “eye bandage” or bandage lenses to protect the cornea and promote corneal reepithelialization after corneal injury or various corneal surgical procedures. Four soft contact lenses are currently approved by FDA for use therapeutically as bandage contact lenses in the treatment of corneal abrasions and other ocular surface problems. It is important to counsel patients who are prescribed contact lenses for this purpose to be diligent in cleaning and disinfecting the lenses.<sup>15,16</sup>

### Gas Permeable Contact Lenses

Rigid contact lenses preceded soft lenses in the market but were quickly surpassed because of one primary factor: patients have greater initial awareness of rigid lenses on the eye. In terms of optical quality, rigid lenses are far superior to soft lenses. However, patients are willing to sacrifice clarity for comfort. In defense of rigid lenses, initial discomfort can dissipate over several weeks as adaptation occurs and nerve endings on the inner surface of the eyelids become desensitized to the presence of the lens.

The first rigid lenses were conventional hard lenses made of PMMA plastic, which has no oxygen permeability. Despite PMMA being a stable, durable plastic, lenses made with PMMA are rarely used in the United States because of the advantages of GP materials, primarily direct oxygen permeability through the lens. GP lenses are made from monomer components of hydrophobic plastic compounds that allow oxygen to diffuse through the lens.<sup>17</sup> Advantages of GP lenses over soft contact lenses include increased oxygen transmissibility, reduced lipophilicity, and sharper vision. These lenses also have less surface reactivity, thereby decreasing tear film deposits.<sup>17</sup> Other advantages of GP lenses over soft contact lenses include fewer adverse inflammatory or infectious consequences. When properly cared for, GP lenses are durable and can be reused repeatedly for months to years before replacement is necessary, making them more economical than soft lenses. Surface scratches and deposits can be removed with powerful cleaners or in-office polishing machines. The disadvantages of GP lenses include less surface wettability; a negative surface charge, which can attract lysozymes and other positively charged deposits; and greater mass, which can affect lens fit, depending on the type of GP lens.

GP lenses are the lens of choice for dealing with complicated corneal disease such as keratoconus, corneal scarring from disease or trauma, and transplanted corneas or those with high astigmatism. Unlike soft lenses that drape over the surface of the cornea, even if it is irregular, GP lenses create a new refracting surface with a tear layer filling the gap between lens and cornea. GP lenses are available in a wide range of designs, including toric lenses for astigmatism and bifocals for presbyopia. Although far fewer in number, some GP materials are also FDA approved for either 7 or 30 days of continuous wear, depending on the material.

### GP Lens Fitting

Most providers who fit contact lenses agree that, compared with soft lenses, fitting GP lenses requires more art and science. Unlike soft lenses, GP lenses are not mass manufactured but rather are custom designed and manufactured on demand, requiring the optometrist to provide the parameters of diameter, base curve, power, and material to order a lens.

### Specialty Contact Lenses

Numerous companies manufacture soft contact lenses. The product offerings of many companies overlap to address the most common myopic, hyperopic, and astigmatic refractive errors. Many companies sell prepackaged, mass-produced lenses that consumers can buy in bulk with a prescription. Some offer customized lenses to address unusual needs. Several promote materials that absorb ultraviolet light. Corrective, tinted lenses are available for easier handling and for cosmetic purposes. Translucent tints facilitate handling by increasing the visibility of the lens and enhance eye color. Opaque lenses cover the iris and hide its natural color. These lenses may also be used as a prosthesis to mask corneal scarring. In contrast, all GP lenses are custom made by laboratories that often use proprietary, computer-generated lens designs. These unique designs are aimed at specialty needs such as keratoconus, post-corneal transplant use, scarred corneas, post-refractive surgery use, aphakia, or high astigmatism. Two specialty lenses worth mentioning are lenses for presbyopia and hybrid lenses.

*Presbyopia* is the loss of accommodation in the aging eye, requiring the addition of plus power (i.e., adjustment for farsightedness) to improve the clarity of vision at a near reading distance. It affects individuals who are near- or farsighted or who have an astigmatism. Presbyopia is not to be confused with cataracts, another common cause of visual loss, which are caused by reduced clarity in the crystalline lens and are usually attributable to long-term oxidation and genetic predisposition. Presbyopes are projected to be the single largest group of contact lens wearers by 2018 at 28%.<sup>18</sup> In glasses, a separate portion of the spectacle lens at the bottom of the lens provides this additional plus power for reading (bifocal glasses). This change in power is more difficult to accomplish with contact lenses. A common method of correcting presbyopia with contact lenses is monovision, a technique that uses standard lenses, with the dominant eye fit for distance and the other eye fit for near vision. Monovision can be effective, but it can affect depth perception, intermediate vision, and night driving. Today, multifocal contact lenses are being designed to provide binocular vision for patients, which provides a smooth transition from the near, intermediate, and far zones of the lens. The practitioner should discuss the options with the patient to determine what would work best for him or her.<sup>19</sup>

A *hybrid contact lens* is a unique contact lens that combines GP and soft lens materials in the same lens. The overall advantages of this lens are excellent optics through the GP portion of the lens, improved comfort from the soft lens portion, greater oxygen permeability (compared with an earlier version of the lens), and the ability to deal with astigmatism and irregular corneas (e.g., keratoconus and corneal transplant). The disadvantages are expense, difficulty with insertion and removal, longer fitting time, and complications of lens wear. The care of these lenses follows the patterns described for soft contact lenses in later sections.

### Formulation Considerations for Lens Care Products

The manufacturing and marketing of contact lenses are regulated by the ophthalmic devices division of FDA.<sup>1</sup> Patients who wear contact lenses should use only lens care products that have been approved by FDA for use with their specific contact lenses.

The basic considerations for a well-formulated contact lens solution include pH, viscosity, isotonicity with tears, stability, sterility, and provisions for maintaining sterility (bactericidal action). The pH range of comfort is not well defined because, although normal tear pH is 7.4, tear pH varies among individuals. It is best to have a weakly buffered solution that can readily adjust to any tear pH, given that highly buffered solutions can cause significant discomfort, even ocular damage, when they are instilled. However, as with therapeutic ophthalmic solutions, the stability of the solution takes precedence over comfort. For that reason, many contact lens solutions are formulated with pH values above or below 7.4. These systems are weakly buffered and are usually well tolerated by the eye.

Solutions from different manufacturers should not be mixed because a precipitate may form.<sup>4,20</sup> For instance, a product containing alkaline borate buffers forms a gummy, gel-like precipitate on lenses if mixed with a wetting solution containing polyvinyl alcohol. Furthermore, solutions containing a cationic preservative, such as chlorhexidine, polyquaternium-1, or polyaminopropyl biguanide, should not be mixed with solutions containing an anionic preservative such as sorbic acid; this combination, too, will cause a precipitate to form.

### Soft Contact Lens Care

The goals of cleaning a contact lens are to (1) remove debris from the lens surface, (2) prevent the accumulation of proteins from the tear layer on the lens, and (3) disinfect the lens of organisms that can bind to the lens surface and potentially lead to infection. Lens disinfection is a crucial step, although all steps must be completed on a daily basis or after each wearing period to avoid ocular complications.<sup>21</sup> The basic care regimen for soft lenses (Figure 28-1)

differs from that for GP lenses.

Since the early days of contact lens use, separate solutions have been available for each step of cleaning, rinsing, disinfecting, storing, and protein removal. These include surfactants for cleaning the lens surface, saline solution for rinsing, disinfecting agents for sterilization, and enzymes for protein removal, in addition to wetting drops for use while lenses are on the eye. To improve convenience and compliance, multipurpose products are available that combine these active ingredients in a biocompatible solution buffered for pH balance for use directly in the eye. Some of these solutions also contain demulcents to increase lubrication and comfort of the eye.

Tables 28-3 and 28-4 provide steps for cleaning soft contact lenses.

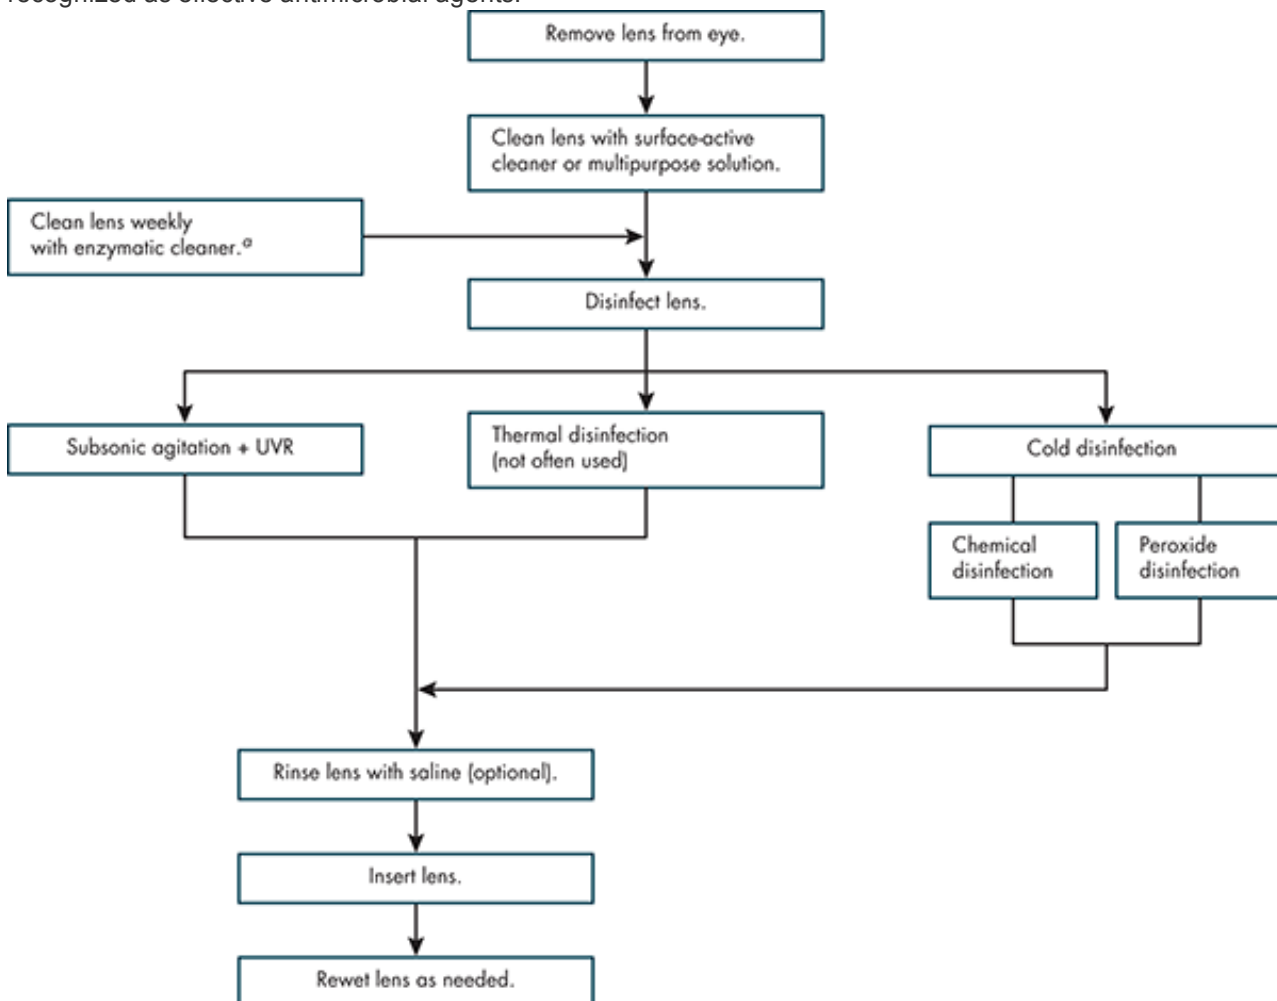

### Soft Lens Disinfection

The lens care regimen must be primarily built around the use of a disinfecting system. Emphasis must be placed on hand hygiene and adherence to the manufacturer's requirements for each disinfecting system, while stressing the minimum soaking time for disinfection.

### Preservatives

The most important point to be made in a discussion of contact lens disinfection regards the preservatives that are used both to keep multiuse solutions sterile and to disinfect the lens. Daily use of the same bottle of any contact lens solution over a long period of time increases the risk of bacterial contamination. The solution must therefore contain a bactericidal agent that is both effective over the long term and nonirritating to the eye with daily use. Despite the presence of preservatives, once opened, any contact lens solution not used within the recommended time frame on the label, typically 1-3 months, must be discarded. Patients should be encouraged to write the date that the bottle is opened on the outside of the bottle.<sup>22</sup>

Edetate disodium and sorbic acid are the most commonly used preservatives in saline, daily cleaners, and wetting drops for contact lenses; benzalkonium chloride is used less frequently. Polyquaternium and polyhexamethylene biguanide are the preservatives used most commonly as disinfecting agents for soft contact lens solutions; both are recognized as effective antimicrobial agents.<sup>22</sup>

º Step is not necessary for planned replacement or disposable lenses.

**TABLE 28-3 General Cleaning Procedures for All Lens Types**

- Wash hands with noncosmetic soap and rinse them thoroughly before handling lenses.
- Clean contact lenses only with commercially manufactured products made specifically for that type of lens. Homemade cleansers can scratch the lenses or cause eye irritation or injury.
- Do not mix contact lens care products from different manufacturers unless an eye care provider says the products are compatible.
- When handling lenses over a sink, cover or close the drain to prevent loss of a lens.
- During cleaning, check lenses for scratches, chips, or tears and for the presence of foreign particles, warping, or discoloration. Also, check that lenses are clean and thoroughly rinsed of cleaner. These factors could cause eye discomfort.
- When cleaning a lens, rub it in a back-and-forth, rather than a circular, direction, even if using a no-rub solution.
- Clean the second lens as thoroughly as the first.
- Discard cleansers and other lens care products if the labeled expiration date has passed.

**TABLE 28-4 Specific Cleaning Procedures for Soft Lenses**

- Clean regular soft lenses daily with a surface-active cleaner. Clean continuous-wear and disposable soft lenses with a surface-active cleaner after each wearing.
- Wash hands before handling your lenses.
- Place several drops of a cleaning product on the lens; gently rub the lens between the thumb and forefinger or between the fingertip of the forefinger and the palm of the opposite hand for 20-30 seconds, even if using a no-rub product, to ensure protein removal.
- Avoid cutting the lens with a fingernail or scratching the lens surface with grit or dirt on the hands.
- Rinse lenses with a sterile isotonic buffered solution. Never use tap water. It is not isotonic and contains harmful microorganisms.
- Clean lenses at least weekly (or every day if using a daily product) with enzymatic cleaners, either separately from disinfection or as part of the disinfecting process.
- When combining enzymatic cleaning and disinfecting of the lenses as one step, see [Table 28-6](#) for the appropriate combinations of products.
- Discard any enzyme cleaner that is discolored.

### Polyquaternium-1

Polyquaternium-1 (Polyquad) is a quaternary ammonium preservative shown to be effective against certain bacteria, fungi, and yeast. When it was introduced to the market, formulations containing polyquaternium-1 were not compatible with lenses that had high water content because the methacrylic acid component of the lens had the ability to adsorb the preservative at toxic levels. However, recent formulations do not seem to have this problem. To date, few toxicity or sensitivity problems have been noted with these formulations.<sup>23</sup>

### Polyhexamethylene Biguanide

Polyhexamethylene biguanide, also known as polyaminopropyl biguanide, Dymed, or polyhexanide, is a cationic polymeric biguanide that is effective against certain bacteria and yeast, although its activity against *Acanthamoeba* and fungi is limited. No significant adverse effects of polyaminopropyl biguanide have been reported in lens wearers.

### Disinfecting Methods

FDA recommends disinfecting soft contact lenses before each reinsertion.<sup>21,22</sup> Chemical-based disinfection is by far the most popular ([Table 28-5](#)). Thermal, or heat, disinfection is no longer a viable method of caring for soft contact lenses. The other alternative is an electronic system, PuriLens, that uses subsonic ultrasound agitation for cleaning and high-intensity ultraviolet light for disinfection. However, one study suggests that additional antimicrobial agents may be needed because some bacteria may survive the disinfection process.<sup>24,25</sup>

**TABLE 28-5 Guidelines for Disinfecting Gas Permeable and Soft Lenses**

#### Chemical Disinfection with Hydrogen Peroxide

- Using the cup provided with the hydrogen peroxide product, soak lenses for the length of time specified by the manufacturer. Do not use lens cups or cases that came with other products.
- To disinfect and neutralize in one step, place platinum catalytic disk in lens case and leave the disk there until time to replace it. Add hydrogen peroxide, insert lenses, and leave for at least 6 hours.
- Never place neutralizing solution in a lens case with a catalytic disc. An unwanted chemical reaction may occur, or a gummy residue may form on the disc.

- Before inserting lenses in the eyes, make sure the hydrogen peroxide is completely neutralized by carefully following product instructions.
- Rinse lenses thoroughly with saline before inserting them.

#### Chemical Preservative Disinfection

- Store lenses for the prescribed period of time (usually a minimum of 4 hours) in a preservative disinfecting solution that is appropriate for the lenses.
- If you experience irritation, rinse lenses thoroughly with saline to remove disinfecting solution.

#### Combination Enzyme Cleaning and Disinfection

- When combining enzyme cleaning and disinfecting of the lenses as one step, select products compatible with your disinfecting system.
- Add appropriate solution (hydrogen peroxide or chemical disinfecting product) to the storage case of the disinfecting system.
- Add lenses and then add appropriate enzymatic cleaner.
- Follow directions for appropriate disinfecting system listed previously.
- Rinse lenses thoroughly with saline to remove residual enzymes.

In chemical disinfection, lenses are stored for a prescribed period of time (usually 4-6 hours) in a solution containing bactericidal agents that are compatible with soft lens materials. Two basic chemical disinfection methods are available in the United States. The first is based on the original chemical disinfecting solutions, which consisted of antimicrobial preservatives at sufficient concentration in storage solutions composed primarily of saline.<sup>22,26</sup> These original disinfecting solutions contained chlorhexidine and thimerosal, both of which induce sensitivity reactions in many soft lens wearers.<sup>26,27</sup> To avoid this problem, manufacturers are currently marketing solutions with less-sensitizing disinfecting preservatives for soft contact lens care. Some of these preservatives are sorbic acid, polyquaternium-1, polyaminopropyl biguanide, and amidoamine, which are touted as being much less toxic or allergenic than their predecessors. However, some of these agents may also be less effective, especially against fungi and protozoans.<sup>26</sup> The second chemical method uses hydrogen peroxide as the antimicrobial agent. Soft lenses are placed in purified hydrogen peroxide only and disinfected by the liberation of oxygen from peroxide. Household hydrogen peroxide solution should not be used; its pH is too low and it may discolor lenses. After disinfection is completed, the peroxide is neutralized to trace levels by a neutralizing tablet that contains a delayed-release catalase or by the catalytic action of a platinum disc.<sup>28</sup>

One potential disadvantage of hydrogen peroxide disinfection is that patients may mistakenly insert the lens directly from the peroxide solution without neutralization. Patients must be warned not to perform a final rinse with the disinfecting solution prior to inserting their lenses, as they might do with a multipurpose chemical system. Emphasis on the neutralization step is critical. A peroxide-soaked lens placed on the eye will cause a toxic keratitis with symptoms of pain, photophobia, and redness. If this occurs, the patient should immediately remove the lens from the eye and flush the eye copiously with sterile saline solution. If symptoms do not abate, the patient should consult an eye care provider.<sup>28</sup> The catalytic disc used with some systems must be replaced every 3 months. Any sensation of discomfort or burning experienced by the user when inserting contact lenses that have been disinfected with hydrogen peroxide likely means incomplete neutralization and the need to replace the disc. Patients must also be instructed that once disinfection of contact lenses with a hydrogen peroxide system is completed, the remaining liquid is nonpreserved and is not suitable for prolonged storage (maximum of 7 days). Bacterial contamination may occur after that time. Hydrogen peroxide systems are not recommended for patients who wear lenses intermittently; these patients should be advised to switch to a multipurpose solution or to change to daily disposable contact lenses. Although the catalytic disc systems require only one step, disinfection and neutralization require 6 hours, which decreases the system's flexibility and rules out morning use. Clear Care is the most readily available catalytic disc-based oxidation system. It contains a built-in cleaner and is approved as a "no-rub" product, but it does require a 5-second rinse before disinfection. Clear Care is the only peroxide system approved by FDA for use with silicone hydrogel materials.<sup>29</sup> Unizyme enzymatic cleaner may be added weekly for protein removal. Clear Care can also be used for cleaning, disinfection, and storage of GP lenses, but the lenses require digital rubbing. Oxysept UltraCare is a catalase-based system. With this product, the user adds a delayed-release neutralizing tablet at the beginning of the 6-hour disinfecting cycle. Disinfection and neutralization then occur at the appropriate time intervals. This tablet contains catalase and cyanocobalamin; the latter ingredient turns the solution pink, reminding the user that the tablet has been added.<sup>29</sup> The tablet is coated with hydroxypropyl methylcellulose, which helps lubricate the eye if the lens is not rinsed again between disinfection and insertion. A separate daily cleaning step is required. Unizyme enzymatic cleaner may be added weekly for protein removal. Patients using Oxysept UltraCare should know the following:

- This product requires a minimum of 6 hours for complete disinfection of the lenses and neutralization of the

peroxide.

- The neutralizing tablet should not be crushed or used if there are cracks in the coating because the tablet will start neutralizing the peroxide before adequate disinfection occurs.
- Pliagel, used for surface-active cleaning, can leave a film on the lenses and lens cup if it is not carefully rinsed off the lenses before peroxide disinfection. This film may result in foaming and overflow of the peroxide-neutralizer solution. If this occurs, lenses should be rinsed more carefully or another surface-active cleaner should be used.
- The user should clean the lens case once a week. Remove lenses from the case if they are not being worn, and then fill the case with fresh Oxysept UltraCare disinfection solution and tighten the cap. Do not add a neutralization tablet. Turn the cup upside down to allow the solution to bathe the upper portion of the cup and cap. Soak the case in this manner until lenses need to be disinfected. Replace the solution for the next disinfection cycle.
- Before lenses are to be inserted in eyes, the case should be turned upside down to ensure full neutralization of all residual disinfecting solution in the case. Then the lenses can be removed from the case and inserted.

Patients also may use Sauflon One-Step (Sauflon), which has a built-in cleaner. Sauflon is considered a no-rub system and contains a rewetting agent. Patients must rinse each side for 5 seconds before disinfection. However, Sauflon is not available in the retail setting and can only be obtained through an eye care professional.<sup>29</sup> When counseling a patient about the best disinfecting method to use, the primary care provider should consider the patient's compliance, wearing schedule, and convenience. Peroxide-based systems provide excellent disinfection against many organisms and essentially eliminate solution sensitivity issues. They are not well suited, however, for intermittent wear of disposable lenses or for careless patients who may inadvertently instill peroxide in their eye. If the patient has a history of sensitivity reactions to lens solutions or is unsure whether sensitivity exists, it is best to recommend a product containing one of the nonsensitizing preservatives.

### Multipurpose Products

Initially manufacturers recommended three separate products for the cleaning, removal of protein, and disinfection of soft contact lenses. However, there has been a trend toward using multipurpose solutions for these functions, and some solutions claim to be effective for all three procedures.

The major problem with a multipurpose solution is that ingredients required in its formulation perform different and somewhat incompatible functions. For example, high concentrations of preservatives are necessary to kill bacteria; however, these same concentrations can cause ocular irritation when placed directly on the eye with a contact lens. If lenses are stored overnight in a cleaning solution containing an anionic surfactant, the detergent may eventually build up on the lens and cause irritation.<sup>30</sup>

Reactions to solutions should always be the differential diagnosis when trying to discern the cause of patient symptoms or findings of surface irritation during an eye examination. Most, if not all, of the chemicals listed as preservatives can cause irritation to the epithelium.<sup>31</sup> If symptoms are related to solution use, possible remedies are to use a final saline rinse prior to lens insertion or to change to another formulation of multipurpose solution that uses a different preservative. Another alternative for patients who are sensitive to chemical-based care systems is the PuriLens system, as discussed earlier.

A common source of confusion among patients is the concept of no-rub multipurpose solutions. The original sequence for cleaning contact lenses was to rub, rinse, and then soak. All of the no-rub products still require thorough rinsing of the lenses first, not just soaking.

Solutions that fail this test can still be approved if they pass the FDA regimen test that requires the manufacturer to recommend the additional steps of rubbing and rinsing in addition to soaking. The point of the requirement is that some mechanical force, either digital rubbing or a steady stream of liquid, is required to debulk the surface of the lens of debris and pathogens.

Patients should be counseled not to "top off" or reuse the contact lens solution in the case, as the solution is less effective once used. Recent research has indicated that when using any multipurpose contact lens solution, the best method of disinfection includes rubbing the contact lens.<sup>32</sup> FDA, American Optometric Association, and American Academy of Ophthalmology all have issued new recommendations that include rubbing each side of the contact lens for 5-10 seconds.<sup>21</sup>

These products are useful for patients with planned replacement lenses, because these lenses are usually discarded before a significant amount of protein or lipid builds up on the lens. Use of these products is usually more of a problem with longer lens replacement schedules.

### Cleaning Products

A troublesome aspect of soft lens wear is the accumulation of deposits on the lens. Daily use of separate cleaners and protein removal products, in addition to use of multipurpose solutions, generally is not necessary for disposable

lenses that will be discarded after a few weeks of wear. These products should be recommended if patients have long replacement schedules (>1 month) or demonstrate rapid, heavy formation of deposits on lenses. The nature of deposits varies, but they generally consist of proteins and lipids from lacrimal secretions.

Soft lens cleaning solutions generally contain a nonionic detergent, a wetting agent, a chelating agent, buffers, preservatives, and, in some cases, polymeric cleaning beads. Although the surface-active cleaners are generally quite effective in removing lipid deposits, they remove tenacious protein debris less successfully. Enzymatic cleaners are an additional cleaning aid that can solve this problem. These enzymes hydrolyze polypeptide bonds of protein and dissolve the protein deposits. For the enzyme solution to work properly, however, the lens must be cleaned with a surface-active cleaner first; enzymes are ineffective on debris that covers or is mixed with protein.

Enzymatic cleaners are recommended according to the disinfection system used by the patient. Ultrazyme and Unizyme are used weekly with hydrogen peroxide cleaning systems.<sup>33</sup> These products can be placed in the peroxide solution, thereby cleaning and disinfecting at the same time. For chemical-based systems, OPTI-FREE SupraClens Daily Protein Remover can be added directly to OPTI-FREE multipurpose solutions during the disinfection cycle. SupraClens must be rinsed off before lens insertion. ReNu 1 Step Daily Protein Remover is the companion product for patients using Renu Sensitive Multi-Purpose Solution. If the patient uses another chemical disinfection system, product comparisons are very idiosyncratic unless the patient is allergic to one of the components. Table 28-6 lists characteristics of various enzymatic products. Cleaning with a surface-active cleaner can be done daily or, in the case of continuous-wear lenses, each time they are removed from the eyes. In addition to surfactants, some products contain mild abrasives that aid in the removal of lens deposits. Patients who have difficulty removing deposits from their lenses will benefit from this type of cleaner. These products should be shaken before use. Some patients may have difficulty rinsing these cleaners off their lenses. Care should be taken to ensure that no residue from the cleaning solution remains on the lens prior to insertion. Some surface-active cleaners (e.g., Bausch & Lomb Sensitive Eyes Daily Cleaner) have a lower viscosity and may be easier to rinse off the lens. These products are good choices for patients who have difficulty completely rinsing the cleaner off their lenses.

Products that combine enzymatic cleaning and disinfecting steps tend to increase compliance by decreasing the number of lens care steps that a patient must perform. Of note, in addition to product patent expirations, which lead to generic formulations, solutions also change in the marketplace according to usage and trends in lens care. Daily cleaners, enzymatic cleaners, and saline solutions are used much less frequently because of the convenience of combination products. Some of the products mentioned in this chapter may be available only through online retailers.

**TABLE 28-6 Enzymatic Cleaners**

<i>Trade Name</i>	<i>Active Ingredient</i>	<i>Concurrent Use with Chemical Preservative Disinfection</i>	<i>Concurrent Use with Hydrogen Peroxide Disinfection</i>
OPTI-FREE SupraClens Daily Protein Remover	Liquid pancreatin	Yes, with OPTI-FREE multipurpose solutions	No
ReNu 1-Step Daily Protein Remover	Subtilisin A	Yes, with Renu Sensitive Multi-Purpose Solution	No
Ultrazyme/Unizyme	Subtilisin A	No	Yes

### Saline Solutions

A common source of confusion among patients is the use of saline solutions in lieu of disinfecting agents. The hydrophilic soft contact lens must be maintained in a constant state of hydration. Soft lenses in the nonhydrated (dry) state are rigid and extremely brittle, and they should not be handled by the wearer. Furthermore, the hydrated lens must be isotonic with tears, because changes in tonicity can alter the conformation and optical properties of the lens. At one point, isotonic normal saline was the basic solution used for rinsing, thermally disinfecting, and storing soft contact lenses.<sup>27</sup> That regimen is no longer recommended. The health care provider should emphasize that saline used alone lacks disinfecting properties and direct the patient toward a suitable multipurpose or hydrogen peroxide solution.

Saline still has a use as a final rinsing agent prior to insertion, especially for patients who are irritated by the chemicals in multipurpose solutions. Prepared saline is available in either preserved or preservative-free forms. Sorbic acid-preserved products are commonly promoted for sensitive eyes and appear to be acceptable to most wearers. Several preservative-free saline solutions are also available but must be used within 30 days if they are in a multiuse bottle. Patients using nonpreserved saline should be counseled that only aerosolized solutions can be used to rinse lenses just before insertion into the eye. Multipurpose nonpreserved saline (e.g., Unisol 4) should never be used to rinse lenses just before insertion, unless the bottle is new and has not been opened. Once these products have been opened, they should be used only if a disinfection step will be performed before insertion. Patients should avoid using other forms of saline, such as intravenous normal saline or saline squirts. These products are usually too

acidic for use with soft contact lenses. Patients should not try to make their own saline solution, as it can become easily contaminated and cause infections.

### Rewetting Solutions

Because dryness and discomfort with contact lens wear are common, additional lubricating or wetting drops are often recommended for use while wearing lenses. Exposing lenses to wind and high temperature also causes some dehydration, even with the lens in the eye. These accessory solutions permit lubricating and rewetting and, in some cases, cleaning of the soft lens while on the eye. Patients should be directed toward products specific for use with contact lenses to avoid drops preserved with benzalkonium chloride, as discussed earlier. Preservative-free lubricating drops are also a good alternative. The resulting discomfort is sometimes relieved by 1 or 2 drops of rewetting solution. To minimize contamination, the tip of the applicator bottle should not touch the eye, eyelid, or any other surface.

### Generic Solutions

Many generic versions of brand-name solutions are now available. It should be noted, however, that patients who choose to buy generic (e.g., mass merchandiser labeled) multipurpose lens solutions may be purchasing older, potentially obsolete formulas. Mass merchandisers generally purchase older formulations of nationally known brands of multipurpose solutions and then market them under their private label. In addition, the composition of a particular generic formulation can vary because the stores submit bids to manufacturers two to three times per year. Generally, patients should not use generic brands unless they carefully read the label and compare all ingredients with those of the product that was recommended by their eye care or other provider. Manufacturers are not required to use the same name for generic and brand-name ingredients, so comparing formulations may be difficult.<sup>34</sup>

### Product Incompatibility

Several incompatibilities may occur during mixing of soft lens products. Most manufacturers test for compatibility within their own product lines; however, compatibility with other manufacturers' products is usually not determined. Generally, chemical disinfecting solutions should not be used interchangeably or concurrently, as discussed earlier.

### Product Selection Guidelines

Table 28-7 lists examples of products designed specifically for soft contact lenses.

**TABLE 28-7 Selected Products for Soft Lenses**

<i>Trade Name</i>	<i>Primary Ingredients</i>
<b>Surface-Active Cleaning Solutions</b>	
Sensitive Eyes Daily Cleaner	Hydroxypropyl methylcellulose; sorbic acid 0.25%; EDTA 0.5%; NaCl; borate buffer; poloxamine
Opti-Clean II Daily Cleaner	Nylon 11; polysorbate 21; hydroxyethyl cellulose; polyquaternium-1; EDTA; boric acid; sodium borate; NaCl
OPTI-FREE Daily Cleaner	Nylon 11; polysorbate 21; hydroxyethyl cellulose; polyquaternium-1 0.001%; EDTA; boric acid; sodium borate; hydrochloric acid and/or sodium hydroxide
Pliagel	Sorbic acid 0.25%; EDTA 0.5%; poloxamer 407; KCl; NaCl
<b>Enzymatic Cleaning Products</b>	
OPTI-FREE SupraClens Daily Protein Remover <sup>a</sup>	Highly purified porcine pancreatin enzymes; PEG; sodium borate
ReNu 1-Step Daily Protein Remover	Subtilisin; glycerin; borate buffers
Ultrazyme Enzymatic Cleaner	Subtilisin A; effervescing agents; buffers
Unizyme Enzymatic Cleaner	Subtilisin A
<b>Hydrogen Peroxide Disinfecting Solutions and Rinsing/Neutralizing Products</b>	

AOSEPT	Disinfecting solution: hydrogen peroxide 3%; NaCl 0.85%; phosphate buffers; phosphoric acid
Clear Care	Hydrogen peroxide 3%; Pluronic
Oxysept UltraCare	Disinfecting solution: hydrogen peroxide 3%; sodium stannate; sodium nitrate; phosphates
<b>Preserved Saline Solutions</b>	
Sensitive Eyes Plus Saline	Sorbic acid 0.1%; NaCl; borate buffer; EDTA
<b>Preservative-Free Saline Products</b>	
Unisol 4	NaCl; sodium borate; boric acid
<b>Rewetting/Lubricating Solutions</b>	
Clerz Plus	Clens 100; Tetric 1304
Clerz 2	Hydroxyethyl cellulose; sorbic acid 0.1%; EDTA 0.1%; NaCl; KCl; sodium borate
OPTI-FREE Rewetting Drops	Polyquaternium-1 0.001%; citric acid; sodium citrate; NaCl
ReNu Rewetting Drops	Sorbic acid 0.15%; EDTA; borate buffer; poloxamine; NaCl
<b>Multipurpose Solutions</b>	
AQuify	Sorbitol; dexpanthenol; Pluronic F127; tromethamine; polyhexanide; EDTA
Biotrue	Polyaminopropyl biguanide 0.00013%; polyquaternium 0.0001%; hyaluronan; sulfobetaine; poloxamine; boric acid; sodium borate; edetate disodium; NaCl
OPTI-FREE Express or RepleniSH	Polyquaternium-1 0.001%; EDTA; sodium citrate; NaCl; citric acid; myristamidopropyl demethylamine; citrate buffer; C9-ED3A; Tetric 1304
Renu Fresh	Polyaminopropyl biguanide; EDTA; NaCl; sodium borate; boric acid; poloxamine
Renu Sensitive	Polyaminopropyl biguanide; EDTA; NaCl; sodium borate; boric acid; poloxamine
Complete	Polyhexamethylene biguanide 0.0001%; phosphate buffer; Poloxamer 237; edetate disodium; NaCl; KCl
RevitaLens OcuTech	Alexidine dihydrochloride 0.00016%; polyquaternium-1 0.00030%; boric acid; sodium borate decahydrate; TETRONICa 904; edetate disodium; trisodium citrate dehydrate; NaCl
Naturalens RDS (not for use with silicone hydrogel materials)	Polyhexanide 0.0001%; edetate disodium dehydrate 0.025%; NaCl; bis-tris propane; Pluronic F127; cremophor RH40

Key: EDTA = Ethylenediamine tetraacetic acid; KCl = potassium chloride; NaCl = sodium chloride; PEG = polyethylene glycol.

<sup>a</sup> Preservative-free formulation.

## Insertion and Removal

Table 28-8 provides instructions for inserting and removing soft lenses.

**TABLE 28-8 Insertion and Removal of Soft Lenses**

<b>Insertion</b>
<ul style="list-style-type: none"> <li>• Wash your hands with noncosmetic soap and rinse thoroughly; dry hands with a lint-free towel.</li> <li>• Remove the lens for the right eye from its storage container.</li> </ul>

- Rinse the lens with saline solution to dilute any preservatives left from disinfection (optional).
- Place the lens on the top of a finger, and examine it to be sure it is not inside out. This determination can be made by using the “taco test.” Gently fold the lens at the apex (not the edges) between the thumb and forefinger. The edges should look like a taco shell with the edges pointed inward. If the edges roll out, the lens is inverted and must be reversed.
- Examine the lens for cleanliness. If necessary, clean it and rinse again.
- Insert the lens on the right eye using the procedure described for GP lenses ([Table 28-11](#)).
- Repeat the process for the left eye.

### Removal

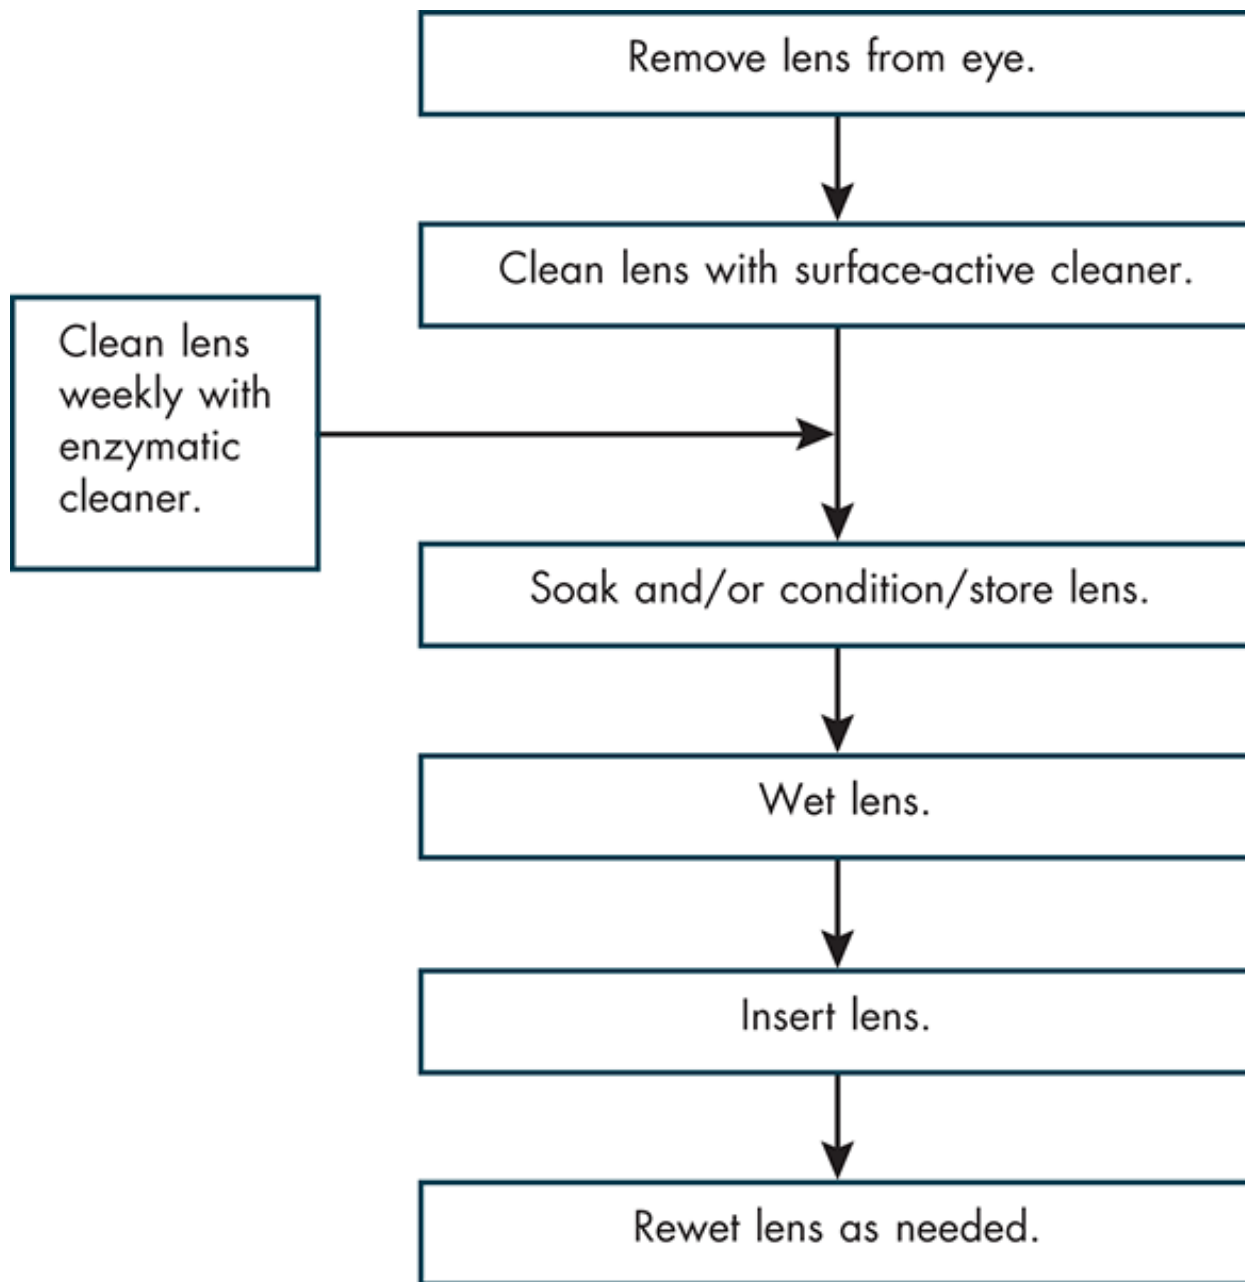

- Before removing the lenses, wash hands with a noncosmetic soap; rinse hands thoroughly and dry them with a lint-free towel.
- Using the right middle finger, pull down the lower lid of the right eye. Touch the right index finger to the lens and slide the lens off the cornea, as shown in drawing A.
- Using the index finger and thumb, grasp the lens and remove it (drawing B).
- Repeat the procedure for the left eye.

### GP Lens Care

The care of GP contact lenses follow the same general guidelines as for soft lenses, but the solutions for GP and soft lenses are not interchangeable. Lens wearers should be advised by their eye care providers about the products and regimens recommended for their particular lenses and advised against substituting other products for those specifically recommended.

Rigid lens care involves the steps of cleaning, disinfecting, soaking, and wetting ([Figure 28-2](#)), which should be performed each time the lenses are removed from the eye for optimal lens care. Modern solutions combine these steps in various combinations. Because GP lenses are replaced less frequently, providing more time for deposits to accumulate, separate solutions for daily cleaning and protein removal are still popular. Oxidation systems (hydrogen peroxide) can also be used, but heat disinfection should not be used with GP lenses. Rinsing with tap water is also not recommended because of microorganisms in the water.<sup>35</sup> [Tables 28-3](#), [28-5](#), [28-6](#), and [28-9](#) provide proper cleaning and disinfecting procedures for rigid contact lenses.

Self-care of GP lenses.

#### Product Selection Guidelines

With the abundance of combination wetting/disinfection solutions now on the market, the appropriate lens care regimen for GP lenses is fairly straightforward. Patients wearing GP lenses should be advised to purchase a surface-active cleaning product, an enzymatic product, and a conditioning or soaking solution, depending on the type of lens worn. A rewetting or reconditioning product should also be recommended. [Table 28-10](#) lists examples of products for GP lenses.

#### TABLE 28-9 Specific Cleaning Procedures for GP Lenses

- Use the cleansing, soaking, and conditioning products recommended by your eye care provider to clean your lenses.
- If you are unsure of your lens type, ask the eye care provider about proper cleaning procedures.
- Upon removal, apply an appropriate cleaning solution to both surfaces of the lens. Then rub the lens between the forefinger and palm of the opposite hand in a back-and-forth motion to avoid chipping an edge, which may occur if the lens is cleaned between the fingers. Do not apply too much pressure. If debris is still on the lens, soak a cotton swab in the surfactant cleaner, and use the swab to clean the lens.
- Soak and store the lenses in a soaking or conditioning solution recommended by the eye care provider for the specified amount of time. Rewet lenses before inserting them in the eyes.
- Enzymatic cleaning may also be recommended by your eye care provider and is typically performed weekly.

**TABLE 28-10 Selected Products for Gas Permeable Lenses**

<i>Trade Name</i>	<i>Primary Ingredients</i>
<b>Cleaning Solutions</b>	
Boston Advance Cleaner <sup>a</sup>	Silica gel; alkyl ether sulfate; ethoxylated alkyl phenol; triquaternaly cocoa-based phospholipids
Original Formula Boston Cleaner	Silica gel; alkyl ether sulfate; titanium dioxide; NaCl
Optimum CDS (for cleaning, disinfection, and storage; not for use in the eye)	Lauryl sulfate salt of imidazoline; octylphenoxy polyethoxyethanol; benzyl alcohol 0.3%; disodium edetate 0.5%
<b>Enzymatic Cleaning Products</b>	
Boston One Step Liquid Enzymatic Cleaner	Subtilisin; glycerol
<b>Wetting/Soaking/Disinfecting Solutions</b>	
Boston Advance Comfort Formula Conditioning Solution	Cellulosic viscosifier; polyvinyl alcohol; cationic cellulose derivative polymer; derivatized PEG; chlorhexidine gluconate 0.003%; polyaminopropyl biguanide 0.0005%; EDTA 0.05%
Boston Conditioning Solution	Hydroxyethyl cellulose; polyvinyl alcohol; cationic cellulose derivatives; poloxamer 407; chlorhexidine gluconate 0.006%; EDTA 0.05%
Optimum Wetting/Rewetting	Polyvinyl alcohol; polyvinylpyrrolidone; hydroxyethyl cellulose; NaCl; KCl; sodium carbonate; sodium bisulfite 0.02%; benzyl alcohol 0.1%; disodium edetate 0.1%; sorbic acid 0.05%
<b>Rewetting/Lubricating Solutions</b>	
Boston Rewetting Drops	Hydroxyethyl cellulose; polyvinyl alcohol; cationic cellulose derivatives; poloxamer 407; chlorhexidine gluconate 0.006%; EDTA 0.05%
<b>Multipurpose Solutions</b>	
Boston Simplus	Poloxamine; hydroxyalkylphosphonate; boric acid; sodium borate; NaCl; hydroxypropylmethyl cellulose; Glucam; chlorhexidine gluconate 0.003%; polyaminopropyl biguanide 0.0005%
Naturalens RDS	Polyhexanide 0.0001%; edetate disodium dehydrate 0.025%; NaCl; bis-tris propane; Pluronic F127; cremophor RH40
OPTI-FREE GP	Polyquad (polyquaternium-1) 0.0011%; hydroxypropyl guar; PEG; Tetronic 1304; boric acid; propylene glycol; edetate disodium 0.01%

Key: EDTA = Ethylenediamine tetraacetic acid; KCl = potassium chloride; NaCl = sodium chloride; PEG = polyethylene glycol.

<sup>a</sup> Preservative-free formulation.

### Cleaning Solutions

Normal tears are composed of secretions from many specialized glands lining the lacrimal apparatus, conjunctiva, and lids. Many components are somewhat hydrophobic and tend to adhere to the surface of a rigid lens during normal daily wear. This residue, primarily proteinaceous debris and lipids, acts as a growth medium for bacteria. If it is not routinely removed by daily cleaning, the residue may harden to form coatings or tenacious deposits that create an irregular surface on the lens. Decreased visual acuity and shorter toleration time are likely consequences of a cloudy

lens created by this residue.

Contact lens cleaning solutions typically contain nonionic or amphoteric surfactants that emulsify lipids and aid in solubilizing other debris. Proteins and lipids are soluble in highly alkaline media, but high pH can cause lens decomposition. Weak alkaline solutions may dislodge deposits from the lens in conjunction with the surface tension-lowering properties of the surfactants. Cleaners formulated for tenacious deposits contain silica gel, which acts to mechanically break the adhesive bonds that have formed between the lens and the deposits. Homemade cleaning solutions such as baking soda mixed with distilled water or household cleaning solution should never be used because they may scratch lenses and may not rinse off easily. Use of household cleansers and homemade solutions (including salt tablet solutions) of any kind should be strongly discouraged to prevent lens damage, contamination leading to infection, and ocular irritation.

### Soaking Solutions

These solutions are used to store rigid contact lenses after removal and during insertion of the lens in the eye. The solution maintains lenses in a constant state of hydration for maximum comfort and visual acuity, and it aids in removing deposits that accumulate on the lenses during wear. If lenses are allowed to dry out during overnight storage, accumulated deposits are more difficult to remove with normal cleaning.

An ideal soaking solution performs the following functions: (1) converts the hydrophobic lens surface to a hydrophilic surface by means of a uniform film that does not easily wash away; (2) increases comfort by providing cushioning and lubrication between the contacting surfaces; (3) places a viscous coating on the lens to protect it from oil on the fingers during insertion; and (4) stabilizes the lens on the fingertip to ease insertion, particularly for individuals with poor manual dexterity or unsteady hands. Cellulose gum derivatives are often used, but they do not promote uniform wetting of a rigid lens; therefore, polyvinyl alcohol is also often used to decrease surface tension.

Because GP lenses that contain high levels of silicone have decreased surface wettability, conditioning solutions are generally used instead of soaking solutions to aid the formation of a cushioning tear layer. A conditioning solution is essentially a specially formulated wetting solution that enhances wettability of the lens, increases comfort, and disinfects the lens. Saliva should never be used to wet contact lenses because it can lead to infection by many pathogens.

### Rewetting Solutions

Rewetting solutions are intended to clean and rewet the contact lens while it is in the eye. These solutions depend on the use of surfactants to loosen deposits; removal is assisted by the natural cleaning action of blinking. Although these products function well to recondition the lens, the cornea benefits more if the lens is actually removed, cleaned, and rewetted. Removing the lens for even a brief time allows the cornea to be resurfaced with a new proteinaceous or mucinaceous layer.

To maintain sterility in rewetting products, preservative levels are carefully selected. Higher levels do not necessarily result in increased effectiveness and may lead to impaired wetting or corneal irritation because of the adsorption of preservatives onto the lens. Most rewetting agents are preserved, multidose products. Patients who use these products frequently should be encouraged to use preservatives such as oxychloro complex or perborates. Patients should be informed that preserved artificial tears and rewetting agents are different; most preserved artificial tears are incompatible with contact lenses.<sup>36</sup>

### Enzymatic Solutions

As the silicone content of GP lenses increases, so does the amount of protein adherence. Silicone acrylate lenses have an active surface that promotes the binding of tear constituents. Protein deposits on a lens will decrease the oxygen permeability, and the patient may experience discomfort. If daily cleaning is not sufficient, lenses of this type should be cleaned with an enzymatic product once weekly.<sup>35</sup> Failure to comply with this cleaning step may result in the need for professional polishing or replacement of the lens.

### Insertion and Removal

Wearers of GP lenses should be counseled to follow proper insertion and removal procedures ([Tables 28-11](#) and [28-12](#)).

#### **TABLE 28-11 Insertion of Gas Permeable Lenses**

After washing your hands, remove one lens from the lens storage case, rinse it with fresh conditioning/soaking solution, and inspect it for cleanliness and signs of damage (cracks or chips).

- If a wetting or conditioning solution is being used, place a few drops on the lens.
- Place the lens on the top of the index finger, as shown in drawing A.

- Place the middle finger of the same hand on the lower lid and pull it down (drawing B).
- With the other hand, use a finger to lift the upper lid, and then place the lens on the eye (drawing C).
- Release the lids and blink.
- Check vision immediately to see if the lens is in the proper position.
- If vision is blurred, blink three to four times. If vision is still blurred, the lens may be off center, on the wrong eye, or dirty.
- Instill 1-3 drops of rewetting or reconditioning drops into the eye.
- If vision is not improved, remove the lens, place several drops of wetting/conditioning solution onto both surfaces, and reinsert lens.
- Repeat all steps with the other lens.

**TABLE 28-12 Removal of Gas Permeable Lenses**

- Before removing the lens, fill the storage cases with soaking/conditioning solution.
- Remove the top from the cleaning solution.
- Place a hand (or a towel) under the eye.
- Use one of the following methods to remove the lens from the eye.

#### **Two-Finger Method of Removing Lenses**

- Place the tip of the forefinger of one hand on the middle of the upper eyelid by the lashes, as shown in drawing A.
- Place the forefinger of the other hand on the center of the lower lid margin (drawing A).
- Push the lids inward and then together, as shown in drawing B. The lens should pop out.
- If the lens becomes decentered onto only the white part of the eye, recenter the lens and try again.

### Temporal Pull/Blink Method of Removing Lenses

- Place an index finger on the temporal edge of the lower and upper lids. Initially, widen the eyelids a little (drawing C).
- Stretch the skin outward and slightly upward without allowing the lid to slide over the lens. Blink briskly, as shown in drawing D. The lens will pop out because of the pressure of the eyelids at the top and bottom of the lens. Blinking facilitates removal after the lids have been tightened around the lens.

### Lens Storage Case

Patient education on the care of all contact lenses must include discussion of the proper care and cleaning of the contact lens storage case as well as the lens material. A dirty lens case can be contaminated with a biofilm that will attract pathogens and increase the risk of infection. The lens case should be cleaned daily. After lens insertion, the case (and lids, if separate) must be emptied, rinsed with the same disinfecting solution, wiped, and air-dried between uses.<sup>37</sup> Tap water should not be used. All solutions should be discarded daily. The case should not be used if cracked and should be replaced periodically, at least every 3 months.<sup>35,37</sup>

### Follow-Up Care

Follow-up care is essential for the long-term success of contact lens wear. The minimum recommendation is 1 year between visits in the case of uncomplicated lens wear. These visits allow the prescriber to evaluate the integrity of the

lenses worn and the condition of the cornea. Patient education, including the wearing schedule, replacement schedule, and care regimen, should also be reviewed. Regular contact lens follow-up care is an important aspect in the prevention of contact lens complications.

### Contact Lens-Related Problems

Both soft and GP contact lenses provide good vision and safe, comfortable wear over years of use, provided they are fitted properly and patients adhere to correct care regimens. Unfortunately, complications of contact lens wear have not been eradicated with advances in material, lens design, and solutions. In general, soft contact lens patients tend to have more complications because there is less tear exchange beneath the lens and because the lenses are worn for longer hours, including overnight. Problems with GP lenses tend to be related to improper fit. Although occasional symptoms of mild redness and discomfort are common with contact lens wear, eye care providers should distinguish more severe symptoms that may cause significant complications, including threats to sight. Whenever a patient presents with signs or symptoms that are believed to be related to contact lens wear, discontinuing lens wear is recommended until the underlying cause is diagnosed and treated. Therefore, every patient should have glasses to wear as a backup to contact lenses.

Evaluation of a contact lens-related problem should begin with a thorough history of the problem. During the patient interview, the eye care provider should determine what types of eye problems exist and how long the patient has been experiencing them. Asking the patient whether a history of eye problems exists and what medications are currently being taken will give a general sense of the etiology and urgency of the current eye problem. The answers will also help to determine whether the problem is related to noncompliance with care regimens or to drug-lens interactions. Determining which type of contact lenses a patient is wearing and how long the patient has worn them is crucial in assessing problems that are related to improper lens care or deteriorated lenses. Patients should be asked to describe how they care for their lenses, which lens care products they use, and whether they have recently changed products.

Unfortunately, mild and severe complications of lens wear present with similar symptoms that overlap and vary in degree. For example, mild redness and irritation in both eyes occurring at the end of the day for several weeks or months likely suggest dryness that might resolve with a change in lens material, wearing schedule, or lubricating drops. However, a patient who presents with acute symptoms of marked, sectoral redness in one eye, accompanied by photophobia and pain that started 1 day earlier, suggests a more severe concern, such as a corneal ulcer. The following symptoms are common for lens-related problems:

- *Itching*: Patients are usually not allergic to lens materials, but they may have an allergy to solutions. Itching may also be a sign of allergic conjunctivitis unrelated to lens wear.
- *Blurred vision*: Mild blurring may suggest wrong lens power, lenses switched between eyes, lenses placed on the eye inside out, or debris buildup on the lens. Blurring also accompanies problems with the ocular surface, such as superficial keratitis, corneal abrasion, and corneal edema associated with infiltration or ulceration.
- *Redness*: Redness can occur as a response to numerous insults. The degree of redness typically, but not always, corresponds to the severity of the problem. Mild, diffuse redness can accompany end-of-day dryness, whereas severe redness, especially sectoral, can indicate a corneal problem. Ocular decongestants reduce mild conjunctival hyperemia associated with prolonged lens wear. However, upon cessation of their use, these topical decongestants can induce a rebound hyperemia, especially if they are used for more than 72 hours. Therefore, routine use of these products should be avoided, and if symptoms persist, the patient should be referred to an eye care provider.
- *Pain*: Pain is a significant finding because it is likely related to the eye's corneal nerve endings. Mild discomfort or irritation is not uncommon among all contact lens wearers. It may be related to the material, lens fit, or a torn or dirty lens. Severe pain or deep aching of the eye can signify corneal abrasions, infiltrates, or ulcers and typically persists even after removal of the lens. These symptoms represent urgent, sight-threatening conditions, and referral to an eye care provider is advised.
- *Fogging*: Misty or smoky vision can be caused by coatings or deposits on lens surfaces or by poor wetting of the lens while on the eye.
- *Photophobia (light sensitivity)*: Similar to pain, photophobia suggests complications with the cornea or a symptom of iritis, which should be referred to an eye care provider.
- *Excessive tearing*: Corneal nerves start a feedback loop that promotes tearing; therefore, irritation to the corneal surface, such as a torn or dirty lens, will increase tearing.
- *Flare*: Point sources of light that have a sunburst or streaming quality can be caused by inadequate optic zone size or decentration of a poorly fitting lens.
- *Lens falling out of the eye*: Improper fit is usually the cause; however, even properly fitted rigid lenses may occasionally slide off the cornea or be blinked out of the eye. Soft lenses that dry out on the eye may move excessively and dislocate.
- *Squinting*: This effect is caused by excessive movement of a lens or by a poorly fitted lens. The wearer will squint to center the optical portion of the lens over the pupil. Squinting may also indicate improper lens power.

Symptoms of redness, discomfort, and dryness are the most common complaints and the leading causes of discontinuing lens wear. Even brand new contact lenses disrupt the tear film and alter the environment of the anterior ocular surface. Changes in lens material or solutions, alteration of lens fit, or use of lubricating drops usually improves symptoms.

In contrast, microbial keratitis (corneal ulceration) is the worst complication of contact lens wear. The health care provider should be alert for symptoms of blurred vision, redness, pain, light sensitivity, and watering that often worsen even after discontinuation of lens wear. A white infiltrate visible on the cornea requires urgent referral for evaluation by an eye care provider. Removal of contact lenses and prompt treatment are crucial to improve outcomes. Overall, distinguishing common lens wear-associated complaints from signs of more severe inflammatory or infectious complications can be difficult. Considerations include whether one or both eyes are involved, the duration of symptoms, the severity of symptoms, and whether symptoms are isolated or found in conjunction with each other. Even experienced health care providers have problems distinguishing inflammatory from infectious complications. Timely referral to an eye care provider is indicated if there is any doubt that symptoms suggest more than lens wear-associated symptoms.

### Precautions for Contact Lenses

#### Adverse Effects of Drugs

Many undesired effects have been reported when a patient who wears contact lenses ingests, applies, or encounters certain drugs ([Table 28-13](#)). Wearers of soft hydrophilic contact lenses should be particularly cautious in exposing their lenses to chemicals. These chemicals, many of which penetrate and bind with the lens material, can come from cosmetics, environmental pollutants, and ophthalmic and systemic products. The health care provider must understand these drug-induced problems to counsel patients effectively.

**TABLE 28-13 Drug-Contact Lens Interactions**

<i>Changes in Tear Film and/or Production</i>
<b><i>Decreased Tear Volume</i></b>
Alcohol
Anticholinergic agents
Antihistamines
Beta-blockers
Benzodiazepines
Botulinum toxin type A (Botox)
Conjugated estrogens
Diuretics
Oral contraceptives
Phenothiazines
Serotonin reuptake inhibitors
Sildenafil citrate
Statins
Timolol (topical)
Tricyclic antidepressants
Vardenafil HCl
<b><i>Increased Tear Volume</i></b>
Cholinergic agents
Garlic (dietary supplement)

Reserpine
<b>Changes in Lens Color (Primarily Soft Lenses)</b>
Diagnostic dyes (i.e., fluorescein)
Epinephrine (topical)
Fluorescein (topical)
Nicotine
Nitrofurantoin
Phenazopyridine
Phenolphthalein
Phenothiazines
Phenylephrine
Rifampin
Sulfasalazine
Tetracycline
Tetrahydrozoline (topical)
<b>Changes in Tonicity</b>
Pilocarpine (8%)
Sodium sulfacetamide (10%)
<b>Lid/Corneal Edema</b>
Chlorthalidone
Clomiphene
Conjugated estrogens
Oral contraceptives
Primidone
<b>Ocular Inflammation/Irritation</b>
Diclofenac (topical ophthalmic)
Garlic (dietary supplement)
Gold salts
Isotretinoin
Salicylates
<b>Changes in Refractivity (Induction of Myopia)</b>
Acetazolamide
Sulfadiazine
Sulfamethizole
Sulfamethoxazole
Sulfisoxazole

<b>Changes in Pupil Size</b>
<b><i>Pupillary Dilation</i></b>
Anticholinergic agents
Antidepressants
Antihistamines
CNS stimulants
Kava
Phenothiazines
<b><i>Pupillary Miosis</i></b>
Opiates
<b>Miscellaneous Agents (Effects)</b>
Digoxin (increased glare)
Hypnotics/sedatives/muscle relaxants (decreased blink rate)
Ribavirin (cloudy lenses)
Topical ciprofloxacin/prednisolone acetate (precipitate)

Key: CNS = Central nervous system.

### Topical Drugs

In general, patients should be counseled not to place any ophthalmic solution, suspension, gel, or ointment into the eye when contact lenses are in place. A nonprescription ophthalmic product that is not specifically designed for use with contact lenses also should not be used when lenses are in the eye. Soft lenses can absorb chemical compounds from topically administered ophthalmic products.<sup>38</sup> Topical administration of ophthalmic drugs also may have physiologic consequences or may modify pharmacologic responses to drugs. The use of solutions that may be considered benign, such as artificial tears, may reduce tear breakup time and alter the distribution of the mucoid, aqueous, and lipid components of tears, perhaps causing initial discomfort on instillation of the drops.<sup>38</sup> A topical drug administered while soft lenses are in place may have an exaggerated pharmacologic effect. The soft lens may absorb the drug and either release it over time, creating a sustained-release dosage form, or bind it tightly so that none of it is released into the eye. Furthermore, the presence of any kind of contact lens may increase the amount of time the medication is in contact with the eye. Finally, increased drug absorption may occur secondary to a compromised corneal epithelium during contact lens wear.<sup>38</sup> The only exceptions to this rule are products specifically formulated to be used with contact lenses, such as rewetting drops, or those products that an eye care provider has specifically recommended for use with contact lenses.

If a drug solution is instilled into the eye prior to lens insertion, the wearer must not insert a lens until the solution has cleared from the lower eyelid's precorneal (conjunctival) pocket (about 5 minutes). Ideally, when topical ophthalmic ointments, gels, or suspensions are being used, the lenses should not be worn at all.

### Airborne Drugs and Particulate Matter

Some drugs that are present in indoor air may damage lenses, so health care providers should be cautious with medications that are administered via inhalation. Similarly, contact lens wearers who have been exposed to a large amount of cigarette smoke have discovered a brown discoloration and nicotine deposits on their lenses.

### Systemic Medications

Use of a systemic medication often has far-reaching and unanticipated effects aside from the expected pharmacodynamic actions. Perhaps the most visible manifestation of ocular-related systemic drug toxicity is found

among contact lens users who develop ocular discomfort or irritation and contact lens intolerance while using a particular systemic drug. Contact lens patients will often present with complaints of new onset of eye dryness or irritation and intolerance to contact lens wear and request a nonprescription product to provide symptomatic relief. Although such symptoms are similar to other, more common causes, such as contact lens hygiene, health care professionals should consider the pharmacology of specific systemic medications as well as potential relationships between medication initiation and onset of symptoms.<sup>38</sup>

The effects of medications on the eye vary by drug class.<sup>38</sup> As a general rule, compounds with anticholinergic effects can reduce tear volume and induce dry eye, with or without concomitant loss of accommodation and blurry vision.<sup>39</sup> Other classes of drugs, such as hormones (most notably birth control pills), may also alter tear volume and the shape of the corneal surface, resulting in blurring and contact lens intolerance. Some systemic medications are secreted into tears and may interact with (primarily soft) contact lenses. For example, rifampin will stain both lenses and tears orange. Drugs and dietary supplements such as gold salts and garlic are secreted into the tears and may cause ocular irritation. Other drugs may affect tear production, the refractive properties of the eye, the shape of the cornea, or the actual lens (Table 28-13).<sup>40</sup> Some medications may influence the size of the pupil, causing complaints of glare or flare when lenses are in place. Visual performance may be diminished, especially in patients who wear multifocal lenses or GP lenses for which pupil size may determine placement of the reading segment or the optic zone of the lens, respectively.<sup>41</sup>

### Use of Cosmetics

Patients who wear contact lenses should choose—and use—cosmetics with care. Individuals should insert lenses before applying makeup and should avoid touching the lens with eyeliner or mascara. Cosmetics, moisturizers, and makeup removers with an aqueous base should be used, because oil-based products may cause blurred vision and irritation if they are deposited on the lens. Water-based products are preferable, and when possible, users should choose makeup that has been specifically formulated for contact lens wearers. Lens wearers should avoid loose powders (e.g., face, eye) and instead use pressed or cream-based products, if available. Water-resistant mascara (as opposed to waterproof mascara, which requires an oil-based remover) should be applied only to the very tips of the lashes. Eyeliners should never be applied inside the eyelid margin; the liner can clog glands in the eyelid and contaminate the contact lens. Eye makeup should be replaced at least every 3 months.<sup>42</sup> Aerosol products, in particular, must be used with caution; users should close their eyes when applying the product and step out of the mist before opening their eyes. Nail polish, hand creams, and perfumes should also be applied only after the lenses have been inserted. Men often contaminate their lenses with hair preparations and spray deodorants. Lens wearers should be reminded to take special care to clean their hands thoroughly before handling their lenses. Soaps that contain cold cream or deodorants should be avoided.<sup>42</sup>

### Corneal Hypoxia and Edema

An adequate supply of oxygen exists only if the cornea is continuously bathed with oxygenated tears. During blinking, metabolic byproducts from the surface epithelium are flushed from under the contact lenses, and oxygen is brought in as the lenses move toward and away from the cornea. Even when properly fitted, however, both rigid and soft lenses can produce a progressive hypoxia of the cornea while the lenses are in place, especially in individuals who have low blink frequency or incomplete blinks.

### Corneal Abrasions

Corneal abrasions are surface defects in the epithelial layer of the cornea. The causes of these abrasions range from poorly fitted lenses or simple overwear to the entrapment of foreign bodies under the lens. The cornea is sensitive to abrasion, so blepharospasm (reflexive lid closure), tearing, and rubbing of the affected eye occur immediately. However, rubbing the eye can cause more extensive damage while the lens remains in the eye and must be avoided. Fortunately, the pain associated with corneal abrasion is usually greater than the damage. The epithelium regenerates quickly; most minor epithelial defects generally heal within 12-24 hours. The lens should be left out for 2-7 days. The wearer may then proceed to use a modified break-in schedule suggested by the eye care provider. Corneal abrasions require the attention of an eye care provider.

### Exclusions for Self-Care

When lens care is appropriate but the lenses are old or, in the case of hard lenses, chipped or scratched, the patient should see an eye care provider for replacement lenses. Other situations that require referral are suspected vision changes, deep aching of the eyes, last eye examination occurring more than 1 year ago, and a suspected interaction between the lenses and systemic medications. Patients experiencing lens problems that are related to the medical conditions or other factors discussed in Contraindications and Warnings for Contact Lenses should also be referred

for further evaluation.

Cases 28-1 and 28-2 illustrate the assessment of patients with contact lens-related problems.

### Case 28-1

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of a "fogginess" in both eyes that is not present when she wears her glasses. She reports that this has been going on for the past 2 days, but it typically occurs toward the end of each month. She wears monthly disposable soft contact lenses and has been wearing the current contact lenses for 3 weeks. She reports changing them on the first of each month and does not sleep in them. The patient's lens care regimen includes soaking the lenses daily by topping off the solution in the case using Biotrue multi-purpose solution, or whatever is on sale when she needs more. She also reports she sometimes forgets to rinse the contact lenses daily.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient reports she experiences less itching and redness when she first starts a new pair of contact lenses.
c. description of the patient's efforts to relieve the symptoms	Patient has not tried anything.
d. patient's identity	Emma Smith
e. age, sex, height, and weight	30 years old, female, 5 ft 6 in., 170 lb
f. patient's occupation	Administrative assistant
g. patient's dietary habits	NA
h. patient's sleep habits	Gets about 8 hours of sleep per night.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Hypertension; treated with lisinopril
j. allergies	NKA

k. history of other adverse reactions to medications	None
l. other (describe) _____	Nonsmoker, social alcohol use on the weekends
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Discomfort due to poor contact lens hygiene and care
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer the patient to an eye care provider. (2) Recommend self-treatment. (3) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Recommend using proper contact lens care and hygiene.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Your symptoms suggest you are not using an appropriate care regimen for your contacts. Topping off the solution can increase the risk of infection and not rinsing or rubbing your lenses daily can build up proteins on your lens, leading to fogginess. Also, generic solutions may not contain the same ingredients as the brand your eye care provider recommended."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Fogginess is a common contact lens complaint. Your symptoms are present only when you wear the contact lenses and toward the end of the month when appropriate contact lens care has not been used. This does not cause a concern that requires you to see an eye care provider at this time."
<b>Patient Education</b>	
8. When recommending	

self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. appropriate dose and frequency of administration	“Discard and use new contact lens multipurpose solution daily. Rinse and rub contact lenses to remove proteins daily for at least 20 seconds. Use the recommended contact lens solutions from your eye care provider.”
b. maximum number of days the therapy should be employed	“Use appropriate lens care daily.”
c. product administration procedures	NA
d. expected time to onset of relief	“Symptoms should resolve within the next day.”
e. degree of relief that can be reasonably expected	“Fogginess should disappear with proper cleaning.”
f. most common side effects	NA
g. side effects that warrant medical intervention should they occur	“Fogginess that does not go away needs medical attention.”
h. patient options in the event that condition worsens or persists	“See your eye care provider if the fogginess persists even after proper cleaning of the lenses.”
i. product storage requirements	“Solution should be stored at room temperature in a dry place. Contact lens case should be allowed to dry while contact lenses are not in it.”
j. specific nondrug measures	NA
Solicit follow-up questions from the patient or caregiver.	“What if I don’t want to have to do this every day?”
Answer the patient’s or caregiver’s questions.	“You can call your eye care provider and talk to him or her about that. The provider could potentially change you to daily disposable contact lenses.”
<b>Evaluation of Patient Outcome</b>	

9. Assess patient outcome.

"Please call me and let me know how everything is going and if these suggestions worked for you or if you have any more questions."

Key: NA = Not applicable; NKA = no known allergies.

### Case 28-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of pain and aching in his left eye this morning. He reports he initially woke up with this yesterday morning and thought it would go away when he slept last night, but the pain has become a bit worse, even when he didn't wear his contact lenses all day. He follows all of his eye care provider recommendations for cleaning and use of his GP contact lenses. He reports his last eye exam was over a year and a half ago.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient reports that not wearing contact lenses helps.
c. description of the patient's efforts to relieve the symptoms	The patient has not tried anything to help the situation other than not wearing contact lenses yesterday.
d. patient's identity	Ralph Estes
e. age, sex, height, and weight	50 years old, male, 6 ft 5 in., 240 lb
f. patient's occupation	Engineer
g. patient's dietary habits	Patient eats a balanced diet.
h. patient's sleep habits	Patient stays up late watching the news but gets about 6 hours of sleep per night.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Patient has acid reflux and takes Tums as needed.
j. allergies	Penicillin
k. history of other adverse reactions to medications	None

1. other (describe) _____	Patient is nonsmoker and drinks beer at sporting events.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Corneal abrasion, contact lens induced
3. Identify exclusions for self-treatment.	Possible corneal abrasion caused by overwear, possible poor fit, or a chip or scratch in the lens Pain that does not improve with removal of contact lenses
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer the patient to eye care provider. (2) Recommend self-treatment. (3) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Inform patient that he needs to get immediate care from his eye care provider or go to the emergency room to identify the extent of the problem. The patient should not use self-care treatment at this time.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Your symptoms suggest that you have injured your eye and you need to go to either your eye care provider or the emergency room immediately."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Self-care treatment is not recommended right now, and there are no nonprescription products to treat these problems right now. You need to go to either your eye care provider or the emergency room immediately to prevent any permanent damage, such as vision loss."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"It is a really busy week at work. Do you think I can wait until this evening to contact my eye care provider?"
Answer the patient's or caregiver's questions.	"No. You need to be seen by your eye care provider or an emergency room immediately. You could suffer permanent damage to your eye if it is not treated immediately."
<b>Evaluation of Patient Outcome</b>	

9. Assess patient outcome.

“Please call me and let me know how everything worked out. Also, in the future, feel free to contact me with any questions you may have.”

Key: GP = Gas permeable.

### Patient Counseling for Prevention of Contact Lens-Related Disorders

Instruction on lens insertion and removal should always be provided at the time lenses are fit. Patients should also be instructed on proper care techniques, with a specific recommendation for a care system. Often the prescriber's advice for a particular product is ignored, and patients select products according to price alone, especially with the availability of generic solutions. Similar product labels and lack of standardized labeling lead to further confusion. Patients often ask whether it matters which solution they use. The correct answer is that it does matter because solutions can be the cause of contact lens complications. Lens care products are typically formulated for use either with soft or gas permeable lenses and, with a few exceptions, should not be used interchangeably. The box Patient Education for Prevention of Contact Lens-Related Disorders outlines the care regimen for each type of contact lens.

The objective of contact lens care is to prevent lens-related problems such as abrasions or infections of the cornea. For most patients, following the prescribed lens care regimen, product instructions, and self-care measures listed here will help ensure trouble-free use of contact lenses.

#### General Care Instructions for All Contact Lens Types

- See [Table 28-3](#). Wash hands with noncosmetic soap and rinse them thoroughly before handling or caring for contact lenses.
- Each time contact lenses are removed, clean, rinse, and disinfect them before wearing them again.
- Gently rub both surfaces of the contact lens, rinse thoroughly, and soak lenses overnight in the recommended solution according to the eye care provider's instructions.
- When using contact lens products, use only the products recommended by the prescribing eye care provider.
- Do not change brands or products unless instructed to do so by the eye care provider. (Not all care systems are alike, and some may not be compatible with the contact lenses prescribed.)
- Do not top off a storage solution in the case after the solution has been used.
- Replace soaking/disinfecting solutions in the lens case after each use.
- Store contact lenses in fresh disinfecting solution overnight for the minimum soaking time recommended by the manufacturer to provide adequate disinfection.
- If lenses are worn intermittently, check and replace the solution weekly; consider daily disposable lens wear.
- Discard open bottles of solution if not used within the recommended time frame after being opened. Refer to the package labeling for individual products because the time frame varies from 1-3 months depending on the product. Write the date the solution is first used on the outside of the bottle.
- Store contact lenses in a proper lens case when not in use. Clean the contact lens case daily by rubbing with a disinfecting solution and allowing the case to air-dry.
- Replace the contact lens case every 3 months.
- Saline solution is used only to rinse lenses; saline will not clean or disinfect contact lenses and should not be used as a storage solution.
- Do not use tap water to rinse contact lenses or to clean cases. Never store lenses in tap water.
- Do not place contact lenses in your mouth to clean or lubricate the lens. This practice can result in eye infections.
- To prevent contamination, do not touch dropper tips or the tips of lens care product containers.
- While wearing lenses, use only ophthalmic solutions specifically formulated for contact lens use.
- Avoid swimming, showering, hot tubs, or natural bodies of water while wearing contact lenses unless external eye protection, such as watertight goggles, is used.
- Follow prescribed wearing and replacement schedules.
- Avoid exposing contact lenses to extreme temperatures.
- Avoid wearing oily cosmetics while wearing lenses. Bath oils or soaps with an oil or a cream base may leave a film on the hands, which will be transferred to the lenses. Apply cosmetics after inserting contact lenses.
- To avoid mixing up the lenses, always insert or remove the same lens first. Check hard lenses for a dot in the lens periphery to avoid mixing up the lenses.
- If the lenses are not comfortable after insertion or vision is blurred, check to see if they are on the wrong eyes or are inside out.
- To avoid damaging lenses, either apply aerosol cosmetics and deodorants before lens insertion or keep eyes closed until the air is clear of spray particles.
- Except for prescription continuous-wear lenses, do not wear lenses while sleeping.

- To avoid excessive dryness of the eyes, do not wear lenses while sitting under a hair dryer, overhead fans, or air ducts.
- When lenses are worn outside on windy days, protect the eyes from soot and other particles that may become trapped under the lens and scratch the cornea.
- Use eye protection in industry, sports, or any other occupation or hobby that has the potential for eye damage.
- Do not insert lenses in red or irritated eyes. If the eyes become irritated while lenses are being worn, remove the lenses until the irritation subsides. If irritation or redness does not subside, consult an eye care provider.
- If an eye infection is suspected, see an eye care provider immediately.

### Instructions for Soft Lenses

- See [Tables 28-3](#) and [28-4](#) for guidelines on cleaning and disinfecting soft lenses.
- Handle soft lenses carefully because they are very fragile and can be torn easily.
- Remove these lenses before instilling any ophthalmic preparation not specifically intended for concurrent use with soft contact lenses. Wait at least 20-30 minutes before reinserting the lenses, unless directed otherwise by an eye care provider.
- Do not wear lenses when a topical ophthalmic ointment is being used.
- Do not wear soft contact lenses in the presence of irritating fumes or chemicals.

### Instructions for GP Lenses

- See [Tables 28-3](#) and [28-9](#) for guidelines on cleaning GP lenses.
- Do not use tap water to rinse off cleaner or to rewet lenses. If tap water is used, disinfect lenses before inserting them in the eyes.
- See [Table 28-5](#) for guidelines on using disinfecting systems.

### Instructions for Continuous-Wear Lenses (GP or Soft)

- Remove mascara before sleeping because it can flake off during sleep and become trapped underneath the lens.
- If lenses appear to be lost on awakening, check eyes to see whether the lenses were displaced. Soft lenses can fold over on themselves and get lodged underneath the top or bottom eyelid.
- Each morning, check eyes carefully for unusual, persistent redness, discharge, or pain. If redness does not abate within 45 minutes, or if discharge or pain is present, remove the lens and call your eye care provider.
- Check vision after inserting lenses. (Some hazy vision is normal on awakening because of corneal hypoxia, which develops overnight.) Apply a few drops of rewetting solution to improve hydration of the lens and help resolve hypoxia. If the problem is not resolved, remove lenses, clean them, and reinsert. If vision is not improved within an hour, remove lenses and call your eye care prescriber.

### Key Points for Prevention of Contact Lens-Related Disorders

- Following the prescribed lens care program is the best strategy for avoiding lens wear-related problems.
- The health care provider should explain the care regimen for the patient's particular lens type and stress that the patient should use only the products recommended for his or her lenses.
- Instructions on avoiding practices or situations that can cause eye irritation or lens damage are also important in educating the patient about successful wearing of contact lenses:
  - Used contact lens solutions should not be "topped off" or reused.
  - Even when using "no-rub" solutions, patients should be counseled to rub and rinse contact lenses to fully remove protein deposits.
- The patient should be advised of signs and symptoms that indicate that medical care is needed. Patients should be informed that if eye redness or pain or blurry vision occurs while wearing any form of contact lens, they should immediately remove the lens and see an eye care provider for evaluation prior to reinserting the lens.

## Handbook of Nonprescription Drugs &gt; Chapter 29. Otic Disorders

**Otic Disorders: Introduction**

Ear complaints are common and vary from simple complaints of excessive earwax (cerumen) to itching or painful ear infections. Ear disorders affect all ages, with children and geriatric patients being the most prone. Otic disorders account for 1.5% of ambulatory care visits per year.<sup>1</sup> Cerumen impaction can affect up to 10% of children and more than 30% of the elderly nursing home population; it is one of the most common causes of temporary hearing loss in all ages.<sup>2,3,4</sup> Approximately 12 million patients will visit their primary care physician annually because of cerumen impaction.<sup>5</sup>

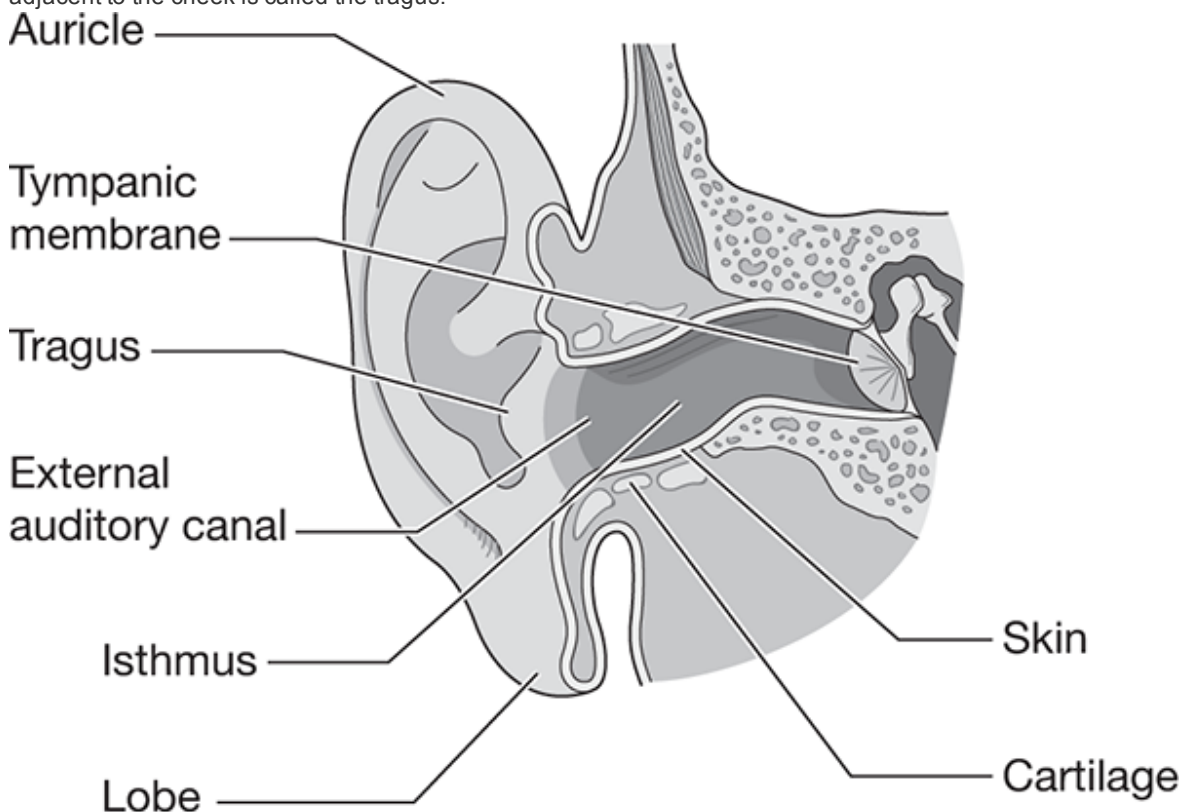

Self-treatment with nonprescription medications and complementary therapies should be restricted to external ear disorders, which include disorders of the auricle and the external auditory canal (EAC). Excessive cerumen and water-clogged ears are self-treatable EAC disorders for which the Food and Drug Administration (FDA) has approved nonprescription otic medications. Other self-treatable disorders of the auricle include seborrhea and psoriasis, and allergic and contact dermatitis. Chapters 33 and 34, respectively, provide a detailed discussion of the etiology and treatment of the latter disorders.

Diseases of the head and neck can cause referred pain, which the patient often perceives as pain originating from the ear. The health care provider must attempt to determine the cause of pain prior to recommending self-treatment or medical referral. The assessment of self-treatable otic disorders and discussions for patient counseling and evaluation of patient outcomes are presented later in the chapter. This chapter briefly examines the anatomy and pathophysiology of the ear and associated nonprescription therapies for excessive/impacted cerumen and water-clogged ears.

*Editor's Note:* This chapter is based on the 17th edition chapter of the same title, written by Linda Krypel.

**Pathophysiology of Otic Disorders**

The external ear consists of the auricle (also called the pinna), the EAC (Figure 29-1), and the tympanic membrane (eardrum), which separates the external ear from the middle ear.<sup>6</sup> The auricle is composed of a thin layer of highly vascular skin that is tightly bound to cartilage. Adipose, or subcutaneous, tissue, which would insulate blood vessels, is absent except in the lobe. The lobe has fewer blood vessels and is composed primarily of fatty tissue. The triangular piece of cartilage in front of the ear canal adjacent to the cheek is called the tragus.

Anatomy of the auricle and external ear.

The EAC consists of an outer cartilaginous portion, which comprises one-third to one-half of its length, plus an inner body, or osseous, portion.<sup>6</sup> The canal forms a blind cul-de-sac. Children have a shorter, straighter, and flatter EAC than that of adults, whose canal tends to lengthen and form an "S" shape.<sup>7</sup> At the same time, an adult's eustachian tube (part of the inner ear)

lengthens downward as it enters the nasal cavity. This shape helps to promote drainage and inhibits aspiration of pharyngeal and nasal contents into the middle ear, which may help to explain why children suffer from more middle ear infections compared with adults.<sup>8</sup>

The skin that covers the auricle is especially susceptible to bleeding when scratched because of the lack of flexibility usually afforded by a subcutaneous layer of fat and the large blood supply to the area.<sup>9</sup> The skin is highly innervated, causing a disproportionate otalgia (ear pain) when inflammation is present. Skin farther into the EAC is thicker, and contains apocrine and exocrine glands as well as hair follicles.<sup>6,7</sup> The skin in the canal is continuous with the outer layer of the tympanic membrane. Oily secretions from the exocrine glands mix with the milky, fatty fluid from the apocrine glands to form cerumen, which appears on the surface of the skin on the outer half of the EAC. Cerumen lubricates the canal, traps dust and foreign materials, and provides a waxy, waterproof barrier to the entry of pathogens.<sup>7</sup> It also contains various antimicrobial substances, such as lysozymes, and it has an acidic pH, which also aids in inhibition of bacterial and fungal growth. The canal skin is shed continuously and mixes with cerumen. The debris-laden cerumen slowly migrates outward with jaw movements (such as chewing and talking). This migration serves as a process of self-cleaning.<sup>5</sup> Cerumen may appear dry and flaky or oily and paste-like. Color varies from individual to individual; it can be honey-colored to light gray or tan and may darken on exposure to air.<sup>10</sup>

The natural defenses of the ear canal include the skin layer with its protective coating of cerumen, an acidic pH (<6.5), and hairs that line the outer half of the canal. Together, they protect against injury from foreign material and infection. It is important for the provider to explain the normal role and function of cerumen when educating patients.

Because the EAC forms a blind cul-de-sac, it is especially prone to collecting moisture. Its dark, warm, moist environment is ideal for fungal and bacterial growth. In the preinflammatory stage, moisture, local trauma, or both remove the lipid layer covering the skin. Local trauma from fingernails, cotton-tipped swabs, or other items inserted into the canal can abrade the skin and allow pathogens to enter. Because a normal, healthy ear canal is impervious to potentially pathogenic organisms, skin integrity generally must be interrupted before an organism can produce an infection. Trauma to the ear from thermal injuries, sports injuries, ear piercing, and poorly fitting or improperly cleaned ear devices or hearing aids can contribute to the breakdown of the EAC's natural defenses.<sup>7</sup> Dermatologic skin disorders, such as contact dermatitis, seborrhea, psoriasis, and malignancies, also compromise these defenses.<sup>6</sup>

Viral illnesses, such as colds and upper respiratory infections, can contribute to the breakdown of natural defenses of the middle and inner ear, especially in children, who are very susceptible to middle ear infections following such illnesses. Because a child's eustachian tube is shorter and angled flatter than that of an adult, it is commonly believed that nasopharyngeal secretions can easily be aspirated and accumulate in the middle ear, leading to proliferation of bacteria.<sup>8</sup> Holding back or trying to stifle a sneeze can force secretions into the middle ear and therefore should be strongly discouraged, even in adults.

### **Excessive/Impacted Cerumen**

Cerumen can be considered an undervalued defense system. Widespread misinformation has often led the public to believe that cerumen production is a pathologic condition and that cerumen must be continually removed. Improper or excessive attempts to remove cerumen can actually damage the EAC.<sup>5</sup>

### **Pathophysiology of Excessive/ Impacted Cerumen**

Individuals who have abnormally narrow or misshapen EACs, excessive hair growth in the canal, overactive ceruminous glands, or who wear hearing aids, earplugs, or sound attenuators often suffer from impacted cerumen caused by the disruption of normal cerumen migration to the outer EAC.<sup>10</sup> Frequent removal and proper cleaning of ear devices may help prevent wax buildup.

Older adults often experience impacted cerumen resulting from atrophy of ceruminous glands.<sup>6</sup> This population secretes drier cerumen, which is more difficult to expel from the ear.

### **Clinical Presentation of Excessive/Impacted Cerumen**

The most common symptoms of impacted cerumen are a sense of fullness or pressure in the ear and a gradual hearing loss, which can lead to a decrease in cognition in the elderly.<sup>5,10</sup> A dull pain is sometimes associated with this disorder, along with vertigo (a sensation of spinning or whirling), tinnitus (ringing, hissing, or buzzing noises in the ear), chronic cough, or mild pain.<sup>3</sup> Hardened cerumen generally does not cling to cotton-tipped applicators, and using them may serve only to remove the protective waxy layer and force the cerumen plug further into the canal. The most important complication of improper cerumen removal results when the delicate skin of the EAC is scratched or damaged, providing an entry point for water and pathogens.<sup>4,7,11</sup> Patients experiencing an abrupt loss of hearing associated with a sharp pain should be referred immediately to their primary care provider because this may indicate a ruptured tympanic membrane. Severe pain should also be referred.

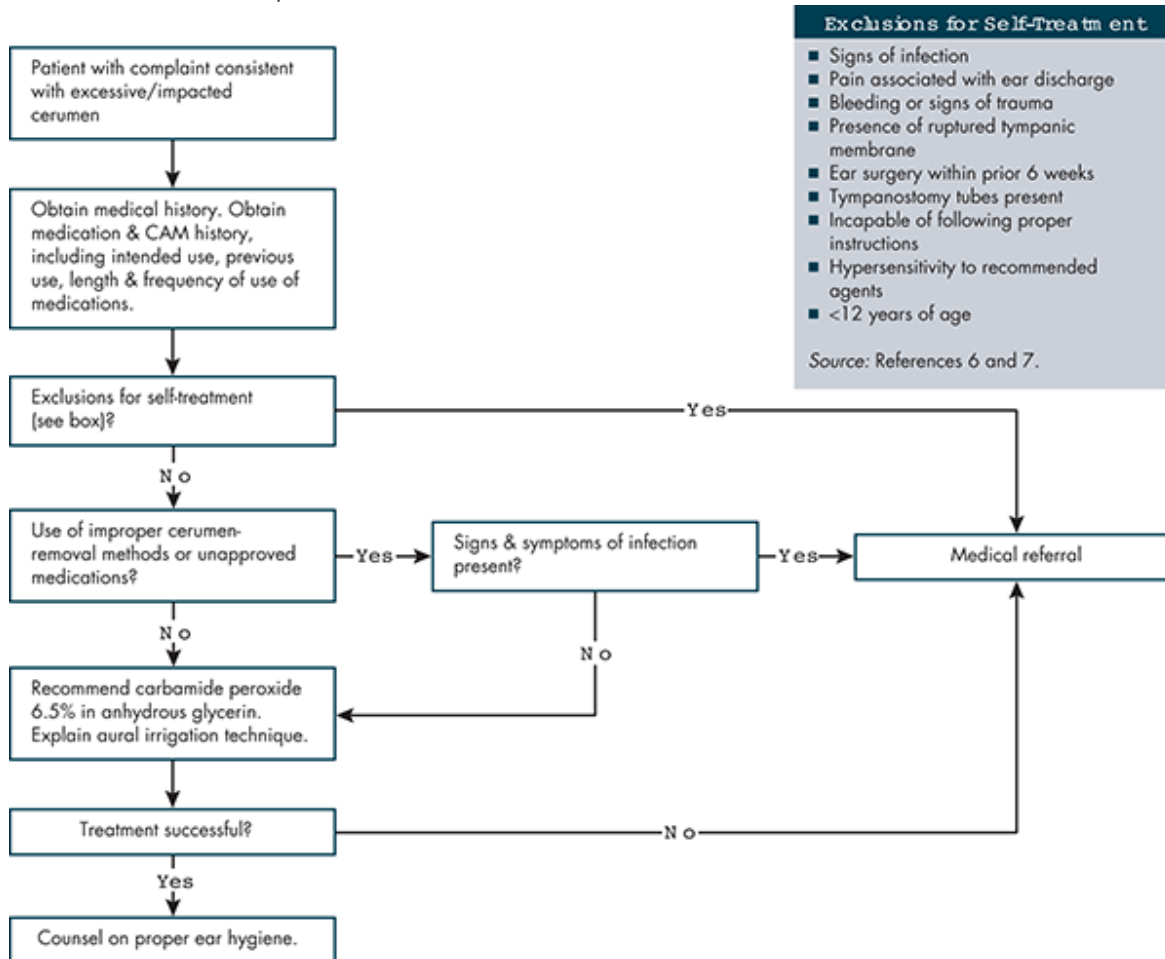

### **Treatment of Excessive/Impacted Cerumen**

#### **Treatment Goals**

The goal of treating excessive/impacted cerumen is to soften and remove it using proper methods and safe, effective agents. Proper treatment should eliminate temporary hearing loss and other symptoms.

#### **General Treatment Approach**

The initial step in removing impacted cerumen is the use of a safe and effective agent to soften cerumen. Gently irrigating the ear, using an otic bulb syringe filled with warm water, is often recommended after cerumen has been softened. Caution must be used to ensure complete removal of water and to avoid a possible infection attributable to water-clogged ears. Cotton-tipped swabs or other foreign objects should not be used to remove cerumen or water. The algorithm in Figure 29-2 outlines the appropriate self-treatment of excessive/impacted cerumen and lists exclusions for self-treatment.

Self-care of excessive/impacted cerumen. Key: CAM = Complementary and alternative medicine.

### Nonpharmacologic Therapy

Earwax should be removed only when it has migrated to the outermost portion of the EAC. The only recommended nonpharmacologic method of removing cerumen is to use a wet, wrung-out washcloth draped over a finger. Making this procedure part of daily aural hygiene can prevent impacted cerumen if physiologic abnormalities or physical devices are not the cause of the impaction. This method is not effective once cerumen becomes impacted.

### Pharmacologic Therapy

Carbamide peroxide 6.5% in anhydrous glycerin is currently the only FDA-approved nonprescription cerumen-softening agent.<sup>12</sup> Other agents such as mineral oil, olive oil (sweet oil), docusate sodium, glycerin, sodium bicarbonate, and dilute hydrogen peroxide have been used by primary care providers and patients as inexpensive home remedies to soften cerumen. However, no data support these remedies as being more effective than carbamide peroxide in anhydrous glycerin.<sup>3,13</sup>

### Carbamide Peroxide

Carbamide peroxide 6.5% in anhydrous glycerin is approved as safe and effective in softening, loosening, and removing excessive earwax in adults and children ages 12 years and older.<sup>12</sup> (See Table 29-1 for proper instillation of eardrops.) Carbamide peroxide is prepared from hydrogen peroxide and urea. When carbamide peroxide is exposed to moisture, nascent oxygen is released slowly and acts as a weak antibacterial. The effervescence that occurs during this process, along with the effect of urea on tissue debridement, helps to mechanically break down and loosen cerumen that has been softened by anhydrous glycerin.<sup>14</sup> Glycerin, which has emollient and humectant properties, is widely used as a solvent and vehicle.<sup>14</sup> It is safe and nonsensitizing when applied to abraded skin.

Any cerumen remaining after treatment may be removed with gentle, warm-water irrigation administered with a rubber otic bulb syringe (Table 29-2). Caution is important in that improper use of an otic syringe can leave excess moisture in the canal or further compress cerumen. Self-use of an oral jet irrigator is not recommended. Either of these actions can also cause otitis externa,

perforated tympanic membrane, pain, vertigo, otitis media, and tinnitus.<sup>3,15</sup>

Carbamide peroxide solution is generally considered to be nonirritating and may be used twice daily for up to 4 days. Adverse effects reported after proper use include pain, rash, irritation, tenderness, redness, discharge, or dizziness.<sup>16</sup> If adverse effects develop or symptoms persist after 4 days, the patient should see a primary care provider for evaluation.<sup>17</sup>

**TABLE 29-1 Guidelines for Administering Eardrops**

1. Wash your hands with soap and warm water; then dry them thoroughly.
2. Carefully wash and dry the outside of the ear with a damp washcloth, taking care not to get water in the ear canal. Then dry the ear.
3. Warm eardrops to body temperature by holding the container in the palm of your hand for a few minutes. Do not warm the container in hot water or microwave. Using hot eardrops can cause ear pain, nausea, or dizziness.
4. If the label indicates, gently shake the container to mix contents.
5. Tilt your head (or have the patient tilt his or her head) to the side, as shown in drawing A. Or lie down with the affected ear up, as shown in drawing B. Use gentle restraint, if necessary, for an infant or a young child.
6. Open the container carefully. Position the dropper tip near, but not inside, the ear canal opening. Do not allow the dropper to touch the ear, because it could become contaminated or injure the ear. Eardrop bottles must be kept clean.
7. Pull your ear (or the patient's ear) backward and upward to open the ear canal (drawing A). If the patient is a child younger than 3 years, pull the ear backward and downward (drawing B).
8. Place the proper dose or number of drops into the ear canal. Replace the cap on the container.
9. Gently press the small, flat skin flap (tragus) over the ear canal opening to force out air bubbles and push the drops down the ear canal.
10. Stay (or keep the patient) in the same position for the length of time indicated in the product instructions. If the patient is a child who cannot stay still, the primary care provider may tell you to place a clean piece of cotton gently into the child's ear to prevent the medication from draining out. Use a piece large enough to remove easily, and do not leave it in the ear longer than an hour.
11. Repeat the procedure for the other ear, if needed.
12. Gently wipe excess medication off the outside of the ear, using caution to avoid getting moisture in the ear canal.
13. Wash your hands to remove any medication.

Source: APhA Special Report: Medication Administration Problem Solving in Ambulatory Care. Washington, DC: American Pharmaceutical Association; 1994:9.

**TABLE 29-2 Guidelines for Removing Excessive/Impacted Cerumen**

#### Ceruminolytics

1. Place 5-10 drops of the cerumen-softening solution into the ear canal, and allow it to remain for at least 15 minutes, as described in [Table 29-1](#).

2. Perform this procedure daily for no longer than 4 consecutive days.

### Irrigation Technique

The use of ceruminolytics and irrigation together may improve overall removal of impacted cerumen. The ceruminolytic agent is administered first. Then follow the irrigation technique as described below, paying special attention to cautionary instructions.

1. Prepare a warm (not hot) solution of plain water or other solution as directed by your primary care provider. Eight ounces of solution should be sufficient to clean out the ear canal.
2. To catch the returning solution, hold a container under the ear being cleaned. An emesis basin is ideal because it fits the contour of the neck. Tilt the head down slightly on the side where the ear is being cleaned.
3. Gently pull the earlobe down and back to expose the ear canal, as shown in drawing A.
4. Place the open end of the syringe into the ear canal with the tip pointed slightly upward toward the side of the ear canal (drawing A). Do not aim the syringe into the back of the ear canal. Use caution and make sure the syringe does not obstruct the outflow of solution.
5. Squeeze the bulb gently—not forcefully—to introduce the solution into the ear canal and to avoid rupturing the eardrum. (*Note:* Only health professionals trained in aural hygiene should use forced water sprays [e.g., Water Pik] to remove cerumen.)
6. Do not let the returning solution come into contact with the eyes.
7. If pain or dizziness occurs, remove the syringe and do not resume irrigation until a health care provider is consulted.
8. Make sure all water is drained from the ear to avoid predisposing to infection from water-clogged ears.
9. Rinse the syringe thoroughly before and after each use, and let it dry.
10. Store the syringe in a cool, dry place (preferably, in its original container) away from hot surfaces and sharp instruments
11. If cerumen still remains, consult a provider.

Docusate Sodium

Docusate sodium is classified as an emollient and has been topically applied in the ear canal to soften earwax. Evidence for its effectiveness over approved agents is conflicting.<sup>3,13,18,19</sup> Docusate sodium is more expensive, has varying results, and may cause superficial erythema.

#### Hydrogen Peroxide

Hydrogen peroxide releases nascent oxygen when exposed to moisture and acts as a weak antibacterial.<sup>14</sup> Hydrogen peroxide 3% has been used to flush the ear canal when softening or removing earwax.<sup>3</sup> Because hydrogen peroxide solutions contain water, overuse may predispose the ear to infection from tissue maceration caused by excessive water left in the canal.

#### Olive Oil (Sweet Oil)

Olive oil is used as an emollient and has been used as a home remedy to soften earwax.<sup>6,17</sup> It has also been used in the ear canal to alleviate itching and pain.<sup>19</sup> Using olive oil to treat ear pain may delay seeking proper treatment.

#### Product Selection Guidelines

Table 29-3 lists examples of cerumen-softening and other otic products. No nonprescription cerumen-softening agents are approved for patients younger than 12 years. No special consideration is necessary for pregnant, lactating, or geriatric patients.

**TABLE 29-3 Selected Products for Otic Disorders<sup>a</sup>**

<i>Trade Name</i>	<i>Primary Ingredients</i>
<b>Cerumen-Softening Products</b>	
Auro Ear Drops	Carbamide peroxide 6.5%; anhydrous glycerin
Debrox Earwax Removal Aid Kit	Carbamide peroxide 6.5%; glycerin; packaged with syringe
<b>Ear-Drying Products</b>	
Auro-Dri Drops	Isopropyl alcohol 95%; anhydrous glycerin
Swim Ear Drops	Isopropyl alcohol 95%; anhydrous glycerin
<b>Botanical and Homeopathic Products</b>	
Herbs for Kids Willow/Garlic Ear Oil	Extra virgin olive oil; garlic, calendula; willow bark <sup>b</sup> ; usnea; vitamin E oil
Similasan Healthy Relief Homeopathic Ear Drops	Chamomilla HPUS 10X; mercurius solubus HPUS 15X; sulfur HPUS 12X; glycerin
Similasan Ear Wax Relief	Causticum HPUS 12X; Graphites HPUS 15X; Lachesis HPUS 12X; Lycopodium HPUS 12X

Key: HPUS = *Homeopathic Pharmacopoeia of the United States*.

<sup>a</sup> FDA has not approved any product in children < 12 years of age.

<sup>b</sup> Contains salicylate.

#### Complementary Therapies

Although major herbal references do not list herbal remedies for self-treatable otic disorders,<sup>20,21,22</sup> some folk remedies remain popular in many regions. One of the more interesting—and dangerous—is the use of ear candles to remove cerumen. A hollow candle is burned with one end inserted in the ear canal. The intent is to create negative pressure and draw cerumen from the ear. Studies have shown that this method does not aid in removing cerumen but has caused serious ear injuries and burns to patients.<sup>23</sup> FDA issued an alert warning against the import and sale of these devices in 2007.<sup>24</sup>

A product advertised for ear pain in children contains olive oil, garlic oil, and willow bark; the latter is a form of salicylate.<sup>20,21</sup> Although garlic oil claims to have some antibacterial properties, self-treating ear pain can delay seeking an appropriate diagnosis. Another available herb is chamomilla, which is believed to help with ear inflammation. Although these herbal and homeopathic products are available, no published studies document safety and effectiveness (Table 29-3). (See Chapters 51 and 52 for more information on complementary therapies.)

#### Water-Clogged Ears

Water-clogged ears is a separate disorder from swimmer's ear (external otitis). FDA has not approved any nonprescription products for preventing or treating external otitis. Manufacturers have argued that removing moisture from water-clogged ears

with an approved agent may prevent tissue maceration, a process that can lead to inflammation and infection of the EAC (commonly referred to as swimmer's ear). FDA, however, prohibits this extrapolation, and manufacturers may not label their products as preventing swimmer's ear.<sup>25,26</sup>

### **Pathophysiology of Water-Clogged Ears**

Some patients are more prone to retaining water because of the shape of their ear canals or the presence of excessive cerumen. The cerumen can swell, thereby trapping water. Excessive moisture in the ears can result from hot, humid climates, sweating, swimming, bathing, or improper use of aqueous solutions to cleanse the ear. Therefore, simple attempts to remove water by mechanical manipulation may be insufficient. In addition, the use of cotton-tipped applicators has been linked to external otitis.<sup>3,27</sup>

### **Clinical Presentation of Water-Clogged Ears**

A feeling of wetness or fullness in the ear, accompanied by gradual hearing loss, can occur after exposure to any of the etiologic factors. The trapped moisture can compromise the natural defenses of the EAC, causing tissue maceration that, in turn, can lead to itching, pain, inflammation, or infection.<sup>4,7</sup> Severe pain, inflammation, or signs of infection should be referred to a primary care provider.

### **Treatment of Water-Clogged Ears**

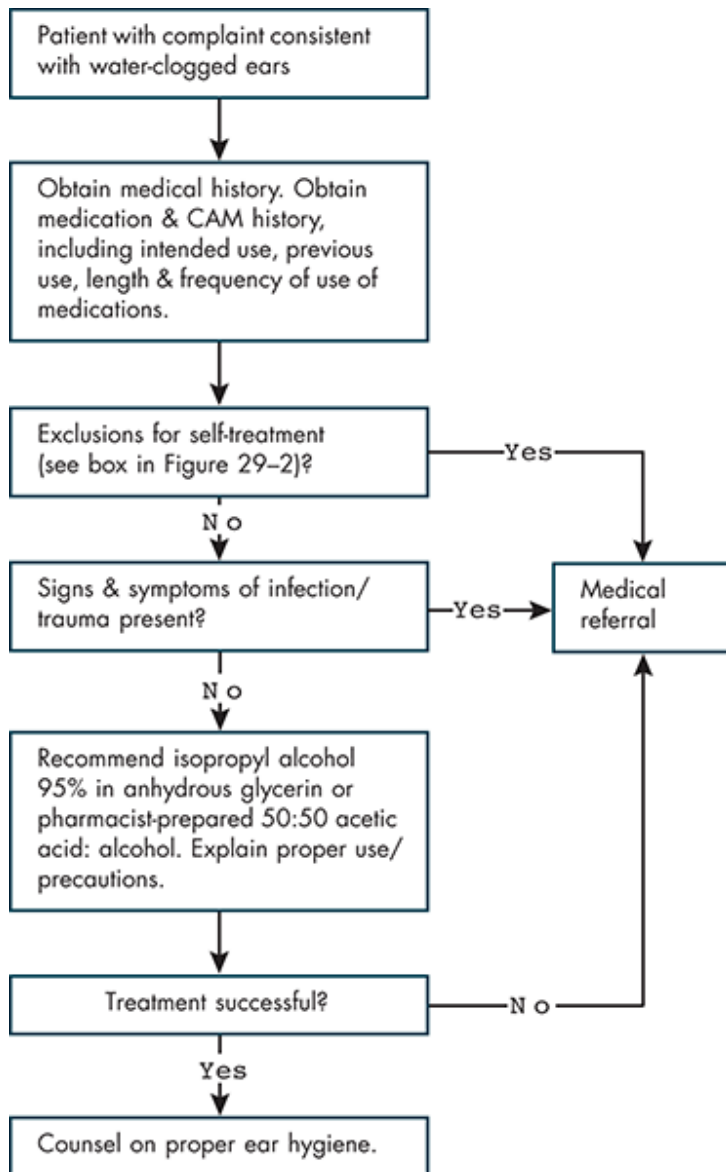

#### Treatment Goals

The goals of treating a water-clogged ear are to dry it using a safe and effective agent and to prevent recurrences in persons who are prone to retaining moisture in the ears.

#### General Treatment Approach

Before recommending an agent to treat water-clogged ears, the health care provider should determine whether a patient has a ruptured tympanic membrane or has a tympanostomy tube in place. Ear-drying agents are very painful if instilled in either of these situations. [Figure 29-2](#) lists additional exclusions for self-treatment. The algorithm in [Figure 29-3](#) outlines the appropriate treatment of water-clogged ears.

Copyright © American Pharmacists Association  
All rights reserved. Any use is subject to the Terms of Use.

Self-care of water-clogged ears. Key: CAM = Complementary and alternative medicine.

### Nonpharmacologic Therapy

Tilting the affected ear downward and gently manipulating the auricle can expel excessive water from the ear. This procedure should be performed after swimming or bathing, or during periods of excessive sweating, especially by persons who are prone to developing this disorder. Using a blow-dryer on a low heat and speed setting around (not directly into) the ear immediately after swimming or bathing may help dry the ear canal. One-time-use water-absorbing earplugs (ClearEars) are available for patients ages 17 years and older. These earplugs will not prevent water from entering the ear during bathing or swimming. When used to dry ears, they should be removed after a maximum of 10 minutes and discarded. If these earplugs are accidentally ingested, small children or pets can choke as the earplug expands upon contact with the fluid in the throat. No clinical trials of this product have been conducted as of this time.<sup>28</sup> In one study, cotton wool with petrolatum was ranked the most effective for waterproofing ears and the easiest to insert.<sup>29</sup>

### Pharmacologic Therapy

FDA has approved only isopropyl alcohol 95% in anhydrous glycerin 5% as a safe and effective “ear-drying aid.”<sup>25,26</sup> (See [Table 29-3](#) for examples of products containing these agents.) In addition, a 50:50 mixture of acetic acid 5% (white household vinegar) and isopropyl alcohol 95% has commonly been recommended to help dry water-clogged ears.<sup>4,7</sup>

Ear-drying agents recommended for use in adults and children ages 12 years and older may be used whenever ears are exposed to water. [Table 29-1](#) presents guidelines for administering these agents. Medical referral is necessary if symptoms persist after several days of simultaneous use of ear-drying agents and prevention of exposure of ears to water.

### Isopropyl Alcohol in Anhydrous Glycerin

Alcohol is highly miscible with water and acts as a drying agent. In concentrations greater than 70%, alcohol is also an effective

skin disinfectant.<sup>14</sup> Glycerin has been used in pharmaceutical preparations for its solvent, emollient, or hygroscopic properties. It is safe but stings when applied to open wounds or abraded skin. Repeated use of alcohol alone can cause overdrying of the canal. The combination of alcohol and glycerin, however, provides a product that reduces moisture in the ear without overdrying.

#### Acetic Acid

Acetic acid in a 50:50 mixture of acetic acid 5% and isopropyl alcohol 95% has bactericidal and antifungal properties.<sup>14</sup> Species of *Pseudomonas*, *Candida*, and *Aspergillus* are particularly sensitive to this agent. Care must be taken to advise patients against using cider vinegar instead of white vinegar. Cider vinegar is produced from fruit and contains impurities that could hinder antibacterial activity. A 50:50 mixture of white vinegar 5% and isopropyl alcohol 95% provides an acetic acid 2.5% solution. Concentrations of acetic acid between 2% and 3% may lower the pH of the ear canal below the optimal pH of 6.5-7.5 needed for bacterial growth.<sup>14</sup> The solution is well tolerated and nonsensitizing and does not induce resistant organisms. It may sting or burn slightly, especially if the skin is abraded. The provider should direct the patient in how to properly compound this solution by preparing it from ingredients that are not expired and discarding any remainder after use.

#### Product Selection Guidelines

Table 29-3 lists examples of ear-drying and other otic products. No nonprescription ear-drying agents are approved for patients younger than 12 years. No special consideration is necessary for pregnant, lactating, or geriatric patients.

#### Assessment of Otic Disorders: A Case-Based Approach

The most common complaints of ear disorders are otalgia, pruritus (itching), and hearing loss. Evaluating the characteristics of particular symptoms, such as pain and hearing loss, and the specific combination of symptoms is the key to assessing otic disorders. The discussion of common otic symptoms in Cases 29-1 and 29-2 describes the possible causes. Table 29-4 compares the signs and symptoms and other features of common otic disorders, and Table 29-5 describes the common etiologies and treatments for otalgia, otic pruritus, hearing loss, dizziness, and tinnitus.<sup>30,31,32,33</sup> A verbal 5-minute hearing loss test is available at the American Academy of Otolaryngology Head and Neck Surgery, Inc., Web site ([www.entnet.org/healthinformation/hearing-loss.cfm](http://www.entnet.org/healthinformation/hearing-loss.cfm)) and will quickly assess in adults how often and the circumstances when the patient experiences hearing loss.

#### Case 29-1

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Two days ago, the patient started to experience a sense of fullness in her left ear after her water aerobics class.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	She experience hearing loss in her left ear after she tried to dry her ears with a cotton swab after her morning shower. She denies experiencing pain in her ear.
c. description of the patient's efforts to relieve the symptoms	After her water aerobics class, she used isopropyl alcohol 95% in anhydrous glycerin drops to dry the water in her ears.
d. patient's identity	Lillian Keller
e. age, sex, height, and weight	68 years old, female, 5 ft 2 in., 155 lb
f. patient's occupation	Retired; previous occupation was an administrative assistant.
g. patient's dietary habits	Recently began weight-loss program where she purchases 3 meals and 2 snacks per day to limit her caloric intake to 1200-1400 kcal/day.
h. patient's sleep habits	She sleeps 7-8 hours each night.

i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Hypertension: enalapril 10 mg daily; hydrochlorothiazide 25 mg daily; Dyslipidemia: atorvastatin 20 mg daily in the evening; multivitamin; calcium citrate 600 mg and vitamin D 400 IU 2 caplets twice daily; glucosamine 1500 mg with evening meal
j. allergies	NKA
k. history of other adverse reactions to medications	None
l. other (describe) _____	The patient participates in a water aerobics class 5 days a week. Earlier this month the patient began using hearing aids to help improve the overall clarity of her hearing.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s) (Table 29-4).	Lillian is experiencing cerumen impaction that is likely the result of the improper attempt to remove any water from the ear and recently starting to wear hearing aids.
3. Identify exclusions for self-treatment (Figure 29-2).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Lillian to appropriate health care provider. (2) Recommend nonprescription cerumen-softening agent with proper ear hygiene (Table 29-3). (3) Recommend continuation of nonprescription ear-drying agent (Table 29-3). (4) Recommend self-care until Lillian can see an appropriate health care provider. (5) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The patient would like to try to use a self-care product until she can be seen by her health care provider.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"The cerumen-softening agent carbamide peroxide 6.5% can help soften and aid in the removal of excessive earwax."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"People who wear hearing aids can often experience impacted earwax. Attempting to use cotton swabs to dry the water in your ears added to the cerumen impaction. The cerumen-softening drops with gentle water irrigation can help remove the impacted cerumen."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	"You should use proper ear hygiene and avoid placing objects like cotton-tipped swabs in your ears." See the box Patient Education for Self-Treatable Otic Disorders.
a. appropriate dose and frequency of administration	"Place 5-10 drops of the cerumen-softening solution into ear canal, and allow it to remain for at least 15 minutes." "Continue with irrigation technique to assist with cerumen impaction removal."

b. maximum number of days the therapy should be employed	“Do this procedure twice daily for no longer than 4 consecutive days.”
c. product administration procedures	See <a href="#">Table 29-1</a> .
d. expected time to onset of relief	“Fullness or pressure sensation relief can often be felt after first treatment. However, it may take additional treatments to fully resolve symptom relief.”
e. degree of relief that can be reasonably expected	“Full resolution of symptoms can be expected within 4 days.”
f. most common side effects	“The medication may cause bubbling or crackling sound in the ear.”
g. side effects that warrant medical intervention should they occur	“You may experience pain, rash, irritation, tenderness, redness, discharge, or dizziness from the medication.”
h. patient options in the event that condition worsens or persists	“Stop using the product and see your primary care provider.”
i. product storage requirements	“Keep cap on bottle when not in use. Store drops in original carton at room temperature. Rinse syringe thoroughly before and after use, and let dry. Store ear syringe in a cool, dry place and in its original container.”
j. specific nondrug measures	See the box Patient Education for Self-Treatable Otic Disorders.
Solicit follow-up questions from the patient or caregiver.	“Will I always have earwax impaction because I started to wear hearing aids?”
Answer the patient’s or caregiver’s questions.	“Although wearing hearing aids may put you at risk for experiencing cerumen impaction, it does not mean that this will be a continual problem for you. Frequent removal and cleaning of your hearing aids can help prevent earwax buildup. In addition, daily safe ear hygiene techniques will help reduce that risk.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Offer to contact the patient in 2 days to evaluate her response.

Key: NKA = No known allergies.

### Case 29-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient’s symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient reports gradual hearing loss and itchiness over the last 3 days in his right ear and began experiencing intense pain this afternoon in the same ear.
b. description of any factors that seem to	The hearing loss began about 2 days after returning home from family vacation

precipitate, exacerbate, and/or relieve the patient's symptom(s)	at water park. He noticed a small amount of fluid drainage from his ear and felt that excess water was draining from the ear.
c. description of the patient's efforts to relieve the symptoms	Patient applied 5-10 drops of water-drying drops (isopropyl alcohol 95% in anhydrous glycerin) in an effort to remove the water that was clogging his ears. The drops provided no relief and caused mild pain when administered.
d. patient's identity	David Peterson
e. age, sex, height, and weight	43 years old, male, 5 ft 7 in., 145 lb
f. patient's occupation	Business analyst
g. patient's dietary habits	Eats 3 meals per day, with minimal vegetable intake.
h. patient's sleep habits	8 hours nightly
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Allergic rhinitis: fexofenadine 180 mg and pseudoephedrine 240 mg daily; fluticasone propionate 50 mcg nasal spray 2 sprays each nostril daily. Sinus headaches: ibuprofen 400 mg twice daily with food as needed
j. allergies	NKA
k. history of other adverse reactions to medications	None
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s) (Table 29-4).	Patient could be suffering from otitis externa rather than excessive water in the ear.
3. Identify exclusions for self-treatment (Figure 29-2).	Recent onset of intense ear pain
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Immediate referral of patient to health care provider for a differential diagnosis. (2) Recommend continuation with self-care until patient can see an appropriate health care provider. (3) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Patient should consult a health care provider.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should consult a health care provider for treatment."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"The best option for you is to discontinue any additional self-treatment and seek immediate care from a health care provider. The recent onset of the pain you are feeling is not due to water in the ears, but rather an ear infection. Nonprescription ear products will not be able to treat this. In your case, you may need prescription ear drops to treat the condition."

<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	“How might I be able to prevent this problem in the future?”
Answer the patient’s or caregiver’s questions.	“Consider using ear plugs to prevent water from entering your ears when swimming.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact patient in 1 day to ensure that he sought medical care.

Key: NKA = No known allergies.

### Patient Counseling for Otic Disorders

Patients who self-treat otic disorders must understand how easily the EAC can be injured. The health care provider should discourage common harmful practices of relieving itching of the ear using cotton swabs, fingernails, or other devices, and instruct patients on the proper methods of removing excessive cerumen and moisture from the ears. Patients who are susceptible to these disorders should be advised to incorporate the proper removal methods as part of their aural hygiene. The provider should explain the proper use and possible adverse effects of all recommended medications. The box Patient Education for Self-Treatable Otic Disorders lists specific information to provide patients.

**TABLE 29-4 Differentiation of Common Otic Disorders**

<i>Disorder</i>	<i>Etiology</i>	<i>Pain</i>	<i>Itching</i>	<i>Loss of Hearing</i>	<i>Discharge</i>	<i>Other Features</i>
Ruptured tympanic membrane	Otitis media or trauma to ear such as sharp blows, diving into water, forceful irrigation of ear	Brief, severe	No	Abrupt	If associated with otitis media	May be associated with otitis media (see subsequent text)
External otitis (swimmer’s ear)	Local trauma to EAC caused by excessive moisture or abrasions; subsequent fungal/bacterial infections	Acute onset, varies from mild to severe, increases with movement of tragus or auricle	Yes	Occasional	Occasionally, clear discharge changing to seropurulent	Swollen ear canal, stuffiness, discharge, swollen lymph nodes, fever, usually occurs in summer or in warm, humid climates
Otitis media	Bacterial infection of middle ear, usually following upper respiratory tract infections	Sharp, steady, frequently unilateral; does not increase with movement of tragus or auricle	No	Is sometimes decreased	Possible exudate through perforated eardrum	Perforated or bulging eardrum, lymph nodes sometimes swollen, fever, dizziness, usually occurs in winter
Foreign object in ear	Insects, insertion of objects by children, hearing aids, sound attenuators	Dull-severe pain with sense of fullness or pressure during chewing	Yes	Yes	Possible exudate from secondary bacterial infection	If obstruction not removed promptly, acute otitis externa and tinnitus may develop

Trauma to ear	Burns from curling iron, frostbite, hematomas/injuries from contact sports or ill-fitting helmets, ear piercing, improper cerumen removal techniques, abrasions of EAC, rapid changes in air pressure	Varies from sharp and steady to brief and severe	Rare	Varies, can be abrupt to seldom	Seldom	Untreated hematomas may cause swelling/scarring; ear piercing may cause metal sensitivities, keloids, perichondritis, toxic shock syndrome, hepatitis B
Tinnitus	Hearing disorders, blockage of EAC, exposure to high noise levels, acoustic trauma, systemic diseases, drug toxicities (salicylate, quinidine, aminoglycosides, and other antibiotics)	Possible	No	Sometimes	None	Continuous or intermittent alien noises in ear such as ringing, roaring, or humming
Excessive/impacted cerumen	Overactive ceruminous glands, obstructed migration of cerumen	Rare, dull pain if present	No	Often	None	Sense of fullness or pressure in the ears
Water-clogged ears	Excessive moisture in EAC	None	No	Often	None	Sense of fullness or wetness

Key: EAC = External auditory canal.

Source: References 3, 4, 6, 8, 12, 16, 30, and 33.

**TABLE 29-5 Treatment of Common Otic Disorders**

<b>Disorder</b>	<b>Etiology</b>	<b>Treatment</b>
Otalgia	Intrinsic: infection, trauma, foreign objects, perichondritis Extrinsic: dental or jaw problems, nasopharyngeal infections, tumors, cysts, migraine headaches, neuralgias, cervical arthritis	Medical referral unless cause is clearly obvious, self-limiting, and self-treatable; always refer infections; self-care may delay seeking proper treatment
Otic pruritus	Seborrhea, psoriasis, contact dermatitis; infection (external otitis); excessive dryness related to decreased sebum production	See <a href="#">Chapters 33</a> and <a href="#">34</a> ; medical referral if infection suspected; excessive dryness: 1-2 drops of mineral oil
Hearing loss	Foreign objects or water trapped in EAC; infection, congestion, neoplasms, tympanic membrane perforation, medications, excessive pressure, cerumen, or noise in EAC	Medical referral unless hearing loss is related to excessive water or impacted cerumen
Dizziness	Inner ear lesions, otitis media, rapid change in pressure on the tympanic membrane, migraine headache, ototoxic drugs, postural hypotension, cardiac disease, neoplasms, irrigation of ear canal with very hot or cold water, motion sickness	Medical referral unless related to motion sickness
Tinnitus	See <a href="#">Table 29-4</a>	Check for impacted cerumen; medical referral otherwise
Foreign body	Insects, beads, seeds, small batteries, or other objects	Medical referral; mineral oil can quickly suffocate an insect until removed by a provider; moisture causes seeds to swell, making removal more difficult

Key: EAC = External auditory canal.

Source: References 3, 4, 6-8, 12, and 30-33.

### Evaluation of Patient Outcomes for Otic Disorders

If the symptoms of excessive/impacted cerumen or water-clogged ears persist or worsen after 4 days of proper self-treatment, the patient should consult a primary care provider. The patient should also consult a primary care provider if ear pain or discharge

develops during treatment. The provider can follow up by phone in 4 days to determine whether the therapy is successful.

### Key Points for Otic Disorders

- Limit the self-treatment of otic disorders to minor symptoms such as a sense of fullness, pressure, or wetness in the ears.
- Refer for further evaluation patients younger than 12 years, as well as those with signs and symptoms of ear infection, bleeding or signs of trauma, tympanostomy tubes, ruptured tympanic membrane, or ear surgery within the past 6 weeks.
- Instruct patients on how to use specific otic products that have been proven safe and effective (Tables 29-1 and 29-2).
- Advise patients with self-treatable symptoms to contact a primary care provider if symptoms worsen or do not improve after 4 days.
- Advise patients about proper ear hygiene and the importance of cerumen to prevent further problems.

Patient Education for Self-Treatable Otic Disorders

#### Excessive/Impacted Cerumen

The objective of self-treatment is to soften and remove excessive or impacted cerumen (earwax) that is already present or to prevent the disorder from recurring in susceptible patients. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

##### **Nondrug Measures**

- Use a washcloth draped over a finger to remove earwax from the outer canal.
- Do not insert objects in the ear to remove earwax. Such attempts may injure the ear canal or push the wax farther into the canal.
- Never use the hollow candle method to remove earwax; it can cause serious ear injury or burns to other areas of the body.

##### **Nonprescription Medications**

- Cerumen is necessary to lubricate the canal, trap dust and foreign materials, and provide a waxy, waterproof barrier to the entry of pathogens.
- Carbamide peroxide and anhydrous glycerin are combined to soften and mechanically break down excessive/impacted cerumen.
- See Tables 29-1 and 29-2 for guidelines on using carbamide peroxide to remove excessive or impacted earwax.
- Do not let the medication come into contact with the eyes.
- Do not use this medication if you have a fever, ear drainage, pain more severe than a dull pain, dizziness, or a ruptured eardrum, or if you had ear surgery within the past 6 weeks.
- Do not use this medication to treat inflamed ear tissue, swimmer's ear, or itching of the ear canal.
- Prolonged contact between carbamide peroxide solution and skin of the ear canal can cause dermatitis. Discontinue treatment if irritation or a rash appears.
- Store product in a cool, dry area and check expiration date before using.

##### **When to Seek Medical Attention**

- Monitor for changes in your hearing and symptoms of infection such as pain and itching.
- If severe pain occurs or your hearing worsens, see a primary care provider immediately. Severe pain may indicate a ruptured eardrum.

#### Water-Clogged Ears

The objective of self-treatment is to remove water from ears already clogged with water or to prevent the disorder in persons who are susceptible to excessive moisture in the ears. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

##### **Nondrug Measures**

- Tilt the affected ear down, and gently manipulate it to help drain water from the ear. Immediately after swimming or bathing, use a blow-dryer on a low heat and speed setting to help dry the ear canal. Do not blow air directly into the ear canal.

##### **Nonprescription Medications**

- Water can become trapped in the ear, causing a sense of fullness or wetness.
- Use a product that reduces moisture content in the ear without overdrying. Isopropyl alcohol 95% in anhydrous glycerin 5% is the only FDA-approved formula.
- Do not use the medication if you have a ruptured eardrum or have tympanostomy tubes in place.
- Place 5-10 drops of the solution in the ear canal, and allow the solution to remain for 1-2 minutes.
- See Table 29-1 for further instructions on instilling the medication.
- Do not let the medication come into contact with the eyes.
- Discontinue the medication if stinging or burning occurs.
- Store product in a cool, dry area and check expiration date before using.

##### **When to Seek Medical Attention**

- If pain, fever, or discharge develops, see a primary care provider immediately.

### Dermatologic Disorders of the Ear

The objective of self-treatment is to relieve the symptoms. For most patients, carefully following product instructions and the self-care measures listed in [Chapters 33](#) and [34](#) will help ensure optimal therapeutic outcomes.

**Handbook of Nonprescription Drugs** > Chapter 30. Prevention of Hygiene-Related Oral Disorders**Update: New FDA Recommendation for Fluoride Added to Bottled Water**

Content Update for [Chapter 30](#), "Prevention of Hygiene-Related Oral Disorders." Posted June 1, 2015.

In April 2015, the U.S. Food and Drug Administration (FDA) issued a letter to industry regarding levels of fluoride added to bottled water.<sup>1</sup> In accordance with new guidance from the U.S. Public Health Service (PHS) for fluoridation of community water supplies,<sup>2</sup> FDA recommends that manufacturers, distributors, and importers of bottled water limit the amount of fluoride added to no more than 0.7 mg/L. This recommendation replaces the previously recommended level of 0.7 – 1.2 mg/L and aims to promote balance between protection from dental caries, which lead to tooth decay, and the risk of dental fluorosis. Dental fluorosis is a discoloration of tooth enamel that occurs in children and results from exposure to excessive amounts of fluoride. This new PHS recommendation results from evaluation of recent systematic reviews regarding fluoride in drinking water and the epidemiology of dental caries and fluorosis. The evaluation was performed by the U.S. Department of Health and Human Services Federal Panel on Community Water Fluoridation, which drew experts from many federal agencies. The FDA recommendation is specific only to fluoride added to bottled water.<sup>1</sup>

**Prevention of Hygiene-Related Oral Disorders: Introduction**

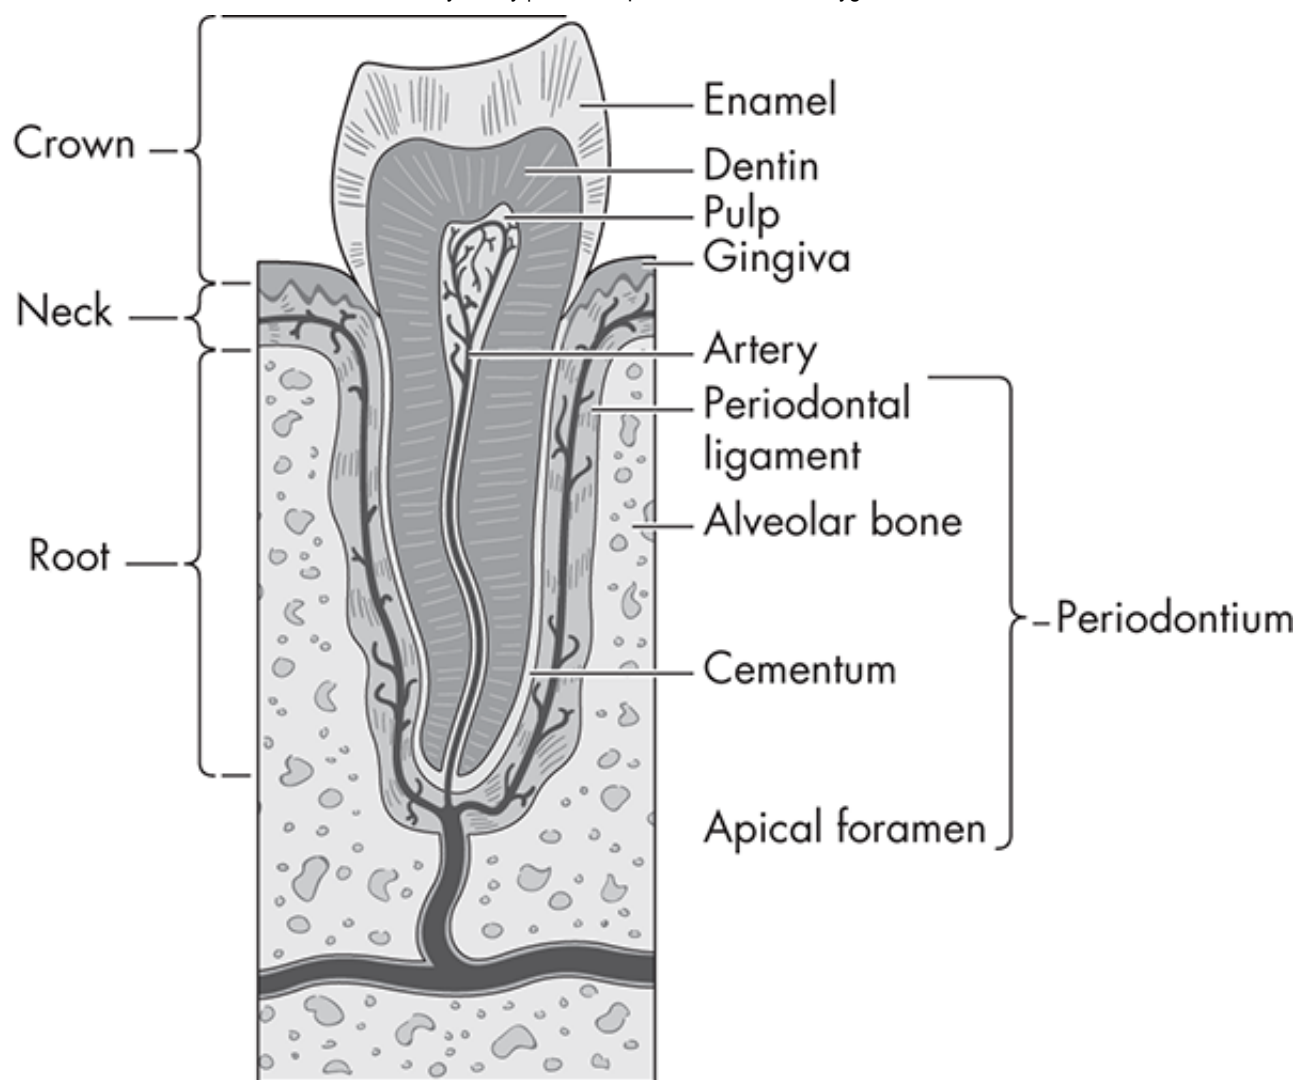

Dental diseases and disorders impact the health and well-being of Americans throughout their lifespan. Dental caries (tooth decay) is the most common childhood condition, being five times more prevalent than asthma and seven times more prevalent than hay fever. Individuals should receive professional care to maintain oral health, yet 50% of the population is in need of dental treatment. Routine dental care is recommended twice per year for children and adults; children should have their first visit to the dentist within 6 months of getting their first tooth or no later than 12 months of age. Fifty percent of children ages 5-9 years have at least one cavity or filling; this number increases to 78% by the time individuals are 17 years of age. Oral health is reflective of overall general health.<sup>1</sup>

Improper oral hygiene is a direct cause of dental caries, periodontal disease (gingivitis and periodontitis), halitosis, and some cases of denture-related discomfort. Nonprescription products for prevention of oral disease are widely available in pharmacies, food stores, and other retail stores; therefore, educating the public about proper use of these products is the key to preventing dental diseases.

The teeth and supporting structures are necessary for normal mastication and articulation, as well as for normal appearance. The primary (deciduous, or baby) dentition first appears at approximately 6 months of age, when the mandibular (lower jaw) central incisors erupt; the process is usually complete with the eruption of the upper second molars at approximately 24 months of age. Each of the upper and lower arches holds 10 deciduous teeth, 20 in all. Generally, the first permanent dentition (adult tooth) appears when the mandibular first molar erupts behind the deciduous second molar at approximately 6 years of age, and the process continues in a regular pattern, usually replacing shedding deciduous teeth. Of the 32 total permanent teeth, 28 are usually present by age 14; third molars (wisdom teeth) may appear between 17 and 21 years of age.

Anatomically, the teeth are viewed grossly as having two parts, the roots and the crown ([Figure 30-1](#)). Normally, the roots are below the gingival (gum) line or margin; roots are essential in supporting and attaching the tooth to the surrounding tissues. The crown is above the gingival margin and is responsible for mastication. Each tooth has four major components: enamel, dentin, pulp, and cementum.

#### Anatomy of the tooth.

Enamel is composed of very hard, crystalline calcium phosphate salts (hydroxyapatite). It is 1.5-2 mm thick at its thickest part and protects the underlying tooth structure. It covers the crown of the tooth, ending around the gum line at the cements-enamel junction. Enamel's hardness enables the crown to withstand the wear of mastication. Dentin, which is softer, lies beneath the enamel and makes up the largest part of the tooth structure. It is transected by microscopic tubules that transport nutrients from the dental pulp. Dentin protects the dental pulp from mechanical, thermal, and chemical irritation. The bone-like cementum is softer than dentin and covers the root of the tooth, extending apically from the cements-enamel junction.

The pulp occupies the pulp chamber and canal. It is continuous with the tissues surrounding the tooth by an opening at the apex of the root (apical foramen). The pulp consists primarily of vascular and neural tissues. The only nerve endings in the pulp are free nerve endings; therefore, any type of stimulus to the pulp is interpreted as pain.

The periodontium comprises the hard and soft tissues that surround the teeth, including the periodontal ligament, the encompassing alveolar bone, and the gingiva. The tooth is suspended hammock-like in bone by the periodontal ligament. The cementum's major function is to attach the tooth to the periodontal ligament by periodontal fibers. The periodontal ligament is connective tissue that attaches the tooth to the surrounding alveolar bone and gingival tissue. The periodontal ligament performs supportive, formative, sensory, and nutritive functions. The alveolar bone forms the sockets of the teeth. The gingiva is the soft tissue surrounding the teeth. Gingiva is categorized as either keratinized attached gingiva or unkeratinized unattached gingiva. Attached gingiva is normally pink, stippled (like an orange peel), and keratinized. It is attached to the cementum by the gingival group of periodontal ligament fibers. The major salivary glands (parotid, submandibular, and sublingual) are responsible for secreting saliva, an alkaline, slightly viscous, clear secretion that contains enzymes (lysozymes and ptyalin), albumin, epithelial mucin (a mucopolysaccharide), immunoglobulin, leukocytes, and minerals. Normal salivary gland function promotes good oral health in several ways. First, saliva lubricates and facilitates the removal of carbohydrates and microorganisms from the oral cavity. Second, saliva also buffers the decline in pH caused by the acid formed by carbohydrate fermentation. Third, the mineral components of saliva have a protective role in the demineralization and remineralization of tooth enamel.

*Editor's Note:* This chapter is based on the 17th edition chapter of the same title, written by Amy W. Rudenko.

## Caries

The increase in dental caries globally among both children and adults is a great public health concern. Although no consensus exists as to the cause of this increase, health care providers should focus attention on public health strategies that have been successful in reducing caries in the past (e.g., fluoridation of the municipal water supply, topical fluoride treatments, education on proper tooth brushing with a fluoride dentifrice, daily flossing, a proper diet, and regular dental office visits).<sup>2</sup>

Patients with poor oral hygiene are at greatest risk for developing caries. Patients at increased risk for caries include those with orthodontic appliances, xerostomia (dry mouth), and gum tissue recession that exposes root surfaces. Certain medications may cause xerostomia (see [Chapter 31](#)); xerostomia is more likely to manifest in patients who have undergone head and neck radiation therapy.

Increased dental caries is also associated with the use of tobacco products, which may be attributable to changes in salivary function, buffering capacity, or composition, including bacterial flora.<sup>3</sup> Because alcohol consumption can cause xerostomia, individuals who consume alcohol may also have a higher risk of caries.

## Pathophysiology of Caries

Dental caries is now considered an infectious disease that affects the calcified tissues of the teeth. Certain plaque bacteria generate acid from dietary carbohydrates; the acid demineralizes tooth enamel and dentin, leading to the formation of soft carious lesions (pits or fissures of smooth surface that, if left untreated, will eventually destroy the tooth). Formation of dental caries requires growth and attachment of many cariogenic microorganisms (e.g., *Streptococcus mutans*, *Lactobacillus casei*, and *Actinomyces viscosus*) to exposed tooth surfaces. If oral hygiene is neglected, dental plaque (the biofilm containing these organisms) remains on the tooth surfaces and, in time, attracts more bacteria, thereby promoting decay.

The carious process is characterized by alternating periods of destruction (demineralization) and repair (remineralization). Demineralization is caused by organic acids, (e.g., lactic and formic acids), which are produced (usually anaerobically) by microbial metabolism of low-molecular-weight carbohydrates (sugars) that readily diffuse into plaque. The resulting reduction in pH on the tooth surface causes demineralization of dental enamel. Saliva, which is rich in calcium and phosphate ions, is crucial in remineralizing early carious lesions. The presence of fluoride ions in the mouth also promotes remineralization and slows demineralization, thereby retarding enamel dissolution.

A carious lesion starts slowly on the enamel surface and initially produces no clinical symptoms. Once demineralization progresses through the enamel to the softer dentin, the destruction proceeds much more rapidly, becoming clinically or radiographically evident as a carious lesion. At this point, the patient can become aware of the lesion either by observing it or by experiencing symptoms of sensitivity to stimuli (e.g., heat, cold, or sweet foods) or chewing. If untreated, the carious lesion can damage the dental pulp (with continuous pain as a common symptom) and eventually cause necrosis of vital pulp tissue.

## Clinical Presentation of Caries

Plaque is commonly recognized as the source of microbes that cause caries and periodontal disease; therefore, plaque buildup is directly related to the incidence of oral disease. After meals, food residue may be incorporated into plaque by bacterial degradation. Left undisturbed, plaque thickens, and bacteria proliferate. Plaque growth begins in protected cracks and fissures and along the gingival margin. If not removed within 24 hours, dental plaque (especially in areas opposite the salivary glands) begins to calcify by calcium salt precipitation from the saliva, forming calculus, or tartar. This hardened, adherent deposit is removable only by professional dental cleaning. Calculus is generally considered to be a substrate on which additional plaque can develop and is not considered the primary cause in periodontal disease. However, most periodontists agree that supragingival (above) and subgingival (below the gingival margin) calculus can promote the progression of periodontal disease by accumulating new bacterial plaque in contact with sensitive tissue sites and by interfering with local self-cleaning efforts to remove plaque.

## Prevention of Caries

### General Approach

The key to preventing caries is controlling dental plaque. Because a combination of diet (carbohydrate substrate), oral bacteria, and host resistance is involved in developing caries, prevention should be aimed at modifying these factors. The frequency of refined carbohydrate intake should be reduced; plaque (which supports cariogenic bacterial growth) should be removed, usually by mechanical means (e.g., brushing and flossing); and host resistance should be increased through appropriate exposure to fluoride ion. Antiplaque products aid in mechanical removal of plaque

or retard its buildup. The declining prevalence of dental caries in children in the United States may be attributed to a combination of these interventions (e.g., increased exposure to fluoride in drinking water, dentifrices, and mouth rinses; changed patterns of diet; and overall improved oral hygiene).

Two methods are used to manage plaque: The first is mechanical removal (brushing with a dentifrice and flossing), and the second is chemical management (e.g., using specific products to prevent plaque accumulation or aid its removal). The best way to ensure the health of teeth and gingival tissues is to remove plaque buildup mechanically by brushing at least twice daily and flossing at least once daily. Toothbrushing removes plaque from the lingual (tongue side), buccal (cheek side), and occlusal (biting) surfaces of the teeth. Plaque found on interproximal (between the teeth) surfaces can only be removed efficiently with dental floss and other interdental cleaning aids (e.g., interproximal brush, dental tape, and tapered picks).

## Nonpharmacologic Therapy

### Dietary Measures

Cariogenic foods and beverages should be avoided in favor of those that are less cariogenic. A food is considered highly cariogenic if it contains more than 15% sugar, clings to the teeth, and remains in the mouth after it is chewed. Conversely, foods are less cariogenic if they have a high water content (e.g., fresh fruit); stimulate the flow of saliva (e.g., carrots and other fibrous foods that require a lot of chewing); or are high in protein (e.g., dairy products). Both the water content of fresh fruit and the resulting flow of saliva tend to wash away the fruit's sugar and neutralize the acid it creates. Milk protein also raises pH and tends to inhibit binding of bacteria.

Oral hygiene products (e.g., mouth rinses and dentifrices) may contain a low concentration of saccharin, which is a potent noncariogenic sugar substitute that appears to present no caries hazard. Other noncariogenic sugar substitutes such as sugar alcohols (sorbitol and xylitol) and aspartame (amino acid methyl ester) are currently used as sweetening agents.

### Plaque Removal Devices

Toothbrushes, dental floss, oral irrigating devices, and specialty aids (e.g., interproximal dental brushes) are the primary devices used in facilitating plaque removal.

#### **Toothbrushes**

The toothbrush is the most universally accepted device available for removing dental plaque and maintaining good oral hygiene.

The proper frequency and method of brushing will vary from patient to patient. Thoroughness of plaque removal without gingival trauma is more important than the method used. [Table 30-1](#) describes the proper method of brushing teeth.

#### **TABLE 30-1 Guidelines for Brushing Teeth**

- Brush teeth after each meal or at least twice a day.
- If using toothpaste, apply a small amount of paste to the toothbrush.
- Use a gentle scrubbing motion with the bristle tips at a 45-degree angle against the gum line so that the tips of the brush do the cleaning.
- Do not use excessive force because it may result in bristle damage, cervical abrasion, irritation of delicate gingival tissue, and gingival recession with associated hypersensitivity.
- Brush for at least 2 minutes, cleaning all tooth surfaces systematically.
- Gently brush the upper surface of the tongue to reduce debris, plaque, and bacteria that can cause oral hygiene problems.
- Rinse the mouth, and spit out all the water.

Manual toothbrushes vary in size, shape, texture, and design, with new product designs proliferating rapidly. These toothbrushes have either nylon or natural bristles that are usually rated as soft, medium, or firm.

Powered toothbrushes (which are widely available on the market) are either battery operated or have a rechargeable battery system. The battery-operated devices (e.g., the Arm & Hammer Spinbrush and Colgate 360 Sonic Power Toothbrush) use a rotary and/or vibratory motion and are less expensive, but their effectiveness deteriorates over time as the disposable battery loses power. Rechargeable battery toothbrushes use a rotary and/or vibrating motion (e.g., Oral B) or ultrasonic vibration (e.g., Sonicare and Oral B) to remove plaque. These power brushes tend to be more expensive, but they maintain constant efficiency because of their rechargeability. Powered toothbrushes may benefit certain patients, such as those who are disabled or who have dexterity issues.<sup>1</sup>

Patients can expect best results by using a brush carrying the American Dental Association's (ADA) Seal of Acceptance described in the box [The American Dental Association Seal of Acceptance](#)<sup>4</sup> and by following a dental professional's specific directions for use. The ADA criteria for acceptance are based on safety and efficacy concerns.

Research has shown no evidence of a statistically significant difference in the effectiveness between powered and manual toothbrushes. Although electric toothbrushes appear to significantly reduce plaque and gingivitis in both the short- and long-term, the clinical significance of this finding is unknown.<sup>5</sup>

The American Dental Association Seal of Acceptance

ADA evaluates the safety and efficacy of dental products used by dental professionals and the public through the Council on Scientific Affairs' Seal of Acceptance evaluation program. Manufacturers of dentifrices or mouth rinses with therapeutic potential for gingivitis and supragingival dental plaque control may voluntarily submit data to ADA for evaluation. Product labels and promotional material must also comply with ADA standards.<sup>5</sup>

The ADA Council on Scientific Affairs allows only products that demonstrate a significant effect against gingivitis to make plaque-control or plaque-modification claims. A product that can demonstrate significant plaque reduction but no concomitant significant reduction in gingivitis will not be eligible for acceptance.<sup>10</sup> ADA has approved two statements to be used for products classified under these guidelines—one for both gingivitis and plaque reduction, and one for gingivitis reduction only:

- [Product name] has been shown to help prevent and reduce [whichever is appropriate] gingivitis [and supragingival plaque accumulation] when used as directed in a conscientiously applied program of oral hygiene and regular professional care. Its effect on periodontitis has not been determined.<sup>10</sup>

Once a product has earned the ADA seal, it may display that seal for 3 years, provided it continues to meet all the requirements.<sup>5</sup> The ADA online home page ([www.ada.org](http://www.ada.org)) provides searchable access to a current listing of dental consumer products that have been awarded the ADA Seal of Acceptance.

No definite guideline exists as to how often a patient should buy a new toothbrush, although 3 months has been suggested as the average toothbrush life expectancy. Marketing data suggest that consumers, on average, replace their toothbrushes only 1.7 times per year. Two compelling reasons exist for replacing toothbrushes frequently: wear and bacterial accumulation. Different brushing methods cause bristles to wear differently. Worn, bent, or matted bristles do not remove plaque effectively. Therefore, patients should replace toothbrushes at the first sign of bristle wear, rather than after a defined period of use. Ideally, they should rotate among 2 or 3 toothbrushes to allow each to dry completely between uses, thereby decreasing bristle wear and matting. Some brands of toothbrushes have color-impregnated bristles that indicate the need for replacement when the color disappears halfway down the bristles.

**Product Selection Guidelines.** Dental professionals recommend toothbrushes according to the individual patient's manual dexterity, oral anatomy, and periodontal health. The toothbrush should be of a size and shape to allow the patient to reach every tooth in the mouth. Innovations in head shapes and bristle configurations continue to be introduced in an attempt to improve cleaning contact with tooth and gum line surfaces. Toothbrush firmness is not standardized; toothbrushes designated as soft, medium, or hard may not be comparable across manufacturers. Use of medium- or hard-bristled toothbrushes may result in damage to the tooth enamel and gingival tissue. Softer bristles are more effective at working themselves into crevices and spaces between the teeth, and they are less abrasive on teeth with exposed recession. Many dentists and dental hygienists prefer soft, rounded, multi-tufted, nylon bristle brushes, because nylon bristles are more durable and easier to clean than natural bristles, and because soft, rounded bristle tips are more effective in removing plaque below the gingival margin and on proximal tooth surfaces. The handle size and shape of a toothbrush should allow the individual to maneuver the brush easily while maintaining a firm grasp. Many modifications (e.g., angle bends or flexible areas in the handle) that may improve contact between the bristles and some less-accessible tooth surfaces have been introduced. Dentists can fabricate customized handles for physically impaired individuals by adding moldable acrylic to the handles.

Children's toothbrushes are smaller than adult toothbrushes and are available in two sizes: baby (for children up to 6 or 7 years of age) and junior (for children 7 years of age to teens). Toothbrush size and shape should be individualized according to the size of the child's mouth. Soft bristles are recommended for children's toothbrushes. Children can usually remove plaque more easily with a brush that has short and narrow bristles.

### Dental Floss

Plaque accumulation in the interdental spaces contributes to proximal caries and periodontal pocketing. Interdental plaque removal has been reported to reduce gingival inflammation and prevent periodontal disease and dental caries. Dental flossing is the most widely recommended method of removing dental plaque from proximal tooth surfaces that are not adequately cleaned by toothbrushing alone. By removing plaque and debris interproximally, proper flossing also polishes the tooth surfaces and reduces gingival inflammation. Proper flossing technique requires some finger dexterity and practice. If performed improperly, flossing can injure gingival tissue and cause cervical wear on proximal root surfaces.<sup>1</sup> Table 30-2 describes the proper use of dental floss.

Most floss is a multifilament nylon yarn that is available in waxed or unwaxed form and in varying widths, from thin thread to thick tape. Many brands feature product lines of flosses that are impregnated or coated with additives, such as flavoring, baking soda, and fluoride. In addition, several manufacturers are marketing floss made of materials with superior antishredding properties (e.g., Glide and Oral B Essential). ADA has recognized nearly 30 brands of dental floss and tape as safe and effective.<sup>5</sup>

**TABLE 30-2 Guidelines for Using Dental Floss**

- Pull out approximately 18 inches of floss, and wrap most of it around the middle finger.
- Wrap the remaining floss around the same finger of the opposite hand. About an inch of floss should be held between the thumbs and forefingers.
- Do not snap the floss between the teeth; instead, use a gentle, sawing motion to guide the floss to the gum line.
- When the gum line is reached, curve the floss into a C-shape against one tooth, and gently slide the floss into the space between the gum and tooth until you feel resistance.
- Hold the floss tightly against the tooth, and gently scrape the side of the tooth with an up and down motion.
- Curve the floss around the adjoining tooth, and repeat the procedure.

**Product Selection Guidelines.** Because no particular product has been proved superior, patient factors (e.g., tightness of tooth contacts, tooth roughness, manual dexterity, and personal preference) should be considered in product selection. Similarly, clinical studies show no difference between various floss types in terms of removing plaque and preventing gingivitis.<sup>6</sup> Evidence does not support concern about waxed floss leaving a residual wax film on tooth surfaces.

Waxed floss may pass interproximally between tight-fitting teeth with less shredding than unwaxed floss. Teflon floss (e.g., Glide), also resists shredding and slips easily between tight teeth. If contacts at the crowns of teeth are too tight to force floss interdentally, floss threaders can be used to pass floss between the teeth and under the replacement teeth (pontics) of fixed bridges. Floss threaders (available in reusable and disposable forms) are usually thin plastic loops or soft plastic, needle-like appliances. Patients who wear braces may find that the use of threaders aids in the flossing process. Electrically powered interdental cleaning devices may be used to remove interproximal debris. However, electrically powered interdental devices or floss threaders should be used cautiously to avoid physical trauma of the gingiva.<sup>7</sup> Floss holders have one or two forks that are rigid enough to keep floss taut and a mounting mechanism that allows quick rethreading of floss. These products are recommended for patients who lack manual dexterity and for caregivers who assist disabled or hospitalized patients.

### Specialty Aids

Cleaning devices that adapt to irregular tooth surfaces better than dental floss are recommended for interproximal cleaning of teeth with large interdental spaces. These large interdental spaces are often characteristic of periodontal disease. The G-U-M Flossbrush is such a device; it features woven dental floss that contains a time-release fluoride system and is molded into a plastic handle for interdental cleaning. The most common aids are tapered triangular wooden toothpicks (Stim-U-Dent), holders for round toothpicks (Perio-Aid), miniature bottle brushes (Proxabrush), rubber stimulator tips, denture brushes, and denture clasp brushes.

### Oral Irrigating Devices

Oral irrigators work by directing a high-pressure stream of water through a nozzle to the tooth surfaces. These devices can remove only a minimal amount of plaque from tooth surfaces. Therefore, oral irrigators cannot be viewed as substitutes for a toothbrush, dental floss, or other plaque-removal devices, but they should be considered as adjuncts in maintaining good oral hygiene. These devices are useful for removing loose debris from those areas that cannot be cleaned with a toothbrush (e.g., around orthodontic bands and fixed bridges). Several brands on the market carry the ADA Seal of Acceptance.<sup>5</sup>

Oral irrigators are also valuable as vehicles for administering chemotherapeutic agents that inhibit microbial growth in inaccessible regions of the mouth. Patients with advanced periodontal disease should use these devices only under professional supervision because transient bacteremia may occur after manipulative procedures with the oral irrigator. Oral irrigation devices are also contraindicated in patients who are predisposed to bacterial endocarditis.

### Pharmacologic Therapy

#### Chemical Management of Plaque

Chemical management of plaque and calculus can enhance mechanical removal either by acting directly on the plaque bacteria or by disrupting components of plaque to aid in its removal during routine oral hygiene. The use of chemical agents in plaque control may be particularly appropriate for selected patients who may be unable to brush and floss effectively. Physically or mentally disabled individuals (who may not be able to master the manual techniques necessary to brush and floss effectively) and orthodontia patients (i.e., those with fixed prostheses) may benefit from adding antiplaque agents to their oral hygiene regimen.

Desirable characteristics for antiplaque agents include the following:

- Selective antibacterial activity; interference with the rate of accumulation or metabolism of supragingival plaque
- Substantivity (sustained retention of the agent in the mouth)

- Compatibility with dentifrice ingredients
- Lack of undesirable side effects for the user
- Noninterference with the natural ecology of the normal oral microflora

### Use of Fluoride

Fluoride is believed to help prevent dental caries through a combination of effects. When it is incorporated into developing teeth, fluoride systemically reduces the solubility of dental enamel by enhancing the development of a fluoridated hydroxyapatite (which is more resistant to demineralizing acids) at the enamel surface. The topical effect facilitates remineralization of early carious lesions during repeated cycles of demineralization and remineralization. Some evidence exists that fluoride interferes with the bacterial cariogenic process. Fluoride that is chemically bound to organic constituents of plaque may interfere with plaque adherence and may inhibit glycolysis (the process by which sugar is metabolized to produce acid).<sup>1</sup>

Fluoridation of the public water supply is an effective and economically sound public health measure that has played a major role in decreasing the incidence of caries.<sup>8</sup> According to the Centers for Disease Control, nearly 70% of the U.S. population resides in communities in which the public water supply contains either naturally occurring or added fluoride at optimal levels for decay prevention (1 ppm or 1 mg/L). In addition to reducing dental caries in children, fluoridation has benefits that extend through adulthood, resulting in (1) fewer decayed, missing, or filled teeth; (2) greater tooth retention; and (3) a lower incidence of root caries. Systemic fluoride supplementation in children is based on the preventive mechanism of fluoride when incorporated into developing enamel. Current concepts of the action of fluoride relative to its presence in saliva and plaque provide a rationale for its topical application to prevent caries in all age groups. Any decision to supplement fluoride intake must factor in the concentration of fluoride already present in the drinking water.<sup>1</sup> Bottled water does not contain fluoride.

Mouth rinses and gels that contain sodium fluoride are therapeutic topical applications of fluoride for prevention of dental caries (Table 30-3). Fluoride mouth rinsing enables patients to apply fluoride interproximally.

Patients who may benefit from fluoride rinsing include those with orthodontic appliances, those with decreased salivary flow, those at risk for developing root caries, and anyone with difficulty maintaining good oral hygiene. Orthodontic patients are at risk of developing decalcified areas during treatment, and their ability to thoroughly clean interdental spaces may be inhibited.

**TABLE 30-3 Selected Nonprescription Topical Fluoride Products**

<i>Trade Name</i>	<i>Primary Ingredient</i>
ACT Anticavity Fluoride Rinse	Sodium fluoride 0.05%
Gel-Kam Gel	Stannous fluoride 0.4%
Crest Pro-Health For Me Anti-Cavity Fluoride Rinse	Sodium fluoride 0.022%
Phos-Flur Fluoride Rinse	Sodium fluoride 0.044%

**TABLE 30-4 Guidelines for Using Topical Fluoride Treatments**

<ul style="list-style-type: none"> <li>• Use topical fluoride treatments no more than once a day.</li> <li>• Brush teeth with a fluoride dentifrice before using a fluoride treatment.</li> <li>• If using a fluoride rinse, measure the recommended dose (most commonly 10 mL), and vigorously swish it between the teeth for 1 minute.</li> <li>• If using a fluoride gel, brush the gel on the teeth. Allow the gel to remain for 1 minute.</li> <li>• After 1 minute, spit out the fluoride product. Do not swallow it.</li> <li>• Do not eat or drink for 30 minutes after the treatment.</li> <li>• Supervise children as necessary until they can use the product without supervision.</li> <li>• Instruct children younger than 12 years in good rinsing habits to minimize swallowing of the product.</li> <li>• Consult a dentist or primary care provider before using fluoride products in children younger than 6 years.</li> </ul>
--

Because fluoride rinses and gels provide a therapeutic fluoride treatment, package directions should be followed closely to maximize the safe and effective use of these products. Table 30-4 describes the proper method of applying fluoride treatments.<sup>9</sup> When recommending a nonprescription fluoride mouth rinse, the health care provider should stress that parents and caregivers should supervise children younger than 12 years as necessary until they are capable of using the product correctly. Furthermore, children younger than 6 years should use these products only as directed by a dentist or primary care provider.

Dental fluorosis (a mottled appearance of the surface enamel of the tooth) may develop in certain children. Fluorosis

develops in children who, during the time of tooth formation, receive optimal fluoride intake from the water supply or from supplements but inadvertently ingest additional fluoride from dentifrices. Although a mild degree of fluorosis is an aesthetic concern, more severe cases can result in pitting and surface defects (see Color Plates, photograph 5). In response to the aesthetic concerns related to fluorosis, FDA considered issuing comments regarding formulation of a reduced-strength fluoride dentifrice during the anticaries final rule process. FDA determined that, unlike dental caries, mild dental fluorosis does not compromise oral health or tooth function; therefore, the risk of dental caries from inadequate fluoride protection is a greater health hazard than the cosmetic effect of fluorosis.

## Dentifrices

Dentifrices (e.g., toothpastes or gels) are used with a toothbrush for cleaning accessible tooth surfaces. Use of a dentifrice enhances removal of dental plaque and stains, resulting in a decreased incidence of dental caries and gum disease, reduced mouth odors, and enhanced personal appearance.

Dentifrices are available as pastes or gels (Table 30-5). The gels and pastes commonly contain an abrasive, a surfactant, a humectant (moistening agent), a binder/thickener, a sweetener, flavoring agents, and one or more therapeutic agents (e.g., fluoride) for anticaries activity.

**TABLE 30-5 Selected Nonprescription Dentifrices**

<i>Trade Name</i>	<i>Primary Ingredients</i>
<b>Fluoride Toothpastes</b>	
Aquafresh Extra Fresh Toothpaste	Calcium carbonate; hydrated silica; sodium monofluorophosphate (fluoride 0.15%)
Colgate Cavity Protection Toothpaste	Dicalcium phosphate dihydrate; sodium monofluorophosphate (fluoride 0.15%)
Crest Cavity Protection Gel	Hydrated silica; sodium fluoride (fluoride 0.15%)
<b>Tartar-Control Toothpastes</b>	
Aquafresh Tartar Protection Whitening Toothpaste	Hydrated silica; sodium fluoride (fluoride 0.15%); tetrapotassium pyrophosphate; tetrasodium pyrophosphate
Colgate Tartar Protection Whitening Toothpaste	Hydrated silica; sodium fluoride (fluoride 0.15%); pentasodium triphosphate; tetrasodium pyrophosphate
Crest Tartar Protection Gel/Toothpaste	Hydrated silica; sodium fluoride (fluoride 0.15%); tetrapotassium pyrophosphate; disodium pyrophosphate; tetrasodium pyrophosphate
<b>Antiplaque/Antigingivitis Toothpastes</b>	
Colgate Total Gum Defense Toothpaste	Hydrated silica; sodium fluoride (fluoride 0.24%); triclosan 0.3%
Crest Pro-Health Clinical Gum Protection Toothpaste	Hydrated silica; stannous fluoride (fluoride 0.16%); sodium hexametaphosphate; trisodium phosphate
<b>Whitening Toothpastes</b>	
Aquafresh Ultimate White Toothpaste	Hydrated silica; sodium fluoride (fluoride 0.15%); titanium dioxide
Colgate Optic White Toothpaste	Sodium monofluorophosphate (fluoride 0.15%); tetrasodium pyrophosphate; hydrogen peroxide
Rembrandt Deeply White Plus Peroxide Whitening Toothpaste	Hydrated silica; urea peroxide; sodium monofluorophosphate
<b>Sodium Lauryl Sulfate-Free Toothpastes</b>	
Biotène Antibacterial Dry Mouth Toothpaste	Lactoperoxidase; glucose oxidase; lysozyme; lactoferrin; sodium monofluorophosphate 0.14%
Sensodyne Iso-Active Toothpaste	Potassium nitrate 5%; sodium fluoride (fluoride 0.15%)

<b>Botanical-Based Toothpastes</b>	
Tom's of Maine Botanically Bright	Peppermint or spearmint; carrageenan; propolis
Jason Powersmile Whitening Toothpaste	Calcium carbonate; carrageenan; bamboo powder; parsley extract; grapefruit seed extract; peppermint; sodium bicarbonate

Dentifrice abrasives are pharmacologically inactive and insoluble compounds; common abrasives include silicates, dicalcium phosphate, alumina trihydrate, calcium pyrophosphate, calcium carbonate, and sodium metaphosphate. Although dentifrices vary in their degree of abrasiveness, factors such as the size and shape of the abrasive particle, individual brushing technique, and individual salivary characteristics affect the abrasive's potential effectiveness.<sup>1</sup>

The ideal abrasive would provide maximal cleaning aid while causing minimal damage to tooth surfaces.

Unfortunately, because of the variability in patients' brushing techniques and oral conditions, the ideal dentifrice abrasive does not exist. Low-abrasive dentifrices (including most dentifrice formulations currently marketed in the United States) usually have a low concentration of silica abrasives (10%-25%), whereas high-abrasive dentifrices typically have higher concentrations of the inorganic calcium or aluminum salts previously mentioned (40%-50%).

Baking soda, a mild abrasive, is found in a number of dentifrices. Although they are safe to use, toothpastes with baking soda have not been shown to clean teeth better than toothpastes without it.

### Fluoride Dentifrices

Fluoride dentifrices are indicated for both preventing and treating carious lesions. All countries that show a reduction in caries use fluoride-containing dentifrices for caries prevention. ADA accepts fluoride-containing toothpaste and fluoride-containing gel dentifrice formulations with compatible abrasives as safe and effective. Concentrations of various fluoride dentifrices are outlined in [Table 30-6](#).

About 10%-20% of patients experience slight (but noticeable) tooth discoloration after using stannous fluoride continuously for 2-3 months. The staining is not permanent and is readily removed at the next professional dental cleaning. Stannous fluoride is for use by adults and children ages 12 years and older.

**TABLE 30-6 FDA-Approved Active Ingredients for Anticaries Dentifrices**

<i>Ingredient</i>	<i>Concentration (ppm) (dosage form)</i>
Sodium fluoride	850-1150 (paste)
Sodium monofluorophosphate	850-1150 (paste)
Stannous fluoride	850-1150 (paste)

### Tartar-Control Dentifrices

A number of fluoride dentifrices contain anticalculus (tartar control) compounds. Although plaque—not supragingival calculus—is the primary etiologic factor in marginal periodontal disease, reducing calculus formation remains a goal of good oral hygiene. The ingredients that prevent or retard new calculus formation are zinc chloride, zinc citrate, and soluble pyrophosphates (which act to inhibit crystal growth).

ADA regards the inhibition of supragingival calculus as a nontherapeutic use and, therefore, does not evaluate anticalculus claims. However, all advertising claims made for accepted products are reviewed for accuracy. ADA has directed that the following additional statement appear on all package and container labeling for accepted fluoride dentifrice products with calculus-control activity: “[Product name] has been shown to help prevent and reduce [whichever is appropriate] gingivitis and supragingival plaque formation when used as directed in a conscientiously applied program of oral hygiene and regular professional care. Its effect on periodontitis has not been determined.”<sup>10</sup>

The use of tartar-control toothpastes has been associated with a type of contact dermatitis in the perioral region. Adding pyrophosphate compounds to these products increases alkalinity and requires increased concentrations of other components for solubilizing (e.g., flavorings and surfactants). The pyrophosphates (either alone or in combination with the higher concentrations of inactive ingredients) are hypothesized to be the cause of irritant contact dermatitis. Patients experiencing such a reaction should be advised to discontinue the tartar-control dentifrice and should switch to a non-tartar-control fluoride product.

### Antiplateque/Antigingivitis Dentifrices

Colgate Total contains triclosan, an antibacterial agent and promoter of substantivity that has antigingivitis and antiplateque activity. The product also contains fluoride for caries protection and a copolymer delivery system for the triclosan. This toothpaste is currently accepted by ADA for both antiplateque and antigingivitis indications.<sup>5,10</sup> Approval was based on clinical data for safety and efficacy. The product is not intended for use in children younger than 6 years.

### Whitening/Antistain Dentifrices

Cosmetic dentifrices make no therapeutic claims and are usually chosen by patients because of taste, whitening ability, or antistain properties. Some dentifrices that claim to remove coffee or tobacco stains may contain higher

concentrations of abrasives. High-abrasive formulations are not advised for long-term use or for use by patients with exposed root surfaces. Plain baking soda (a water-soluble, mild abrasive) and toothpastes containing baking soda have limited polishing and stain-removal capacity. Other products may contain a pigment (e.g., titanium dioxide) that produces a temporary brightening effect. Rembrandt Whitening Toothpaste contains a chemical complex of aluminum oxide, a citrate salt, and papain. Whitening dentifrices that contain oxygenating agents rely on a debriding action to remove stained pellicle. Numerous products offer a combination of baking soda and peroxide with fluoride. Whitening dentifrices should not be confused with tooth-bleaching products described in the box A Word about Tooth-Bleaching Products.

#### A Word About Tooth-Bleaching Products

The popularity of tooth bleaching has increased in the United States in recent years. Three methods are currently in use: (1) in-office dental bleaching, (2) dental office-supported home bleaching, and (3) nonprescription home bleaching. All three methods use basically the same chemical agents: carbamide peroxide or hydrogen peroxide in various strengths. The in-office method has the advantage of a one-time treatment, but the stronger bleach and the accelerator light are not necessary to obtain the same result with the dental office-supported home-bleaching process. The latter method involves the use of custom trays. With this process, patients can fine-tune the extent of lightening to their own preferences.

The following two nonprescription products (from among many) may aid in lightening teeth:

- Rembrandt Intense Stain Dissolving Strips contain hydrogen peroxide. The kit contains 56 whitening strips that are applied to upper and lower teeth. Strips dissolve in 5-10 minutes with nothing to remove. The kit is designed for use over a 2-week period.
- Crest 3D WhiteStrips Vivid provide translucent film strips impregnated with hydrogen peroxide and other ingredients. The strips are peeled away from a protective backing and folded over the six upper or lower front teeth (different strips are provided for upper and lower teeth). The teeth will look as though they are covered with small pieces of transparent food wrap. The strips are applied once a day and left in place for 30 minutes. A kit contains enough strips for 10 days. An Advanced version of the same system is also available over the counter and is used for a longer period of time.

#### Administration Guidelines

**Table 30-1** describes the proper method for brushing teeth using a fluoride dentifrice. Children are usually unable to brush by themselves until they are 4 or 5 years of age; to clean their teeth effectively, children may require supervision until 8 or 9 years of age. FDA recommends that parents instruct children ages 6-12 years about good brushing and rinsing habits to minimize swallowing of fluoride. Parents should apply only a pea-sized amount of toothpaste to a child-sized toothbrush and should brush preschoolers' teeth until the children can manage toothbrushing properly without assistance. Children should be taught to rinse thoroughly and expectorate after brushing. Only regular-strength fluoride toothpaste is recommended for use in children 2-6 years of age. Fluoride toothpaste should be used in children younger than 2 years only under the direction of a dentist or primary care provider. Non-fluoridated pediatric toothpastes are advised for young children who may ingest toothpaste instead of rinsing and expectorating.

All fluoride dentifrice products must contain the following warning on the labeling: "Warning: Keep out of the reach of children under 6 years of age. If you accidentally swallow more than used for brushing, seek professional assistance or contact a Poison Control Center immediately."

#### Product Selection Guidelines

Unless otherwise advised by their dentists, patients (especially those with periodontal disease, significant gum recession, and/or exposed root surfaces) should choose the least abrasive dentifrice that effectively removes stained pellicle. Although dentifrice abrasives do not pose a risk to dental enamel, toothbrushing action and excessive abrasiveness (which may lead to tooth hypersensitivity) can damage the cementum (the softer material of exposed root surfaces) and dentin.

Children younger than 6 years should not use a fluoride dentifrice unless their parents can ensure the children can rinse and expectorate appropriately. Extra-strength fluoride dentifrices may be beneficial to patients who have a greater tendency to develop cavities or who reside in an area with non-fluoridated water.

Flavored gel dentifrices disperse rapidly in the mouth and are popular with children. Manufacturers of gel dentifrices have advertised that children brush longer and more thoroughly because of the gel's consistency, translucence, dispersibility, and flavor. This claim has not been substantiated, but many dentifrices marketed for children are of the gel type. Children's products usually have fruit flavors rather than the breath-freshening minty or cinnamon flavors that adults prefer.

Mouth Rinses

**TABLE 30-7 Selected Nonprescription Mouth Rinses**

<i>Trade Name</i>	<i>Primary Ingredients</i>
-------------------	----------------------------

<b>Cosmetic Mouth Rinses</b>	
Bioténe	Lactoferrin; lysozyme; lactoperoxidase; aloe vera gel; glucose oxidase
Lavoris	Clove oil; zinc chloride; zinc oxide
<b>Therapeutic Mouth Rinses</b>	
Crest Pro-Health Rinse	Cetylpyridinium chloride 0.07%
Crest Pro-Health Clinical Rinse	Cetylpyridinium chloride 0.1%
Gly-Oxide	Carbamide peroxide 10%
Scope	Cetylpyridinium chloride
<b>Botanical-Based Mouthwashes</b>	
Listerine	Thymol; eucalyptol; methyl salicylate; menthol
Tom's of Maine	Peppermint or spearmint; xylitol; menthol

A mouth rinse with plaque- or calculus-control properties is indicated as an adjunct to proper flossing and toothbrushing with fluoride toothpaste. Further research is necessary to determine the efficacy of the antiplaque activity of these products.

Mouth rinse and dentifrice formulations are very similar. As with dentifrices, mouth rinses may be cosmetic or therapeutic (Table 30-7). Both may contain surfactants, humectants, flavor, coloring, water, and therapeutic ingredients.

A mouth rinse approximates a diluted liquid dentifrice that contains alcohol but no abrasive. Alcohol adds bite and freshness, enhances flavor, solubilizes other ingredients, and contributes to the mouth rinse's cleansing action and antibacterial activity. Flavor contributes pleasant taste and breath freshening action. Surfactants are foaming agents that aid in the removal of debris. Other active ingredients may include astringents (alum or zinc chloride), demulcents (sorbitol or glycerin), antibacterial agents (cetylpyridinium chloride or thymol), and fluoride.

Cosmetic mouth rinses freshen the breath and clean some debris from the mouth. Mouth rinses can be classified by appearance, flavor, alcohol content, and active ingredients. In general, mouth rinses are minty or spicy, or medicinal or alcoholic, and contain various ingredients such as (1) glycerin, a topical protectant that tastes sweet and is soothing to oral mucosa; (2) benzoic acid, an antimicrobial agent; or (3) zinc chloride/citrate, an astringent that neutralizes odoriferous sulfur compounds produced in the oral cavity. The most popular cosmetic mouth rinses are medicinal and mint flavored. Healthy individuals normally have some degree of oral malodor (e.g., morning breath). This malodor results from reduced activity of tongue, cheeks, and salivary flow, which enhances bacterial activity and production of odoriferous sulfur compounds. Therefore, products that are intended to eliminate or suppress mouth odor of local origin in healthy people with healthy mouths are considered by the FDA Advisory Review Panel on Over-the-Counter Oral Health Care Products to be cosmetics, unless they contain antimicrobial or other therapeutic agents. ADA's acceptance program does not evaluate mouth rinses labeled and advertised as only cosmetic agents. One important consideration is the potential for breath-freshening mouth rinses to disguise or delay treatment of pathologic conditions that may contribute to lingering oral malodor (e.g., periodontal disease, purulent oral infections, and respiratory infections). If marked breath odor persists after proper toothbrushing, the cause should be investigated and not masked with mouth rinse.

Since the 1990s, nonprescription mouth rinses promoted for antiplaque or tartar-control activity have proliferated. Plaque control ingredients include (1) aromatic oils (thymol, eucalyptol, menthol, and methyl salicylate), which are antibacterial and have some local anesthetic activity; and (2) agents with antimicrobial activity (e.g., quaternary ammonium compounds). Listerine, containing the active ingredients thymol, eucalyptol, methyl salicylate, and menthol, was the first mouth rinse to be accepted by ADA as a nonprescription antiplaque/antigingivitis mouth rinse. The phenol oils (active ingredients) control plaque by destroying bacterial cell walls, inhibiting bacterial enzymes, and extracting bacterial lipopolysaccharides. ADA has since added Cool Mint, FreshBurst Listerine, and more than 100 similarly formulated private-label antiseptic mouth rinses to the antiplaque/antigingivitis category of accepted therapeutic products.<sup>5</sup>

Many dental providers have found anecdotally that use of rinses containing phenol oils, methyl salicylate, and alcohol may bring about a sloughing of the oral epithelium, which subsides when the rinse is discontinued. A similar event seems to occur with the use of lozenges or candies containing cinnamon or other common flavoring substances.

Mouth rinses and gels are generally safe when used as directed, but occasional adverse reactions (e.g., burning sensation or irritation) have been reported. Overuse should be discouraged. Consultation with a health professional

is indicated if irritation occurs and persists after the patient discontinues use of the product. The detergent sodium lauryl sulfate is present in nearly all toothpastes and has been implicated as a cause of oral mucosal irritations such as aphthous ulcers (canker sores; see Chapter 31).<sup>11</sup> Some dentifrices that do not contain sodium lauryl sulfate are listed in [Table 30-5](#).

Unsupervised use of mouth rinses is contraindicated in patients with mouth irritation or ulceration. These products should be kept out of children's reach. In case of accidental ingestion, the caregiver should seek professional assistance or contact a poison control center.

The alcohol content in mouth rinses ranges from 0% to 27%; the most popular adult mouth rinses contain between 14% and 27%. Ingestion of alcohol-containing products poses a danger for children, who may be attracted by the products' bright colors and pleasant flavors. Toxicity data concerning children's ingestion of alcohol-containing mouth rinses demonstrate that the amount of alcohol in available mouth rinse preparations is sufficient to cause serious illness and injury. Acute alcoholic intoxication and death resulting from high-dose ingestion are possible. For a child weighing 26 pounds, 5-10 ounces of a mouth rinse containing alcohol can be lethal.<sup>1</sup> Responding to concern over the potential danger to children, the Consumer Products Safety Commission issued a final rule that required child-resistant packaging for mouth rinses containing 3 grams or more of absolute alcohol per package—the amount that is present in a small quantity (approximately 2.6 ounces) of a mouth rinse with alcohol 5%: For the purposes of this final rule, the term *mouthwash* includes liquid products that are variously called mouthwashes, mouth rinses, oral antiseptics, gargles, fluoride rinses, antiplaque rinses, and breath fresheners. The rule does not include throat sprays or aerosol breath fresheners. These products should be kept out of children's reach and should not be administered to children younger than 12 years. Labeling includes a warning not to swallow the product but to seek professional assistance or contact a poison control center immediately in case of accidental ingestion.

### Special Population Considerations for Plaque Removal

At birth, the 20 primary teeth that will erupt are present but not visible. Oral hygiene must be started early in life. Accordingly, the health care provider should recommend that caregivers remove plaque and milk residue from a baby's mouth after each feeding by wiping the baby's gums with a wet gauze pad. The deciduous teeth will usually start to erupt at about 6 months of age and can decay at any time. "Baby bottle caries" results when an infant is allowed to nurse continuously from a bottle of juice, milk, or sugar water. The prolonged contact of teeth with the cariogenic liquid promotes caries.

When the teeth have erupted, a soft, child-sized toothbrush can be used for cleaning. Parents must do the brushing and should take care to use only a very small amount of fluoride toothpaste or none at all. Children at this age will swallow the toothpaste, which will contribute to overall systemic fluoride ingestion. Therefore, younger children need to be taught the proper brushing technique and should be supervised while brushing.

In patients with fixed orthodontia, very careful attention to oral hygiene to prevent gingivitis and caries is required because of the ease with which plaque accumulates along the orthodontic brackets. Patients with these appliances require a combination of toothbrush types to clean all surfaces effectively. Use of power toothbrushes or oral irrigating devices may help remove plaque and debris around orthodontic bands. Orthodontic patients may want to use a nonprescription fluoride mouth rinse while undergoing treatment.

Patients with removable orthodontic appliances should consult their orthodontist about using a denture cleanser. In addition to brushing orthodontic appliances, some dental providers recommend a denture cleanser to remove plaque, tartar, odor-causing bacteria, and stain that accumulate on orthodontic appliances.

In patients of advanced age who have natural dentition, topical fluoride application in the form of a dentifrice, rinse, or gel is indicated to prevent coronal and root caries. Health care providers should continue to recommend fluoride anticaries products to their older adult patients. When counseling an older patient on oral health care, the provider must consider the patient's medication use. Because this population is more likely to be taking multiple medications, the incidence of drug-induced or disease-related changes in oral physiology is increased.

### Assessment of Caries

When asked to recommend plaque-control products, the provider should determine what dental care measures the patient is taking, whether these measures meet recommended oral hygiene standards, and how often the patient sees a dentist. The patient's concern about caries should alert the provider to ask whether the patient has a history of caries or if the patient suspects that a new carious lesion has developed. Refer patients with dental caries symptoms (toothache; tooth sensitivity with chewing; or tooth pain with hot, cold, or sweet foods or beverages) to their dentist for evaluation and treatment.

### Patient Counseling for Caries

The provider should tailor all explanations of the purposes of various oral hygiene products and the methods for using them to the patient's level of knowledge. Patients with a history of caries should be encouraged to brush after meals and to consult with a dentist regarding the use of topical fluoride products. If caries recur or are widespread,

the patient should be encouraged to visit a dentist for treatment. The provider may recommend products with anticaries agents (e.g., chlorhexidine or xylitol). The provider should explain the precautions for these products as well as the possible adverse effects of some therapeutic ingredients in other products. Patients should be advised of signs and symptoms that indicate a dental evaluation is necessary. The box Patient Education for Prevention of Caries, Gingivitis, and Halitosis lists specific information to provide patients about plaque-induced oral disorders.

## Gingivitis

Periodontal disease (which may result in tooth loss) affects an estimated 47% of U.S. adults ages 30 years and older.<sup>12</sup> Controlling buildup of plaque can prevent or control this common and significant public health problem. All forms of periodontal disease are associated with oral hygiene status, not with age. However, as life spans increase and people retain more teeth later in life, both the number of teeth at risk and the time for development of periodontal disease increase.<sup>1</sup>

Gingivitis, the mildest form of periodontal disease, is common and reversible. Gingivitis may progress to more severe periodontal diseases (e.g., acute necrotizing ulcerative gingivitis and periodontitis, the latter of which can cause significant, irreversible alveolar bone loss).

Gingivitis is inflammation of the gingiva without loss or migration of epithelial attachment to the tooth, but periodontitis occurs when the periodontal ligament attachment and alveolar bone support of the tooth have been compromised or lost. This process involves apical migration of the epithelial attachment. (See Color Plates, photographs 6 and 7.) Pregnant patients are more susceptible to both dental caries and gingivitis. “Pregnancy gingivitis” is characterized by red, swollen gingival tissue that bleeds easily. Local factors cause this gingivitis, but varying hormone levels may make gingival tissue more sensitive to bacterial dental plaque. These changes in the connective tissues that compose the periodontium appear to be the primary factor leading to pregnancy gingivitis.<sup>1</sup> Pregnancy gingivitis can be prevented or resolved with thorough plaque control. The severity of the inflammatory response and the resulting gingivitis decrease postpartum and return to pre-pregnancy levels after approximately 1 year.

## Pathophysiology of Gingivitis

Gingivitis results from the accumulation of supragingival bacterial plaque. If this accumulation is not controlled, the plaque proliferates and invades subgingival spaces. At the same time, specific types of bacteria are associated with plaque at different stages of accumulation; the composition of the bacterial flora changes to a more complex mix of organisms. Although not all gingivitis progresses to periodontitis, the progression from supragingival plaque to gingivitis to periodontitis does occur; therefore, controlling gingivitis is a reasonable approach to limiting periodontitis.<sup>1</sup>

Other possible etiologies include medications such as calcium channel blockers, cyclosporine, and phenytoin. Anticholinergics and antidepressants may cause gingivitis by reducing the flow of saliva. The use of tobacco (both smokeless and smoked) has also been linked to periodontal disease.

## Clinical Presentation of Gingivitis

The marginal gingiva (the border of the gingiva surrounding the neck of the tooth) is held firmly to the tooth by a network of collagen fibers. Microorganisms present in the plaque in the gingival sulcus (the space between the gingiva and the tooth) are capable of producing harmful products (e.g., acids, toxins, and enzymes) that damage cellular and intercellular tissue. Early-stage gingivitis symptoms include dilation and proliferation of gingival capillaries, increased flow of gingival fluid, and increased blood flow with resulting erythema of the gingiva. The gingiva may also enlarge, change contour, and appear puffy or swollen as a result of the inflammation (see Color Plates, photograph 6). The inflammatory process of early-stage gingivitis is reversible with effective oral hygiene. In time and with neglect, some common indications that early-stage gingivitis has become chronic gingivitis include changes in gingival color, size, and shape, as well as changes in the ease with which gingival bleeding occurs. Both the patient and the dental provider can recognize these symptoms. Additionally, the flat knife-edge appearance of healthy gingiva is replaced by a ragged or rounded edge. Progression of these conditions is usually slow and insidious—and often painless.

Left untreated, chronic gingivitis may advance to the inflammatory condition of chronic destructive periodontal disease, or periodontitis (see Color Plates, photograph 7). Bacterial species that predominate in periodontitis but that are not present in healthy periodontium have been found in low proportions in gingivitis. Progression of gingivitis may parallel the increasing proportions of bacterial species implicated in the genesis of periodontitis.

## Prevention of Gingivitis

Because prevention of gingivitis and caries depends on calculus prevention and plaque control, the same measures described in Prevention of Caries pertain to gingivitis. The active antigingivitis ingredients in dentifrices, mouth rinses, and other plaque removal and antiplaque products include triclosan, cetylpyridinium chloride, and stabilized

stannous fluoride.<sup>13</sup>

Brushing and flossing can cure early gingivitis that arises from irritating food debris and plaque. The most important factors in reversing gingivitis and in preventing and controlling periodontal disease are adequate removal and control of supragingival plaque. Health care providers should immediately refer for dental care any patient who describes bleeding during brushing or shows signs of early gingivitis.

### Assessment of Gingivitis: A Case-Based Approach

Before recommending oral hygiene products, the provider should evaluate the patient's oral hygiene regimen. At a minimum, the provider should find out whether the patient has a history of gingivitis, whether signs and symptoms of gingivitis are currently present, and what preventive measures the patient has tried or is using. Checking the patient's medical and medication history will identify asymptomatic patients who are at risk for gingivitis. Refer patients with signs or symptoms of gingivitis (swollen gums, gums that bleed with brushing or flossing, receding gums, gums that appear darker red than usual) to their dentist for evaluation and treatment.

The provider is quite often alerted to pregnancy gingivitis during counseling on prescription prenatal vitamins. Besides monitoring the pregnant patient's medications for safety, the provider has an opportunity to encourage the patient to have a dental checkup and to stress the importance of careful attention to brushing and flossing to avoid oral health complications.

### Patient Counseling for Gingivitis

Because gingivitis is usually not associated with pain, patients are unlikely to seek dental care for this problem alone. More likely, patients will ask for oral hygiene information and product recommendations. The provider may have to suggest oral hygiene methods and alert the patient to the possible adverse effects of certain products. Case 30-1 provides an example of assessment of a patient with gingivitis. The box Patient Education for Prevention of Caries, Gingivitis, and Halitosis lists specific information to provide patients.

The provider should also use this opportunity to warn patients with suspected gingivitis (bleeding, swollen gums) that this disease is a serious problem warranting professional attention. The provider should stress that adherence to an oral hygiene program is vital to preventing gingivitis.

### Case 30-1

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b><i>Information Gathering</i></b>	
1. Gather essential information about the patient's symptoms, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient has been experiencing sore, swollen gums for the past several weeks.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Gum tissue bleeds freely during toothbrushing; bleeding increases with use of dental floss.
c. description of the patient's efforts to relieve the symptoms	Patient has continued brushing teeth twice daily and flossing once daily as normal.
d. patient's identity	Louise Baker
e. age, sex, height, and weight	63 years old, female, 5 ft 3 in., 135 lb
f. patient's occupation	Retired

g. patient's dietary habits	Normal, healthy diet
h. patient's sleep habits	6-8 hours of sleep each night
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Hypertension: takes lisinopril 10 mg daily and a women's multivitamin daily.
j. allergies	Penicillin
k. history of other adverse reactions to medications	None
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Louise appears to have gingivitis.
3. Identify exclusions for self-treatment.	Bleeding, swollen gums (see the box Patient Education for Prevention of Caries, Gingivitis, and Halitosis)
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Louise to a dentist. (2) Recommend appropriate nonprescription products along with education about proper oral care and referral to a dentist. (3) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Refer patient to a dentist.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You need to see a dentist because you have signs of gingivitis."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Although there are steps you can take to improve your oral hygiene, a dentist will need to evaluate your condition and develop a treatment plan. It appears that you are appropriately caring for your teeth and gums, but sometimes changes can occur to your gum tissue. You should get a thorough checkup and cleaning from your dental health provider to ensure that you and your teeth and gums stay healthy."
<b>Patient Education</b>	

8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"Is there a nonprescription medication that might work?"
Answer the patient's or caregiver's questions.	"Nonprescription medications do not treat gingivitis. They may reduce the symptoms, but ultimately your dental care provider will need to develop a treatment strategy. Once you have been diagnosed, there are nonprescription products you may use as part of your oral care regimen. Gingivitis and periodontal disease, if left untreated, may result in tooth loss and other complications."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact Louise in a day or two to ensure she made an appointment and sought medical care.

Key: NA = Not applicable.

#### Patient Education for Prevention of Caries, Gingivitis, and Halitosis

The primary objective of self-care is the removal of plaque to prevent caries, gingivitis, and halitosis. For most patients, carefully following product instructions and the self-care measures listed here will help ensure good oral hygiene.

#### **Nondrug Measures and Other Considerations**

- Avoid cariogenic foods, such as foods that contain more than 15% sugar, that cling to the teeth, and that remain in the mouth after they are chewed.
- Eat low-cariogenic foods, such as foods that have a high water content (e.g., fresh fruit); that stimulate the flow of saliva (e.g., fibrous foods that take longer to chew); or that are high in protein (e.g., dairy products).
- To help prevent mouth odor, maintain proper oral hygiene and limit or avoid foods and products that may cause oral malodor. Also, if you wear dentures, do not wear them while sleeping.
- Note that use of alcohol and tobacco are associated with caries, gingivitis, and halitosis.
- Note that hormonal changes during pregnancy increase the risk of gingivitis.

#### **Plaque Removal**

##### ***Brushing Teeth***

- Mechanically remove plaque buildup by brushing teeth at least twice daily with a fluoride dentifrice. (See [Table 30-1](#) for proper brushing technique.)
- Use a brush with soft nylon bristles.
- Replace the brush when the bristles show signs of wear.
- For children younger than 2 years, clean the teeth with a soft cloth and massage the gums.
- For preschool children, apply a pea-sized amount of toothpaste to a child-sized toothbrush, and brush the child's teeth until the child can brush properly.
- Use only regular-strength fluoride toothpaste for children ages 2-6 years. Consult a dentist before using fluoride toothpastes in children younger than 2 years.
- Teach children how to rinse the mouth and spit out the toothpaste to avoid swallowing fluoride.
- Note that tartar-control toothpastes have been related to a type of contact dermatitis in the perioral region. If you experience itching or irritation of the mouth after brushing, discontinue the tartar-control toothpaste, and switch to a non-tartar-control fluoride toothpaste.
- If you are prone to developing caries or gingivitis, consider using toothpaste classified as having antiplaque/antigingivitis activity. Such toothpastes contain stannous fluoride.
- If you are prone to developing aphthous ulcers, consider using toothpaste that does not contain sodium lauryl sulfate.

## Flossing Teeth

- Floss your teeth at least once a day. (See [Table 30-2](#) for proper flossing technique.)
- Use waxed or Teflon-coated floss for teeth with tight contacts.

## Using Mouth Rinses and Gels

- To freshen breath, use a mouth rinse that contains zinc chloride and zinc citrate. Zinc chloride and chlorine dioxide are found in Smart-Mouth Tri-Oral 2-part rinse. These ingredients eliminate odoriferous volatile sulfur compounds.
- If you are prone to developing caries or gingivitis, consider using a mouth rinse classified as having antiplaque/antigingivitis activity. Such mouth rinses contain cetylpyridinium chloride or a combination of thymol, eucalyptol, methyl salicylate, and menthol.
- To use plaque-softening mouth rinses (Advanced Formula Plax) effectively, use them before brushing. Vigorously swish 1-2 tablespoons of rinse in the mouth and between the teeth for about 30 seconds, and spit out the rinse. Do not smoke, eat, or drink for 30 minutes following use.
- Note that overuse of mouth rinses containing cetylpyridinium can stain teeth.

## Using Topical Fluoride Treatments

- If your drinking water is not fluoridated (including bottled water), or if you are prone to developing caries, consider using topical fluoride treatments. (See [Table 30-4](#) for proper use of these products.)
- Supervise children younger than 12 years until they are capable of using the product correctly.
- Consult a dentist or primary care provider before using these products in children younger than 6 years.

## When to Seek Medical Attention

- See a dentist if any of the following occurs:
  - You develop symptoms of a toothache.
  - Your teeth develop a mottled appearance.
  - Your gums bleed, swell, or become red.
  - Mouth odor persists despite regular use of fluoride toothpaste, or the cause of the mouth odor cannot be identified.

## Halitosis

Halitosis (oral malodor, usually known as bad breath) may be a symptom of oral pathology. However, in 90% of cases, poor oral hygiene is the cause.

### Pathophysiology of Halitosis

Causes of halitosis may be related to both systemic and oral conditions; however, about 85% of cases are generally related to an oral cause. Oral causes may include dental caries, periodontal disease, oral infections, mucosal ulcerations, tongue coating, and impacted food or debris.<sup>14</sup>

Xerostomia can also cause mouth odor. Medications that have anticholinergic properties often cause xerostomia. Many foods and products such as garlic, tobacco, onions, alcohol, and other substances may contribute to mouth odor, as well.

Most foul breath odors occur because of volatile sulfur compounds (VSCs), which can be produced by breakdown of food debris left in the mouth or by systemic conditions that eliminate VSCs through exhaled air.<sup>15</sup>

### Prevention of Halitosis

Prevention of halitosis relies on the removal of plaque and the prevention of calculus formation as described in Prevention of Caries. One of the primary sites for the formation of VSCs is the back of the tongue. Plaque and VSCs in this area of the mouth can seed the tonsillar crypts with malodorous debris. Brushing both the teeth and tongue is helpful, but some dentists have found that the use of a tongue-cleaning device (e.g., a tongue blade) may be the best way to clean the circumvallate papillae area of the tongue. Cleaning this posterior dorsal area not only will remove the fetid VSCs but also will prevent them from spreading to the tonsils.

Zinc salts and chlorine dioxide are most effective in the chemical prevention of oral malodor. The two are combined in 2-part rinses such as Smart-Mouth (Triumph Pharmaceuticals) or as single ingredients in CloSYS (Rowpar Pharmaceuticals). Zinc chloride, citrate, and acetate reduce the receptor binding necessary for VSC production. Chlorine dioxide breaks di-sulfide bonds and oxidizes the precursors of VSCs. In addition, the zinc salts kill gram-negative bacteria.

Any patient who complains of severe or lingering halitosis without a readily identifiable cause (e.g., smoking) should

be advised to see a dentist for a thorough evaluation. Masking foul taste and odor with cosmetic mouth rinses may delay necessary dental or medical assessment and any needed treatment.

### Assessment of Halitosis: A Case-Based Approach

When assessing a patient for halitosis, the health care provider should evaluate the patient's dental hygiene. Ideally, the provider should obtain a medication and medical history to determine whether the halitosis might arise from one of the oral pathologies discussed in Pathophysiology of Halitosis (see also Xerostomia in [Chapter 31](#)). Refer patients with medical conditions that cause halitosis and patients with halitosis that persists despite proper dental hygiene to their dentist for evaluation and treatment.

### Patient Counseling for Halitosis

For patients with mouth odor related to poor dental hygiene, the provider should reinforce proper techniques for maintaining dental hygiene, including brushing and flossing. Providers should also recommend appropriate products and explain their use. The provider should stress to patients whose mouth odor is related to medical conditions that proper oral hygiene is still necessary to prevent tooth and gum problems. The box Patient Education for Prevention of Caries, Gingivitis, and Halitosis lists specific information to provide patients.

### Hygiene-Related Denture Problems

Pain along the gingival ridge under a denture prosthesis suggests conditions such as denture stomatitis (an inflammation of the oral tissue in contact with a removable denture), inflammatory papillary hyperplasia, and chronic candidiasis. Denture stomatitis, which results from poor cleaning of dentures, can lead to chronic candidiasis (fungal infection).<sup>16</sup>

### Pathophysiology of Hygiene-Related Denture Problems

Dentures accumulate plaque, stain, and calculus by a process very similar to that occurring on natural teeth. The denture plaque mass that is in contact with oral tissues produces predictable toxic results. Poor denture hygiene contributes to fungal and bacterial growth that not only affects the patient aesthetically (unpleasant odors and staining) but also seriously affects the patient's oral health (inflammation and mucosal disease) and ability to wear the dentures successfully.

Chronic atrophic candidiasis (sometimes referred to as denture stomatitis or denture sore mouth) is common in patients with full or partial dentures. This condition may be attributed to infection with *Candida* organisms, which are more prevalent in denture wearers.<sup>1</sup> Symptomatically, the inflamed denture-bearing area may appear granular or erythematous and edematous with soreness or a burning sensation (see Color Plates, photograph 8). Inflammation secondary to *Candida* organisms is generalized to the entire denture-bearing tissue area, whereas inflammation secondary to the trauma of ill-fitting dentures is usually localized to the specific area of the trauma. Failure to remove the denture at bedtime and clean it regularly worsens this condition. Angular cheilitis (soreness and cracking at corners of the mouth) is commonly associated with chronic atrophic candidiasis, other forms of oral candidiasis, and poor denture fit. The corners of the mouth can often be treated effectively with terbinafine cream. If a staphylococcal organism is also involved, a prescription will be needed.

### Prevention of Hygiene-Related Denture Problems

Removing plaque from dentures helps prevent gum infections, staining of dentures, and mouth odor. Specialty brushes and aids are available to remove plaque from hard-to-clean areas (e.g., spaces around a fixed bridge, implant, or orthodontic band) and dentures. Dentures should be cleaned thoroughly at least once daily to remove unsightly stain, debris, and plaque. Abrasive and chemical cleansers formulated specifically for dentures are available ([Table 30-8](#)). A combination regimen of brushing dentures with an abrasive cleaner and soaking them in a chemical cleanser is recommended.

**TABLE 30-8 Selected Nonprescription Denture Cleaners**

Trade Name	Primary Ingredients
Efferdent Plus Tablets	Potassium monopersulfate; sodium bicarbonate; sodium perborate
Polident Dentu-Cream Paste	Dicalcium phosphate dihydrate; calcium carbonate; aluminum silicate
Polident Tablets	Potassium monopersulfate; sodium perborate; sodium carbonate; sodium bicarbonate; citric acid

Denture cleansers (paste or powder) containing mild abrasives (e.g., calcium carbonate) must be applied properly with specialty brushes adapted to the denture's contour to remove stains, plaque, and calculus. Overly vigorous scrubbing can abrade the denture's acrylic materials and bend the metal clasps. To prevent irritation of oral tissues, the patient should rinse the abrasive cleaner from the denture thoroughly.

The brushing routine can be followed by soaking the denture in an alkaline peroxide cleansing solution to help remove remaining plaque and bacteria. Plaque removal is then enhanced by brushing the denture after it has soaked; instructions for this procedure are included on some products.

The other method of cleaning is to use a soaking solution containing one of the three chemical cleansers: alkaline peroxide, hypochlorite, or dilute acids.

Alkaline peroxide cleaners are the most commonly used chemical denture cleansers. These powders or tablets become alkaline solutions of hydrogen peroxide when dissolved. The ingredients are alkaline detergents and perborates; the latter cause oxygen release for a mechanical cleaning effect. These products are most effective on new plaque and stains when the denture is soaked for 4-8 hours. The alkaline peroxides have few serious disadvantages and do not damage the surface of acrylic resins.

Hypochlorite (bleach) removes stains, dissolves mucin, and is both bactericidal and fungicidal. Denture plaque consists of cells embedded in a matrix that serves as a surface on which calculus may develop. Hypochlorite cleansers act directly on the organic plaque matrix to dissolve its structure, but they cannot dissolve calculus once it has formed. The most serious disadvantage of hypochlorite is that it corrodes metal denture components (e.g., the framework and clasps of removable partial dentures, solder joints, and possibly the pins holding the teeth). The addition of anticorrosive phosphate compounds has greatly reduced this problem, but these products should be used for only 10-minute soaks (to limit exposure) and not more often than once a week.

Acid-containing soaking solutions can also be corrosive to metals, and short soaking times are recommended for these solutions. A sonic or ultrasonic cleaning device, when used with a commercially prepared solution, is easier to use and cleans more effectively than soaking alone. However, some hand brushing may still be required.

All denture-cleansing products should be rinsed off the denture completely before it is inserted into the mouth. If abrasive cleansers come in contact with oral or other mucous membranes, they may cause tissue irritation. Chemical cleansers may cause tissue irritation or possibly severe chemical burns. All denture cleansers should be kept out of children's reach because of the potential for eye or skin irritation and because they are toxic if accidentally ingested. Stains that are resistant to proper denture brushing and soaking in available solutions should be evaluated by a dentist.

Only products that are specifically formulated for denture cleansing should be used. Household cleansers (sometimes used by patients for soaking dentures) are not appropriate and may be ineffective or may damage the denture material. The use of whitening toothpastes (which are formulated for use with natural dentition) should be discouraged because they are too abrasive to be used safely on denture material.

Patients should not soak or clean dentures in hot water or hot soaking solutions, because distortion or warping may occur.

Patients of advanced age or disabled patients may prefer an alkaline peroxide soak solution for daily, overnight cleaning. Unlike alkaline hypochlorite and acid cleansers, alkaline peroxide cleansers do not corrode metal components of dentures.

### Assessment of Hygiene-Related Denture Problems

Before recommending any type of oral hygiene product, the health care provider should determine what denture care measures the patient is taking and whether those measures are adequate. At a minimum, the provider should determine whether the patient suffers from denture stomatitis or inflammation secondary to ill-fitting dentures. Patients with denture stomatitis or inflammation secondary to ill-fitting dentures should be referred to their dentist for evaluation and treatment. Case 30-2 illustrates assessment of a patient with a hygiene-related denture problem.

#### Case 30-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient feels that he is unable to get his dentures as clean as he would like.

b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	NA
c. description of the patient's efforts to relieve the symptoms	He soaks his dentures in an alkaline peroxide cleanser overnight.
d. patient's identity	Ray Williams
e. age, sex, height, and weight	71 years old, male, 5 ft 9 in., 190 lb
f. patient's occupation	Bank manager
g. patient's dietary habits	Normal healthy diet; enjoys sweet foods.
h. patient's sleep habits	Light sleeper; averages 5-7 hours per night.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Seasonal allergic rhinitis (spring and fall): loratadine 10 mg, 1 tablet daily
j. allergies	NKA
k. history of other adverse reactions to medications	Morphine: itching
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Patient seems to have residual plaque on dentures despite daily soaks.
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Ray to a dentist. (2) Recommend appropriate nonprescription products along with education about proper oral care and a referral to a dentist. (3) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Ray should also be using a denture brush and denture paste daily because soaking only provides superficial cleaning.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Denture brushes and pastes are specially designed to remove deposits from dentures."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the	"Effective manual brushing removes more plaque and biofilm from dentures than soaking alone."

considered therapeutic alternatives.	
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	“Dentures should be brushed daily.”
b. maximum number of days the therapy should be employed	NA
c. product administration procedures	“All surfaces of the denture should be brushed. To avoid breaking the denture, brush it over a folded towel or a sink filled with water. Thoroughly rinse the denture after brushing.”
d. degree of relief that can be reasonably expected	“Daily brushing may help remove plaque and stains.”
e. most common side effects	“Only denture paste should be used because dentures are easily scratched by regular toothpastes.”
f. side effects that warrant medical intervention should they occur	NA
g. patient options in the event that condition worsens or persists	“A dentist should evaluate stains that are resistant to proper brushing and soaking in available solutions.”
h. product storage requirements	NA
i. specific nondrug measures	“Continue regular denture hygiene and maintenance.”
Solicit follow-up questions from the patient or caregiver.	“Can I increase the frequency of brushing or use whitening toothpastes to provide additional cleaning?”
Answer the patient’s or caregiver’s questions.	“No. Brushing too often and using toothpastes other than denture paste may scratch and damage dentures.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome	Ask the patient to call to update you on his response to your recommendations, or follow up with a call in 1 week to evaluate his response.

Key: NA = Not applicable; NKA = no known allergies.

### Patient Counseling for Hygiene-Related Denture Problems

Denture wearers may tend to blame the appliances for any oral discomfort rather than their hygiene regimen. The provider should stress that diligent plaque removal from dentures is the key to preventing denture stomatitis. The methods of cleaning dentures, including their advantages and disadvantages, should be explained. The provider should recommend a denture cleanser according to the patient's preferences and reinforce the methods of use. The box Patient Education for Hygiene-Related Denture Problems lists specific information to provide patients.

#### Patient Education for Hygiene-Related Denture Problems

The objective of self-care is to prevent bacterial or fungal infections of the mouth by removing plaque from the dentures. For most patients, carefully following product instructions and the self-care measures listed here will help ensure good denture hygiene.

- Thoroughly clean dentures at least once daily to remove unsightly stain, debris, and potentially harmful plaque.
- Preferably, brush dentures with an abrasive cleaner, and then soak them in a chemical cleanser. This combination regimen is more effective in removing plaque and bacteria.
- Apply the abrasive cleaner to the denture, using a brush designed to adapt to the denture's contour.
- Do not scrub the denture surface vigorously; this action can abrade the acrylic materials and bend the metal clasps.
- To prevent irritation of oral tissues, thoroughly rinse the abrasive cleaner from the denture.
- After brushing the dentures, soak them in an alkaline peroxide cleansing solution for 10-20 minutes. Rinse the dentures thoroughly to avoid chemical burns of the mouth.
- If possible, brush the dentures again, and rinse them thoroughly.
- If using an alkaline or sodium hypochlorite cleanser, soak the dentures for only 10 minutes to avoid corrosion of metal denture components.
- Keep all denture cleansers out of children's reach. These agents can cause eye or skin irritation or toxicity if accidentally ingested.
- Do not use household cleansers or whitening toothpastes to clean dentures. These agents may damage denture material.
- Do not soak or clean dentures in hot water or hot soaking solutions. Distortion or warping of the denture may occur.
- Do not sleep while wearing your dentures. Decreased levels of saliva during sleep may contribute to plaque buildup on the denture.

#### When to Seek Medical Attention

- If your mouth becomes sore or shows sign of infection, see a dentist.

#### Key Points for Prevention of Hygiene-Related Oral Disorders

- Removing plaque and modifying the diet are the main goals of self-care to prevent caries, gingivitis, and halitosis.
- Mechanical removal of plaque by brushing and flossing is essential for good oral health.
- Mouth rinses may augment brushing and flossing procedures and may be used to freshen breath and/or as antiplaque/ antigingivitis adjuncts.
- Topical fluorides may be used in individuals with high caries activity.
- Parents must supervise children younger than 12 years as necessary until they can use the products without supervision.
- Denture cleaners may be used to remove debris physically and to prevent bacterial and/or fungal infections.
- If individuals have specific problems related to the purpose or use of these products, consultation with a dentist should be recommended.

**Handbook of Nonprescription Drugs > Chapter 31. Oral Pain and Discomfort****Oral Pain and Discomfort: Introduction**

Oral pain and discomfort are common ailments that affect people worldwide.<sup>1</sup> Many children experience irritation and soreness during the teething process. In adulthood, oral pain may be associated with sudden exposure of or damage to nerves in a tooth; unexpected cracking or breaking of teeth, fillings, or crowns (caps) may also occur. Similarly, pain in the mucosa of the oral cavity and lips can be generated by injury to the mouth, recurrent aphthous stomatitis (canker sores), or herpes simplex labialis (cold sores). Some adults experience xerostomia (dry mouth) that is significant enough to require treatment with nonprescription medications. Oral pain and discomfort can interfere with daily activities such as drinking, eating, and working; cause mental anxiety and distress; and result in cost to the patient from visits to their health care providers.<sup>2,3</sup> Distinguishing the patient's self-treatable problems from those potentially requiring professional dental or medical care is an important advisory role for oral health care providers.

**Tooth Hypersensitivity**

Tooth hypersensitivity, or dentin hypersensitivity, is characterized by a short, sharp pain arising from exposed dentin (i.e., mineralized tissue of teeth internal to crown enamel and root cementum) in response to a stimulus (thermal, chemical, or physical) that cannot be ascribed to any other form of dental defect or disease.<sup>4,5,6,7,8</sup> Tooth hypersensitivity affects 15%-20% of the adult population, with peak incidence between the ages of 30 and 39 years.<sup>4</sup>

**Pathophysiology of Tooth Hypersensitivity**

Two processes are essential for the development of dentin hypersensitivity: (1) dentin must become exposed (lesion localization) through loss of enamel or gingival recession, and (2) the dentin tubules must be open to both the oral cavity and the pulp (lesion initiation).<sup>4,5,6,7,8</sup> The roots of teeth are usually covered by gum tissues (gingiva), but infection (e.g., periodontal disease) or injury (e.g., traumatic brushing) can cause the gums to recede. The cementum covering affected root surfaces may be reduced by further injury (attrition, abrasion, or erosion), eventually exposing the underlying porous dentin. When stimuli such as heat, cold, pressure, or acid touch exposed dentin or reach an open tubule, fluid flow in the dentinal tubule is increased, and the underlying nerves are stimulated, resulting in pain.<sup>4,5,6,7,8</sup>

Enamel, which covers the anatomic crowns of the teeth and is the most mineralized body tissue, is resistant to abrasion by normal toothbrushing, but excessive brushing with an abrasive dentifrice or a medium- or hard-bristled toothbrush can be problematic. The etiology of dental erosion is primarily attributed to the presence of extrinsic or intrinsic acid.<sup>6,7</sup> Extrinsic sources of acid include frequent consumption of acidic medications, foods, or drinks. Persons who regularly consume citrus juices and fruits, carbonated drinks, wines, and ciders may be at risk for tooth hypersensitivity. The most common source of intrinsic acid is regurgitation of gastric contents into the mouth, which occurs with disorders such as gastroesophageal reflux disease or bulimia nervosa.<sup>6,7</sup>

Tooth hypersensitivity is more common in individuals with periodontitis or after procedures such as deep scaling, root planing, orthodontic tooth movement, or periodontal (gum) surgery.<sup>4,5,6,7,8</sup> Sensitivity to hot and cold for several weeks after dental therapy is normal. Hypersensitivity can also occur as a result of clenching or grinding teeth and from gumline grooves formed by abrasive or inappropriate toothbrushing technique.<sup>6</sup> Tooth whitening procedures, whether done at home or by a trained clinician, can cause dentin sensitivity. Tooth sensitivity is the most common reason why patients fail to complete or comply with a tooth whitening regimen.<sup>7</sup> Tooth whitening products are discussed in further detail in [Chapter 30](#).

**Clinical Presentation of Tooth Hypersensitivity**

A patient with tooth hypersensitivity experiences pain from hot or cold and sweet or sour solutions, as well as when hot or cold air touches the teeth. As individual pain thresholds vary, so does the pain experienced from tooth hypersensitivity. Pain varies from mild discomfort to sharp, excruciating pain. Although tooth hypersensitivity is self-treatable, toothache is not; therefore, it is critical to differentiate between these two conditions ([Table 31-1](#)). Resolution of pain associated with toothache, fractured dentition, ill-fitting dentures, or suspected infection (abscess) requires professional dental care. Only a dentist can adequately evaluate and treat these conditions; therefore, the patient should see a dentist without delay.

**TABLE 31-1 Differentiation of Tooth Hypersensitivity and Toothache**

	<b><i>Tooth Hypersensitivity</i></b>	<b><i>Toothache</i></b>
Etiology	Exposed and open dentin tubules	Bacterial invasion to the pulp
Pathophysiology	Stimuli (heat, cold, pressure, acid) cause fluid in the dentinal tubules to expand and shrink, stimulating pulp nerve fibers and resulting in pain	Inflammatory response to invading bacteria stimulates free nerve endings in the pulp
Causes	Attrition, abrasion, erosion, tooth/restoration fracture, faulty restoration, or gingival recession	Cavitation/decay present in tooth/teeth under existing restoration, tooth/restoration fracture, or trauma to the dentition
Symptoms	A quick, fleeting, sharp, or stabbing pain on stimulation by thermal, chemical, or physical stimuli, which stops after stimuli are no longer present	Pain that remains even in the absence of stimulus; intermittent, short, and sharp pain on stimulation may indicate reversible damage; continuous, dull, and throbbing pain without stimulation usually indicates irreversible damage
Assessment	Hypersensitivity due to attrition, abrasion, or erosion is not serious and is self-treatable; sensitivity due to fracture, faulty restoration, or gingival recession should be referred to a dentist	Requires dental care for resolution

Source: References 4, 6, and 7.

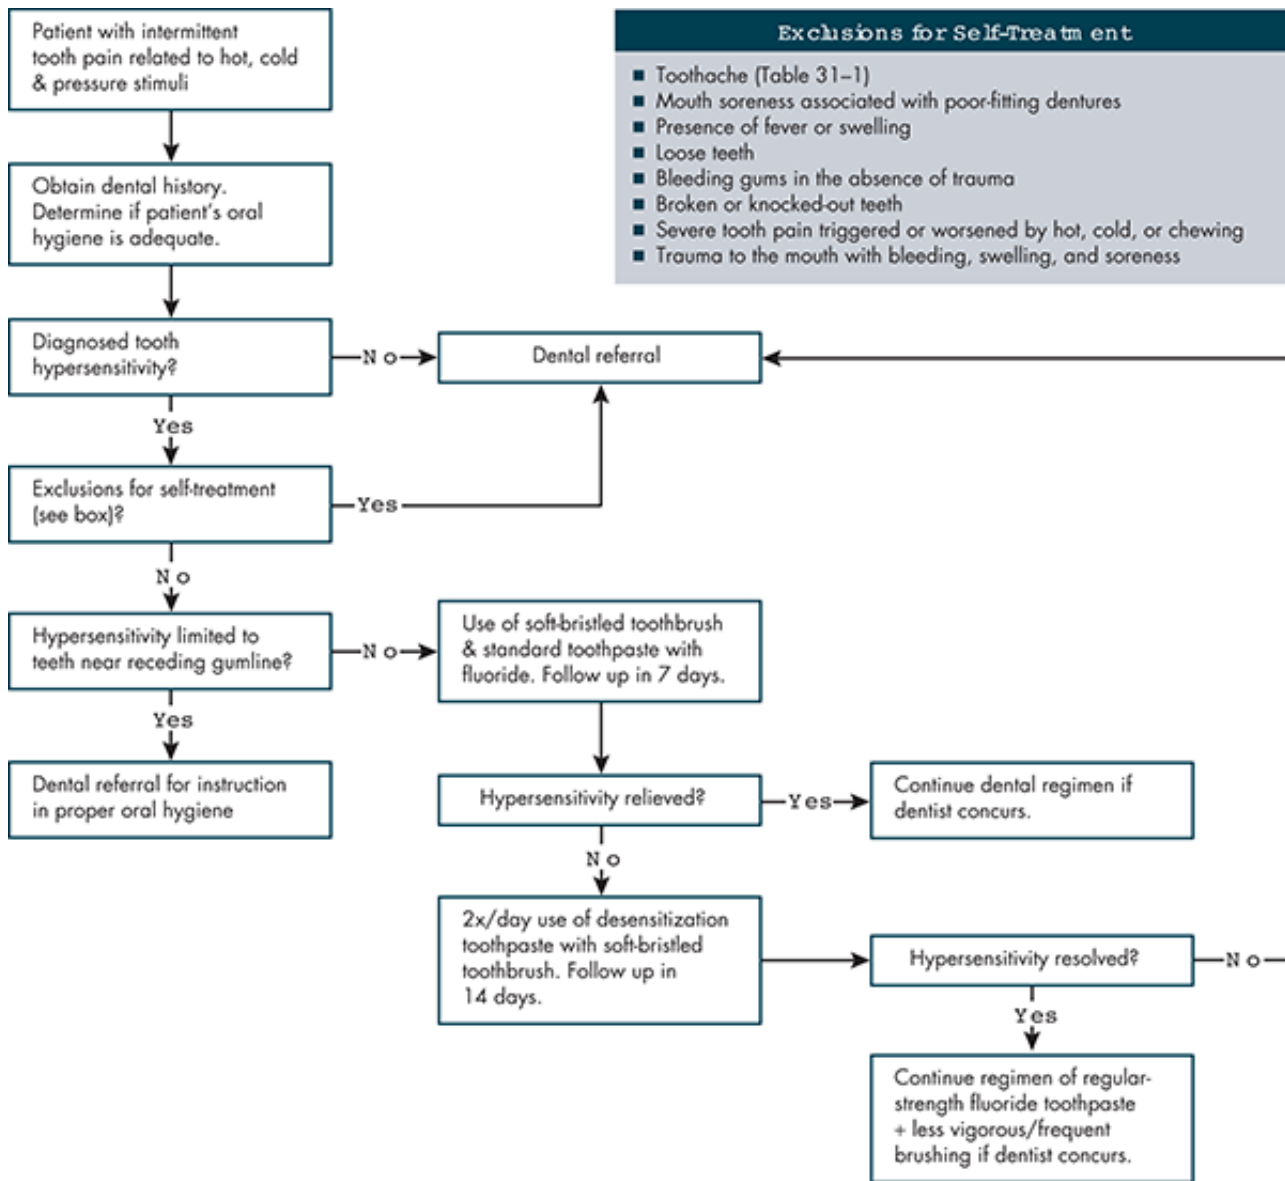

### Treatment of Tooth Hypersensitivity

#### Treatment Goals

The goals of self-treating tooth hypersensitivity are to (1) repair the damaged tooth surface using the appropriate toothpaste and (2) stop abrasive toothbrushing practices. When these goals have been achieved, tooth hypersensitivity may be eliminated.

#### General Treatment Approach

Pain related to tooth hypersensitivity can be challenging. Acute pain may cause anxiety and the patient may not seek care. Patients will likely not seek treatment by a dentist, but rather will try to self-treat.<sup>5,6</sup> Before recommending self-treatment of tooth pain, the provider should determine if the patient is a self-care candidate. [Figure 31-1](#) outlines the self-treatment of tooth hypersensitivity and lists exclusions for self-care.<sup>5,6,7,8,9</sup>

Self-care of tooth hypersensitivity. (Source: References 5-9.)

### Nonpharmacologic Therapy

Treatment plans for tooth hypersensitivity should include identification and elimination of predisposing factors, such as extrinsic and intrinsic acid and improper (harsh) toothbrushing technique. Tooth hypersensitivity can be prevented by brushing less vigorously with standard fluoride dentifrice (toothpaste) and a soft-bristled toothbrush. One should avoid brushing teeth within 30-60 minutes of consuming acidic foods or drinks to reduce the effects of acids and abrasions. Dentin permeability can be increased after ingesting acidic foods or beverages.<sup>6</sup> Fluoride is discussed in further detail in [Chapter 30](#).

### Pharmacologic Therapy

In general, two pharmacologic mechanisms are designed to treat tooth hypersensitivity. The first involves depolarizing the excited nerves in the tubules and pulp to disrupt the pain stimuli neuronal response.<sup>8</sup> A potassium salt, usually potassium nitrate, diffuses along the dentinal tubules to decrease the excitability of intradental nerves and alter its membrane potential. The potassium nitrate acts on the dentin to block the perception of stimuli that patients with healthy teeth usually do not experience. The second involves minimizing the flow of fluid by sealing the exposed dentin.<sup>8</sup> A new technology using 8% arginine, an amino acid naturally found in saliva, combined with calcium carbonate works by occluding the exposed dentinal tubules.<sup>8</sup> This treatment prevents the fluid from moving into the tubules, which is the cause of hypersensitivity. [Table 31-2](#) lists selected desensitizing toothpastes and their active ingredients.

**TABLE 31-2 Selected Nonprescription Desensitizing Toothpastes**

<b>Trade Name</b>	<b>Primary Ingredients</b>
Colgate Sensitive Multiprotection	Potassium nitrate 5%; sodium fluoride 0.24%
Colgate Sensitive Pro-Relief Original	Potassium nitrate 5%; sodium fluoride 0.24%
Colgate Sensitive Pro-Relief Enamel Repair	Potassium nitrate 5%; sodium monofluorophosphate 1.14%
Colgate Sensitive Pro-Relief Whitening	Potassium nitrate 5%; sodium fluoride 0.24%
Colgate Total Zx Pro-Shield Plus Sensitivity	Potassium nitrate 0.24%; sodium monofluoride 0.055%; zinc citrate trihydrate 0.096%
Crest Sensitivity: Clinical Sensitivity Relief Extra Whitening	Potassium nitrate 5%; sodium fluoride 0.243%
Crest Sensitivity Whitening Plus Scope	Potassium nitrate 5%; sodium fluoride 0.243%
Sensodyne Maximum Strength with Fluoride	Potassium nitrate 5%; sodium fluoride 0.15%
Sensodyne Pronamel	Potassium nitrate 5%; sodium fluoride 0.15%
Tom's Sensitive	Potassium nitrate 5%; sodium fluoride 0.24%

Potassium nitrate 5% is the most widely used and generally accepted ingredient used for teeth sensitivity. Most commercially available desensitizing dentifrices are combination products containing potassium nitrate and sodium fluoride, in varying concentrations. Studies have shown these products to be highly efficacious for the treatment of tooth sensitivity.<sup>9,10</sup> The Pro-Argin technology, which combines 8% arginine and calcium carbonate, though highly efficacious,<sup>8,11</sup> is not currently available to consumers for home use.

Guidelines for brushing teeth can be found in the previous chapter ([Table 30-1](#)) and can be applied to brushing with desensitizing dentifrices.<sup>9,10</sup> A single application has no effect; for some patients, long-term use (2-4 weeks) may be necessary to relieve the symptoms. The desensitizing dentifrice should be used until the sensitivity subsides or as long as a dentist recommends its use. In about 25% of adults, hypersensitive teeth are a chronic problem and require long-term treatment provided by a dentist.<sup>5,6</sup> If tooth hypersensitivity is not relieved within 14-21 days of using a desensitizing dentifrice, the patient should see a dentist for an in-office method of treatment or an appropriate health care provider for further evaluation.<sup>5,6</sup>

#### Product Selection Guidelines

Dentifrices containing potassium nitrate 5% are not recommended for children younger than 12 years. Patients with hypersensitive teeth should be cautioned against using high-abrasion toothpastes such as cosmetic pastes that whiten teeth or remove stains.

#### Assessment of Toothache and Tooth Hypersensitivity: A Case-Based Approach

The primary objectives of the assessment are to determine whether the patient has a history of dental problems, whether the patient regularly cares for his or her teeth, and whether the patient receives regular professional dental care. This information will help determine the patient's level of care and risk for a toothache versus tooth hypersensitivity ([Table 31-1](#)).

#### Patient Counseling for Tooth Hypersensitivity

Subsequent to a definite diagnosis of tooth hypersensitivity, patients should be counseled on the proper use of desensitizing toothpastes and safe methods of toothbrushing, as outlined in the box Patient Education for Tooth Hypersensitivity. Patients should use the desensitizing toothpaste for as long as the dentist recommends and then switch to a low-abrasion (nonwhitening) fluoride dentifrice.

#### Patient Education for Tooth Hypersensitivity

The objectives of self-treatment of tooth hypersensitivity are to (1) repair the damaged tooth surface using the appropriate toothpaste and (2) stop abrasive toothbrushing practices. For most patients, carefully following product instructions, the dentist's recommendations, and the self-care measures listed here will help ensure optimal therapeutic outcomes.

- If correct brushing techniques with a fluoride toothpaste are ineffective, a desensitizing toothpaste should be used.

- If a desensitizing toothpaste is needed, apply a 1-inch strip of toothpaste to a soft-bristled toothbrush. Brush at least twice daily.
- Note that relief of the sensitivity may take several days to several weeks. The better the patient is at removing bacterial plaque, the quicker the sensitivity will resolve.
- Use the toothpaste for as long as the dentist recommends, and then switch to a low-abrasion (nonwhitening) fluoride dentifrice.
- Note that some cases of hypersensitive teeth require long-term treatment or several repeated treatments.
- Do not use desensitizing toothpastes in children younger than 12 years.
- Do not use high-abrasion toothpastes, such as cosmetic pastes that whiten or remove stains.

### When to Seek Medical Attention

- See a dentist if the pain worsens during treatment or if new symptoms develop.

### Evaluation of Patient Outcomes for Tooth Hypersensitivity

The patient with hypersensitive teeth should use a desensitizing dentifrice for a maximum of 4 weeks. If the pain is resolved, the patient should continue treatment as recommended by a dentist. The patient should be advised to continue the recommended dental hygiene measures (i.e., brush teeth twice daily and visit the dentist twice a year). If the pain persists or worsens, or if new symptoms develop after 14-21 days, the patient should see a dentist for further evaluation.<sup>5,6,8</sup>

### Teething Discomfort

Not all babies suffer discomfort during teething. For those who do, nonprescription products can provide symptomatic relief.

### Pathophysiology of Teething Discomfort

Teething is the eruption of the deciduous (primary or baby) teeth through the gingival tissues. Usually, this normal physiologic process is uneventful. However, it can cause pain, sleep disturbances, or irritability in some children.

### Clinical Presentation of Teething Discomfort

Mild pain, irritation, reddening, excessive drooling, mouth biting, gum rubbing, low-grade fever, or slight swelling of the gums while teething may precede or accompany sleep disturbances or irritability.<sup>12</sup> Teething is not associated with vomiting, diarrhea, nasal congestion, malaise, fever, or rashes, but these symptoms may be a sign of ear or stomach infection. Bluish, soft, round swellings (called eruption cysts) sometimes form over emerging incisors and molars. Eruption cysts are not the result of infection and will disappear if left alone. In addition, three bumps (called mamelons) may be present on the biting surfaces (incisal edges) of emerging incisors. The mamelons will wear away as the teeth begin to occlude against the opposing dentition. If the underside of the tongue becomes irritated, a dentist may try to smooth the edges of the mamelons to prevent further irritation. Teeth eruption can begin as early as 6 months of age, and for each tooth that erupts, the teething period usually occurs over an 8-day window.<sup>12</sup>

### Treatment of Teething Discomfort

#### Treatment Goals

The goal of self-care of teething discomfort is to relieve gum pain and irritation, thereby reducing the child's irritability and sleep disturbances.<sup>12</sup>

#### General Treatment Approach

Parents and caregivers should be cautioned to exercise restraint in treating a child's teething discomfort. Eruption cysts are a part of the normal physiologic process and should be left alone to resolve spontaneously. If cut or punctured, the cysts will leave scars that may delay the tooth's eruption. Parents should try all nonpharmacologic measures to determine which ones are helpful. If additional treatment is needed pediatric doses of systemic analgesics can be used.

#### Nonpharmacologic Therapy

If the baby cooperates, massaging the gum around the erupting tooth may provide relief. Babies may be made more comfortable by giving them a cold teething ring. Teething products made of plastic and filled with fluid should not be subjected to extreme temperatures, like boiling to sanitize or freezing, as this can weaken the plastic and lead to

leakage of the fluid.<sup>12</sup> The cold temperature causes local vasoconstriction in addition to the pressure on the gums that the child feels when he or she bit the object. If the child is at an age to tolerate food such as dry toast or teething biscuits, he or she may be given such food to chew. Foods high in sucrose should be avoided.<sup>12</sup>

### Pharmacologic Therapy

Pharmacologic management of infant teething discomfort is limited to pediatric doses of systemic analgesics. Topical analgesics that are approved for use in infants carry strict FDA warnings against their use.

#### Topical Oral Analgesics

Benzocaine is available in concentrations ranging from 5% to 20% are generally not accepted as safe topical anesthetics/analgesics for teething pain. Benzocaine is a drug product classified as Pregnancy Category C.<sup>13</sup> In the highest concentration approved for nonprescription use (20%), benzocaine is too potent for infants and can even cause death from drug overdose.<sup>12</sup> In April 2011, FDA released a MedWatch safety alert that warned health care providers of the reports linking benzocaine use and methemoglobinemias.<sup>14</sup> Methemoglobinemia is a serious but rare condition whereby the amount of oxygen circulating in the blood is greatly reduced.<sup>12</sup> FDA recommends that benzocaine products not be used on children younger than 2 years, except under the advice and supervision of a health care professional.<sup>12,14</sup> Patients with known hypersensitivity to common local anesthetics should not use a product containing benzocaine. Benzocaine is a known sensitizer (allergen), and its use in these patients can cause a hypersensitivity reaction.

In June 2014, FDA released a Drug Safety Communication that discussed the use of topical agents used for infant and child teething discomfort.<sup>15</sup> The communication warns that prescription oral viscous lidocaine 2% solution should not be used to treat infants and children with teething pain. Further, the agency requires the following *Boxed Warning* be added to these products: "Oral viscous lidocaine solution is not approved to treat teething pain, and use in infants and young children can cause serious harm, including death." In addition, the communication recommends against use of nonprescription topical medications for teething pain, which would include benzocaine containing products. These products are sold under different brand names, such as Anbesol, Hurracaine, Orajel, Baby Orajel, Orabase, and various store brands. FDA recommends following the American Academy of Pediatrics' recommendations to help lessen teething pain. These modalities are discussed in detail above in the section Nonpharmacologic Therapy.

#### Systemic Analgesics

Pediatric doses of systemic nonprescription analgesics (e.g., acetaminophen) may be used to relieve teething discomfort. (See [Chapter 5](#) for discussion of these agents and their recommended dosages.)

### Product Selection Guidelines

Topical teething products labeled for the temporary relief of sore gums due to teething in infants and children ages 4 months and older are no longer recommended by FDA as safe and effective.<sup>15</sup> Nonpharmacologic management and systemic analgesics, given at the appropriate pediatric doses, should be used for symptom management.

### Assessment of Teething Discomfort: A Case-Based Approach

In most cases, teething discomfort must be assessed on the basis of the parent's description of the child's symptoms. If the child cooperates, visual inspection of the gums may confirm that the child is teething. Nonetheless, the signs and symptoms of teething must be distinguished from those of an infection.

### Patient Counseling for Teething Discomfort

Parents should be counseled about both nonpharmacologic and pharmacologic remedies for teething discomfort, as outlined in the box Patient Education for Teething Discomfort. Parents should be urged to contact a primary care provider when uncharacteristic symptoms of teething discomfort are present.

#### Patient Education for Teething Discomfort

The objective of self-treatment of teething discomfort is to relieve gum pain and irritation, thereby reducing the child's irritability and sleep disturbances. For most patients, the parent's or caregiver's careful following of product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Nondrug Measures

- If possible, massage the gum around the erupting tooth to provide relief.
- Give the baby a cold teething ring or cold wet cloth, or food (e.g., dry toast or teething cookies) to chew.
- The American Dental Association recommends regular dental checkups, which includes a dental visit within 6 months of the child's first tooth but no later than the child's first birthday.

## Nonprescription Medications

### Topical Analgesics

- Do not use teething preparations containing benzocaine on infants and young children.
- Do not use prescription viscous lidocaine 2% solution on infants and young children.

### Systemic Analgesics

- If desired, use pediatric formulations of oral nonprescription analgesics such as acetaminophen to relieve teething discomfort.
- Read the label carefully, and do not exceed recommended doses or frequency of use.

### When to Seek Medical Attention

- If the baby is vomiting or has diarrhea, fever, nasal congestion, malaise, pain, or other symptoms not typical of teething discomfort, take the baby to a family physician or pediatrician.

### Evaluation of Patient Outcomes for Teething Discomfort

The parent should be asked to call back after 3-5 days of treatment. If neither nonpharmacologic therapy nor nonprescription medications are relieving the symptoms, the parent should be advised to take the baby to a primary care provider, pediatrician, or pediatric dentist. Furthermore, if symptoms uncharacteristic of teething discomfort have developed, the baby should be evaluated by a primary care provider or pediatrician.

## Recurrent Aphthous Stomatitis

Recurrent aphthous stomatitis (RAS), also known as canker sore or aphthous ulcer, affects approximately 2.5 billion people worldwide.<sup>16</sup> Prevalence of RAS is influenced by the population, diagnostic criteria, and environmental factors.<sup>17</sup> The onset of RAS appears to peak between the ages of 10 and 19 years.<sup>17</sup> Eighty percent of patients with RAS are considered to have a mild form of the disease. The lesions affect only nonkeratinized mucosa (e.g., labial or buccal) and will spontaneously heal in 10-14 days.<sup>18</sup>

### Pathophysiology of Recurrent Aphthous Stomatitis

The cause of RAS is unknown in most patients. Precipitating factors such as local, systemic, immunologic, genetic, allergic, and nutritional have been proposed. Local trauma (e.g., smoking, chemical irritation, biting of the inside of cheeks or lips, or injury caused by toothbrushing or braces) has been implicated as a leading cause of lesions.<sup>17,18</sup> Streptococci and Varicella zoster virus have been implicated as microbial causes.<sup>17</sup> Systemic conditions associated with RAS include Behçet's disease, systemic lupus erythematosus, neutrophil dysfunction, inflammatory bowel disease, and human immunodeficiency virus/acquired immunodeficiency syndrome. Nutritional conditions include gluten-sensitive enteropathy and deficiencies of iron; vitamins B<sub>1</sub>, B<sub>2</sub>, B<sub>6</sub>, and B<sub>12</sub>; and folic acid. A genetic component to the disease is possible, given that 40% of RAS patients have a familial history: children with parents who have RAS have a 90% chance of developing RAS themselves compared with a 20% chance in children whose parents do not have RAS.<sup>17</sup> Additional precipitating or contributing factors may include food allergy (e.g., preservatives) and hormonal changes (e.g., menstrual cycle).<sup>18</sup>

### Clinical Presentation of Recurrent Aphthous Stomatitis

RAS appears as an epithelial ulceration on nonkeratinized mucosal surfaces of movable mouth parts, such as the tongue, floor of the mouth, soft palate, or inside lining of the lips and cheeks. Rarely, ulcerations affect keratinized tissue such as the gingiva or the external lips (vermillion). Individual ulcers are usually (1) round or oval, (2) flat or crater-like, and (3) gray to grayish yellow, with an erythematous halo of inflamed tissue surrounding the ulcer (see Color Plates, photograph 9).

RAS occurs in three clinical forms: minor, major, and herpetiform. The RAS form can be distinguished primarily by the number of lesions, the size of the ulcer, and the number of days that the lesion persists. [Table 31-3](#) compares the features of the three forms of RAS and cold sores.<sup>17,21,22,23</sup> Some patients may experience a pricking or burning sensation (prodrome) about 2-48 hours before the lesion actually appears.<sup>17</sup> The lesions can be very painful, with the pain increasing with eating and drinking, and may inhibit normal eating, drinking, swallowing, talking, and routine oral hygiene. Usually, fever or lymphadenopathy does not accompany RAS; however, such symptoms may arise if a secondary bacterial infection is present.

### TABLE 31-3 Differentiation of RAS and HSL

	<b>RAS (canker sores)</b>			
	<b>Minor</b>	<b>Major</b>	<b>Herpetiform</b>	<b>HSL (cold sores)</b>
Manifestation	Oval, flat ulcer; erythematous tissue around ulcer	Oval, ragged, gray/yellow ulcers; crater form	Small, oval ulcers in crops, similar to minor RAS	Red, fluid-filled vesicles; lesions may coalesce; crusted when mature
Location	All areas except gingiva, hard palate, vermillion (border of the oral mucosa and external skin)	Any intraoral area, but prefers lips, soft palate and throat	Any intraoral area	Junction of oral mucosa and skin of lip and nose
Incidence	13%-26%	1.5%-3%	0.5%-1%	20%-30%
Incidence among RAS sufferers	80%	10%	5%-10%	NA
Number of lesions	1-5	Several (1-10)	10-100 (in crops)	Several
Size of lesion	<0.5 cm	>0.5 cm	<0.5 cm	1-3 mm
Duration (days)	10-14	≥6 weeks	7-10	10-14
Pain	None-moderate	None-moderate	Moderate-severe	None-moderate
Scarring	None	Common	None	Rare
Comments	Immunologic defect	Immunologic defect	Immunologic defect	Induced by HSV-1

Key: HSL = Herpes simplex labialis; HSV-1 = herpes simplex virus-1; NA = not applicable; RAS = recurrent aphthous stomatitis.

Source: References 17 and 21-23.

### Treatment of Recurrent Aphthous Stomatitis

RAS cannot be cured; however, nonprescription medications can provide symptomatic relief.

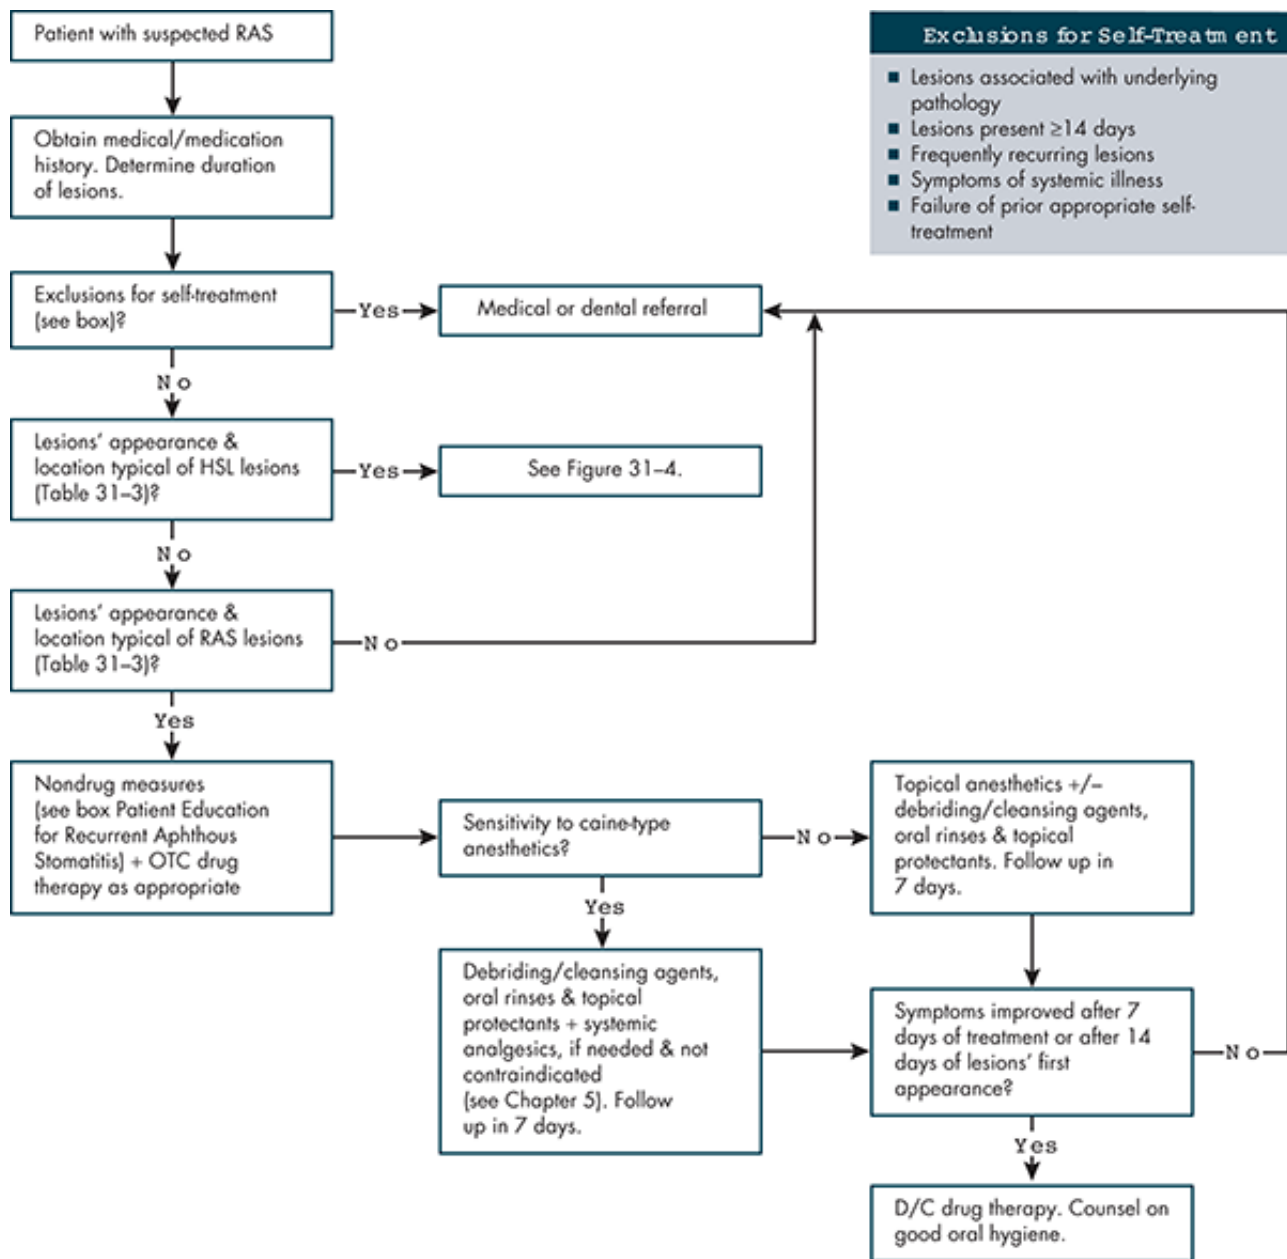

#### Treatment Goals

The primary objective of self-treatment of RAS is to relieve pain and irritation so the lesions can heal, and the patient can eat, drink, and perform routine oral hygiene. The secondary objective is to prevent complications, such as secondary infection.<sup>19</sup>

#### General Treatment Approach

If possible, the lesions should be inspected to determine whether their appearance and location are characteristic of RAS. If possible, factors that may have led to development of the ulcer should be identified, and precipitating or contributing factors should be removed. For example, if trauma is suspected, perhaps a gentler toothbrush and gentler brushing technique could be suggested. It is also helpful to determine whether the patient has a history of RAS. If the treatments used are appropriate and have been successful for the patient, they should be continued.

Figure 31-2 outlines the self-treatment of RAS and lists exclusions for self-care.<sup>13,17,18,19,20</sup>

Self-care of recurrent aphthous stomatitis. Key: D/C = Discontinue; HSL = herpes simplex labialis; OTC = over-the-counter; RAS = recurrent aphthous stomatitis. (Source: References 13, 17-20.)

### Nonpharmacologic Therapy

If a nutritional deficiency (e.g., iron, folate, or vitamins) is diagnosed as a contributing factor, the patient should increase consumption of foods high in these nutrients or take nutritional supplements. For patients in whom a food allergy is thought to be a contributing factor, elimination of the offending agent from the diet may help to improve or resolve RAS. Because stress may play a role in the development of RAS, relaxation and stress removal may be useful and have shown reductions in ulcer frequency.<sup>17</sup> The box Patient Education for Recurrent Aphthous Stomatitis lists additional nonpharmacologic therapy.

#### Patient Education for Recurrent Aphthous Stomatitis

The primary objective of self-treatment of RAS is to relieve pain and irritation so the lesions can heal and so the patient can eat, drink, and perform routine oral hygiene. The secondary objective is to prevent complications, such as secondary infection. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Nondrug Measures

- If a deficiency of iron, folate, or vitamin B<sub>12</sub> is diagnosed as a contributing factor, increase consumption of foods high in these nutrients, or take nutritional supplements.
- Avoid spicy or acidic foods until the lesions heal.

- Avoid sharp foods that may cause increased trauma to the lesion.
- If desired, apply ice directly to the lesions in 10-minute increments but not longer than 20 minutes in a given hour.
- Do not use heat. If an infection is present, heat may spread the infection.

### Nonprescription Medications

- If longer-lasting relief is desired, nonprescription medications such as debriding and cleansing agents, topical oral anesthetics, topical oral protectants, oral rinses, and systemic analgesics can be used.

#### Oral Debriding and Wound Cleansing Agents

- Use a product containing one of the following ingredients: carbamide peroxide 10%-15% or hydrogen peroxide 1.5%. Apply after meals up to 4 times daily.
- Do not use these medications longer than 7 days. Chronic use can cause tissue irritation, decalcification of enamel, and black hairy tongue.
- Do not swallow these medications.

#### Topical Oral Anesthetics

- Use products containing one of the following medications: benzocaine 5%-20%, benzyl alcohol 0.05%-0.1%, butacaine sulfate 0.05%-0.1%, dyclonine 0.05%-0.1%, hexylresorcinol 0.05%-0.1%, or salicylic alcohol 1%-6%.
- Do not use benzocaine if you have a history of hypersensitivity to other benzocaine-containing products.

#### Topical Oral Protectants

- Use topical oral protectants or denture adhesives to coat and protect the lesions. These agents will also provide temporary relief of discomfort.
- Apply these products as needed.

#### Oral Rinses

- Rinse the mouth with Original Listerine Antiseptic to hasten healing of the lesions.
- Rinse the mouth with a saline solution to soothe discomfort or to prepare the lesion for application of a topical medication. For saline solution, add 1-3 teaspoons of salt to 4-8 ounces of warm tap water.

#### Systemic Analgesics

- Oral analgesics (e.g., aspirin, NSAID, or acetaminophen) can be used for additional relief of mouth discomfort.
- Do not hold aspirin in the mouth or place it on oral lesions. The acid can cause a chemical burn and tissue damage.

#### When to Seek Medical Attention

- See a primary care provider if any of the following occur:
  - Symptoms do not improve after 7 days of treatment with oral debriding or wound-cleansing agents.
  - The lesions do not heal in 14 days.
  - Symptoms worsen during self-treatment.
  - Symptoms of systemic infection, such as fever, rash, or swelling, develop.

#### Pharmacologic Therapy

Several types of nonprescription medications (oral debriding and wound-cleansing agents, topical oral anesthetics, topical oral protectants, oral rinses, and systemic analgesics) provide symptomatic relief of RAS, but they do not prevent its recurrence. Table 31-4 lists a variety of the commercially available products for oral pain and discomfort and their pregnancy category rating, if known.

**TABLE 31-4 Selected Nonprescription Medications for RAS and HSL**

Trade Name	Primary Ingredients	Pregnancy Category

<b>Oral Debriding and Wound-Cleansing Agents<sup>a</sup></b>		
Cankaid Liquid Oral Antiseptic	Carbamide peroxide 10%	ID
Gly-Oxide Antiseptic Oral Cleanser	Carbamide peroxide 10%	ID
Orajel Antiseptic Rinse for Mouth Sores	Hydrogen peroxide 1.5%	C
Colgate Peroxyl Mouth Sore Rinse	Hydrogen peroxide 1.5%	C
<b>Topical Oral Anesthetics</b>		
Anbesol Regular Strength Gel/Liquid	Benzocaine 10%	C
Zilactin-B Gel	Benzocaine 10%	C
Anbesol Maximum Strength Gel	Benzocaine 20%	C
Kank-A Liquid	Benzocaine 20%	C
Orabase Paste	Benzocaine 20%	C
Benzodent	Benzocaine 20%	C
Orajel Mouth Sore Gel	Benzocaine 20%; benzalkonium chloride 0.02%; zinc chloride 0.1%	C
Campho-Phenique Gel/Liquid	Camphor 10.8%; phenol 4.7%	ID
Blistex Lip Medex Ointment	Camphor 1%; menthol 1%; phenol 0.54%; petrolatum 59.14%	ID
Carmex Lip Balm Ointment	Menthol 0.7%; camphor 1.7%; phenol 0.4%	ID
Herpicin-L Lip Balm	Dimethicone 1%; meradimate 5%; octinoxate 7.5%; octisalate 5%; oxybenzone 5%	ID
<b>Topical Oral Protectants<sup>a</sup></b>		
Canker Cover	Menthol 2.5 mg	ID
<b>Oral Rinses</b>		
Original Listerine Antiseptic	Eucalyptol 0.092%; menthol 0.042%; methyl salicylate 0.060%; thymol 0.064%	ID
<b>Topical Treatments<sup>b</sup></b>		
Abreva	Docosanol 10%	ID

Key: HSL = Herpes simplex labialis; ID = insufficient data to determine pregnancy category; RAS = recurrent aphthous stomatitis.

<sup>a</sup> Use limited to RAS.

<sup>b</sup> Use limited to HSL.

Accessed at <http://www.clinicalpharmacology.com>, August 14, 2013.

### Oral Debriding and Wound-Cleansing Agents

Oral debriding agents and wound cleansers may be used to (1) aid in the removal of debris or phlegm, mucus, or other secretions associated with a sore mouth; (2) cleanse minor wounds or minor gum inflammation; and (3) cleanse recurrent aphthous ulcers. Products that release nascent oxygen can be used as debriding and cleansing agents to provide temporary relief of RAS discomfort. Hydrogen peroxide and carbamide peroxide release oxygen immediately on contact with tissue enzymes (catalase and peroxidase), but tissue and bacterial exposure to the oxygen is very brief.<sup>20,24</sup>

For direct application, a few drops of carbamide peroxide (10%-15%) or hydrogen peroxide (1.5%) are applied to the affected area and allowed to remain in place for 1 minute. As a rinse, carbamide peroxide drops are placed on the tongue, mixed with saliva, and swished in the mouth for 1 minute. An aqueous solution of hydrogen peroxide 3% should be mixed with an equal amount of water before rinsing the mouth. Some products (e.g., Peroxyl Rinse) are a solution of hydrogen peroxide 1.5% and should be used without dilution. Prolonged rinsing with oxidizing products can lead to soft-tissue irritation, transient tooth sensitivity from decalcification of enamel, cellular changes, and overgrowth of undesirable organisms that will possibly lead to a black, hairy tongue.<sup>20</sup>

### Topical Oral Anesthetics

Topical oral anesthetic/analgesic products, including benzocaine 5%-20%, benzyl alcohol 0.05%-0.1%, butacaine sulfate 0.05%-0.1%, dyclonine 0.05%-0.1%, hexylresorcinol 0.05%-0.1%, and salicylic alcohol 1%-6%, are generally recognized for temporary relief of pain associated with RAS.<sup>17</sup> To reduce the incidence of RAS, patients should also avoid the use of dentifrices containing sodium lauryl sulfate.<sup>17,18</sup>

### Topical Oral Protectants

Oral mucosal protectants are pharmacologically inert substances that coat and protect the ulcerated area. Coating the ulcer with a topical oral protectant can be effective in protecting ulcerations, decreasing friction, and giving temporary symptomatic relief. These products create a barrier by using a paste, an adhering film, or a dissolvable patch to cover the lesion. Some products are available in combination with an oral anesthetic. Products available as a patch or dissolving disc must be placed against the sore for 10-20 seconds. Once the disc adheres to the lesion, the barrier is formed and the disc will stay in place until dissolved, about 8-12 hours.<sup>25</sup>

### Oral Rinses

Rinsing the mouth with an antiseptic rinse will hasten the healing of the lesions. Saline rinses (1-3 teaspoons of salt in 4-8 ounces of warm tap water) may soothe ulcers and can be used before topical application of a medication. Similarly, a paste of baking soda applied to the lesions for a few minutes may soothe irritation.

### Systemic Analgesics

Systemic nonprescription analgesics (e.g., aspirin, nonsteroidal anti-inflammatory drugs, and acetaminophen) give additional relief of mouth discomfort. (See [Chapter 5](#) for discussion of these agents and their recommended dosages.) Aspirin should not be retained in the mouth before swallowing, nor placed in the area of the oral lesions. The acid can cause a chemical burn with subsequent tissue damage (see Color Plates, photograph 10).

### Product Selection Guidelines

Patients with known hypersensitivity to common local anesthetics should not use a product containing a local anesthetic. Benzocaine is a known sensitizer (allergen), and its use in these patients can cause a hypersensitivity reaction. Patients with known sensitivity to aspirin should avoid salicylic acid. Various dosage forms exist (e.g., liquid, gel, rinse, and dissolvable patch); however, drug delivery is a major concern because topical applications can be easily washed away by saliva. Gels are the preferred drug delivery application because they are easy to apply and are not easily washed away.<sup>17-19</sup> A topical anesthetic will provide short-term relief of the pain and discomfort associated with RAS, and the oral debriding agents will help to keep the ulcer clean. Using both of these agents should help alleviate immediate discomfort and heal the ulcer quickly.

### Assessment of Recurrent Aphthous Stomatitis: A Case-Based Approach

Controlling the pain and preventing infection are the primary concerns when RAS is suspected. If possible, factors that may have precipitated or contributed to the development of the ulcer should be identified and then removed. The patient should be asked about previous self-treatments and their effectiveness. If the treatments used are appropriate and have been successful for the patient, they should be continued.

Case 31-1 provides an example of the assessment of a patient with RAS.

### Patient Counseling for Recurrent Aphthous Stomatitis

All nonpharmacologic and pharmacologic measures for treating RAS, as outlined in the box Patient Education for Recurrent Aphthous Stomatitis, should be explained to the patient. The patient should also be cautioned about using ineffective or harmful therapies. Possible adverse effects, contraindications, and precautions should then be

explained for all nonprescription agents. In addition, patients must be alerted to the conditions that warrant dental or medical evaluation.

#### Evaluation of Patient Outcomes for Recurrent Aphthous Stomatitis

Minor RAS lesions are typically self-limiting and resolve within 14 days. Oral debriding and wound-cleansing agents are labeled for use for up to 7 days. If the symptoms have improved, the patient should discontinue treatment but continue other dental hygienic measures (e.g., twice-daily toothbrushing). Symptoms that are unimproved or that have worsened during treatment require medical evaluation.

#### Case 31-1

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient noticed a burning/prickling sensation about a day ago. When she looks in her mouth she notices an oval shaped lesion that looks bumpy and is grayish in color.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient was recently diagnosed with a gluten sensitivity.
c. description of the patient's efforts to relieve the symptoms	Patient has not tried anything yet.
d. patient's identity	Rebecca Sithgib
e. age, sex, height, and weight	32 years old, female, 5 ft 9 in., 155 lb
f. patient's occupation	High school German teacher
g. patient's dietary habits	Excellent eater, although she admits to having a "sweet tooth."
h. patient's sleep habits	6-8 hours nightly
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Multivitamin > 2 years; Nuvaring > 2 months
j. allergies	NKDA
k. history of other adverse reactions to medications	None
l. other (describe) _____	NA
<b>Assessment and Triage</b>	

2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s) (Table 31-3).	Given the location and appearance of the lesion it is highly likely that the patient has RAS. She is at high risk for developing RAS given that she has gluten sensitivity and fluctuation in hormone levels that is associated with recent insertion of a Nuvaring.
3. Identify exclusions for self-treatment (Figure 31-2).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Rebecca to an appropriate health care provider. (2) Recommend an OTC product to treat RAS. (3) Recommend other self-care options until Rebecca can see an appropriate provider. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	An oral debriding and wound-cleansing agent, e.g., hydrogen peroxide 1.5% (Peroxyl), and a topical anesthetic, e.g., benzocaine 20% (Anbesol) would be appropriate initial options. (Table 31-4 lists other options.)
6. Describe the recommended therapeutic approach to the patient or caregiver.	"A topical anesthetic will provide short-term relief of the pain and discomfort. An oral debriding and wound-cleansing agent will help to keep the ulcer clean to aid in healing."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Using both of these agents should help to ease your discomfort as well as heal the ulcer quickly. If you are not experiencing pain or discomfort the topical anesthetic does not need to be used."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	"The debriding and cleansing mouth rinse can be used up to 4 times a day (after meals)."
b. maximum number of days the therapy should be employed	"Do not use the product for more than 7 days."
c. product administration procedures	See the box Patient Education for RAS.
d. expected time to onset of relief	See the box Patient Education for RAS.
e. degree of relief that can be reasonably expected	"The discomfort should dissipate within 7 days and the ulcer should begin improving. It should be completely resolved within 14 days from the day it started."

f. most common side effects	See the box Patient Education for RAS.
g. side effects that warrant medical intervention should they occur	See the box Patient Education for RAS.
h. patient options in the event that condition worsens or persists	See the box Patient Education for RAS.
i. product storage requirements	“Store in a cool, dry place out of children’s reach.”
j. specific nondrug measures	See the box Patient Education for RAS.
Solicit follow-up questions from the patient or caregiver.	“Should I maintain my normal oral hygiene routine?”
Answer the patient’s or caregiver’s questions.	“Yes. Continue to brush and floss twice a day, and use a toothpaste that contains fluoride.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Ask the patient to call to update you on her response to your recommendations; or you could call her in a week to evaluate response.

Key: NKDA = No known drug allergies; NA = not applicable; OTC = over-the-counter; RAS = recurrent aphthous stomatitis.

### Minor Oral Mucosal Injury or Irritation

#### Pathophysiology of Minor Oral Mucosal Injury or Irritation

Minor wounds or inflammation resulting from minor dental procedures; accidental injury (e.g., biting of the cheek or abrasion from sharp, crisp foods); or other irritations of the mouth, gums, or palate may be treated with various nonprescription medications.

#### Treatment of Minor Oral Mucosal Injury or Irritation

Treatment of mouth injury (traumatic laceration or ulcer) and irritation is similar to that for RAS. Mouth injury and irritation differ from RAS with regard to etiology and certain treatment considerations.

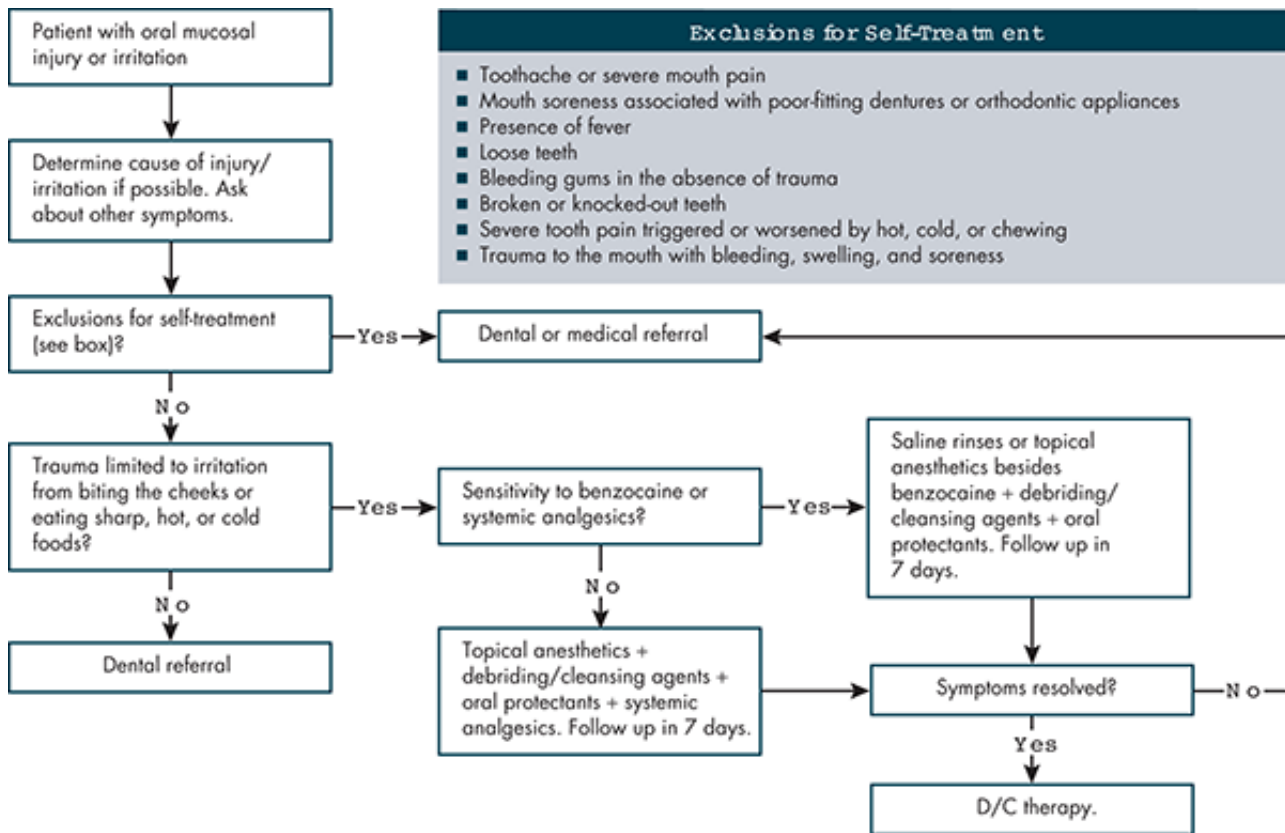

#### Treatment Goals

The goals of treating minor mucosal injury and irritation are to (1) control discomfort and pain, (2) aid healing with the appropriate use of nonpharmacologic and pharmacologic measures, and (3) prevent secondary bacterial infection.

#### General Treatment Approach

Treatment should focus first on relieving discomfort. Application of ice can relieve discomfort. Local anesthetics, oral analgesics, and saline rinses are safe and effective. Once the discomfort has resolved, patients should focus on healing the affected area. Homemade sodium bicarbonate rinses and oral debriding and wound-cleansing agents can help achieve this objective. Finally, concomitant use of oral protectants can relieve discomfort and aid healing by protecting the area from further irritation. [Figure 31-3](#) outlines this approach and lists exclusions for self-care.<sup>21,22,23</sup>

Copyright © American Pharmacists Association  
All rights reserved. Any use is subject to the Terms of Use.

Self-care of minor oral mucosal injury or irritation. Key: D/C = Discontinue. (Source: References 21-23.)

### Nonpharmacologic Therapy

When tissues of the lips, cheeks, or palate are bruised, direct application of ice may reduce the swelling. Ice should be applied in 10-minute increments but not longer than 20 minutes in a given hour. Longer application times may cause local tissue damage. Sodium bicarbonate solutions (1/2-1 teaspoon of household baking soda in 4 ounces of water) can act as an oral debriding agent and wound cleanser.<sup>23</sup> The solution is swished in the mouth over the affected area for at least 1 minute and then expectorated. Sodium bicarbonate's mucolytic action is related to its alkalinity. Saline rinses (1-3 teaspoons of salt in 4-8 ounces of warm tap water) can cleanse and soothe the affected area.

### Pharmacologic Therapy

As with RAS, topical analgesics/anesthetics, oral protectants, and oral debriding and wound-cleansing agents are the mainstay of pharmacologic therapy. The Pharmacologic Therapy section for treatment of RAS discusses these agents in further detail. In addition to these agents, astringents may be used. Astringents cause tissues to contract or arrest secretions by causing proteins to coagulate on a cell surface.<sup>26</sup> Dentists may suggest that their patients use oxidizing mouth rinses or topically applied steroids (which are available only by prescription) as an adjunctive treatment of specific conditions or as a postoperative aid to cleaning the affected area, relieving discomfort, and assisting the healing process.

### Assessment of Minor Oral Mucosal Injury or Irritation: A Case-Based Approach

The cause and nature of the injury or irritation are the primary considerations in patient assessment. If the disorder is self-treatable, the patient should be asked whether the injury or irritation has occurred previously, how it was treated, and whether the patient has known contraindications to the nonprescription medications used to treat the disorder.

### Patient Counseling for Minor Oral Mucosal Injury or Irritation

Once the problem is determined to be minor irritation or injury of the mouth, the patient should be counseled on (1) the steps in the treatment regimen, (2) the purpose of each agent, and (3) the length of time the products can be used safely. Signs and symptoms that indicate infection should also be explained. (See the box Patient Education for Minor Oral Mucosal Injury or Irritation.)

### Patient Education for Minor Oral Mucosal Injury or Irritation

The objectives of self-treatment of minor oral mucosal injury or irritation are to (1) control discomfort and pain, (2) aid healing with the appropriate use of drug and nondrug measures, and (3) prevent secondary bacterial infection. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

### **Nondrug Measures**

- Rinse with a sodium bicarbonate solution to remove injured tissue and cleanse the affected area. Add 1/2-1 teaspoon of sodium bicarbonate to 4 ounces of water. Swish the solution in the mouth over the affected area for at least 1 minute, then spit out the solution. This can be done up to four times a day.
- Use saline rinses to cleanse and soothe the affected area. Add 1-3 teaspoons of salt to 4-8 ounces of warm tap water. This can be done up to 4 times a day.
- For bruised lips or cheeks, apply ice in 10-minute increments to reduce swelling. Do not apply ice longer than 20 minutes in a given hour.

### **Nonprescription Medications**

- If longer-lasting relief is desired, use the following types of nonprescription medications: debriding and cleansing agents, topical oral anesthetics, topical oral protectants, and systemic analgesics.

#### ***Debriding and Cleansing Agents***

- Use a product containing one of the following ingredients: carbamide peroxide 10%-15%, hydrogen peroxide 1.5%, or perborates.
- Do not use these medications longer than 7 days. Chronic use can cause tissue irritation, decalcification of enamel, and black hairy tongue.
- Do not swallow these medications.
- These products should be used after meals (3-4 times a day), and the patient should avoid eating or drinking for at least 30 minutes after application. Swish the liquid around the mouth for 10-15 minutes (or as long as the patient can; no longer than 15 minutes).

#### ***Topical Oral Anesthetics***

- Use a product containing one of the following medications: benzocaine 5%-20%, benzyl alcohol 0.05%-0.1%, butacaine sulfate 0.05%-0.1%, dyclonine 0.05%-0.1%, hexylresorcinol 0.05%-0.1%, or salicylic alcohol 1%-6%.
- Do not use benzocaine if you have a history of hypersensitivity to other benzocaine-containing products.
- Avoid potentially inflammatory products containing substantial amounts of menthol, phenol, or camphor. These agents may cause tissue irritation and damage or systemic toxicity.
- These products should be used after meals (3-4 times a day), and the patient should avoid eating or drinking for at least 30 minutes after application.

#### ***Topical Oral Protectants***

- Use topical oral protectants or denture adhesives to coat and protect the lesions.
- These products should be used after meals (3-4 times a day), and the patient should avoid eating or drinking for at least 30 minutes after application.

#### ***Systemic Analgesics***

- If desired, take an oral analgesic (e.g., aspirin, NSAID, or acetaminophen) for additional relief of mouth discomfort.
- Do not hold aspirin in the mouth or place it on oral lesions. The acid can cause a chemical burn and tissue damage.

### **When to Seek Medical Attention**

- See a primary care provider if any of the following occur:
  - Symptoms persist after 7 days of treatment.
  - Symptoms worsen during self-treatment.
  - Symptoms of systemic infection such as fever, redness, or swelling develop.

*Source:* References 21, 23, 24, and Camphor and phenol. Clinical Pharmacology, 2012. Tampa, FL: Elsevier/Gold Standard. Accessed at <http://www.clinicalpharmacology.com>, August 14, 2013.

Evaluation of Patient Outcomes for Minor Oral Mucosal Injury or Irritation

Minor injury or irritation should resolve within 7 days of treatment and within 10 days of the initial insult or injury.<sup>26</sup> If the symptoms are resolved, no further treatment is necessary. If symptoms persist or worsen, or swelling, rash, or fever develops, the patient should be evaluated by a primary care provider.

## Herpes Simplex Labialis

Herpes simplex labialis (HSL), also known as cold sores or fever blisters, is a disorder caused by a virus of the family Herpesviridae. Herpes simplex virus 1 (HSV-1) is primarily associated with oral and labial lesions, whereas herpes simplex virus 2 (HSV-2) usually produces genital sores. However, preference of a specific HSV type for an anatomic site is changing, in part because of varying sexual practices.<sup>23</sup> Any of the human herpes viruses (e.g., cytomegalovirus and Epstein-Barr virus), not just HSV-1 and 2, can cause oral lesions. Anyone who comes in contact with the herpes virus can potentially become infected. After the primary infection, HSV can be latent and reactivate at a later date as the more commonly known herpes labialis or “cold sore.”<sup>21</sup>

### Pathophysiology of Herpes Simplex Labialis

HSV is contagious and believed to be transmitted by direct contact. Fluid from herpes vesicles contains live virus and may transmit the virus from patient to patient. Because the virus remains viable on surfaces for several hours, contaminated objects may also be a source of infection. Transmission commonly occurs through kissing or sharing utensils or drinks.<sup>21</sup> HSV enters the host through a break in the skin or intact mucous membranes. Once the virus has infected a host, it remains in a latent state in the trigeminal ganglia. The virus can be reactivated upon exposure to a trigger, such as ultraviolet radiation, stress, fatigue, cold, and windburn. Other possible triggers include fever, injury, menstruation, dental work, infectious diseases, and factors that depress the immune system (e.g., chemotherapy or radiation therapy).<sup>21</sup> Although the virus can go through periods of dormancy and reactivation, the person is infected for life. Upon reactivation, the lesions often arise repeatedly in the same location.

### Clinical Presentation of Herpes Simplex Labialis

HSL is so named because it commonly occurs on the lip or on areas bordering the lips; the usual site is at the junction of mucous membrane and skin of the lips or nose. However, these lesions may also occur intraorally (primarily involving keratinized mucosa such as the hard palate or gingiva). The lesions are recurrent, painful, and cosmetically objectionable. HSL lesions are often preceded by a prodrome in which the patient notices burning, itching, tingling, or numbness in the area of the forthcoming lesion. Other symptoms include pain, fever, bleeding, swollen lymph nodes, and malaise.

The lesion first becomes visible as small, red papules of fluid-containing vesicles 1-3 mm in diameter. Often, many lesions coalesce to form a larger area of involvement. An erythematous, inflamed border around the fluid-filled vesicles may be present. A mature lesion often has a crust over the top of many coalesced, burst vesicles; its base is erythematous (see Color Plates, photograph 11). Pustules or pus present under the crust of a herpes virus lesion may indicate a secondary bacterial infection; prompt evaluation and treatment with an appropriate antibiotic, if indicated, are appropriate. [Table 31-3](#) further describes the clinical presentation of HSL and compares its features with those of RAS.

A related disease, acute (primary) herpetic gingivostomatitis, is seen mainly in children but can occur in adults, especially those who are immunocompromised. Although the oral lesions of this disease can develop anywhere on the oral mucosal surface, they commonly occur on the lips, areas bordering the lips, or the gums. Herpetic gingivostomatitis is distinguished from RAS gingivostomatitis by infected gums that are very red and covered by a pseudomembrane or that are studded with ulcerations. Other symptoms of herpetic gingivostomatitis may include submandibular lymphadenitis, swallowing difficulties, and halitosis. Referral to a health care professional would be warranted if this is suspected.

The appearance of HSL and RAS should be easy to distinguish from oral candidiasis, which develops as part of yeast infections. In the mouth, candidiasis is often referred to as thrush and is characterized by white plaques with a milk curd appearance. These plaques, which are attached to the oral mucosa, can usually be detached easily, displaying erythematous, bleeding, sore areas beneath (see Color Plates, photograph 8).

### Treatment of Herpes Simplex Labialis

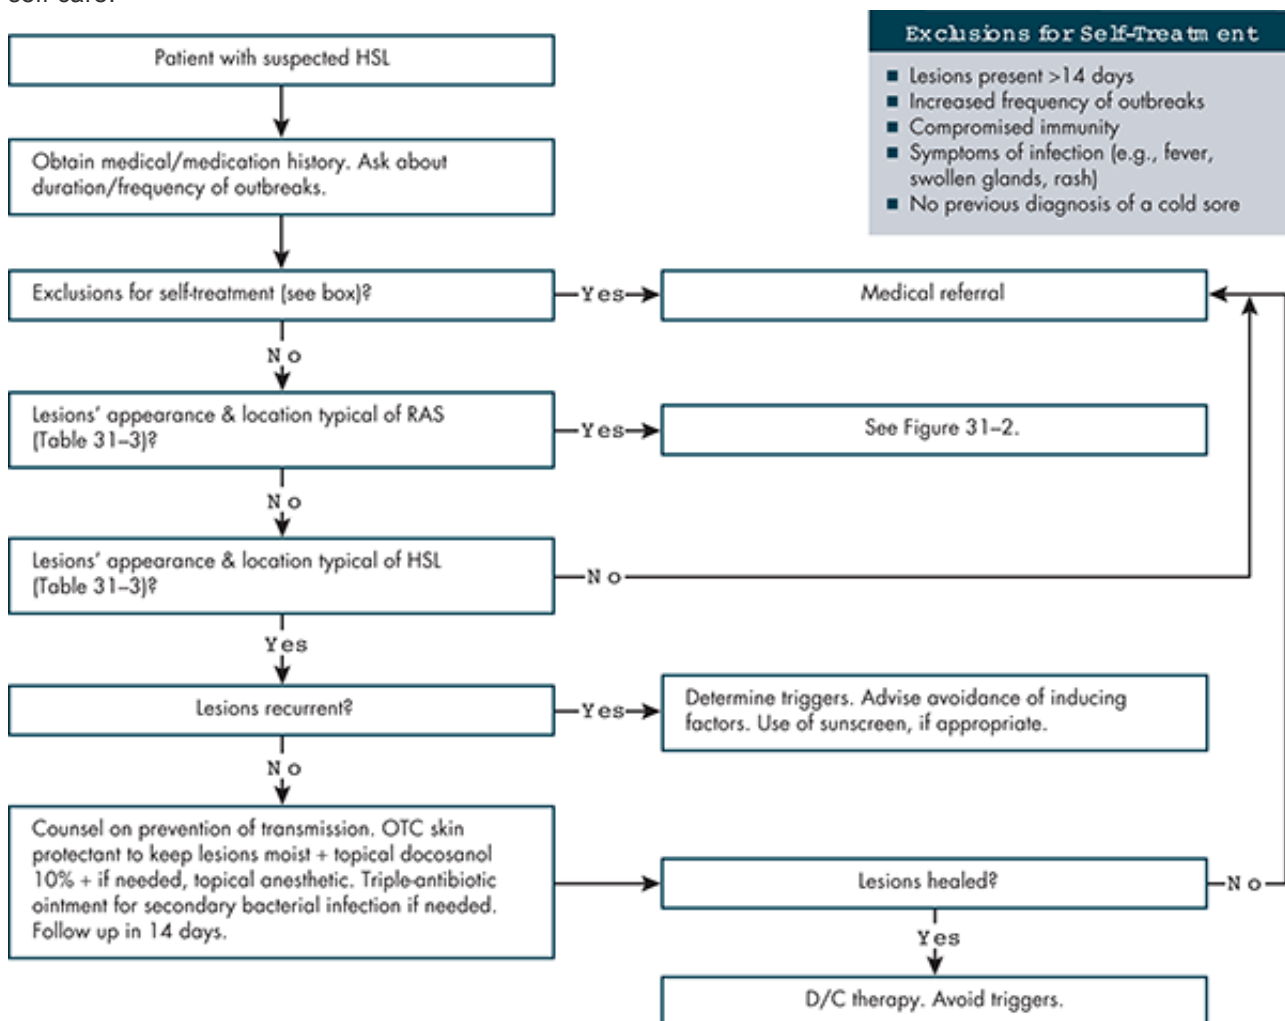

Although the etiologies of HSL and RAS differ, global treatment of these disorders is similar. The patient should be instructed to avoid circumstances that induce more lesions (e.g., stress), keep the lesions free of counterirritants, and keep existing lesions as clean as possible, thereby avoiding secondary infections. [Table 31-4](#) lists common classes of nonprescription medications used to treat RAS and HSL. (*Note:* Of the products listed in [Table 31-4](#), oral debriding and wound-cleansing agents and oral mucosal protectants are not used to treat HSL.)

## Treatment Goals

The objectives of self-treatment of herpes simplex labialis (cold sores) are to (1) relieve pain and irritation while the sores are healing, (2) prevent secondary infection, and (3) prevent spread of the lesions.

## General Treatment Approach

The lesions should be inspected to determine whether their appearance and location are characteristic of HSL. If possible, factors that may have led to development of lesions should be identified; then precipitating or contributing factors should be removed. For example, if trauma is suspected, perhaps a gentler toothbrush and gentler brushing technique could be suggested. It is also helpful to determine whether the patient has a history of HSL. The patient's medical history should be obtained to determine whether an underlying pathology predisposes the patient to recurrent HSL or could complicate treatment. The patient should be asked about previous self-treatments and their effectiveness. If the treatments used are appropriate and have been successful for the patient, they should be continued. Treatment should focus on cleansing the affected area, protecting the lesions from infection, and relieving the discomfort of burning, itching, and pain. [Figure 31-4](#) outlines the self-treatment of HSL and lists exclusions for self-care.<sup>21,22,27,28,29</sup>

Self-care of herpes simplex labialis. Key: D/C = Discontinue; HSL = herpes simplex labialis; OTC = over-the-counter; RAS = recurrent aphthous stomatitis. (Source: References 23, 24, 27-29.)

## Nonpharmacologic Therapy

Lesions should be kept clean by gently washing with mild soap solutions. Handwashing is important in preventing lesion contamination and minimizing autoinoculation of herpes virus. The lesion should be kept moist to prevent drying and fissuring. Cracking of the lesions may render them more susceptible to secondary bacterial infection, may delay healing, and usually increases discomfort. Factors that delay healing (e.g., stress, local trauma, wind, excessive sun exposure, and fatigue) should be avoided. Patients who identify sun exposure as a precipitating event should be advised to routinely use a lip and face sunscreen product. (See [Chapter 38](#) for more detail about sunscreens and sun protection factor [SPF] requirements.)

## Pharmacologic Therapy

Topical skin protectants help to protect the lesions from infection, relieve dryness, and keep the lesions soft. These products should be used after meals (3-4 times a day), and the patient should avoid eating or drinking for at least 30 minutes after application.<sup>22</sup>

Externally applied analgesics/anesthetics, in bland, emollient vehicles, also relieve the discomfort of burning, itching, and pain, but they do not reduce the duration of symptoms. Ingredients that are generally used include benzocaine 5%-20%, dibucaine 0.25%-1%, dyclonine hydrochloride 0.5%-1%, benzyl alcohol 10%-33%, camphor 1%-20%, and menthol 0.1%-1%. Menthol in concentrations greater than 1% can stimulate cutaneous sensory receptors and produce a counterirritant effect and therefore are contraindicated.<sup>30</sup>

Docosanol 10% (Abreva) is the only FDA-approved nonprescription product proven to reduce the duration and severity of symptoms. The agent inhibits direct fusion between the herpes virus and the human cell plasma membrane, thereby preventing viral replication.<sup>28</sup> Docosanol should be applied at the first sign of an outbreak (prodromal stage), 5 times a day until the lesion is healed, but for no more than 10 days. Treatment with docosanol reduces the median time to healing by approximately 1 day (18 hours) compared with placebo. Docosanol-treated patients also note a significant reduction in the duration of symptoms, including pain and/or burning, itching, or tingling, compared with placebo (20% reduction in the median time to complete cessation of these symptoms).<sup>28</sup>

Systemic therapy should always be considered superior to topical therapy. If evidence of secondary bacterial infection (e.g., failure of crusting to occur or persistence of erythematous border) is seen, topical application of a thin layer of triple-antibiotic ointment 3-4 times daily is recommended. (See [Chapter 40](#) for more information about these agents.) Systemic nonprescription analgesics may provide additional pain relief.

Studies suggest that patients suffering from sideropenia, a condition resulting from a deficiency of iron in the body, and who have recurrent HSL may experience fewer episodes following treatment with iron replacement therapy.<sup>26</sup> HSL is not considered a steroid-responsive dermatosis; therefore, the use of topical steroids is contraindicated. Products that are highly astringent should also be avoided. Tannic acid and zinc sulfate should be avoided because their frequent application to the lip and oral cavity could cause oral mucosal absorption and toxicity.<sup>31,32</sup>

## Complementary Therapies

The essential oil of *Melaleuca alternifolia*, or tea tree oil, has activity against HSV in vitro. Studies have shown that, compared with placebo, the healing time is reduced with use of tea tree oil and is similar to that of topical acyclovir 5%.<sup>33</sup> Lysine has preventive effects and has been shown to decrease the frequency of outbreaks when taken daily.<sup>27,34</sup> Extract of the leaves of *Melissa officinalis*, or lemon balm, have also been used in patients with HSL. Studies comparing lemon balm with placebo have shown a reduction in symptoms, shortened healing time, prevention of infection spread, and patient preference for lemon balm.<sup>34</sup>

## Assessment of Herpes Simplex Labialis: A Case-Based Approach

Although many of the same nonprescription medications are indicated for RAS and HSL, the disorders still need to be differentiated. Because herpes simplex lesions are contagious, additional measures are necessary to prevent transmission of the virus. The patient's medical history should be obtained to determine whether an underlying pathology predisposes the patient to recurrent HSL or could complicate treatment.

Case 31-2 provides an example of the assessment of a patient with HSL.

## Patient Counseling for Herpes Simplex Labialis

Patient counseling should stress that HSL lesions are contagious and should explain appropriate measures to prevent transmission of the virus, as outlined in the box Patient Education for Herpes Simplex Labialis. Patients should be advised that the disorder is self-limiting, and that pharmacologic therapy can keep the lesions moist and supple, decrease the itching and pain, protect the lesions from secondary bacterial infection, and help reduce the duration of active infection. The action of each recommended product, its proper use, and possible adverse effects should also be explained.

### Patient Education for Herpes Simplex Labialis

The objectives of self-treatment of herpes simplex labialis (cold sores) are to (1) relieve pain and irritation while the sores are healing, (2) prevent secondary infection, and (3) prevent spread of the lesions. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

### **Nondrug Measures**

- Keep labial or extraoral lesions clean by gently washing them with mild soap solutions.
- Wash hands frequently to prevent contaminating the lesions and to avoid spreading the virus.
- Avoid factors believed to delay healing such as stress, injury to the lesions, wind, excessive sun exposure,

and fatigue.

- If outbreaks are related to sun exposure, use a lip and face sunscreen, with appropriate SPF protection, routinely. Refer to [Chapter 38](#), Sun-Induced Skin Disorders, for further discussion related to SPF.

### Nonprescription Medications

- Use topical anesthetics such as benzocaine or dibucaine to relieve burning, itching, and pain. Do not use benzocaine if you have a history of hypersensitivity to other benzocaine-containing products.
- If using products containing camphor and menthol, make sure the concentration of camphor does not exceed 3% and the concentration of menthol does not exceed 1%.
- Do not apply hydrocortisone to the lesions.
- If evidence of secondary bacterial infection is seen, apply a thin layer of triple-antibiotic ointment 3-4 times daily.
- Apply topical agent docosanol 10% (Abreva) to limit the burning, tingling, and itching sensations. Docosanol 10% can also speed up the healing process, thus reducing the duration of the symptoms.
- If desired, take an oral nonprescription analgesic (e.g., aspirin, NSAID, or acetaminophen) for additional pain relief.
- Do not hold aspirin in the mouth or place it on oral lesions. The acid can cause a chemical burn and tissue damage.
- These products should be used after meals (3-4 times a day), and the patient should avoid eating or drinking for at least 30 minutes after application.

### When to Seek Medical Attention

See a primary care provider if any of the following occurs:

- The lesions do not heal in 14 days.
- The self-treatment measures do not relieve discomfort.
- Symptoms of systemic illness such as fever, malaise, rash, or swollen lymph glands occur.
- Symptoms change or worsen.

Source: References 21, 23, 27, 29, and 34.

### Evaluation of Patient Outcomes for Herpes Simplex Labialis

In immunocompetent patients, HSL is typically mild and self-limiting, resolving within 10-14 days.<sup>21,22,28</sup> If the symptoms have resolved, no further treatment is necessary. However, if the condition worsens (pain and itching persist, redness increases, or signs of secondary infection are apparent), the patient should see his or her primary care provider.

### Case 31-2

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient is complaining of a burning, itching, tingling feeling on the top of his lip, which he has had for almost 3 weeks. He reports that he has had about 6 cold sores over the past 4 months.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient reports that he is under a lot of stress as he has been studying for his law school admission tests for the past 4 months.
c. description of the patient's efforts to relieve the symptoms	He has tried to put ice on it to relieve the burning and itching, which works until the ice melts. He has also used Carmex and Blistex, which did help with the pain

	and discomfort.
d. patient's identity	William Thanyou
e. age, sex, height, and weight	22 years old, male, 6 ft 1 in., 180 lb
f. patient's occupation	Student
g. patient's dietary habits	Eats a lot of fast food, pasta, and pizza.
h. patient's sleep habits	Roughly 6 hours nightly
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Seasonal allergies for which he takes loratadine. Exercise-induced asthma for which he uses albuterol before exertion.
j. allergies	NKDA
k. history of other adverse reactions to medications	None
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s) (Table 31-3).	Patient's signs and symptoms seem to be consistent with recurrent HSL or "cold sore." He seems to be in the prodrome stage, in which a lesion has yet to appear.
3. Identify exclusions for self-treatment (Figure 31-4).	Increased frequency of breakouts, and lesions present for >14 days.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer William to an appropriate health care provider. (2) Recommend an OTC product to treat the HSL outbreak. (3) Recommend self-care until William can see an appropriate provider. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	William is not a self-care candidate because he meets two exclusion criteria.
6. Describe the recommended therapeutic approach to the patient or caregiver.	William should consult an appropriate health care provider for treatment.
7. Explain to the patient or caregiver the rationale for	"Seeing a health care provider is best because you

selecting the recommended therapeutic approach from the considered therapeutic alternatives.	have had these symptoms for 3 weeks and you have had frequent episodes over the past 4 months.”
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	“Is there something I can use to help with the pain and discomfort until I can see my physician tomorrow?”
Answer the patient’s or caregiver’s questions.	“Any product containing benzocaine 20% would provide acute relief (Table 31-4).”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact the patient in a day or two to ensure that he made an appointment and sought medical care.

Key: HSL = Herpes simplex labialis; NA = not applicable; NKDA = no known drug allergies.

## Xerostomia

Xerostomia, commonly referred to as dry mouth, is a syndrome in which salivary flow is limited or completely arrested. A person with normal salivary flow reportedly produces up to 1.5 liters of saliva every 24 hours. Between 10%-50% of the population is said to be afflicted with persistent dry mouth.<sup>35</sup>

### Pathophysiology of Xerostomia

Patients with certain disease states, including Sjögren syndrome (an autoimmune condition in which the salivary glands become partly or completely dysfunctional and patients typically present with dry mouth and/or dry eyes), diabetes mellitus, depression, and Crohn’s disease, are prone to xerostomia. Radiation therapy of the head and neck can cause atrophy of the salivary glands. After this treatment, the vast majority of patients have compromised salivary function for the rest of their lives. Medications that have anticholinergic activity or cause depletion of salivary flow volume (e.g., antihistamines, decongestants, antihypertensives, diuretics, antidepressants, antipsychotics, and sedatives) can cause xerostomia.<sup>36</sup> Older patients who are more likely to be taking multiple medications for chronic diseases may be more greatly affected. However, if xerostomia is drug induced and the medication can be discontinued, the condition may be reversed in some cases.<sup>37</sup> Nonpharmacologic causes of xerostomia include use of alcohol, tobacco, caffeine, or hot spicy food; salivary gland stones (sialolithiasis); and mouth breathing.

### Clinical Presentation of Xerostomia

Xerostomia can result in difficulty talking and swallowing, stomatitis, burning tongue, and halitosis. Unmoistened food cannot be tasted; therefore, xerostomia can cause loss of appetite and eventual decline in nutritional status.<sup>35,36</sup> Patients’ teeth can become hypersensitive, which can be related to a decrease in salivary flow and the lack of buffering capacity that saliva provides.<sup>36</sup> Xerostomia can also result in a higher-than-normal incidence of cervical caries (decay around the root surfaces of teeth) despite excellent oral hygiene. This result can occur because saliva is responsible for washing away food and debris from the teeth, and if saliva is absent and cannot do this, tooth decay can result.<sup>36</sup> Depending on the status of a patient’s dentition, this disorder can increase the incidence of caries, gingivitis, and more severe periodontal disease, or reduce denture-wearing time. Furthermore, reduced flow of saliva can disturb the balance of microflora in the oral cavity and predispose it to candidiasis.

### Treatment of Xerostomia

Dry mouth should never be discounted as inconsequential. Failure to treat it can result in serious complications for some patients.

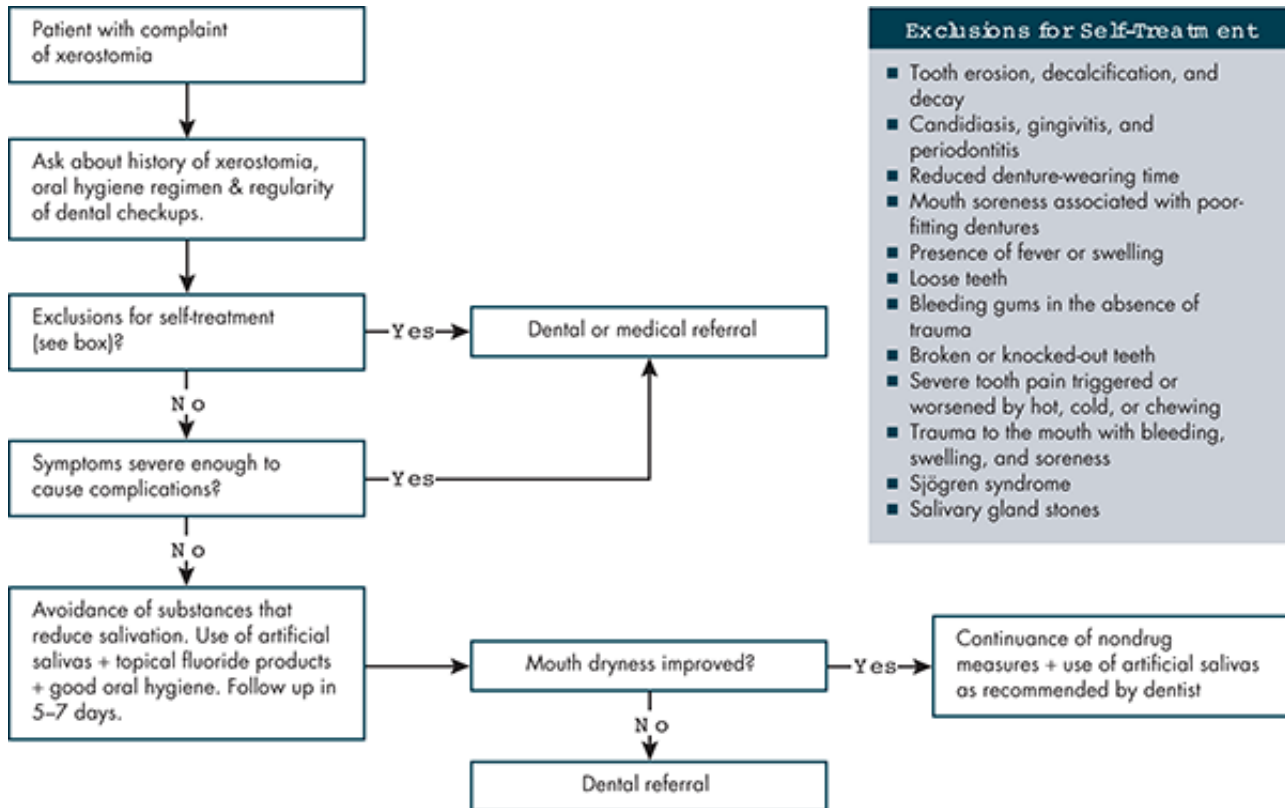

## Treatment Goals

The objectives of self-treatment of xerostomia (dry mouth) are to (1) relieve the discomfort of dry mouth, (2) reduce the risk of dental decay, and (3) prevent and treat infections and periodontal disease.

## General Treatment Approach

The patient should stop using substances that dry the mouth or erode tooth enamel. If possible, medications that are known to cause xerostomia should be discontinued. To reduce the risk of caries, the patient must maintain good oral hygiene. In mild cases, using sugarless sweets and chewing gums or sucking on ice chips can help to stimulate residual salivary flow.

Commercial artificial saliva products can be used as needed to relieve soft-tissue discomfort. [Figure 31-5](#) outlines the self-treatment of xerostomia and lists exclusions for self-care.<sup>35,36,37,38</sup>

Self-care of xerostomia. (Source: References 35-38.)

## Nonpharmacologic Therapy

The patient should avoid substances that reduce salivation, including tobacco (smoked and smokeless), caffeine, hot spicy foods, and alcohol (including mouth rinses). Medication schedules should be modified in consultation with the treating health care provider to coincide with periods of natural stimulation. For example, patients could take medications that cause dry mouth 1 hour prior to meals, because eating naturally stimulates an increase in salivary flow. Consequently, the duration of dry mouth would be reduced.

To prevent tooth decay, the xerostomic patient should limit intake of sugary (e.g., candy), starchy (e.g., cookies, potato chips), and acidic foods (e.g., orange juice) that may have been tolerated before but now pose significant danger to the patient's oral health.<sup>38</sup> Sugar promotes the bacterial production of acid, which causes tooth decay. Acidic foods may also decrease the pH of saliva, resulting in caries and tooth erosion. Chewing gum sweetened with sugar alcohols (e.g., xylitol), however, may be beneficial. Chewing gum increases salivary flow, and xylitol has not been shown to be cariogenic.<sup>35,36</sup> Increasing water intake, especially if it is fluoridated, would also benefit the patient.

Using a humidifier at home can help to add moisture in the air, which may provide some level of relief.<sup>38</sup> Finally, the use of very soft-bristle toothbrushes will help prevent decay by minimizing tissue abrasion.

## Pharmacologic Therapy

Artificial saliva products are the primary agents for relieving the discomfort of dry mouth. They are designed to mimic natural saliva both chemically and physically. However, they do not contain the many naturally occurring protective

components that are present in innate saliva. Because these products do not stimulate natural salivary gland production, they must be considered replacement therapy, not a cure for xerostomia. However, such products can be used on an as-needed basis in patients with little or no saliva flow. Table 31-5 lists selected nonprescription saliva substitutes and other xerostomia products.

**TABLE 31-5 Selected Nonprescription Saliva Substitutes and Other Xerostomia Products**

<i>Trade Name</i>	<i>Primary Ingredients</i>
Biotene Oral Balance Gel/Liquid Biotene Moisturizing Mouth Spray	Glucose oxidase 10,000 units; lactoferrin 16 mg; Lactoperoxidase 15,000 units; lysozyme 16 mg; sodium monofluorophosphate 0.14% (w/v fluoride ion)
Entertainer's Secret Spray	Sodium carboxymethylcellulose; dibasic sodium phosphate; potassium chloride; parabens; aloe vera gel; glycerin
Biotene Dry Mouth Gum	Sorbitol; gum base; xylitol; maltitol syrup
Biotene Dry Mouth Toothpaste	Sodium monofluorophosphate 0.14%

Key: w/v = Weight per volume.

#### Product Selection Guidelines

The majority of artificial saliva products are available as sprays and gels; however, gums and toothpastes are also available. Proper use of a gel involves placing approximately a 1/2-inch length of gel onto the tongue and spreading it thoroughly in the mouth. These products can be used at any time; a minimum suggested use is after meals and before going to bed. Products that contain preservatives, such as methyl- or propylparaben, may cause hypersensitivity reactions in certain patients. Patients on low-sodium diets should avoid artificial salivas that contain sodium.

#### Assessment of Xerostomia: A Case-Based Approach

The patient should be asked about his or her history of xerostomia, oral hygiene practices, and regularity of dental visits. The patient's symptoms should be evaluated to determine whether the symptoms have progressed to the point that complications are likely. A review of the patient's medical and medication history can identify medical conditions and/or medications known to reduce salivation. Furthermore, the reviewer should determine whether lifestyle or other practices could be contributing to the condition. Asking the patient whether he or she has concurrent dry eyes or joint symptoms will assess the risk for Sjögren's syndrome. Similarly, the patient should be questioned as to whether any salivary gland pain or swelling occurs with meals to assess the risk for salivary gland stones.

#### Patient Counseling for Xerostomia

It is generally necessary for xerostomic patients to have professional dental management of their condition in addition to the self-care methods discussed previously and outlined in the box Patient Education for Xerostomia. Patients should be encouraged to practice good oral hygiene measures and to see their dentist regularly. In addition, patients should be given appropriate information about nonpharmacologic and pharmacologic measures they can use to keep the oral cavity moist and to treat dry mouth to minimize their increased risk for tooth decay associated with xerostomia. Finally, patients must be alerted to signs and symptoms that indicate complications from dry mouth. Patient Education for Xerostomia

The objectives of self-treatment of xerostomia (dry mouth) are to (1) relieve the discomfort of dry mouth, (2) reduce the risk of dental decay, and (3) prevent and treat infections and periodontal disease. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### **Nondrug Measures**

- To prevent reduced levels of saliva, avoid use of cigarettes and smokeless tobacco.
- Do not drink or use products that contain alcohol (including mouth rinses) or medications that cause depletion of salivary flow.
- Avoid food or drinks that contain caffeine.
- Avoid hot spicy foods.

- To prevent tooth decay, limit consumption of sugary (e.g., candy), starchy (e.g., cookies, potato chips), and acidic foods (e.g., orange juice). Do not suck on hard candy or lozenges sweetened with sugar.
- If desired, chew gum sweetened with sugar alcohols, such as xylitol, to help increase flow of saliva.
- If possible, take medications 1 hour before meals so that the natural saliva flow caused by food can counteract any mouth dryness.
- To help prevent tooth decay, use a very soft toothbrush to reduce abrasion of the teeth.
- Drink water.
- Use a humidifier at home to help “moisten” the air.

### Nonprescription Medications

- Use artificial saliva products that contain fluoride to relieve the discomfort of dry mouth and prevent tooth decay.
- If you are on a low-sodium diet, avoid artificial salivas that contain sodium.
- Brush and floss your teeth at least twice daily using a regular toothpaste with fluoride, and see your dentist regularly.

### When to Seek Medical Attention

- If your symptoms do not improve or if they worsen, see a dentist.

### Evaluation of Patient Outcomes for Xerostomia

The patient with xerostomia should return for evaluation after 5-7 days of self-treatment. If the mouth dryness is improved, the patient should continue using artificial saliva and fluoride products as recommended by a health care provider. The patient should also be advised to continue the nonpharmacologic measures. If the dryness becomes worse or symptoms of complications develop, the patient should return to a dental health care provider for further evaluation.

### Key Points for Oral Pain and Discomfort

- Tooth hypersensitivity and teething are not serious and are self-treatable problems.
- Self-treatment of toothache should be limited to the temporary relief of pain, because professional treatment is required for complete resolution of pain.
- RAS is amenable to self-treatment of the relief of pain and irritation so the lesions can heal, thereby allowing the patient to eat, drink, and perform routine oral hygiene while preventing further complications.
- Minor oral mucosal injury or irritation may be self-treated by controlling discomfort and pain, by using drug and nondrug measures appropriately to aid healing, and by preventing secondary bacterial infection.
- The goals of self-treatment of HSL (cold sores) are to relieve pain and irritation while the sores are healing, prevent secondary infection, and prevent spread of the lesions to other areas of the body and other individuals.
- Self-treatment of xerostomia (dry mouth) can relieve discomfort from dry mouth, thereby reducing the risk of dental decay as well as preventing and, at times, treating infections.
- If conditions worsen or persist after self-treatment and nondrug measures, medical referral for further treatment is imperative.

**Handbook of Nonprescription Drugs** > Chapter 32. Atopic Dermatitis and Dry Skin**Atopic Dermatitis and Dry Skin: Introduction**

An estimated 5% of the U.S. population suffers from a chronic skin, hair, or nail disorder, and many other Americans experience acute or seasonal disorders.<sup>1</sup> In the United States alone, millions are estimated to suffer from some type of eczematous condition, with atopic dermatitis (AD) specifically reported as a worldwide problem. Furthermore, most patients with this condition are believed either to be undertreated or to use primarily nonprescription medications.<sup>2</sup> Therefore, it is essential for health care providers to be able to recognize and differentiate common skin disorders, suggest appropriate treatment, and know when to refer patients to a primary care provider or dermatologist.

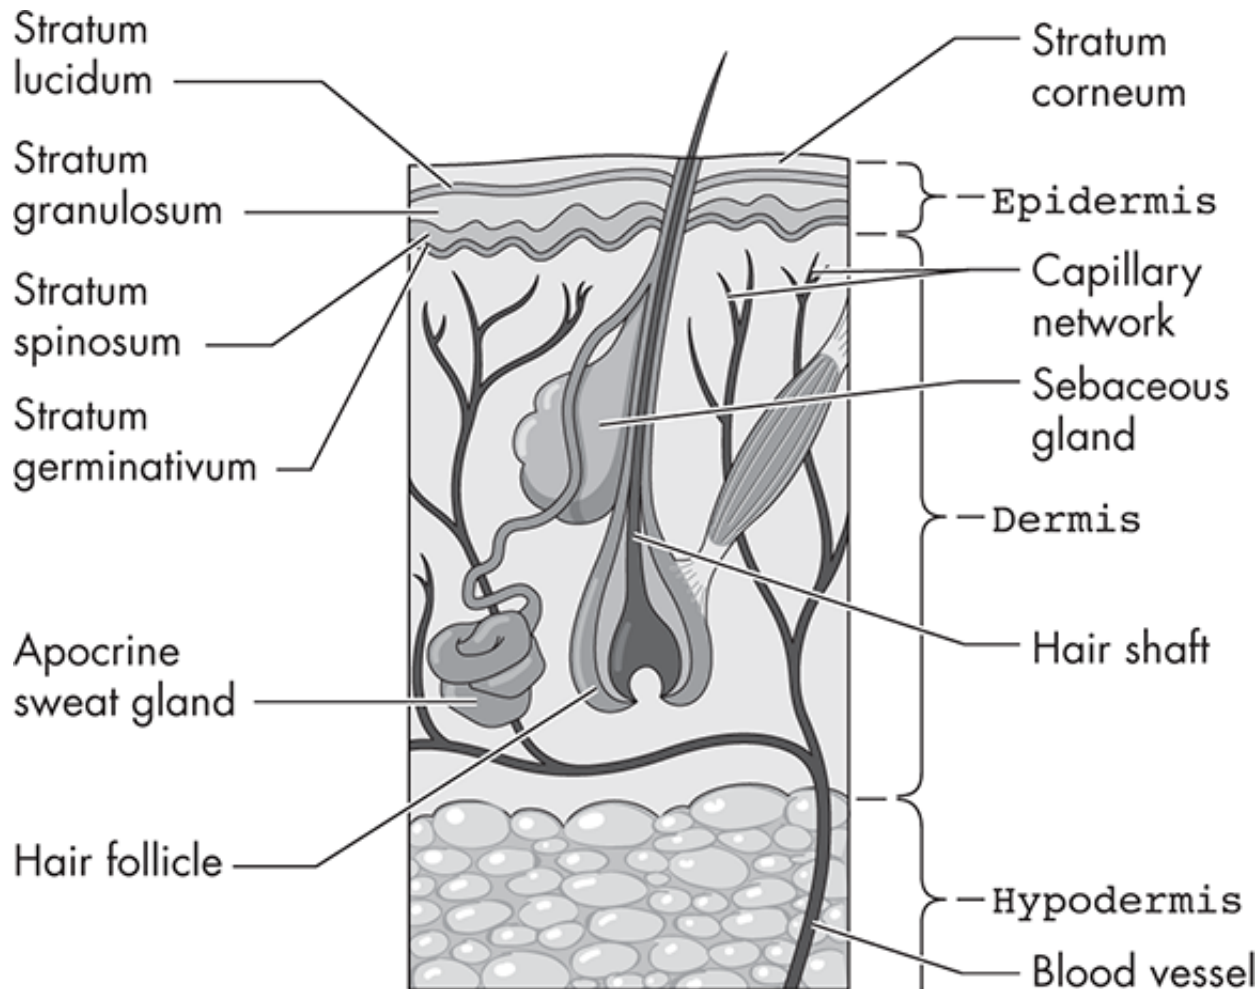

*Dermatitis* is a nonspecific term describing numerous dermatologic disorders that are generally characterized by erythema and inflammation. The terms *eczema* and *dermatitis* are used interchangeably to describe a group of inflammatory skin disorders of unknown etiology. AD (or atopic eczema) is a form of eczema, which is a general term meaning “to boil over” in Greek; it describes inflammatory skin conditions that are typically erythematous, edematous, papular, and crusty.<sup>3</sup> Many types of eczema exist, including allergic or irritant contact dermatitis, AD, drug-related eczematous dermatitis, eczematous insect bite reaction, and photoeczematous eruption.<sup>4</sup> Dry skin is a common complaint in many dermatoses, particularly AD. This chapter focuses on AD and dry skin. Although dry skin is often not severe, it may be associated with decreased quality of life for patients with mild-moderate dryness because of the accompanying pruritus and, in some cases, infection, pain, and inflammation that may occur. Many patients are affected by dry skin, and its incidence increases with age.<sup>5</sup>

*Editor's Note:* This chapter is based on the 17th edition chapter of the same title, written by Steven A. Scott.

**Role of Skin in Drug Absorption**

The skin is involved in numerous physical and biochemical processes. Skin thickness is variable but averages about 1-2 mm. The thickest skin is on the palms and soles, and the thinnest skin is on the genitalia. Thinner skin areas are more permeable, allowing substances to be absorbed more easily than through thicker skin. Although skin is exposed to a variety of chemical and environmental insults, it demonstrates remarkable resiliency and recuperative ability.<sup>6</sup>

Human skin has three functionally distinct regions: epidermis, dermis, and hypodermis (Figure 32-1). The epidermis, the outermost thin layer of the skin, regulates the water content of the skin and controls drug transport into the lower layers and systemic circulation. The middle layer, the dermis, is 40 times thicker than the epidermis and contains nerve endings, vasculature, and hair follicles. The hypodermis primarily provides nourishment and cushioning for the upper two layers.

Cross section of human skin.

The most important function of skin and its appendages (hair and nails) is to protect the body from external harmful agents such as pathogenic organisms and chemicals. The skin's ability to do this depends on age, immunologic status, underlying disease states of the individual, medications, and preservation of an intact stratum corneum. Skin is also important in hydroregulation, controlling moisture loss from the body and moisture penetration into the body. If the stratum corneum becomes dehydrated, it loses elasticity and its permeation characteristics are altered. As individuals age, their skin becomes more fragile, requiring a longer recovery time after injury.<sup>5,7</sup>

A drug applied topically must be released from its vehicle if it is to exert an effect at the desired site of activity (skin surface, epidermis, or dermis). Release occurs at the area of contact between the skin surface and the applied layer of product. The physical-chemical relationship between the drug and the vehicle determines the rate and amount of drug released. Considerations such as the drug's solubility in the vehicle, its diffusion coefficient in the vehicle, and its partition coefficient into the sebum and stratum corneum are significant to its efficacy.<sup>8</sup> The major mechanism of drug absorption is passive diffusion through the stratum corneum, followed by transport through the deeper epidermal regions and then the dermis. Drug movement into and through the skin is enhanced or inhibited to varying degrees depending on the physical-chemical properties of a drug, the sebum, and the location of the skin. The stratum corneum provides the greatest resistance and is often a rate-limiting barrier to percutaneous absorption. The hydration status of the stratum corneum can affect drug diffusion. Occlusion increases hydration of the stratum corneum, which enhances the transfer of most drugs.<sup>8</sup> Wounds, burns, chafed areas, and dermatitis can alter the integrity of the stratum corneum and can result in artificial shunts of the percutaneous absorption process. Inflammation can also enhance percutaneous absorption of topically applied medications, which may result in higher systemic drug levels. Therefore, caution should be used in applying topical medication to compromised skin, particularly if large surface areas are involved.

Topical medications are used to treat many common skin disorders in infants and children. Treatment of any unknown skin disorder in infants younger than 1 year should be initiated only after seeking the advice of a primary care provider. Infants have a reduced capability to biotransform drugs absorbed by the cutaneous route because they have immature hepatic enzyme systems. In addition, because the ratio of surface area to body weight in a neonate is approximately two to three times that of an adult, the proportion of drug absorbed per kilogram of body weight is

greater in a newborn.<sup>9</sup>

## Atopic Dermatitis

AD is a common, pervasive inflammatory condition of the epidermis and dermis that is characterized by episodic flares and periods of remission. AD is estimated to affect from 10% to 20% of children and many of these individuals have symptoms into adulthood.<sup>10,11</sup> Sixty percent of patients are diagnosed within the first year of life while another 30% manifests before the age of 5 years.<sup>12,13</sup> In adults the prevalence is estimated at 1%-3% with the overall lifetime prevalence reported at 7%.<sup>10</sup> Prevalence worldwide is increasing, possibly because of air pollution, industrialization, urbanization, dietary modifications, and higher socioeconomic class.<sup>11,14</sup> The atopic triad is asthma, allergic rhinitis, and atopic dermatitis. Asthma and allergic rhinitis can occur in up to 80% of patients with AD, either in childhood or as individuals age.<sup>15</sup> This phenomenon has been referred to as the “atopic march.”<sup>12</sup> Eighty percent of AD is classified as mild and can be safely treated with nonprescription products.<sup>16</sup> In addition, many patients with AD do not seek medical care and therefore are likely to look for advice regarding self-care of this disorder.<sup>17</sup>

## Pathophysiology of Atopic Dermatitis

AD has a genetic basis, but its expression is modified by a broad spectrum of exogenous manifestations.<sup>17</sup> Atopic skin is inflamed with an expression of cytokines and chemokines; inflammatory cytokines such as interleukin-4 and 13 and tumor necrosis factor are produced.<sup>11,12</sup> A protein in the epidermal differentiation complex, filaggrin (FLG), is related to the development of AD. Even one mutation in FLG increases one’s risk of AD, and 35 mutations are known to exist in the FLG gene.<sup>3</sup> The filaggrin mutation can lead to the deficient skin barrier characteristic of AD.<sup>18</sup> This mutation leads to irritation in atopic skin caused by increased penetration of allergens, a decrease in skin barrier proteins, higher peptidase activity, and lack of protease inhibitors.<sup>19</sup> In addition, because of a decreased concentration of lipid and ceramides, atopic skin has a decreased ability to retain moisture.<sup>20</sup> Seventy percent of AD cases have an atopic family history; if one parent is atopic, the rate of similar symptoms in their children is approximately 50%, whereas if both parents are atopic, this risk rises to 79%.<sup>3</sup>

AD is diagnosed according to clinical criteria (Table 32-1).<sup>21,22</sup> No established confirmatory laboratory tests exist, although many patients have shown an elevated immunoglobulin (Ig) E level and peripheral blood eosinophilia. This elevated IgE level typically does not appear early on, and in some children may never occur.<sup>23</sup> The SCORAD (SCORing Atopic Dermatitis) Index was developed to create a consensus on assessment methods for AD and measures the severity of the AD. The index grades or rates the following items: erythema, edema, papulation (formation of papules), excoriations (abrasion of the epidermis by trauma), lichenification (increased epidermal markings), oozing/crusting, and dryness. The index also uses a visual analogue scale to rate daily pruritus and sleepiness. A SCORAD index of less than 25 is considered mild, 25-50 moderate, and greater than 50 severe.<sup>24</sup>

**TABLE 32-1 Diagnostic Criteria for Atopic Dermatitis**

A pruritic skin disorder, plus three or more of the following criteria:

- Onset at younger than 2 years
- History of skin crease involvement (including cheeks in children younger than 10 years)
- History of generally dry skin
- Personal history of other atopic disease, that is, asthma (or history of any atopic disease in first-degree relative in children younger than 4 years)
- Visible flexural dermatitis (or dermatitis of cheeks/forehead and other outer limbs in children younger than 4 years)

Source: References 21 and 22.

## Clinical Presentation of Atopic Dermatitis

Although AD is often first manifested in infancy, it is rarely present at birth. If it does develop early in life, it typically occurs within the first year, often beginning at 2-3 months of age. Infantile or childhood AD initially appears as erythema and scaling of the infant’s cheeks, which may progress to affect the face, neck, forehead, and extremities (see Color Plates, photographs 12A, B, and C). Crusts and pustules can form from the effects of scratching and rubbing. Remission usually occurs by the end of the second year with xerosis (dry skin) often continuing into adulthood.<sup>25</sup> In older patients, AD presents quite differently when compared with children and may be less severe.<sup>11,25</sup> Plaques appear erythematous, scaly, exudative, or lichenified. Areas affected include antecubital and

popliteal fossae, neck, forehead, eyes and hands.<sup>25</sup> The cause in adults is often environmental, attributed to chemicals or skin trauma.<sup>19</sup> Pruritus, the hallmark symptom of AD, causes morbidity and is sometimes referred to as the “itch that rashes.” Patients with AD react more readily and more persistently to pruritic-inducing stimuli. Scratching and lichenification can produce a vicious cycle and lead to excoriation.<sup>3,19</sup> It is important to note that patients can present atypically, and any undiagnosed skin lesions that do not improve over time or that get worse with self-treatment should be evaluated by a physician.

AD has three clinical forms. Acute AD, characterized by intensely pruritic, erythematous papules or vesicles over erythematous skin, is often associated with excoriation and serous exudate. Subacute AD is characterized by erythematous, excoriated papules and plaques that can be scaly. Chronic AD is characterized by thickened plaques of skin and accentuated skin markings.<sup>26</sup> In chronic AD, all three stages of skin reactions frequently coexist in the patient.

Secondary or associated cutaneous infections, especially bacterial, can be common, difficult to prevent, and typically aggravate AD. More than 90% of the skin lesions in patients with AD (in contrast to 5% of unaffected individuals) harbor *Staphylococcus aureus* (*S. aureus*).<sup>12,17</sup> Although *S. aureus* is the most common cause of infection, streptococci may also be found alone or in association with *S. aureus*. Infections present as yellowish crusting of the eczematous lesions.

Patients with AD may also develop infections with viruses, such as herpes simplex or *Molluscum contagiosum*.<sup>12,26</sup> Although true infection of the skin is more common in children with AD, colonization is higher in adult patients.<sup>11</sup> Patients should be counseled to seek medical attention promptly when signs of bacterial or viral skin infection, such as pustules (circumscribed, elevated lesions, 1 cm in diameter containing pus), vesicles (especially exudate or pus-filled), and crusting (dried exudate), are noticed.<sup>17</sup>

## Treatment of Atopic Dermatitis

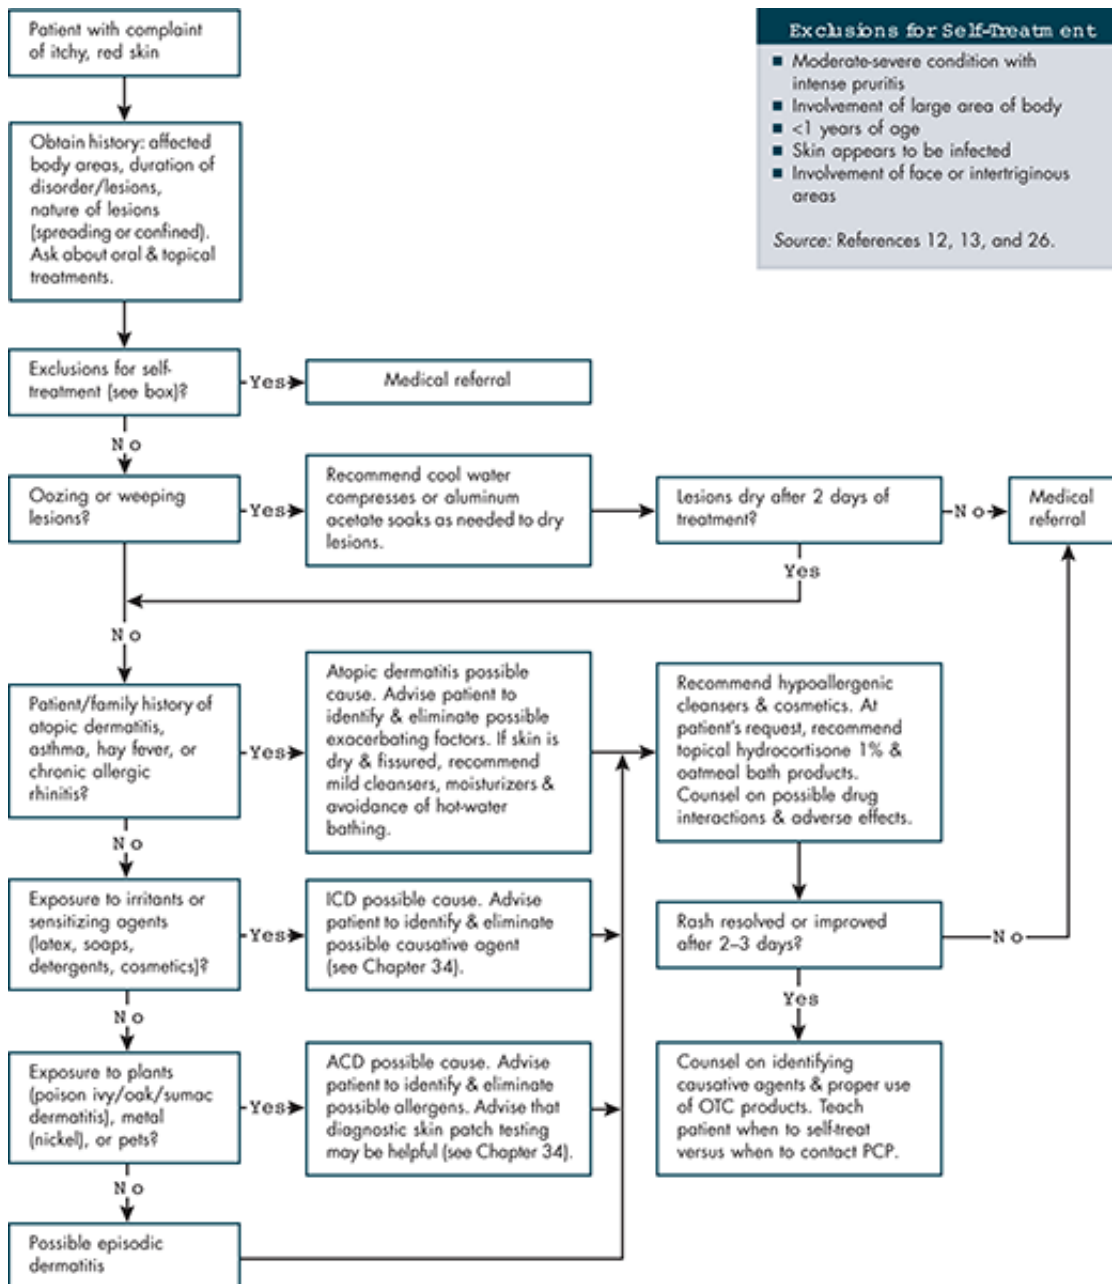

### Treatment Goals

The goals of self-treatment of AD are to (1) stop the itch-scratch cycle, (2) maintain skin hydration, (3) avoid or minimize factors that trigger or aggravate the disorder, and (4) prevent secondary infections.

### General Treatment Approach

To prevent unrealistic expectations, health care providers should stress to patients that AD cannot be cured but that most patients' symptoms can be managed satisfactorily. The disorder should be explained as being multifactorial, and just as there is no cure, there is no single cause. Often no explanation can be found for a particular flare-up of the disorder, and many factors can contribute simultaneously.

Enhancing hydration in atopic skin can be achieved through nonpharmacologic measures and through the use of emollients and moisturizers. Hydrocortisone relieves itching and inflammation, and cool water compresses relieve weeping vesicles. An effective preventive measure is to minimize exposure to factors known to trigger AD. The algorithm in [Figure 32-2](#) outlines the self-treatment of this disorder and lists exclusions for self-treatment.<sup>12,13,26</sup>

Self-care of dermatitis. Key: ACD = Allergic contact dermatitis; ICD = irritant contact dermatitis; OTC = over-the-counter; PCP = primary care provider.

### Nonpharmacologic Therapy

The variability in severity and age of onset requires tailoring treatment to a patient's needs and preferences, bearing in mind the patient's age, gender, and social conditions, along with the site(s) and severity of the lesions. Successful treatment of AD includes (1) skin hydration; (2) the identification and elimination of triggers; and (3) the use of topical therapy and possibly systemic therapy for refractory cases.

Education on trigger avoidance and hydration of the skin are of utmost importance in the prevention as well as treatment of AD. Common triggers that patients should avoid are listed in [Table 32-2](#).<sup>12,18,27</sup> Compared with nonaffected individuals, skin in a patient with AD may be more susceptible to irritants. Therefore, additional preventive measures and lifestyle changes can be made in patients with AD. One suggestion is to use cotton sheets washed in gentle detergents with a second rinse cycle. Laundering and thoroughly rinsing new clothing with unscented laundry detergent is recommended, as is avoiding fabric softeners. If used, liquid fabric softeners are preferred over dryer sheets. Bathing can be helpful in AD sufferers; bathing can hydrate the stratum corneum, remove allergens and irritants, cleanse and debride crusts, and enhance the effects of moisturizers and topical steroids.<sup>13,28</sup> However, baths should be kept to a minimum (3-5 minutes and every other day), and bath water should be tepid; putting colloidal oatmeal in the water can be considered. Common bar soaps are often too drying and irritating for some AD patients.<sup>29</sup> Because of this, mild nonsoap cleansers (e.g., Cetaphil) are often recommended. After bathing,

skin should be patted dry or air dried, followed by application of moisturizers to help to seal in the water. Patients should be reminded to use sunscreens outside; however, zinc and titanium should be avoided as they can aggravate some lesions.

**TABLE 32-2 Triggers Associated with Atopic Dermatitis**

Food allergens (e.g., egg, milk, peanut, soy, wheat, nuts)
Aeroallergens (e.g., dust mites, cat dander, molds, grass, ragweed, pollen)
Stress
Air pollutants (tobacco smoke or traffic exhaust)
Cosmetics/fragrances/astringents
Exposure to temperature extremes (heat/cold)
Electric blankets
Excessive hand or skin washing
Use of irritating soaps, detergents, and scrubs
Tight-fitting or irritating clothes (wool or synthetics)
Dyes and preservatives

*Source:* References 12, 18, and 27.

Although allergens such as plant or animal proteins from food, pollens, or pets can aggravate AD, the role of food allergies in exacerbating AD is unclear. In about one-third of children, food allergies may exacerbate moderate-severe AD.<sup>30</sup> These allergies often include egg, milk, peanut, soy, and wheat. The more severe the AD and younger the patient, the more likely food is the triggering allergen. Although many children who have AD caused by food allergies can outgrow the allergy (and the AD as well), children who present with food allergies and AD should be evaluated by a physician.<sup>16,31</sup> Restricting offending foods, especially in children, creates overwhelming compliance problems. Moreover, although dietary restriction may produce some improvement in the disorder initially, complete resolution is unlikely to occur. Therefore, reserving dietary management for patients who have severe symptoms and are unresponsive to other treatments is probably best.<sup>12</sup> Patients with AD are often intolerant of sudden and extreme changes in temperature and humidity. High temperature may enhance perspiration, leading to increased itching. Low humidity, often found in heated buildings during the winter, dries the skin and increases itching. Use of humidifiers in dry environments can provide some benefit.

Because the pruritus is often bothersome for many patients, keeping the fingernails short, smooth, and clean is important to avoid introduction of bacteria via microfissures; patients can consider the use of cotton gloves at night to prevent constant scratching of the itchy skin. Excessive scratching can result in open sores that may need to be treated with a topical antibiotic. Use of bacitracin/polymyxin B ointment (Polysporin) may be preferred to bacitracin/polymyxin B/neomycin ointment, given that some patients may be sensitized to neomycin.<sup>32</sup>

Because maintaining skin hydration and patency is important, the use of emollients should be included. Emollients are considered standard of care and often referred to as “steroid sparing.”<sup>13,33</sup> Studies have shown their use improves skin response rate in AD.<sup>13,34</sup> Moisturization with emollients at least twice daily is recommended for preventive and maintenance therapy to keep skin soft and pliable. Use of creams or ointments is recommended over lotions to keep the skin soft and hydrated. Oil-in-water preparations (creams and lotions) are often more cosmetically acceptable, but they need to be applied more frequently than ointments because their ability to maintain moisture in the skin is often more short-lived. If applied correctly, creams and lotions should have a good emollient effect and not produce dryness.

Other preventive measures, such as breast-feeding and delaying introduction of solid food, remain controversial. Few studies have looked at these interventions and their role in the prevention of AD; guidelines state that no definite evidence indicates that breast-feeding and solid food introduction will significantly affect AD.<sup>13</sup> Although more recent literature suggests that exclusive breast-feeding can decrease the incidence of AD, no convincing evidence exists that delaying solid foods will help.<sup>12,35</sup>

#### Pharmacologic Therapy

Hydrocortisone in an oil-in-water base is the primary nonprescription pharmacologic agent used to treat AD. This agent is classified as a low-potency corticosteroid and is primarily used to decrease inflammation and relieve itching. This corticosteroid is safe to use short term on virtually any area of the body (including the face, neck, axillae, and groin) and safe to use in children older than 2 years.<sup>13,26</sup> When used properly, hydrocortisone 0.5% and 1% products are associated with a very low risk of local and systemic adverse effects compared with high-potency topical corticosteroid products. Hydrocortisone cream is often the preferred product for most patients with AD because of patient preference for a less greasy preparation.<sup>28</sup> Ointment formulations, while often greasy, are preferred on areas of thick skin or if a patient's skin is dry, lichenified, or scaly.<sup>26,36,37</sup> These products are usually applied 1-2 times daily during AD flare-ups, usually before application of any moisturizers.<sup>8,12,36</sup> Ointments should be avoided if the AD lesions are weeping, and all hydrocortisone products should be avoided if the skin is open or cracked.<sup>38</sup> Refractory cases of AD should be referred to a physician but can further be treated with higher-potency topical corticosteroids; topical calcineurin inhibitors, such as tacrolimus or pimecrolimus; or systemic immunomodulators (e.g., cyclosporine, azathioprine, or methotrexate)<sup>28,39</sup>; however, these agents require a prescription and thus are not covered in detail in this chapter.

Because of the risk of infections, as previously mentioned, preventing and managing infections is important in an AD patient. Topical mupirocin may be initially effective, but the patient will need referral to a physician and require a short course of an oral antistaphylococcal antibiotic, such as cephalexin or penicillin. The benefits of topical or oral antibiotics in improving AD lesions remain under debate.

Guidelines state the use of systemic and topical antibiotics may reduce skin colonization<sup>13</sup> whereas more recent information suggests topical antibiotics are not effective and should not be used long term.<sup>18,28</sup> The use of antiseptics, while of limited benefit, can also be considered, but can be associated with a drying effect. Data on the use of chlorhexidine, triclocarban, and fusidic acid are conflicting, and thus the guidelines do not specifically recommend their use.<sup>13</sup>

### Complementary Therapies

Few complementary therapies exist to manage atopic dermatitis. The use of probiotics, such as lactobacillus, may delay the presentation of AD, although more studies are needed to determine the exact dose, duration, and safety of the use of probiotics.<sup>13,40</sup> The use of phototherapy in patients with AD may be beneficial.<sup>13</sup> Coal tar has also shown benefit in other dermatologic conditions and likewise can be useful in refractory AD, particularly in combination with phototherapy.<sup>3</sup> Safety of the coal tar and phototherapy combination therapy in children, however, has not been established.<sup>41</sup> The use of certain Chinese herbal mixtures has shown benefit in AD,<sup>3</sup> but recent guidelines state insufficient evidence to support their use.<sup>39</sup> Other botanicals used in skin disorders are mentioned in [Chapter 51](#). Although time consuming for patients and caregivers, the use of "wet wraps" (applying a steroid or emollient to affected lesions, then wrapping the lesions in a wet then dry layer, and retaining the wraps for an overnight period) can increase skin hydration and help decrease scratching.<sup>12</sup> A growing body of literature and evidence is available on the use and efficacy of wet wraps.<sup>42,43</sup>

### Dry Skin

Xerosis, or dry skin, is the result of decreased water content of the skin with resultant abnormal loss of cells from the stratum corneum. Environmental dry skin is often associated with long, hot showers or not consuming enough water. The prevention and care of dry skin may become a major focus for health care providers as the population of older adults continues to increase. Among those caring for these older adults, a heightened awareness exists that prophylactic dry skin care can reduce morbidity by minimizing the risk of skin breakdown and, therefore, can ultimately reduce the cost of dermatologic health care.<sup>5</sup>

Dry skin is a common problem and affects more than 50% of older adults. It is also the most common cause of pruritus.<sup>44</sup> Dry skin is a frequent cause of pruritus in cooler climates during the winter season (i.e., "winter itch"). Individuals who live or work in arid, windy, or cold environments also have an increased risk for dry skin.

### Pathophysiology of Dry Skin

Dry skin can result from various etiologies. It can be caused by disruption of keratinization and desquamation.<sup>44</sup> Dry skin may also occur secondary to prolonged detergent use, malnutrition, or physical damage to the stratum corneum. Furthermore, dry skin may signal a systemic disorder such as hypothyroidism or dehydration. Dry skin is related to decreased water retention in the stratum corneum—not to a lack of natural skin oils. Dry air allows the outer skin layer to lose moisture, become less flexible, and crack when flexed, leading to an increased rate of moisture loss. Exposure of skin to high wind velocity will result in moisture loss.

With advancing age, the epidermis changes because of abnormal maturation or adhesion of the keratinocytes, resulting in a superficial, irregular layer of corneocytes. This disorder may be described as a thinning of the entire epidermis, which produces a roughened skin surface. The skin's hygroscopic substances also decrease in quantity with advancing age. Hormonal changes that accompany aging result in lowered sebum output. Older patients also typically have inadequate water intake, which contributes to this disorder.<sup>5,45</sup>

### Clinical Presentation of Dry Skin

Dry skin is characterized by one or more of the following signs and symptoms: roughness, scaling, loss of flexibility, fissures, inflammation, and pruritus. Common clinical findings include fine platelike scaling, particularly on the arms and legs, that may be associated with a "cracked" appearance (eczema craquelé) or fish-scaling (ichthyosis) appearance of the skin.<sup>44</sup>

### Treatment of Dry Skin

#### Treatment Goals

The goals of self-treatment of dry skin are to (1) restore skin hydration, (2) restore the skin's barrier function, and (3) educate the patient about prevention and treatment of this chronic disorder.

#### General Treatment Approach

Treatment involves recognizing the problem as well as modifying the environment (humidity) and bathing habits to maintain skin hydration. Nonprescription products such as bath oils, emollients and moisturizers containing humectants, keratolytic agents, or both, aid in restoring and maintaining barrier function. If needed, topical hydrocortisone can be used to reduce pruritus and erythema.<sup>46</sup>

#### Nonpharmacologic Therapy

The most important aspects of care are the proper use of emollients and modifications to bathing practices. Products such as oiled oatmeal or bath oil added near the end of the bath may be used to enhance skin hydration. The patient should apply oil-based emollients immediately after bathing while the skin is damp and should reapply them frequently. The room humidity should be increased with a portable cool-mist humidifier, or a humidification unit can be added to the home heating system. The patient should be encouraged to stay well hydrated by drinking ample water daily unless contraindicated by any medical disorders. [Table 32-3](#) reviews nonpharmacologic therapy of dry skin.

#### TABLE 32-3 Dry Skin Therapy

- Take tub baths with addition of bath oil 2-3 times per week for brief periods (3-5 minutes). Take sponge baths on other days.
- Bathe in tepid water, not more than 3°F above body temperature.
- Within 3 minutes of getting out of the tub, pat the body dry, leaving beads of moisture, and generously apply body lotion to trap the moisture.
- Apply the body lotion at least 3 more times during the day to the whole body (preferably) or at least the most affected areas.
- Additional measures include:
  - Use corticosteroid ointments rather than creams if indicated for short-term use.
  - Keep room humidity high.

#### Pharmacologic Therapy

Dry skin is more prone to itching, inflammation, and development of secondary infections. Most moisturizers are mixtures of oils and water, but more severe cases of dry skin may require a product containing a humectant (e.g., glycerin, urea, lactic acid) to enhance hydration. Other agents that can be added to these emollients or moisturizers include alpha hydroxy acids and lipid moisturizers such as phospholipids and ceramides.<sup>44</sup>

Dry skin responds minimally to topical corticosteroid therapy, although short-term (≤7 days) use of topical corticosteroids may reduce symptoms of erythema and pruritus.<sup>44</sup> If resolution does not occur within 1 week, a primary care provider should be consulted because other options may be required to improve the dry skin.

### Treatment of Atopic Dermatitis and Dry Skin

Nonprescription products for dermatitis and dry skin that restore skin hydration include bath products and emollients,

which can contain hydrating, keratolytic, and keratin-softening agents. Often these products are combined in commonly available nonprescription products (Table 32-4). Many ingredients are available for use on AD lesions or dry skin; these products are reviewed below. These products can be recommended according to patient preference and therapeutic response.

**TABLE 32-4 Selected Nonprescription Dry Skin Products**

<b>Trade Name</b>	<b>Primary Ingredients</b>
<b>Petrolatum-Containing Products</b>	
Absorbase Ointment <sup>a</sup>	Petrolatum; mineral oil; ceresin wax; wool wax alcohol; potassium sorbate
AmLactin Cream/Lotion	Ammonium lactate 12%
Aquaphor Ointment	Petrolatum 41%; water
Cetaphil Gentle Cleansing Bar <sup>a</sup>	Sodium cocoyl isethionate; stearic acid; sodium tallousate; PEG-20; petrolatum
Eucerin Cream <sup>a</sup>	Petrolatum; mineral oil; mineral wax; wool wax alcohol
Jergens Advanced Therapy Ultra Healing Lotion	Petrolatum; mineral oil; dimethicone; cetearyl alcohol; cetyl alcohol; glycerin; allantoin
Moisturel Cream/Lotion <sup>a</sup>	Petrolatum; dimethicone; cetyl alcohol; glycerin
Vaseline Dermatology Formula Lotion	White petrolatum 5%; mineral oil 4%; dimethicone 1%; glyceryl stearate; cetyl alcohol; glycerin
<b>Colloidal Products</b>	
Aveeno Daily Moisturizing Lotion <sup>a</sup>	Dimethicone 1.25%; cetyl alcohol; oat kernel flour; glycerin
Aveeno Moisturizing Bath Treatment Formula <sup>a</sup>	Mineral oil; colloidal oatmeal 43%
Aveeno Moisturizing Cream/Lotion <sup>a</sup>	Petrolatum; dimethicone; isopropyl palmitate; cetyl alcohol; colloidal oatmeal 1%; glycerin
Aveeno Skin Relief Moisturizing Lotion <sup>a</sup>	Dimethicone 1.25%; menthol 0.1%; oat kernel flour
Aveeno Soothing Bath Treatment Formula <sup>a</sup>	Colloidal oatmeal 100%
Neosporin Eczema Essentials <sup>a</sup>	Colloidal oatmeal; ceramide; mineral oil
<b>Urea-Containing Products</b>	
Carmol 10 Lotion	Urea 10%
Carmol 20 Cream	Urea 20%
Lac-Hydrin Five Lotion	Urea 5%
<b>Counterirritants</b>	
Sarna Anti-Itch Lotion	Camphor 0.5%; menthol 0.5%; carbomer 940; cetyl alcohol; DMDM hydantoin; glyceryl stearate; petrolatum
<b>Miscellaneous Emollients</b>	
Cetaphil Gentle Skin Cleanser Liquid <sup>a</sup>	Cetyl alcohol; stearyl alcohol; PEG
Gold Bond Ultimate Healing Lotion	Glycerin; petrolatum; cetyl alcohol; aloe; cetearyl alcohol; propylene glycol;

	glyceryl stearate
Keri Original Formula Therapeutic Dry Skin Lotion	Mineral oil; lanolin oil; glyceryl stearate; propylene glycol
Lubriderm Advanced Therapy Lotion	Cetyl alcohol; glycerin; mineral oil; PEG-40; emulsifying wax; vitamin E
Lubriderm Daily Moisturizing Lotion	Mineral oil; petrolatum; sorbitol; lanolin; lanolin alcohol; triethanolamine
Neutrogena Body Oil	Isopropyl myristate; sesame oil
Neutrogena Soap	TEA-stearate; triethanolamine; glycerin
Nivea Body Lotion	Mineral oil; glycerin isopropyl palmitate; vitamin E; lanolin alcohol
Purpose Gentle Cleansing Bar	Sodium tallowate; sodium cocoate; glycerin; BHT

Key: BHT = Butylhydroxytoluene; DMDM = dimethylol dimethyl; PEG = polyethylene glycol; TEA = triethanolamine.

<sup>a</sup>Fragrance-free formulation.

## Bath Products

### Bath Oils

Bath oils generally consist of a mineral or vegetable oil plus a surfactant. Mineral oil products are absorbed better than vegetable oil products. Some commercially available bath oil products are combined with colloidal oatmeal in an attempt to provide better relief of itching. Because these commercial products can be expensive, some providers recommend preparing these products at home by processing instant (unflavored) oatmeal in a blender and placing in the bath water. Bath oils are minimally effective in improving a dry skin disorder because they are greatly diluted in water.

When applied as wet compresses, bath oils (1 teaspoon in one-fourth cup of warm water) help lubricate dry skin and may allow a decrease in the frequency of full-body bathing. Bath oils make the tub and floor slippery, creating a safety hazard, especially for older adults or children.

### Cleansers

Typical bath soaps generally contain salts of long-chain fatty acids (commonly oleic, palmitic, or stearic acid) and alkali metals (e.g., sodium or potassium). Combined with water, these products act as surfactants that remove many substances from the skin, including the lipids that normally keep the skin soft and pliable. Providers often recommend special soaps, such as those including glycerin, that contain extra oils to minimize the drying effect of washing. However, these soaps usually lather and clean poorly. Glycerin soaps, which are transparent and more water soluble, have a higher oil content than standard soaps because of the addition of castor oil. They are closer to a neutral pH and are regarded as less drying than traditional soaps, which are alkaline. Although little objective proof exists to prove their superiority, glycerin soaps are advertised for, and well accepted by, people with skin disorders. Mild cleansers such as Cetaphil or pHisoDerm can be recommended if soap is to be avoided. Many products for dry skin are oil free and consist primarily of surfactants. Although these products claim to have a low potential for irritation, clear evidence of enhanced benefit over soaps is lacking.

### Emollients and Moisturizers

Emollients function by filling the space between the desquamating skin scales with oil droplets, but their effect is only temporary. Other products include lubricants (i.e., products that increase skin slip in dry skin), moisturizers (i.e., products that impart moisture to the skin, thereby increasing skin flexibility), and repairing or replenishing products (i.e., those intended to reverse the appearance of aging skin). Most moisturizers consist of water (60%-80%), which functions as a diluent and evaporates, leaving behind the active agents; lipids (essential fatty acids) to augment the skin barrier; emulsifiers, which keep water and lipids in one continuous phase; humectants, which help skin retain water; preservatives; fragrance (or may be fragrance free); and color (dyes). Specialty additives, such as vitamins (vitamins A, C, D, and B complex), which have no known clinical effect, and natural moisturizing factors (e.g., lactate, urea, ammonia, uric acid, and glucosamine) can also be added and are reported to regulate the moisture content of the stratum corneum. A newer lipid additive, ceramide, is being added to some emollient agents for added skin

barrier protection.<sup>28</sup> Facial moisturizers are either oil-in-water emulsions or water-in-oil emulsions. The differences between moisturizer products are due to the addition of fragrances, exotic oils, vitamins, protein or amino acid products, and other minor moisturizing aids. The selection of an appropriate facial moisturizer depends on skin type. Products for those with an oily complexion are oil free or contain small amounts of light oils (mineral oil) with silicone derivatives and talc, clay, starch, or synthetic polymers (oil control). Products for individuals with normal skin contain predominantly water, mineral oil, and propylene glycol, with very small amounts of petrolatum or lanolin. These products leave an oilier residue on the face than oil-free formulations. Dry skin products contain water, mineral oil, propylene glycol, and larger amounts of petrolatum or lanolin.

Body moisturizers come in lotions, creams, ointments, and butters. Creams, ointments, and butters are more difficult to spread, especially in hairy areas. Butters are stiffer moisturizing formulations sold in jars and often contain shea butter, which is extracted from the nut of the African shea tree. Patients with tree nut allergies appear to be able to use these products without fear of an allergic reaction. Hand moisturizers are much heavier than body or facial emollients. The simplest and most economical hand ointment is petroleum jelly. Although it is greasy, which may lead to poor compliance, petroleum jelly is effective when applied at bedtime and covered with wraps or clothing. Because sebum and skin surface lipids contain a relatively high concentration of fatty acid glycerides, vegetable and animal oils derived from avocado, cucumber, mink, peanut, safflower, sesame, turtle, and shark liver are included in dry skin products, presumably because of their unsaturated fatty acid content. Although use of these oils contributes to skin flexibility and lubricity, their occlusive effect is less than that of white petrolatum. Use of these products should be avoided in individuals with an allergy to any component.

Emollients, both occlusive and moisturizing, are used to prevent or relieve the signs and symptoms of dry skin. These products act primarily by leaving an oily film on the skin surface through which moisture cannot readily escape. Cosmetically, emollients make the skin feel soft and smooth by helping reestablish the integrity of the stratum corneum. Lipid components make the scales on the skin translucent and flatten them against the underlying skin. This flattening eliminates air between the scales and the skin surface, which is partly responsible for a white, scaly appearance.<sup>47</sup>

Frequency of application depends on the severity of the dry skin disorder and the hydration efficiency of the occlusive agent. Generally, moisturizers must be applied 3-4 times daily to achieve maximum benefit. For dry hands, the patient may need to apply the occlusive agent after each hand washing, as well as at numerous other times during the day. Emollient products are available as petrolatum-containing ointments that are typically greasy and generally lack consumer appeal because of their texture, difficulty of spreading and removing, and staining properties. To avoid a greasy feel, patients should gently warm the product in the hands, apply a very thin layer, and massage it gently, but thoroughly, into the skin. If an ointment is needed for maximal penetration in an area of thick skin, such as the soles of the feet, a sock could be worn to minimize the mess. Ointments are inappropriate for oozing AD because they do not allow the lesions to dry and ultimately heal. In addition, ointments may be too occlusive in very warm weather, making creams a better choice.<sup>28</sup>

Lotions and creams are either water-in-oil or oil-in-water emulsions. As the lipid content of the moisturizer increases, the occlusive effect increases. In most cases, patients prefer the less effective oil-in-water emulsions for their cosmetic acceptability. These agents help alleviate the pruritus associated with dry skin by virtue of their cooling effect as water evaporates from the skin surface. Lotions may be preferred when dryness is not as severe or in warm weather, when the occlusive properties of ointments is an issue.<sup>28</sup> Lanolin, a natural product derived from sheep wool, is found in many nonprescription moisturizing products. Patients rarely develop an allergic reaction to this substance, presumably because its wool wax fraction is recognized as antigenic. Patients with a previous history of allergic reactions to lanolin should generally avoid lanolin-containing products.<sup>27</sup> Petrolatum should not be applied over puncture wounds, infections, or lacerations because its high-occlusive property may lead to maceration and further inflammation. Application of petrolatum to intertriginous areas (e.g., armpits, groin, and perianal region), mucous membranes, and acne-prone areas should be minimized; only a preparation with a low concentration of petrolatum is tolerated in these areas.

## Humectants

Humectants or hydrating agents are hygroscopic materials that are often added to emollient bases. Commonly used hydrating agents are glycerin, propylene glycol, urea, and phospholipids. Humectants draw water into the stratum corneum to hydrate the skin. Humectants are distinct from emollients, which serve to retain water already present. Because of glycerin's hygroscopic properties, high concentrations may actually increase water loss by drawing water from the skin rather than from the atmosphere. At lower concentrations (i.e., 5%), humectants such as glycerin help decrease water loss by keeping water in close contact with skin and accelerating moisture diffusion from the dermis to the epidermis. In addition, glycerin lubricates the skin surface. Propylene glycol is a viscous, colorless, odorless solvent with hygroscopic properties. It is less viscous than glycerin and is included in many skin care formulations for its humectant action. Urea is mildly keratolytic and increases water uptake in the stratum corneum, giving it a high water-binding capacity. Urea has a direct effect on stratum corneum elasticity because of its ability to bind to skin

protein.<sup>44</sup> Concentrations of 10% have been used on simple dry skin; 20%-30% formulations have been used to treat more resistant dry skin disorders. Lotion and cream formulations containing urea may be better at helping to remove scales and crusts, whereas urea in emollient ointments may be better at rehydrating the skin. However, urea preparations can cause stinging, burning, and irritation, particularly on broken skin.<sup>48</sup>

### Alpha Hydroxy Acids

Alpha hydroxy acids include ammonium lactate and lactic acid. These acids can increase the hydration of human skin and, at low concentrations, may act as a modulator of epidermal keratinization rather than as a keratolytic agent. Lactic acid may be added to urea preparations in creams and lotions for both its stabilizing and its hydrating effects.<sup>44</sup>

### Allantoin

Allantoin and allantoin complexes soften keratin by disrupting its structure. A product of purine metabolism, allantoin is considered a relatively safe skin protectant for adults, children, and infants when applied in concentrations of 0.5%-2.0%.<sup>24</sup> However, it is less effective than urea.<sup>48</sup>

### Topical Hydrocortisone

Hydrocortisone (0.5% or 1%) is currently the only corticosteroid available without a prescription for the topical treatment of dermatitis. Although its exact mechanism is unknown, hydrocortisone most likely suppresses cytokines associated with the development of inflammation and itching, which is associated with various dermatoses. Food and Drug Administration monograph indications for use of hydrocortisone include temporary relief of itching associated with minor skin irritations, inflammation, and rashes caused by dermatitis, seborrheic dermatitis, insect bites, poison ivy/oak/sumac dermatitis, soaps, detergents, cosmetics, and jewelry.<sup>49</sup> Concentrations of 0.5% or 1% are considered appropriate for treating localized dermatitis. Many commercially available nonprescription hydrocortisone products now also contain aloe. The inclusion of aloe may serve as a potential irritant to some patients with dermatitis; thus, products with aloe should be avoided in this population. (See [Chapter 40](#) for more information on aloe.)

Hydrocortisone should be applied sparingly to the affected area 1-2 times a day. For mild dry skin, a cream is acceptable; however, an ointment formulation generally provides the best results for chronic, nonoozing dermatoses. Maximizing the application of moisturizers (lotions, creams, ointments) to dry, itchy skin disorders may lessen the frequency that medicated products, such as hydrocortisone, have to be applied.<sup>26,38</sup>

Hydrocortisone should not be applied to infected skin; it may mask the symptoms of dermatologic infections and allow the infection to progress. Topical hydrocortisone rarely produces systemic complications because its systemic absorption is relatively minimal (approximately 1%). Therefore, the risk of adrenal suppression, growth suppression, osteoporosis, and other metabolic complications is slight when low-potency hydrocortisone is used on a short-term basis or rotated with other agents.<sup>28</sup> Certain local adverse effects such as skin atrophy rarely occur with nonprescription concentrations; they are more common with the more potent prescription products.<sup>28,36</sup> Because response to topical hydrocortisone may decrease with continued use owing to tachyphylaxis, intermittent courses of therapy are advised when possible. This can include use of hydrocortisone daily during periods of flare-ups with once weekly dosing, or no hydrocortisone at all, during remission phases, with continued maintenance strategies (i.e., emollient use).<sup>27,39</sup>

### Antipruritics

The pruritus associated with dermatitis may be mediated through several mechanisms, which may explain how local anesthetics, antihistamines, and hydrocortisone (discussed previously) are useful as antipruritics. Cooling the area through application of a soothing, bland lotion, such as Lubriderm, may reduce the extent of the pruritus, but this effect is only transitory.

The itching sensation is mediated by the same nerve fibers that carry pain impulses. Local anesthetics block conduction along axonal membranes, thereby relieving itching as well as pain. However, because local anesthetics may cause systemic side effects, they should not be used on large areas of the body or over long periods of time, particularly if the skin is raw or blistered. Nonprescription topical anesthetics that appear to be safe and effective are pramoxine, lidocaine, and benzocaine. Topical anesthetics may be applied to affected areas 3 or 4 times daily, but caution should be used because these agents may have a sensitizing effect in some patients. Guidelines do not recommend routine use of these local anesthetics.<sup>18</sup> Counterirritants such as camphor and menthol, in concentrations of 0.5%-1%, are available in or can also be added to lotions and creams and can serve as an inexpensive antipruritic.<sup>48</sup>

Itching may also be mediated by various endogenous substances, including histamine. Therefore, topical

antihistamines (e.g., diphenhydramine) are effective in alleviating this symptom, as well as exerting a topical anesthetic effect. Although topical antihistamines may provide some short-term relief of itching, their use is not recommended, and furthermore, may be associated with sensitization.<sup>13,18,31</sup> Local anesthesia may be the more important mechanism of action, given that the cause of itching in many disorders (e.g., atopic dermatitis) is most likely caused by cytokine release and may not be related to histamine release at all.

Oral antihistamines have traditionally been used to treat the itching of dermatologic disorders. Some researchers claim that the antipruritic effect is a result of the sedative side effect; others claim the efficacy is caused by antihistaminic activity, although with a delayed onset of several days. Oral antihistamines are not recommended for the routine treatment for pruritus in AD because of the lack of demonstrated efficacy and the hypothesis that the pruritus in AD is often not histamine related.<sup>13,18,20</sup> However, an oral antihistamine may help with sleep in the patient who has been staying up all night scratching, and if concurrent depression is a problem, an antidepressant with anticholinergic properties may further help with itching. In either case, sedation may be a problem as may the anticholinergic side effects in patients with disorders such as benign prostatic hypertrophy or closed-angle glaucoma.<sup>38</sup>

#### Product Selection Guidelines

When deciding which product to recommend for dermatitis or dry skin, the provider must evaluate the active ingredients and the vehicle. Primary active ingredients contained in nonprescription skin products are water and oil. However, a variety of secondary ingredients is added to enhance product elegance and stability, and many of these ingredients, such as preservatives, have the potential to produce contact dermatitis through either an irritant or a sensitizing effect.<sup>38</sup>

The type of vehicle (e.g., ointment, cream, lotion, gel, solution, or aerosol) may significantly affect treatment of dermatitis and should be selected based on patient preference and location of lesions. If a drying effect is desired, the provider may recommend solutions, gels, and occasionally creams. However, components may quickly diffuse into the underlying tissue and possibly cause irritation. If lubrication is needed, creams and lotions are preferable. Notably, creams may be less potent than ointments and contain preservatives previously mentioned as potential irritants. Lotions (and gels) are not as greasy, and both dry quickly. Lotions can be useful in hairy areas, as can foams and mousses. If the lesion is dry, thick, or fissured, an ointment is the vehicle of choice. However, use of ointments in intertriginous areas (e.g., groin, axillae) should be avoided because of the potential for maceration.<sup>37</sup> Also, in the acute phase of AD, the occlusive effects of an ointment may cause further irritation.

#### Assessment of Atopic Dermatitis and Dry Skin: A Case-Based Approach

For most forms of dermatitis, the initial signs and symptoms are similar. A diagnosis of AD is often made after excluding other dermatologic disorders such as contact dermatitis (see Chapter 34) or scaly dermatoses (see Chapter 33). Because AD is primarily a disease of the young, patient age is important in assessment. The provider should determine whether the patient (or the patient's family) has a history of atopic disorders. Inquiries should be made regarding onset and duration of the eruption, anatomic location, and distribution of the lesions.

When recommending the use of an appropriate nonprescription product or making a medical referral, the provider must consider the cosmetic, psychological, and work- or recreation-related aspects of a dermatologic disorder in addition to the underlying pathology. If the dermatologic disorder has a significant psychological component and it has not responded to first-line nonprescription treatments, the patient may benefit from referral to a provider who can assist the patient with alternative remedies such as behavioral modification and stress-reducing therapies.

Dry skin is typically visible, with roughness and scaling. Questions about bathing habits, the soaps and detergents used, medications recently started, and other medical disorders that may predispose a patient's skin to excessive dryness should be asked. Patients should note that changes in climate, such as winter air and air from heating sources that dry the skin, can affect their skin.

Care is warranted when making recommendations for the treatment of pruritic skin disorders in special populations. A wide variety of disorders can be associated with pruritus during pregnancy.<sup>50</sup> Although recommending the use of emollients for dry, pruritic skin is generally safe, pregnant patients should be instructed to contact their obstetrician for a more thorough investigation of the skin disorder if the symptoms do not respond adequately in 2-3 days. Although emollients are generally safe to use on dry skin of infants and children, a provider should be consulted prior to recommending the use of any topical medication, such as hydrocortisone, for a prolonged period of time (>7 days).<sup>5</sup> In addition, lower-potency corticosteroids (such as hydrocortisone) are preferred in children, and the use of occlusion (with diapers or tight clothing) should be avoided since this can increase absorption.<sup>36</sup> Older patients are especially prone to dry skin and dermatologic disorders associated with reduced peripheral circulation. Dry skin in these patients will likely respond better to the routine application of moisturizing creams and ointments rather than lotions. In addition, care should be used when recommending sedating antihistamines for pruritus because these patients are more likely to experience cognitive and anticholinergic side effects associated with these agents. Similarly, bath

products that may result in a slippery bathtub should be used with caution in older patients, given their propensity for falls and subsequent complications.

Cases 32-1 and 32-2 are examples of the assessment of patients with AD or dry skin, respectively.

### Case 32-1

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient presents with persistent itching on the wrist and elbow areas, which has intensified during the past 3-4 months. The skin is dry and thickened, and within the past week yellowish exudates and crusting have been present in both areas.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	She states that symptoms seem to have worsened after moving to a new house. The itching is much worse and has resulted in frequent scratching.
c. description of the patient's efforts to relieve the symptoms	She has tried hydrocortisone 1% cream applied twice daily but it has not helped to date.
d. patient's identity	Cathy Smith
e. age, sex, height, and weight	28 years old, female, 5 ft, 4 in., 135 lb
f. patient's occupation	Salesperson
g. patient's dietary habits	Normal diet
h. patient's sleep habits	6-7 hours per night
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Allergic rhinitis: loratadine 10 mg once daily
j. allergies	House dust
k. history of other adverse reactions to medications	None
l. other (describe) _____	Cathy was diagnosed with atopic dermatitis at 12 years of age. It has been controlled fairly well with topical corticosteroids used on an as-needed basis.
<b>Assessment and Triage</b>	

2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Patient has lesions associated with atopic dermatitis that vary with time and are likely to worsen with continued irritation from scratching.
3. Identify exclusions for self-treatment. (Figure 32-2).	The recent development of yellow exudates may indicate a secondary infection; thus, any form of self-treatment should be avoided. Further evaluation should take place prior to using any pharmacologic agent on a chronic basis.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Cathy to a primary care provider or dermatologist for a differential diagnosis. (2) Recommend an appropriate nonprescription product. (3) Recommend an appropriate nonprescription product until Cathy can be seen by a health care provider or dermatologist. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	A topical emollient cream or lotion should be applied 3-4 times daily to the lesions, using clean hands. Cathy should try to keep the lesions and surrounding skin as clean as possible. In addition, she should be seen by her primary care provider or a dermatologist. Hydrocortisone should be avoided because it could delay the healing of a skin infection. She should continue to take her loratadine for her allergic rhinitis that may also minimize the skin itch.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Until you can see your primary care provider or a dermatologist, you may apply a topical emollient cream or lotion 3-4 times daily to the lesions. You may have a skin infection, so you should stop using the hydrocortisone because it could delay the healing of the infection. Continue to take the loratadine; it may help to minimize the itching."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Because of the likelihood of a skin infection, it is important to be sure what the lesions are prior to recommending any long term treatment with any pharmacologic agent, such as hydrocortisone."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	"Try not to scratch the lesions; wearing cotton gloves at night may help with this." See the box Patient Education for Atopic Dermatitis and Dry Skin for additional information that can be discussed with the primary care provider or a dermatologist.
Solicit follow-up questions from the patient or caregiver.	"Is there a nonprescription medication that might help?"
Answer the patient's or caregiver's questions.	"Use of a nonprescription topical antibiotic ointment may not be adequate therapy to eradicate the skin infection. Nonprescription medications are not appropriate to recommend without a definite diagnosis from a health care provider or dermatologist."
<b>Evaluation of Patient Outcome</b>	

9. Assess patient outcome.	Contact the patient in a day or two to ensure that she made an appointment and sought further medical care.
----------------------------	---

**Case 32-2**

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient presents with pruritic, scaly skin on both forearms and lower legs. He claims the soles of his feet and palms of his hands are very rough, with some fissures. Significant flaking is observed, especially in the morning.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	He states the symptoms are more bothersome in the winter months and have worsened as he has aged.
c. description of the patient's efforts to relieve the symptoms	He has tried a store-brand lotion on most mornings with minimal improvement.
d. patient's identity	Ellis Taylor
e. age, sex, height, and weight	79 years old, male, 5 ft 7 in., 230 lb
f. patient's occupation	Retired engineer
g. patient's dietary habits	MNT diet for patients with diabetes
h. patient's sleep habits	7-9 hours of sleep per night
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Hypertension: lisinopril 20 mg once daily; prophylaxis for CVD: ASA 81 mg once daily; type 2 DM: metformin 500 mg twice daily
j. allergies	None
k. history of other adverse reactions to medications	None

1. other (describe) _____	Ellis bathes 5-6 times per week in a tub for 30 minutes at a time. He lives in Madison, Wisconsin. He keeps the temperature in his home at 75 degrees and says that he uses a humidifier in his bedroom during the winter months.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Ellis has dry skin that is most likely caused by environmental factors in combination with his advancing age.
3. Identify exclusions for self-treatment (Figure 32-2).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Ellis to a health care provider or dermatologist. (2) Recommend appropriate nonprescription product(s) and nondrug measures. (3) Recommend appropriate self-care until Ellis can see an appropriate provider. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	A nonprescription emollient will be appropriate for this patient. Applying white petrolatum at bedtime on his arms, legs, and feet and then covering them with sleeves or stockings, as appropriate, will provide the fastest results. Once the disorder improves, a moisturizing cream can be used 2-3 times daily in place of the petrolatum. Hand lotion should be used 4-5 times daily. If intense itching is troublesome, hydrocortisone 1% cream or ointment may be applied to the affected area 2-4 times daily in addition to the emollients.(Table 32-3 provides other information on dry skin therapy.)
6. Describe the recommended therapeutic approach to the patient or caregiver.	See Table 32-3 and the box Patient Education for Atopic Dermatitis and Dry Skin.
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Your skin condition can be managed but not cured with nonprescription topical therapy plus changes to your bathing habits."
<b>Patient Education</b>	
8. When recommending self-care with	

nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	See the box Patient Education for Atopic Dermatitis and Dry Skin.
b. maximum number of days the therapy should be employed	“It is likely the emollient will need to be used chronically. Avoid daily prolonged use (>7 days) of topical hydrocortisone, if possible.” (See the box Patient Education for Atopic Dermatitis and Dry Skin.)
c. product administration procedures	See the box Patient Education for Atopic Dermatitis and Dry Skin.
d. expected time to onset of relief	See the box Patient Education for Atopic Dermatitis and Dry Skin.
e. degree of relief that can be reasonably expected	See the box Patient Education for Atopic Dermatitis and Dry Skin.
f. most common side effects	See the box Patient Education for Atopic Dermatitis and Dry Skin.
g. side effects that warrant medical intervention should they occur	See the box Patient Education for Atopic Dermatitis and Dry Skin.
h. patient options in the event that condition worsens or persists	See the box Patient Education for Atopic Dermatitis and Dry Skin.
i. product storage requirements	See the box Patient Education for Atopic Dermatitis and Dry Skin.
j. specific nondrug measures	See the box Patient Education for Atopic Dermatitis and Dry Skin.
Solicit follow-up questions from the patient or caregiver.	“Can I just use my Jergen’s Lotion rather than using the Vaseline on my feet and legs?”
Answer the patient’s or caregiver’s questions.	“Ointments such as Vaseline hold moisture in the skin better than creams or lotions do. Although you may be able to use only your lotion after your disorder improves, you would have to apply it 4-5 times daily to achieve the same results that Vaseline will provide.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Ask the patient to call you to report how he responds to the recommended therapy, or call the patient in a week to evaluate his response.

Key: ASA = Acetyl salicylic acid; CVD = cardiovascular disease; DM = diabetes mellitus; MNT = medical nutrition therapy.

## **Patient Counseling for Atopic Dermatitis and Dry Skin**

Patients with AD should be counseled on achieving control of their disease, the chronic nature of the condition, exacerbating factors, and appropriate treatment options.

Patients with dry skin should be informed that they have more control over mild-moderate forms of this disorder than over most other types of dermatologic disorders. The provider should also explain factors that cause dry skin and the appropriate measures for restoring barrier function. The box Patient Education for Atopic Dermatitis and Dry Skin lists specific information to provide patients.

### **Patient Education for Atopic Dermatitis and Dry Skin**

The primary objectives of self-treating atopic dermatitis are to (1) stop the itch-scratch cycle, (2) maintain skin hydration, (3) avoid or minimize factors that trigger or aggravate the disorder, and (4) prevent secondary infections. The primary objective in self-treating dry skin—restoring skin moisture and the skin's barrier function—can also help relieve the discomfort of atopic dermatitis. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes. Understanding that patience is required is key with a treatment plan for AD because some therapeutic measures can be time-consuming to implement and often a delay occurs in time to maximal benefit.

### **Atopic Dermatitis**

#### ***Nondrug Measures***

- Avoid factors that trigger allergic reactions. Do not wear tight clothing. Remain in areas that have a moderate temperature and low humidity.
- Bathe or shower every other day, if possible. Take short (3-5 minutes) showers or baths, using warm (tepid) water and a nonsoap cleanser.
- If possible, substitute sponge baths (with tepid water) for full-body bathing.
- Pat dry after bath or shower.
- To dry weeping lesions, apply cool tap water compresses for 5-20 minutes, 4-6 times daily.
- To prevent injury to the affected area caused by scratching, keep your fingernails short, smooth, and clean. At night, wear cotton gloves or socks on your hands to lessen scratching.

#### ***Nonprescription Medications***

- To decrease itching, bathe in tepid water that contains colloidal oatmeal, or add bath oil to the water near the end of the bath.
- Gently wash the affected areas with a nonsoap cleanser before applying any emollient or medication. Gently pat skin dry, and apply an emollient within 3 minutes after washing while skin is still damp.
- Wash hands before and after applying any medication.
- Apply a thin layer of medication over the affected areas.
- Apply hydrocortisone 1-2 times daily to dry lesions to relieve itching. Do not use this medication longer than 7 days.
- With proper use of medications and nondrug measures, noticeable improvement can be observed in 24-48 hours.
- Although completely eliminating the rash and itch is possible, the lesions likely could get worse, especially during the winter and summer months.

#### ***When to Seek Medical Attention***

- Thinning of the skin while using hydrocortisone should be reported to a primary care provider.
- If the atopic dermatitis does not improve or worsens after 2-3 days of treatment, consult a primary care provider.

### **Dry Skin**

#### ***Nondrug Measures***

- Avoid excessive bathing; take brief (3- to 5-minute) full-body baths 2-3 times per week, using bath oil and warm (tepid) water.
- If possible, take sponge baths on other days using warm water to maintain skin hydration.
- Pat dry after bathing or showering.
- Drink plenty of water daily.

- Moisturizer should be generously applied 3-4 times daily and continued as long as dry skin persists.
- Moisturizers should be applied within 3 minutes after bathing, plus an additional 3 times per day.
- Although getting rid of the dry skin completely may be difficult, initial improvement should be seen within 24 hours.
- Avoid caffeine, spices, and alcohol because they can contribute to dehydration.
- Keep the room humidity higher than normal to minimize evaporation from the skin.

### **Nonprescription Medications**

- Add products such as oilated oatmeal or bath oil near the end of your bath to improve skin hydration. Colloidal oatmeal products, if used on a regular basis, may clog plumbing pipes and can leave the tub slick.
- Apply an oil-based emollient immediately after bathing while your skin is damp. Reapply the emollient frequently.
- For more severe cases of dry skin, use a product that contains urea or lactic acid.
- Apply nonprescription topical hydrocortisone ointment to reduce inflammation and itching. Do not use this medication longer than 7 days.

### **When to Seek Medical Attention**

- If skin dryness worsens after 7 days of treatment, consult a health care provider.

### **Evaluation of Patient Outcomes for Atopic Dermatitis and Dry Skin**

A patient with dry skin should be reevaluated in 7 days after initiation of therapy. Visual assessment is the best method of determining treatment response. Therefore, a scheduled visit is the preferred follow-up method. If the symptoms have not improved or have worsened (continued or additional itching, redness, scaling, lesions, or tissue breakdown), medical referral is appropriate.

### **Key Points for Atopic Dermatitis and Dry Skin**

- Most patients with mild-moderate AD or dry skin are candidates for self-treatment with a combination of nonprescription and nonpharmacologic therapies.
- Refer patients with yellow, crusting, eczematous AD lesions and all children younger than 1 year of age with AD to a primary care provider or dermatologist for evaluation and treatment.
- Question patients presenting with dry or eczematous skin lesions about exposure to soaps, detergents, fragrances, chemicals, irritants, changes in temperature, allergens, and other triggers; then provide information about avoiding such triggers.
- Counsel patients with dry skin disorders to take brief baths, use tepid water, pat dry, and apply moisturizers within 3 minutes of completing the bath or shower.
- Advise patients to use mild skin cleansers and to apply copious quantities of moisturizers 3-4 times daily.
- Educate the patient with chronic dry skin disorders about the importance of stopping the itch-scratch cycle and maintaining adequate hydration.
- Advise patients to use ointment-based products, whenever possible, to maximize the hydrating properties of the product. Cream-based products can be recommended for patients who will not comply with use of ointments.
- Instruct patients how to properly apply topical emollients, anti-inflammatory agents, and antipruritic agents, using the smallest amount possible and thoroughly rubbing in.
- Advise patients with self-treatable symptoms to contact their primary care provider if symptoms worsen or do not improve within 7 days.

## Handbook of Nonprescription Drugs > Chapter 33. Scaly Dermatoses

### Scaly Dermatoses: Introduction

Dandruff, seborrheic dermatitis, and psoriasis are chronic scaly dermatoses. These disorders involve the uppermost layer of skin, the epidermis. They all have scales as a primary manifestation. Dandruff or seborrhea is a less inflammatory form of seborrheic dermatitis with relatively fine scaling confined to the scalp. Seborrheic dermatitis, which involves the scalp, face, and chest (usually the sternum), has significant inflammation. Psoriasis is a highly inflammatory skin condition with raised plaques and adherent thick scales that can have profound physical, psychological, and economic consequences.<sup>1</sup>

Nonprescription products are appropriate treatment for most cases of dandruff and seborrheic dermatitis. Mild psoriasis may be responsive to nonprescription treatment, but the initial diagnosis of psoriasis and the management of acute flares require the attention of a dermatologist.

*Editor's Note:* This chapter is based on the 17th edition chapter of the same title, written by Steven A. Scott.

### Dandruff

Dandruff is a chronic, mildly inflammatory scalp disorder that results in excessive scaling of the scalp. It is a substantial cosmetic concern and is associated with social stigma. Previously thought to be a separate entity, this disorder represents the less inflammatory end of the seborrheic dermatitis spectrum. Authorities disagree as to whether inadequate shampooing exacerbates dandruff; however, they agree that a consistent washing routine is important in managing the condition.<sup>1,2</sup>

Dandruff occurs in approximately 1% -3% of the population. Dandruff is uncommon in children and generally appears at puberty, reaches a peak in early adulthood, levels off in middle age, and is less prominent after 75 years of age.<sup>1</sup> Dandruff shows no gender preference, and bald spots are typically dandruff free. Dandruff is less severe during the summer.<sup>1,2</sup> The specific cause of accelerated cell growth seen in dandruff is unclear, but the *Malassezia* species of yeasts is generally agreed to be responsible for the accelerated cell turnover and inflammation seen in both dandruff and seborrheic dermatitis.<sup>3</sup>

### Pathophysiology of Dandruff

Dandruff is a hyperproliferative epidermal disorder, characterized by an accelerated epidermal cell turnover (twice that of normal scalp) and an irregular keratin breakup pattern, resulting in the shedding of large, nonadherent white scales.<sup>1</sup> With dandruff, crevices occur deep in the stratum corneum, resulting in cracking, which generates relatively large scales.<sup>1</sup> If the large scales are broken down to smaller units, the dandruff becomes less visible. The accelerated cell turnover rate is thought to be caused by the irritant inflammatory effects of fatty acids and cytokines produced by *Malassezia* species.<sup>2</sup>

### Clinical Presentation of Dandruff

Dandruff is diffuse rather than patchy and is minimally inflammatory. Scaling, the only visible manifestation of dandruff, is the result of an increased rate of cell turnover on the scalp and the sloughing of large white or gray scales. Although not universal in all patients, pruritus is common. The crown of the head is often a prime location for formation of dandruff flakes.

### Treatment of Dandruff

#### Treatment Goals

The goals of self-treating dandruff are to (1) reduce the epidermal turnover rate of the scalp skin by reducing the number of *Malassezia* species in the scalp, (2) minimize the cosmetic embarrassment of visible scaling, and (3) minimize itch.

#### General Treatment Approach

Washing the hair and scalp with a general-purpose nonmedicated shampoo every other day or daily is often sufficient to control mild-moderate dandruff. If it is not, the health care provider may recommend nonprescription medicated antidandruff products.

Contact time is the key to effectiveness when using medicated shampoos containing pyrrhione zinc or selenium sulfide that suppress the replication of *Malassezia* species.<sup>4,5</sup> The patient should massage the medicated shampoo into the scalp and leave on the hair for 3-5 minutes before rinsing. Repeated rinsing (2-3 times) after the desired contact time is suggested with medicated shampoos containing selenium sulfide to ensure that a residue is not left on the hair, which may result in its discoloration. Medicated shampoos should be used daily for 1 week, then used 2-3 times weekly for 2-3 weeks and thereafter once weekly or every other week to control the condition. Scalp scrubbers are useful in all patients to help ensure adequate contact of the medicated shampoo with the scalp, especially in patients with longer hair.

An agent that reduces *Malassezia* counts on the scalp (e.g., pyrrhione zinc or selenium sulfide) is generally recommended initially. Alternatively, nonprescription ketoconazole shampoo, an antifungal shampoo that also has anti-*Malassezia* activity, can be used. Shampoos containing a cytostatic agent such as coal tar are usually reserved for second-line therapy because they may discolor light hair as well as clothing and jewelry and are of limited efficacy. These agents reduce scaling by decreasing the epidermal turnover rate. A keratolytic shampoo containing salicylic acid or sulfur may also be used but requires far longer treatment periods and is of limited efficacy (see Treatment of Scaly Dermatoses). If dandruff proves resistant to these agents after 4-8 weeks of appropriate use, the patient should be referred to a primary care provider for treatment with products containing a higher concentration of selenium sulfide or ketoconazole.<sup>1</sup>

### Seborrheic Dermatitis

Seborrheic dermatitis is a subacute or chronic inflammatory disorder that occurs predominantly in the areas of greatest sebaceous gland activity (e.g., scalp, face, and chest).<sup>3,4,5</sup> Seborrheic dermatitis is a common chronic, red, scaly, itchy rash typically seen within the first 3 months of life and around the fourth to the seventh decade of life. Seborrheic dermatitis is common in infants and affects 2%-5% of adults (more commonly men). Seborrheic dermatitis is typically more severe in winter and may be aggravated by emotional stress.

### Pathophysiology of Seborrheic Dermatitis

Seborrheic dermatitis is more inflammatory than dandruff and is marked by accelerated epidermal proliferation in areas with dense distribution of sebaceous glands, which is caused by elevated levels of *Malassezia*.<sup>3</sup> Whereas normal epidermal cell turnover is 25-30 days, it is 9-10 days for seborrheic dermatitis compared with 13-15 days for dandruff.<sup>1</sup> The characteristic accelerated cell turnover and enhanced sebaceous gland activity give rise to prominent yellow, greasy scales displayed in the condition.

### Clinical Presentation of Seborrheic Dermatitis

Seborrheic dermatitis occurs in the scalp, eyebrows, glabella, eyelid margins (blepharitis), cheeks, paranasal areas, nasolabial folds, beard area, presternal area, central back, retroauricular (behind the ear) creases, and in and about the external ear canal. The disorder typically presents as dull, yellowish, oily, scaly areas on red skin that are fairly well demarcated. Pruritus is common.<sup>1</sup>

The infantile form, which occurs in the first months of life as greasy scales and scale crusts on a bright erythematous base, affects the scalp (cradle cap), retroauricular creases, lateral neck, and intertriginous folds. Cradle cap usually clears without treatment by age 8-12 months as the hormones passed from the mother to the child before birth gradually disappear. The disease rarely presents again until puberty.

The most common form in adults is characterized by yellow, greasy scales on the scalp that often extend to the middle third of the face with subsequent eyebrow involvement (see Color Plates, photograph 13). For some unknown reason, seborrheic dermatitis is frequently seen in patients with Parkinson's disease. Typically, seborrheic dermatitis on the scalp is manifested by greasy, scaling patches or plaques, exudation, and thick crusting. On the face, flaky scales or yellowish scaling patches on red, itchy skin are seen in the eyebrows and glabella. Red scaling, fissures, and swelling may be present in the ear canals, around the auditory meatus, in the postauricular region, or under the earlobe. V-shaped areas of the chest and back and, much less frequently, intertriginous areas such as the side of the neck, axillae, submammary region, umbilicus, and genitocrural folds may also be involved. In adults, the disease lasts for years to decades, with periods of improvement in warmer seasons and periods of exacerbation in the colder months.

### Treatment of Seborrheic Dermatitis

#### Treatment Goals

The goals of self-treatment of seborrheic dermatitis are to (1) reduce inflammation and the epidermal turnover rate of the scalp skin by reducing the level of *Malassezia* species, (2) minimize or eliminate visible erythema and scaling, and (3) minimize itch.

## General Treatment Approach

The treatment of seborrheic dermatitis is similar to that of dandruff but is often more aggressive because of the inflammatory nature of the disease. Patients should be informed about the chronic nature of the disease, and they need to understand that therapy works by controlling the disease rather than by curing it. Therapy is directed toward loosening and removal of scales and crusts, inhibiting yeast colonization, controlling secondary infection, and reducing erythema and itching. When a medicated shampoo containing pyrithione zinc, selenium sulfide, or ketoconazole is used for treatment, patients should work the shampoo into the scalp and then leave the lather on the hair and affected areas for 3-5 minutes. Initially, the shampoo should be used daily for the first week or two, then 2-3 times per week for the next 4 weeks. When the condition is controlled, the shampoo is applied once a week to prevent relapse. Commercially available products containing salicylic acid and sulfur are of limited effectiveness because they are slow acting, producing therapeutic effects in months rather than days.

In infants, seborrheic dermatitis is usually self-limited and treated primarily by gently massaging the scalp with baby oil, followed by the use of a nonmedicated shampoo to remove scales.<sup>1</sup> For cases that do not respond to this treatment, the patient should be referred to a pediatrician. In adults, regardless of the location of any skin lesions, shampooing is the foundation of treatment, since once the disorder is controlled, at least weekly use of shampoos containing pyrithione zinc, selenium sulfide, or ketoconazole prevents relapses. If the odor of a medicated shampoo is objectionable, it can be followed by a more cosmetically acceptable shampoo or conditioner. A regular nonmedicated shampoo or liquid dishwashing soap (e.g., Dawn) can be used to soften and remove crusts or scales.<sup>5</sup> Seborrheic dermatitis can also be treated by applying the shampoo containing pyrithione zinc or selenium sulfide to the affected areas of the skin at the same time the shampoo is massaged into the scalp and hair, washing it off 5 minutes later when the shampoo is rinsed out of the hair. Topical corticosteroids are not useful in treating dandruff; however, these agents are needed more frequently to treat the greater levels of inflammation in seborrheic dermatitis. These products may be used to manage seborrheic dermatitis whenever erythema persists after therapy with medicated shampoos. Hydrocortisone ointment should be applied no more than twice daily, because of the reservoir effect of the stratum corneum that slowly releases the corticosteroid over time. Treat until symptoms subside for up to 7 consecutive days. Use of nonprescription hydrocortisone should not exceed 7 consecutive days. If the condition worsens or symptoms persist longer than 7 days, a primary care provider should be consulted. A more potent topical corticosteroid may be indicated.<sup>5</sup>

## Psoriasis

Psoriasis is a chronic inflammatory disease estimated to afflict 1%-3% of Americans.<sup>7,8</sup> Lesions are often localized, but they may become generalized over much of the body surface. Remissions and exacerbations are unpredictable. Approximately 30% of people with psoriasis find that lesions may clear spontaneously.<sup>7,8</sup> Unrelenting generalized psoriasis may cause enough psychological distress to adversely affect the patient's quality of life. Treatment of moderate-severe psoriasis can produce a significant physical and economic burden.<sup>8</sup>

The incidence of psoriasis is distributed almost equally among men and women. Psoriasis is seen in all races and geographic regions, but the incidence is lower among people living in countries close to the equator and among people of African American, Native American, and Asian descent.<sup>6,7,8</sup>

The cause of psoriasis is unknown. However, exacerbations of psoriasis can be triggered by the following:

- Environmental factors such as physical, ultraviolet, and chemical injury.
- Various infections (streptococcal infection but also acute viral infections and human immunodeficiency virus infections).
- Prescription drug use (e.g., beta-blockers, lithium, antimalarials, indomethacin, and quinidine) and withdrawal of systemic corticosteroids.
- Psychological stress.
- Endocrine/hormonal changes.
- Obesity.
- Use of alcohol and tobacco.

## Pathophysiology of Psoriasis

Accelerated epidermal proliferation leading to excessive scaling on raised plaques is one hallmark symptom of psoriasis. Epidermal cell turnover rate is approximately 4 days in a psoriatic plaque. The duration of psoriasis is variable, and lesions may last a lifetime or disappear quickly. When lesions disappear, they may leave the skin either hypopigmented or hyperpigmented. The disease course is marked by spontaneous exacerbations and remissions, and it tends to be chronic and relapsing.<sup>8</sup>

## Clinical Presentation of Psoriasis

Regardless of the clinical form, psoriasis is usually symmetrical. Plaque psoriasis is the most common form, occurring in more than 90% of patients. Lesions start as small papules that grow and unite to form plaques. These lesions are well-circumscribed, sharply demarcated, light pink to bright red or maroon plaques, with overlying opaque, thick, adherent, white scales that can be pulled off in layers (see Color Plates, photographs 14A, B, and C). When the scale is lifted from the base of the plaque, punctate bleeding points sometimes occur at the sites of scale removal (Auspitz sign). The most common locations are the extensor surfaces of the elbow and knees, the lumbar region of the back, the scalp, the posterior auricular area, the external auditory canal, and the glans penis.

## Treatment of Psoriasis

### Treatment Goals

The goals of self-treatment of psoriasis are to (1) control or eliminate the signs and symptoms (inflammation, scaling, and itching) and (2) prevent or minimize the likelihood of flare-ups.

### General Treatment Approach

The Food and Drug Administration (FDA) recommends that only very mild cases of psoriasis be self-treated (up to a few isolated lesions no larger than a quarter). Larger areas of involvement, involvement of the face, or the presence of joint pain dictate that the patient be treated by a dermatologist with more effective prescription medications. Individuals with moderate-severe cases, involving more than 5% of body surface area, should be treated by a dermatologist.<sup>7,9</sup> Cases not responding to emollients and nonprescription strengths of hydrocortisone or cases in children younger than 2 years should also be referred to a dermatologist.

Numerous nondrug measures can be used by patients in the treatment of psoriasis. Although these treatments can help symptoms and enhance the local effectiveness of nonprescription products, these measures alone are unlikely to control the signs and symptoms of the disorder. Patients should avoid physical, chemical, or ultraviolet (UV) trauma to the skin because of the Koebner phenomenon where lesions develop at the site of skin trauma. Scale removal is an important treatment modality because scales facilitate the continuation of psoriatic plaques and interfere with the penetration of topical agents. Patients with psoriasis should be encouraged to bathe with lubricating bath products (see [Chapter 32](#)) 2-3 times per week using tepid water. Loose scales can be removed by gently rubbing with a soft cloth. Emollients (e.g., Lubriderm Lotion or Nivea Cream) should be applied to the lesions within minutes of bathing. Pruritic dry skin is common in psoriasis, and emollients and lubricating bath products often provide some relief for these symptoms. Daily lubrication of the skin after a bath or shower is an essential part of therapy. Emollients moisturize, lubricate, and soothe dry and flaky skin, as well as reduce fissure formation within plaques and help maintain flexibility of the surrounding skin. To be effective, they need to be applied liberally with gentle rubbing, up to 4 times daily.

Hydrocortisone ointment 1% is the nonprescription treatment of choice for individual acute lesions. Acute localized flares, characterized by bright red lesions, call for soothing local therapy with emollients and hydrocortisone ointment. Many patients respond well to simple measures, whereas others have a form of disease that requires more aggressive treatments.<sup>8</sup>

For patients who are not candidates for nonprescription treatment, the selection of therapy must be individualized based on the site, severity, duration, previous treatment, and age of the patient. Treatment may be topical, systemic, or a combination of both. Factors in determining appropriate therapy include body surface area affected by psoriasis, age, cost, and ability of the patient to comply with the regimen. In most cases, psoriasis will not be controlled by nonprescription treatment, and referral to a dermatologist will be necessary. Prescription topical agents such as calcipotriol, tazarotene, and more potent corticosteroids are effective. For moderate-severe or recalcitrant psoriasis, more aggressive treatment is necessary. Treatment options available in many dermatologists' offices include phototherapy with narrow-band UVB radiation and a combination of methoxsalen (a chemical photosensitizing psoralen) and UVA radiation. Other treatment options include systemic agents, such as oral retinoids (acitretin), methotrexate, cyclosporine, and the newer biologics (adalimumab, etanercept, infliximab, and ustekinumab).<sup>7</sup> Psoriasis cannot be cured, and remissions do occur. During flare-ups, however, signs and symptoms can usually be controlled adequately with appropriate patient education and treatment. The patient should be reassured that, in most cases, control is possible. This reassurance increases compliance with burdensome and prolonged treatment regimens. In addition, if the patient can be helped to gain some understanding and acceptance of the condition, that knowledge may reduce the patient's emotional stress and psychogenic exacerbations. Prevention of flare-ups should be emphasized. Flare-ups can be prevented by minimizing identified precipitating factors, such as emotional stress, skin irritation, and physical trauma.

### Treatment of Scaly Dermatoses

A variety of products, often in the form of a medicated shampoo, with varying mechanisms of action, is used to treat scaly dermatoses. In addition, hydrocortisone is used to control the inflammation associated with seborrheic dermatitis and psoriasis. Table 33-1 summarizes the concentrations and indications of currently approved agents,<sup>6,10</sup> and the algorithm in Figure 33-1 outlines self-treatment with these agents.

Patients should shampoo with a nonmedicated, nonresidue shampoo to remove scalp and hair dirt, oil, and scales before using a medicated shampoo. Many shampoos leave a residue on the hair shaft and scalp that may aggravate scaly dermatoses of the scalp. Nonresidue shampoos (e.g., Johnson's and Johnson's Baby Shampoo) do not interfere with these scalp conditions; rather they leave the scalp clean and receptive to optimal effects from medicated shampoos. A nonresidue shampoo application and rinse may be followed by a medicated shampoo, left on the scalp for up to 5 minutes. The patient can use this treatment daily, if needed, until symptoms are relieved and then 2-3 times weekly.<sup>5</sup>

**TABLE 33-1 Concentrations of Approved Nonprescription Ingredients for Products Used to Treat Scaly Dermatoses**

Ingredient	Concentration (%)		
	Dandruff	Seborrheic Dermatitis	Psoriasis
Coal tar	0.5-5	0.5-5	0.5-5
Hydrocortisone		0.5-1	0.5-1
Ketoconazole	1	1	1
Pyrithione zinc (brief exposure)	0.3-2	0.95-2	2
Pyrithione zinc (residual)	0.1-0.25	0.1-0.25	0.25
Salicylic acid	1.8-3	1.8-3	1.8-3
Selenium sulfide	1	1	1
Sulfur	2-5	2-5	

Source: References 6 and 10.

## Anti-Malassezia Agents

### Pyrithione Zinc

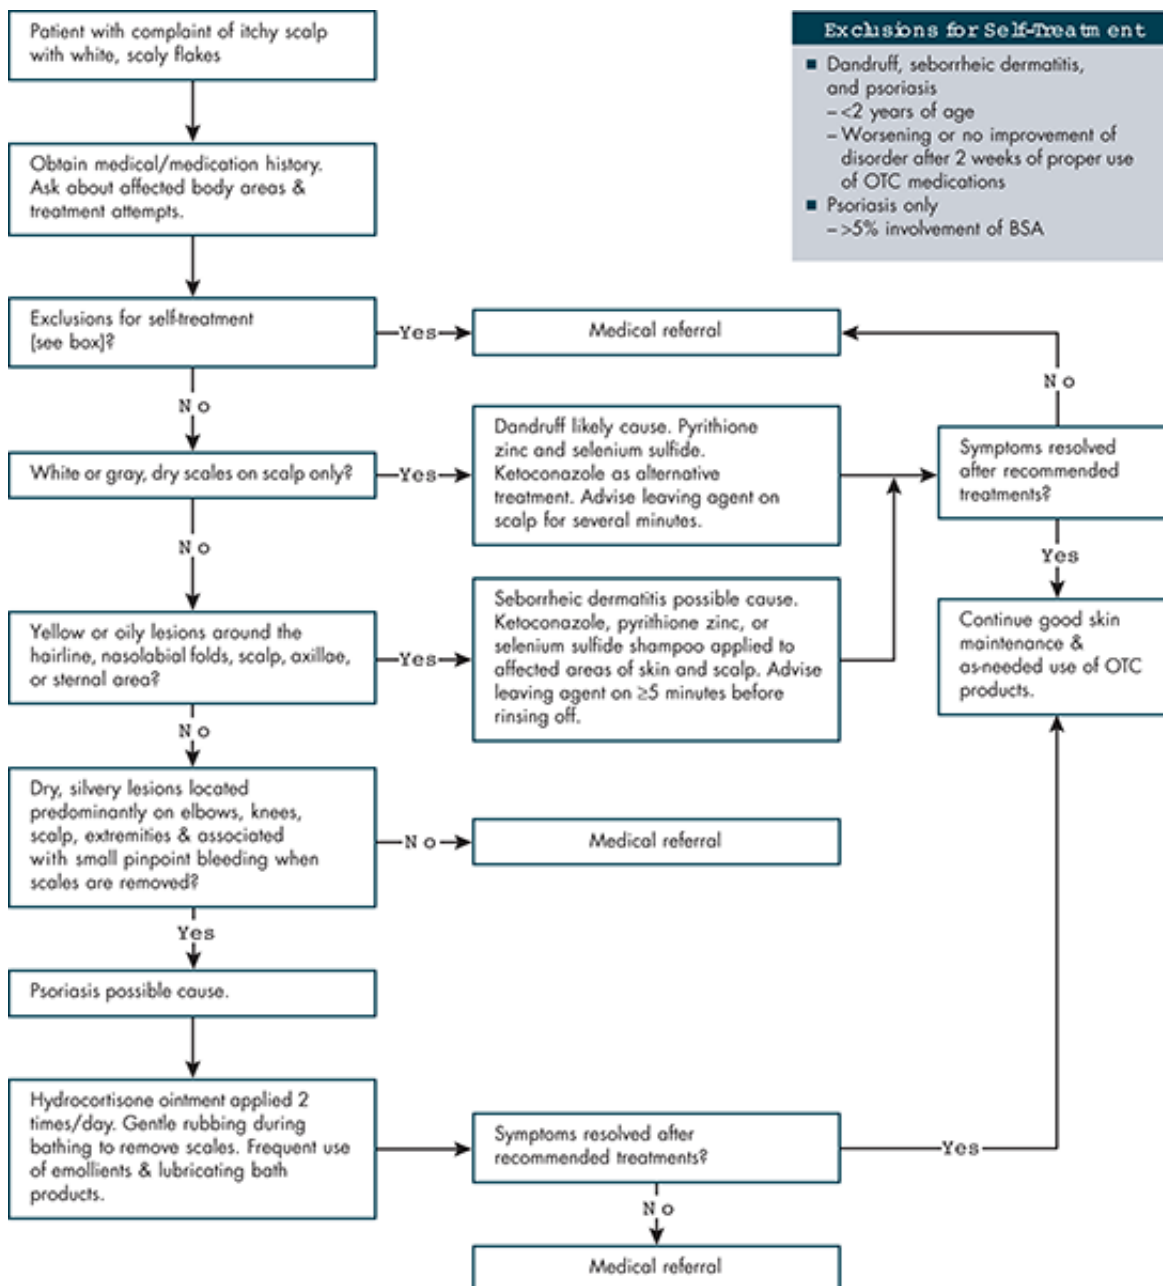

Pyrithione zinc's mechanism of action is its anti-*Malassezia* activity, which reduces the yeast count in the scalp and skin. Product effectiveness is influenced by several factors. Pyrithione zinc binds strongly to both hair and the external skin layers of the scalp, and the extent of binding correlates with clinical performance.

For pyrithione zinc products intended to be applied and washed off within minutes (brief exposure), FDA recommends concentrations of 0.3%-2.0% for treating dandruff and 0.95%-2.0% for treating seborrheic dermatitis. Shampoos and soaps are currently available in 1% and 2% concentrations. Pyrithione zinc shampoo is well tolerated when used as directed and is not associated with any major adverse effects. Contact with the eyes should be avoided to prevent stinging.

### Selenium Sulfide

Selenium sulfide and pyrithione zinc have a similar mechanism of action.<sup>3</sup> Like pyrithione zinc, selenium sulfide is more effective with longer contact time and therefore should be applied in a similar manner.<sup>4,5</sup> Selenium sulfide in prescription strength must be rinsed from the hair thoroughly or discoloration may result, especially in blond, gray, or dyed hair. Frequent use may leave a residual odor and an oily scalp.

Selenium sulfide is approved in a 1% concentration in nonprescription products to treat dandruff and seborrheic dermatitis. A 2.5% lotion formulation is available by prescription for use in resistant cases and other topical fungal infections. The risk of irritation of the mucous membranes and scalp from selenium sulfide is minimal, and no adverse effects are associated with routine use of the 1% shampoo. Contact with the eyelids should be avoided because of the potential for eye irritation.

Self-care of scaly dermatoses. Key: BSA = Body surface area; OTC = over-the-counter.

### Ketoconazole

Ketoconazole, a synthetic azole antifungal agent, is available as a nonprescription shampoo formulation. Ketoconazole 1% is active against most pathogenic fungi but is indicated specifically for *Malassezia*. Therefore, it is used to treat dandruff and seborrheic dermatitis of the scalp. Although the fungal etiology of dandruff and seborrhea has been debated, the efficacy of newer antifungal agents against these conditions has caused an FDA review panel for nonprescription products to endorse these agents for treatment of these two common skin disorders. Patients should use ketoconazole shampoo twice a week for 4 weeks, with at least 3 days between each treatment. Once the condition is controlled, the shampoo can be applied once weekly to prevent relapse. Adverse effects associated with 1% ketoconazole shampoo are minimal, but hair loss, skin irritation, abnormal hair texture, and dry skin have been reported. Patients should be advised to avoid contact of ketoconazole shampoo with the eyes because irritation may occur.

### Cytostatic Agents

Although their mechanism of action is not completely understood, topical cytostatic agents are known to decrease the rate of epidermal cell replication. This action increases the time required for epidermal cell turnover, which in turn allows the possibility of normalizing epidermal differentiation, resulting in a slow decline in visible scales. However, these products have limited efficacy and multiple other issues that make them poor alternatives to anti-*Malassezia*

products.

### Coal Tar

Coal tar products have long been popular for treating dandruff, seborrheic dermatitis, and psoriasis. Many nonprescription products are available but are of limited usefulness because of their potentially unacceptable cosmetic properties and limited clinical efficacy.

For many years, the therapeutic response to coal tar products was believed to be caused solely by its phototoxicity. Now it is believed that the beneficial effect of coal tar lies primarily in its ability to cross-link with DNA and arrest excessive skin cell proliferation.

Coal tar is available in concentrations of 0.5%-5% as creams, ointments, pastes, lotions, bath oils, shampoos, soaps, and gels for self-treatment of dermatologic disorders. This variety of dosage forms is partly a result of an attempt to develop a cosmetically acceptable product, one that masks the odor, color, and staining properties of crude coal tar that most patients find esthetically unappealing.

Side effects are associated with the use of coal tar, including folliculitis (particularly of the axilla and groin); stains to the skin and hair (particularly blond, gray, and dyed hair); photosensitization; and irritant contact dermatitis.<sup>2</sup> Rarely, the disorder may worsen on exposure to coal tar products. This situation is of particular concern in the acute phase of psoriasis, when topical corticosteroids are recommended to reduce inflammation before coal tar preparations are used.

Coal tar products may be applied to the body, arms, and legs, preferably at bedtime. Because coal tar stains most materials, the patient should use bed linen and clothing for which staining would not present a problem. Overnight application is followed by a bath in the morning to remove residual coal tar and loosen psoriatic scales. Patients using coal tar preparations should avoid sun exposure for 24 hours after application.

### Keratolytic Agents

The keratolytic agents salicylic acid and sulfur can be used in dandruff and seborrheic dermatitis products to loosen and lyse keratin aggregates, thereby facilitating their removal from the scalp in smaller particles. These agents act by dissolving the "cement" that holds epidermal cells together. Vehicle composition, contact time, and concentration are important factors in the success of a keratolytic agent. Keratolytic concentrations in nonprescription scalp products (Table 33-2) are not sufficient to impair the normal skin barrier, but they do affect the abnormal, incompletely keratinized stratum corneum. These products have very limited efficacy and are very slow acting, taking weeks to months to see any visible improvement.

Keratolytic agents may produce several adverse effects, and patients should be counseled accordingly. These agents have a primary, concentration-dependent irritant effect, particularly on mucous membranes and the conjunctiva of the eye. They also have the potential of acting on hair and skin keratin; therefore, extended use may alter hair appearance. The directions and precautions for the use of keratolytic shampoos are similar to those for shampoos containing other therapeutic agents, with the exception that prolonged use is usually necessary to obtain a therapeutic response.

### Salicylic Acid

Salicylic acid decreases skin pH, which causes increased hydration of keratin and therefore facilitates its loosening and removal. Topical salicylic acid is useful for psoriasis when thick scales are present. However, application over extensive areas should be avoided because of the potential for percutaneous absorption.

Salicylic acid has been approved in concentrations of 1.8%-3% for the self-treatment of dandruff, seborrheic dermatitis, and psoriasis. At these concentrations, the keratolytic effect typically takes 7-10 days.

### Sulfur

Sulfur is believed to cause increased sloughing of cells and to reduce corneocyte counts. Sulfur has been approved in concentrations of 2%-5% for the self-treatment of dandruff only. Although it is approved as a single-entity active ingredient, sulfur is often combined with salicylic acid. Although not an FDA-approved indication, this combination has been commonly used for the self-treatment of seborrheic dermatitis.<sup>9</sup> The use of nonprescription topical preparations containing sulfur has not been associated with any significant adverse effects.

### Topical Hydrocortisone

Topical hydrocortisone 0.5% and 1% is available without a prescription and is FDA approved for inflammatory skin conditions such as allergic contact dermatitis, insect bites, eczema, and psoriasis. It may be useful for seborrheic dermatitis accompanied by inflammation that is unresponsive to medicated shampoos and is the non-prescription treatment of choice for mild psoriasis.<sup>3,4,5,6</sup>

Nonprescription hydrocortisone products can play a role in managing mild psoriasis. Topical corticosteroids have

several effects (e.g., anti-inflammatory, vasoconstrictive, and immunosuppressive) on cellular activity, which can result in decreased redness and itching. Hydrocortisone ointment is the most potent and effective dosage form. The activity of the ointment can be enhanced in psoriasis by waiting 30 minutes after its application and then covering the area of the psoriatic plaque with a greasy emollient such as petrolatum, which acts as an occlusive dressing.

**TABLE 33-2 Selected Nonprescription Products to Treat Dandruff and Scaly Dermatoses**

<i>Trade Name</i>	<i>Primary Ingredients</i>
<b>Anti-Malassezia Products</b>	
Denorex Everyday Shampoo	Pyrithione zinc 2%
DHS Zinc Shampoo	Pyrithione zinc 2%
Head & Shoulders Dandruff Shampoo	Pyrithione zinc 1%
Head & Shoulders Intensive Treatment Shampoo	Selenium sulfide 1%
Nizoral AD Shampoo	Ketoconazole 1%
Sebulon Shampoo	Pyrithione zinc 2%
Selsun Blue Medicated Treatment Shampoo	Selenium sulfide 1%
Zincon Shampoo	Pyrithione zinc 1%
ZNP Cleansing Bar	Pyrithione zinc 2%
<b>Cytostatic Products</b>	
Balnetar Bath Oil	Coal tar 2.5% in mineral oil
DHS Tar Shampoo	Coal tar 0.5%
DHS Tar Gel Shampoo	Coal tar 0.5%
Neutrogena T/Derm Body Oil	Tar 5% (equivalent to coal tar 1.2%)
Neutrogena T/Gel Extra Strength Therapeutic Shampoo	Tar 4% (equivalent to coal tar 1%)
Neutrogena T/Gel Shampoo	Tar 2% (equivalent to coal tar 0.5%)
Pentrax Shampoo	Coal tar extract 5%
<b>Keratolytics</b>	
MG217 Medicated Tar-Free Shampoo	Salicylic acid 3%; sulfur 5%
Neutrogena Healthy Scalp Anti-Dandruff Shampoo	Salicylic acid 1.8%
Sebucare Lotion	Salicylic acid 1.8%
Sebulex Conditioning Shampoo with Protein	Salicylic acid 2%; sulfur 2%
Sulfoam Medicated Antidandruff Shampoo	Sulfur 2%
Sulray Cleansing Bar	Sulfur 5%
Sulray Dandruff Shampoo	Sulfur 2%
X-Seb Shampoo	Salicylic acid 4%
<b>Combination Products</b>	
Neutrogena T/Sal Maximum Strength Therapeutic Shampoo	Salicylic acid 3%; coal tar extract 2%
P&S Plus Gel	Coal tar solution 8%; salicylic acid 2%
Scalpicin Maximum Strength Foam/Solution	Salicylic acid 3%; menthol

Sebutone Shampoo	Coal tar 0.5%; sulfur 2%; salicylic acid 2%
X-Seb Plus Shampoo	Pyrrithione zinc 1%; salicylic acid 2%
X-Seb T Shampoo	Coal tar solution 10%; salicylic acid 4%
X-Seb T Plus Shampoo	Coal tar solution 10%; salicylic acid 3%; menthol 1%

Adverse effects associated with the use of topical corticosteroids include local atrophy after prolonged use, as well as the aggravation of certain cutaneous infections. The possibility of systemic sequelae exists and is enhanced by the use of the more potent compounds, use of occlusive dressings, or application to large areas of the body.

### Assessment of Scaly Dermatoses: A Case-Based Approach

Differentiation of the scaly dermatoses involves several factors. The appearance of the scales in the early stages of a disorder is not always definitive. In these cases, the presence and nature of other symptoms or the location of the dermatitis provides additional important clues to its assessment. Factors that precipitate or exacerbate the disorder are also helpful in defining the disorder. [Table 33-3](#) describes the distinguishing features of these three dermatoses. Cases 33-1 and 33-2 illustrate the assessment of patients with scaly dermatoses.

**TABLE 33-3 Distinguishing Features of Scaly Dermatoses**

	<i>Dandruff</i>	<i>Seborrheic Dermatitis</i>	<i>Psoriasis</i>
Location	Scalp	Adults and children: head and trunk	Scalp, elbows, knees, trunk, lower extremities
Exacerbating factors	Generally a stable condition, exacerbated by dry climate	Exacerbated by many external factors, notably Parkinson's disease	Exacerbated by irritation, stress, climate, medications, infection, endocrine factors
Appearance	Thin, white, or grayish flakes; even distribution on scalp	Macules, patches, and thin plaques of discrete yellow, oily scales on red skin	Discrete symmetrical, red plaques with sharp border; silvery white scale; small bleeding points when scale is removed; difficult to distinguish from seborrhea in early stages or in intertriginous zones
Inflammation	Absent	Present	Present
Epidermal hyperplasia	Absent	Present	Present
Epidermal kinetics	Turnover rate 2 times faster than normal	Turnover rate about 3 times faster than normal	Turnover rate about 5-6 times faster than normal
Percentage of incompletely keratinized cells	Rarely exceeds 5% of total corneocyte count	Commonly makes up 15%-25% of corneocyte count	Commonly makes up 40%-60% of corneocyte count

Source: References 1 and 2.

### Patient Counseling for Scaly Dermatoses

Patients need to know that scaly dermatoses are rarely cured by pharmacotherapy; rather, nonprescription agents help control the signs and symptoms of the disorders. Patients should also be advised that fluctuation in severity of seborrheic dermatitis and psoriasis may be related to emotional, physical, or environmental factors. Explanations of the proper use of antifungal, cytostatic, and keratolytic agents should include information about the length of time to leave the agent on the affected area. Possible side effects with recommended agents should also be explained. Finally, patients should be advised of signs and symptoms that indicate medical attention is needed. The

box Patient Education for Dandruff and Seborrheic Dermatitis and the box Patient Education for Psoriasis list specific information to provide patients.

### Case 33-1

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of yellow, oily scales along his hairline and around his nose. Some minor erythema is also present in these areas.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The condition has grown worse since the onset of cold weather.
c. description of the patient's efforts to relieve the symptoms	Washing the face twice daily with hand soap has not proven beneficial.
d. patient's identity	Robert Plant
e. age, sex, height, and weight	57 years old, male, 5 ft 9 in., 185 lb
f. patient's occupation	Sales manager
g. patient's dietary habits	Normal healthy diet
h. patient's sleep habits	6-7 hours per night
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Depression: sertraline 50 mg daily; hypertension: hydrochlorothiazide 25 mg daily
j. allergies	NKA
k. history of other adverse reactions to medications	None
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly	Robert appears to have seborrheic dermatitis on his face. His scalp should be examined closely for involvement as well.

identify the patient's primary problem(s) (Table 33-3).	
3. Identify exclusions for self-treatment (Figure 33-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Recommend self-care with an appropriate OTC product and nondrug measures. (2) Recommend self-care with an appropriate OTC product and nondrug measures until a PCP or dermatologist can be consulted. (3) Refer Robert to a PCP or dermatologist. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	OTC treatment with pyrithione zinc shampoo can be used initially. Ketoconazole or selenium sulfide shampoo is a good alternative agent to recommend if the patient prefers to use an alternative product. Hydrocortisone 1% ointment can be added to red areas if 1 week of treatment with medicated shampoo does not resolve redness.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"For the first week, shampoo the hair with the medicated shampoo and apply it to the affected areas of the face daily. Leave on for 5 minutes, then rinse off. For the next 4 weeks, repeat the above procedure only 2-3 times per week. Regardless of the location of the lesions, the hair needs to be shampooed to prevent relapse. Once the condition is controlled, the hair should be shampooed at least once a week to prevent relapse."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"You may use the pyrithione zinc, selenium sulfide, or ketoconazole shampoo according to personal preference and cost."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	See the box Patient Education for Dandruff and Seborrheic Dermatitis.
Solicit follow-up questions from the patient or caregiver.	"What should I use on my hair on the days I do not use the medicated shampoo?"
Answer the patient's or caregiver's questions.	"Any type of nonmedicated shampoo is fine to use. One that does not leave a residue is preferred. Once your condition is controlled, daily use of a shampoo is not necessary unless your scalp is especially oily."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact the patient in a week to assess his progress in resolving his seborrheic dermatitis.

Key: NA = Not applicable; NKA = no known allergies; OTC = over-the-counter; PCP = primary care provider.

### Case 33-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient has had shiny scales bilaterally on her elbows for greater than 6 months. Some minor bleeding occurs when the scales are removed. She now complains of the development of lesions on both of her knees.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The lesions appeared to worsen after her recent divorce from her husband.
c. description of the patient's efforts to relieve the symptoms	Use of hydrocortisone 1% cream once daily has been marginally effective. Use of lotion on the lesions is soothing.
d. patient's identity	Elaine Abel
e. age, sex, height, and weight	43 years old, female, 5 ft 6 in., 195 lb
f. patient's occupation	Factory line worker
g. patient's dietary habits	Normal diet
h. patient's sleep habits	Averages 6-8 hours per night.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Diabetes mellitus > 2 years: fairly well controlled with metformin 500 mg twice daily; hypothyroidism > 15 years: well controlled with levothyroxine 100 mcg once daily; allergic rhinitis > 20+ years: controlled with loratadine 10 mg once daily
j. allergies	Penicillin: rash
k. history of other adverse reactions to medications	None
l. other (describe) _____	Elaine showers once or twice daily.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s) (Table 33-3).	Elaine possibly has a flare of psoriasis. The type of lesions and bilateral appearance support this assessment.

3. Identify exclusions for self-treatment (Figure 33-1).	The worsening symptoms and appearance of the lesions on the patient's knees indicate a worsening condition that requires more than self-care.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Elaine to a dermatologist for a differential diagnosis. (2) Recommend an OTC product (hydrocortisone ointment 1% and emollient therapy) to use until the physician appointment. (3) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Refer the patient to a dermatologist for a differential diagnosis and treatment.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Contact your dermatologist to accurately diagnose your condition. Until the time of your appointment, you could switch to applying hydrocortisone ointment 1% to the affected areas 2 times daily. Wait 30 minutes and then liberally apply an emollient."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"You need to see a dermatologist because OTC therapy won't be as effective as prescription medications for disease as extensive as yours."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	See the box Patient Education for Psoriasis for nondrug measures to treat psoriasis.
Solicit follow-up questions from the patient or caregiver.	"I saw on the Internet that treatment with coal tar products is an option for psoriasis. Should I use one of these products?"
Answer the patient's or caregiver's questions.	"Although coal tar products have been used for a long time, topical corticosteroid therapy is now considered the first-line topical therapy for most patients. The smell and mess associated with using coal tar products are major drawbacks, plus they have limited efficacy."
<b>Evaluation of Patient Outcomes</b>	
9. Assess patient outcome.	Call patient in 2 days to make sure she was able to get an appointment with the dermatologist.

Key: OTC = Over-the-counter.

#### Patient Education for Dandruff and Seborrheic Dermatitis

The primary objective of self-treating dandruff and seborrheic dermatitis is to reduce the turnover rate of skin cells, which is responsible for the scaly lesions. Controlling inflammation and itching of the affected areas is another treatment objective. Although these disorders are chronic and incurable, carefully following product instructions and

the self-care measures can help ensure optimal therapeutic outcomes for many patients.

### General Measures

- Shampoo the hair with the medicated shampoo 3-7 times a week initially, leaving the shampoo on the hair for 5 minutes. Work the shampoo into the scalp and simultaneously apply the shampoo to the affected area of the face. Rinse the scalp and face thoroughly after 5 minutes. Use a scalp scrubber to ensure penetration to the scalp. Repeat this procedure.
- Use the shampoo for a minimum of 2 weeks to determine effectiveness; after 4 weeks of use, apply the shampoo once a week to control the condition.
- If used, apply a thin layer of the hydrocortisone cream no more than 2 times daily. Wash the affected areas before use.
- With use of medication and proper nondrug therapy, noticeable improvement could be observed within 7-14 days. Complete control of the condition is possible with weekly use of the medicated shampoo. It is likely that exacerbations may occasionally appear, especially during the winter months.
- Stinging or burning may occur if medicated shampoo enters the eyes.

### Dandruff

- Use a medicated shampoo containing pyrithione zinc or selenium sulfide. If these agents are ineffective, refer to a physician or dermatologist.
- Coal tar can stain light hair and cause folliculitis (inflammation of hair follicles), dermatitis, and photosensitization (sensitivity of the skin to sunlight).
- Shampoo the hair with the medicated shampoo, and leave it on the hair for 3-5 minutes. Rinse the hair thoroughly and repeat. Rinse hair thoroughly after use of the medicated shampoo.

### Seborrheic Dermatitis

- Use a medicated shampoo containing ketoconazole, pyrithione zinc, or selenium sulfide. Shampoo the hair and scalp, and apply shampoo directly to any lesions on the face and hairline. More aggressive doses of the anti-*Malassezia* shampoos are used for seborrheic dermatitis than for dandruff. Daily use for seborrheic dermatitis is appropriate for the first week; after that reduce use to 2-3 times a week. Regardless of the location of the lesions, the hair needs to be shampooed. The scalp always has the highest concentration of *Malassezia* yeast and is the source of the yeast that causes skin lesions on the face. Washing the hair at least weekly with anti-*Malassezia* shampoos is absolutely essential to preventing relapse, even if lesions were only on the face.
- If redness persists after therapy with medicated shampoos, apply hydrocortisone ointment 2 times a day until symptoms subside, and then apply the ointment intermittently to control acute exacerbations. Do not use this agent longer than 7 days. Prolonged use can cause rebound flare-ups when the hydrocortisone is discontinued.

### When to Seek Medical Attention

- Consult a primary care provider or dermatologist if the condition does not improve or if it worsens after 1-2 weeks of treatment with nonprescription medications.

### Patient Education for Psoriasis

The primary objective of self-treating psoriasis is to reduce the turnover rate of skin cells, which is responsible for the scaly lesions. Controlling inflammation and itching of the affected areas and hydrating the skin are other treatment objectives. Although psoriasis is chronic and incurable, carefully following product instructions and self-care measures can help ensure optimal therapeutic outcomes for many patients.

- For itchy, dry skin, use emollients and lubricating bath products (see [Chapter 32](#)). Remove scales by gently rubbing them with a soft cloth after the bath. Do not rub vigorously.
- For psoriasis involving more than one or two coin-sized lesions, refer to a dermatologist.
- Prevent flare-ups by minimizing factors such as emotional stress, skin irritation, and physical trauma that you know will exacerbate the disorder.

### When to Seek Medical Attention

- If you have psoriasis lesions plus joint pain, see a dermatologist for treatment.
- If hydrocortisone ointment and emollients are not effective, or if the area affected is more than a few less-than-quarter-size lesions, see a dermatologist for treatment with prescription products.
- Consult a dermatologist if the condition does not improve or if it worsens after 2 weeks of treatment with nonprescription medications.

## Evaluation of Patient Outcomes for Scaly Dermatoses

Follow-up on the patient's progress should occur after 1 week of self-treatment. If the symptoms have worsened after this period, the patient should consult a primary care provider. If the disorder has not worsened, the provider should ask the patient to return after a second week of treatment. If the symptoms persist or have worsened after this period, the patient should consult a primary care provider.

## Key Points for Scaly Dermatoses

- Mild-moderate scaly dermatoses can often be effectively managed with topical nonprescription products.
- Product selection should be based on an evaluation of the patient's history and prior response to treatment, as well as a careful evaluation of the risks and benefits of using the nonprescription products.
- The provider should be sure to educate patients about the proper application of topical therapy, which greatly impacts the efficacy of therapy.

**Handbook of Nonprescription Drugs > Chapter 34. Contact Dermatitis****Contact Dermatitis: Introduction**

Contact dermatitis is a condition characterized by inflammation, redness, itching, burning, stinging, and vesicle and pustule formation on dermal areas exposed to irritant or antigenic agents.<sup>1,2</sup> The two primary types of contact dermatitis, classified by etiology and presentation, are discussed separately in this chapter. Irritant contact dermatitis (ICD) is an inflammatory reaction of the skin caused by exposure to an irritant. Allergic contact dermatitis (ACD) is an immunologic reaction of the skin caused by exposure to an antigen.<sup>2</sup>

**Irritant Contact Dermatitis**

The majority of ICD cases are related to occupation, particularly jobs that involve work with water or exposure to irritant substances. ICD occurs frequently in the home; however, the only available statistics are those associated with employment. According to the U.S. Bureau of Labor Statistics (BLS), work-related skin disorders comprised 16.0% of total workplace injuries in 2011. Individuals employed in forestry, agriculture, and fishing industries have the greatest incidence of ICD, at 9.2 per 10,000 workers in each of these sectors. Workers in manufacturing, education, and health services sectors follow, with incidence of 4.6 per 10,000 workers in each of the sectors.<sup>3</sup> The BLS annual survey of occupational illnesses reveals that occupational dermatitis in private industry accounts for approximately 57.1% of all occupational skin diseases, with 41.2% of the cases of contact dermatitis identified as ACD, 26.1% as ICD, and 32.7% as unspecified or other types of dermatitis.<sup>4</sup> The actual number of cases is estimated to be 10-50 times greater than the reported number because of changes in industry procedure, underreporting of incidents, and limitations in data collection for the BLS survey.<sup>5</sup> The estimated cost for managing contact dermatitis is \$1 billion annually, which includes treatment and workdays lost.<sup>6</sup>

**Pathophysiology of Irritant Contact Dermatitis**

ICD is common in individuals who work in environments such as personal service (e.g., hair stylists) and health care. Substances associated with ICD are listed in [Table 34-1](#). Individuals who must wash their hands frequently, handle food, or have repeated contact with other irritants are at increased risk.<sup>7,8,9</sup> Most instances of ICD occur on exposed skin surfaces, especially the face and dorsal surfaces of the hands and forearms. ICD may appear after a single exposure to an irritant or after multiple exposures to the same agent. Mechanisms responsible for causing ICD include disruption of the skin barrier, changes in the cells of the epidermis, and release of proinflammatory cytokines.<sup>7</sup> The substance or irritant may directly damage the epidermal cells by being directly absorbed through the cell membrane and destroying cell systems. Another mechanism may be through the release of cytokines as a result of chemical exposure.<sup>7,10</sup>

**TABLE 34-1 Selected Common Substances Associated with Irritant Contact Dermatitis**

- Acids, strong (e.g., hydrochloric, nitric, sulfuric, hydrofluoric)
- Alkalis, strong (e.g., sodium, potassium, calcium hydroxides)
- Detergents, soaps, and hand sanitizers
- Epoxy resins
- Ethylene oxide
- Fiberglass
- Flour
- Oils (e.g., cutting, lubricating)
- Oxidants, plasticizers, and activators in athletic shoes
- Oxidizing agents
- Reducing agents
- Solvents
- Urine/feces
- Water
- Wood dust and products

Source: Adapted from references 8 and 9.

Several factors may affect the magnitude of the skin response. The presence of existing skin conditions, such as atopic dermatitis, can result in a more profound dermatitis because of the increased or enhanced permeability of the dermis. The quantity and concentration of substance exposure also affect the severity of the response. Chemical irritants, acids, and alkalis are likely to produce immediate and severe inflammatory reactions. Mild irritants, such as detergents, soaps, and solvents, often require repeated exposures before the dermatitis appears. Occlusive clothing and diapers can prolong skin contact with the irritant, allowing greater skin penetrability of the irritant and leading to a more severe reaction. In addition, environmental factors, such as warmer ambient temperature and higher humidity, may contribute to more severe ICD.

### Clinical Presentation of Irritant Contact Dermatitis

Following exposure to an irritant, the skin becomes inflamed, swells, and turns erythematous. Symptoms often are delayed and generally do not occur immediately after exposure. ICD presents primarily as dry or macerated, painful, cracked, and inflamed skin. Itching, stinging, and burning commonly occur with the rash. The inflammatory reaction varies, ranging from these initial symptoms to ulcer formation and localized necrosis. Within days, the dermatitis may crust. If the patient avoids further contact with the irritant, the dermatitis generally resolves in several days. In patients chronically exposed to an irritant, the affected areas of skin will remain inflamed, may develop fissures and scales, and may become hyper- or hypopigmented.<sup>10,11</sup> Some patients who are chronically exposed to irritants recover completely, whereas others improve but continue to have recurrences. In some patients who are chronically exposed to an irritant, necrosis, inflammation, and crusting comparable to or worse than the original insult may be observed.<sup>12</sup> Chronic forms of ICD can present with lichenification, or leathery thickening of the skin.

### Treatment of Irritant Contact Dermatitis

#### Treatment Goals

The goals in self-treating ICD are to (1) remove the offending agent and prevent future exposure to the irritant; (2) relieve the inflammation, dermal tenderness, and irritation; and (3) educate the patient on self-management to prevent or treat recurrences.

#### General Treatment Approach

The primary treatment advice is avoidance of further irritant exposure, institution of preventive measures, and patient education.

#### Nonpharmacologic Therapy

Regardless of the severity, the area of initial exposure to the irritant should be washed with copious amounts of tepid water and cleansed with a mild or hypoallergenic soap, such as Cetaphil or Dove.<sup>7</sup> Immediately washing exposed areas will reduce contact time with the irritant and, if a dermal response occurs, help in localizing symptoms.

#### Preventive Measures

Educating the patient in techniques to reduce risk of exposure is fundamental. Using protective clothing, gloves, or other equipment, and limiting the time skin areas are occluded through frequent changes in coverings will aid in reducing irritant exposure. Emollients, moisturizers, and barrier creams, especially those with dimethicone, are recommended in the treatment and prevention of ICD because they assist in repairing the epidermal barrier.<sup>7</sup>

#### Pharmacologic Therapy

Liberal application of emollients to the affected area will help restore moisture to the stratum corneum and serve as a protectant from further exposure to the effects of a wet working environment. Colloidal oatmeal baths may help in relieving itching.<sup>7</sup> Topical corticosteroids have questionable efficacy in the treatment of ICD and are generally not considered optimal therapy.<sup>7,13</sup> The use of topical caine-type anesthetics should be avoided because of their ability to cause ACD.

### Allergic Contact Dermatitis

Three thousand chemicals have been cited as causes of ACD.<sup>14</sup> Poison ivy, oak, or sumac (*Toxicodendron* genus) is a common cause of ACD in the United States. Metal allergy, most often precipitated by nickel, is also a common cause. Approximately 19% of patients patch-tested for allergies are allergic to nickel.<sup>15</sup> Dermatitis caused by nickel is generally localized to areas at point of contact, such as where jewelry is worn on the ears or around the neckline or

other areas that may touch jewelry with nickel.<sup>14</sup> Products containing latex commonly cause allergic reactions in health care workers, and latex found in waistbands and socks can cause ACD. Fragrances, cosmetics, and skin care products can also cause ACD.<sup>14</sup> Table 34-2 lists selected allergenic substances.<sup>5,13,14,15,16</sup>

**TABLE 34-2 Selected Common Allergens Associated with Allergic Contact Dermatitis**

<b>Allergen</b>	<b>Sources of Allergen</b>
Balsam of Peru	Cough syrups, flavors
Benzocaine	The caine-type anesthetics have crossover allergy to other caine-type local anesthetics, topical medications (for skin, eye, ear), other oral medications
Chromium salts	Potassium dichromate electroplating, cement, leather-tanning agents, detergents, dyes
Cobalt chloride	Cement, metal plating, pigments in paints
Colophony (rosin)	Rosin cake for string instrument bows, sport rosin bags, cosmetics, adhesives
Epoxy resins	Constituents prior to mixing and hardening
Formaldehyde	Germicides, plastics, clothing, glue, adhesives
Fragrances	Cosmetics, household products, eugenol, cinnamic acid, geraniol, oak moss absolute
Lanolin	Lotions, moisturizers, cosmetics, soaps
Latex	Gloves, syringes, vial closures, elastic waistbands, socks, condoms
Nickel sulfate	In jewelry, blue jean studs, utensils, pigments, coins, tools, many metal alloys encountered daily
Neomycin sulfate	Medications, antibiotic ointments, other aminoglycosides
Plants	<i>Toxicodendron</i> species (poison ivy, oak, sumac), primrose ( <i>Primula obonica</i> ), tulips, others
Rubber (carbamix)	Added ingredients, accelerators, activators, other processing chemicals
Thimerosal	Preservative in many medications, injectables, cosmetics

Source: References 13, 15, and 16.

### Pathophysiology of Allergic Contact Dermatitis

ACD is an inflammatory dermal reaction related to exposure to an allergen that activates sensitized T cells, which migrate to the site of contact and release inflammatory mediators. ACD ordinarily does not appear on first contact. Several steps must occur before the dermatitis is manifested. An initial exposure to the antigen must take place to sensitize the immune system. This process is known as the induction phase. With the immune system now sensitized, the next contact with the antigen induces a type IV delayed hypersensitivity reaction, which is a cell-mediated (antigen-sensitized T cell) immune reaction that can take 24 hours to 21 days to develop. This reaction results in the dermatitis and symptoms associated with ACD.<sup>17,18,19</sup> In people previously sensitized, the rash and related symptoms typically appear within 24-48 hours after exposure.<sup>20</sup>

#### Urushiol-Induced ACD

In the United States, four species of *Toxicodendron* plants, which belong to the family Anacardiaceae, are primarily responsible for dermatoses associated with exposure to plants (Table 34-3).<sup>20,21,22,23</sup> Many of these plants were previously considered to belong to the genus *Rhus*, but *Toxicodendron* is now the accepted genus for this group of antigenic plants and is used throughout this chapter. The change in genus and the difficulty in classifying these plants are the result of variability in plant morphology.

**TABLE 34-3 Toxicodendron Plants Indigenous to North America**

<b>Plant</b>	<b>Other Common Names</b>	<b>Common Geographic Location</b>
Poison ivy ( <i>Toxicodendron radicans</i> )	Poison vine, mark weed, three-leaved ivy, poor man's liquid amber	Exists throughout North America, ranging throughout the United States (central plains, Midwest, south central, southeastern, lower Mississippi Valley regions); Canada (Ontario, Nova Scotia); and Mexico
Poison oak, Eastern ( <i>Toxicodendron toxicarium</i> )		Exists widely in the southeastern United States
Poison oak, Western ( <i>Toxicodendron diversilobum</i> )		Exists throughout the Pacific Coast
Poison sumac ( <i>Toxicodendron vernix</i> )	Poison elder, poison ash	Exists from Quebec to Florida, primarily in the eastern third of the U.S. coast

Source: Adapted from references 20-23.

As much as 80% of the U.S. population is estimated to be sensitive to urushiol, the oleoresin in plants of the genus *Toxicodendron*. Urushiol, an antigen, enters the skin within 10 minutes, starting the sensitivity process. Poison ivy/oak/sumac dermatitis has been reported in patients as young as 3 years of age. Sensitivity to urushiol increases into adulthood, with adult sensitization patterns occurring after 10 years of age.<sup>24</sup> However, sensitivity seems to be reduced in elderly individuals.<sup>11,22</sup>

If patients have sensitivity to any one *Toxicodendron* species, they are usually allergic to all members of the genus. These species are most easily identified as having three leaves emanating from a central stem, with the middle leaflet appearing at the terminal end of the stem. The plants flower in the spring and produce small, waxy, white, five-petaled flowers. In the late fall, the leaves turn brilliant red or orange, and the plants develop berries that are greenish white, pale yellow, or tan. A saying taught to children to help identify the plant and avoid exposure to urushiol is "Leaves of three; let it be!" In general, this statement is true, but other members of the genus differ in the number of leaflets attached to the central stalk and in the berry and leaf morphology.<sup>20,22</sup>

Urushiol is quite sensitive to oxidation by ambient air. It changes in appearance from clear fluid to a black inky lacquer that becomes tarry and may harden on the damaged portion of the plant in a matter of minutes. The release of urushiol from the plant can occur only through damage to the plant itself, either through direct damage by an individual who bruises the plant or by damage from natural causes (e.g., wind, rain, insects, or animals). The antigenic urushiol is contained and carried only within resin canals of the plant.<sup>20,22</sup>

Urushiol is not a volatile substance, but it has been implicated in dermatitis when the plant is burned because smoke emanating from burned plants contains the antigen. Urushiol carried by smoke particulates is capable of affecting body surface areas ordinarily viewed as protected, such as the lungs. This source of exposure is a primary occupational hazard in persons who fight forest fires.<sup>20,22</sup> Unwashed contaminated hands and fingers may also transfer urushiol to other body surfaces and to other individuals. Dermatitis can occur on all skin surfaces, including the eyes, lips, underarms, buttocks, anus, and genitalia.

#### Poison Ivy

The most common *Toxicodendron* plant found throughout the United States is poison ivy (*Toxicodendron radicans* and *Toxicodendron rydbergii*). Poison ivy is quite common throughout the central and northeastern United States and Canada. It has been described as a climbing shrub or hairy vine that commonly grows up poles, trees, and building walls (see Color Plates, photograph 15A). It also grows along roads, hiking trails, streams, dry rocky canyons, and embankment slopes. *T. radicans* is composed of nine subspecies that can exist as a shrub or a climbing vine, whereas *T. rydbergii* is a dwarf shrub that has large, broad, spoon-shaped leaves with a hairy underside. *T. rydbergii* is the principal variety of poison ivy growing in the northern United States and southern Canada. *T. radicans* grows across much of the United States as a climbing vine with aerial rootlets.<sup>20,22,23</sup>

## Poison Oak

Poison oak has two species indigenous to the United States: *Toxicodendron diversilobum*, which inhabits the West Coast, and *Toxicodendron toxicarium*, which inhabits the East Coast. Both species possess leaves similar to those of oak trees, with most plants having an unlobed leaf edge and commonly displaying 3 leaflets per stem. The leaves and berries can be covered with fine hairs (see Color Plates, photograph 15B). The plant ordinarily exists as a nonclimbing shrub but is capable of climbing as high as 131 feet (40 meters). Western poison oak (*T. diversilobum*) differs by usually possessing between 3 and 11 leaflets per stem; its leaves are quite similar to California live oak. Poison oak grows along streams, in thickets, on wooded slopes, and in dry woodlands. As a rule, poison oak grows well at altitudes below 4000-5000 feet.<sup>20,22,23</sup>

## Poison Sumac

Poison sumac (*Toxicodendron vernix*) grows in remote areas of the eastern third of the United States in peat bogs and swampy areas. It appears as a shrub or small tree, attains a height of roughly 9.8 feet (3 meters), and may somewhat resemble elder or ash trees, hence its other names, "poison elder" and "poison ash." Its leaves are odd numbered and pinnate and may be almost 16 inches (40 cm) long, with 7-13 leaflets. The edges of the leaves are smooth and come to a tip.<sup>20,22,23</sup> (See Color Plates, photograph 15C.)

## Clinical Presentation of Allergic Contact Dermatitis

### General Presentation

ACD can be distinguished from ICD by the distribution and presentation of the rash. Both ICD and ACD can occur anywhere on the body where there is exposure to an irritant, but ICD is usually limited to the hands and forearms as a result of occupational exposure. The rash in ACD is limited to the area of antigen contact and the area immediately surrounding the antigen contact. For example, reactions to latex gloves involve only the hands or areas covered by the glove. Sensitivity to latex in undergarments occurs in areas touched by the latex, such as the waist (by waistbands) or calves (from men's socks). Urushiol-induced ACD, however, can be linear or occur over a broader area because urushiol is transferred from hands or inanimate objects, such as clothing, to other parts of the body. ACD usually presents with papules, small vesicles, and sometimes large bullae over inflamed, swollen skin. Significant itching is a prominent feature of ACD. Chronic forms of ACD can present with lichenification.

### Presentation of Urushiol-Induced Dermatitis

Presentation of this condition is highly variable and depends on the sensitivity of the patient and extent of exposure. The dermal reaction to urushiol is an intense itching of the exposed skin surfaces, followed by erythema. As the dermatitis progresses, vesicles or bullae form depending on an individual's sensitivity. The vesicles or bullae may break open, releasing their fluid (see Color Plates, photograph 16A). Papules and plaques may develop in addition to or instead of vesicles and bullae. Vesicular fluid does not contain any antigenic material and cannot cause further transfer of the dermatitis. Streaks of vesicles that correspond to the points of urushiol contact from the damaged plant suggest poison ivy or oak exposure (see Color Plates, photograph 16C). Oozing and weeping of the vesicular fluid continues to occur for several days and cannot cause further spread of the dermatitis. In the last stage of the dermatitis, the affected area develops crusts and begins to dry (see Color Plates, photograph 16B).

### Severity of Poison Ivy/Oak/Sumac Dermatitis

Mild dermatitis is characteristically seen as linear streaks. Clinically, the dermatitis is localized on unprotected areas of the body exposed to the urushiol oil. Itching may be minimal. Signs of moderate dermatitis include the appearance of erythema, bullae, papules, vesicles, and inflammation of the exposed skin, in addition to pruritus. Severe dermatitis is distinguished by extensive involvement and edema of the extremities and/or face. Marked swelling of the eyelids without associated swelling of other parts of the face may occur<sup>23</sup> and is caused by rubbing the eyelids with urushiol-contaminated fingers and hands. Often the eyelids are swollen closed. Extreme itching, irritation, and formation of numerous vesicles and bullae may also be present. Furthermore, daily activities may be hampered. Dermatitis or edema affecting large areas of the face, eyes, or genitalia requires immediate medical referral for systemic therapy.

### Complications of Poison Ivy/ Oak/Sumac Dermatitis

Patients may continue to scratch for several days after exposure and excoriate the surface dermal layer, leading to open lesions and the potential for secondary wound infections. Common microbes found in infected poison ivy dermatitis include *Staphylococcus aureus*, group A *Streptococcus*, and *Escherichia coli*.<sup>25</sup> In addition to these microbes, other organisms may be identified, depending on where the infection originated on the skin.

## Treatment of Allergic Contact Dermatitis

### Treatment Goals

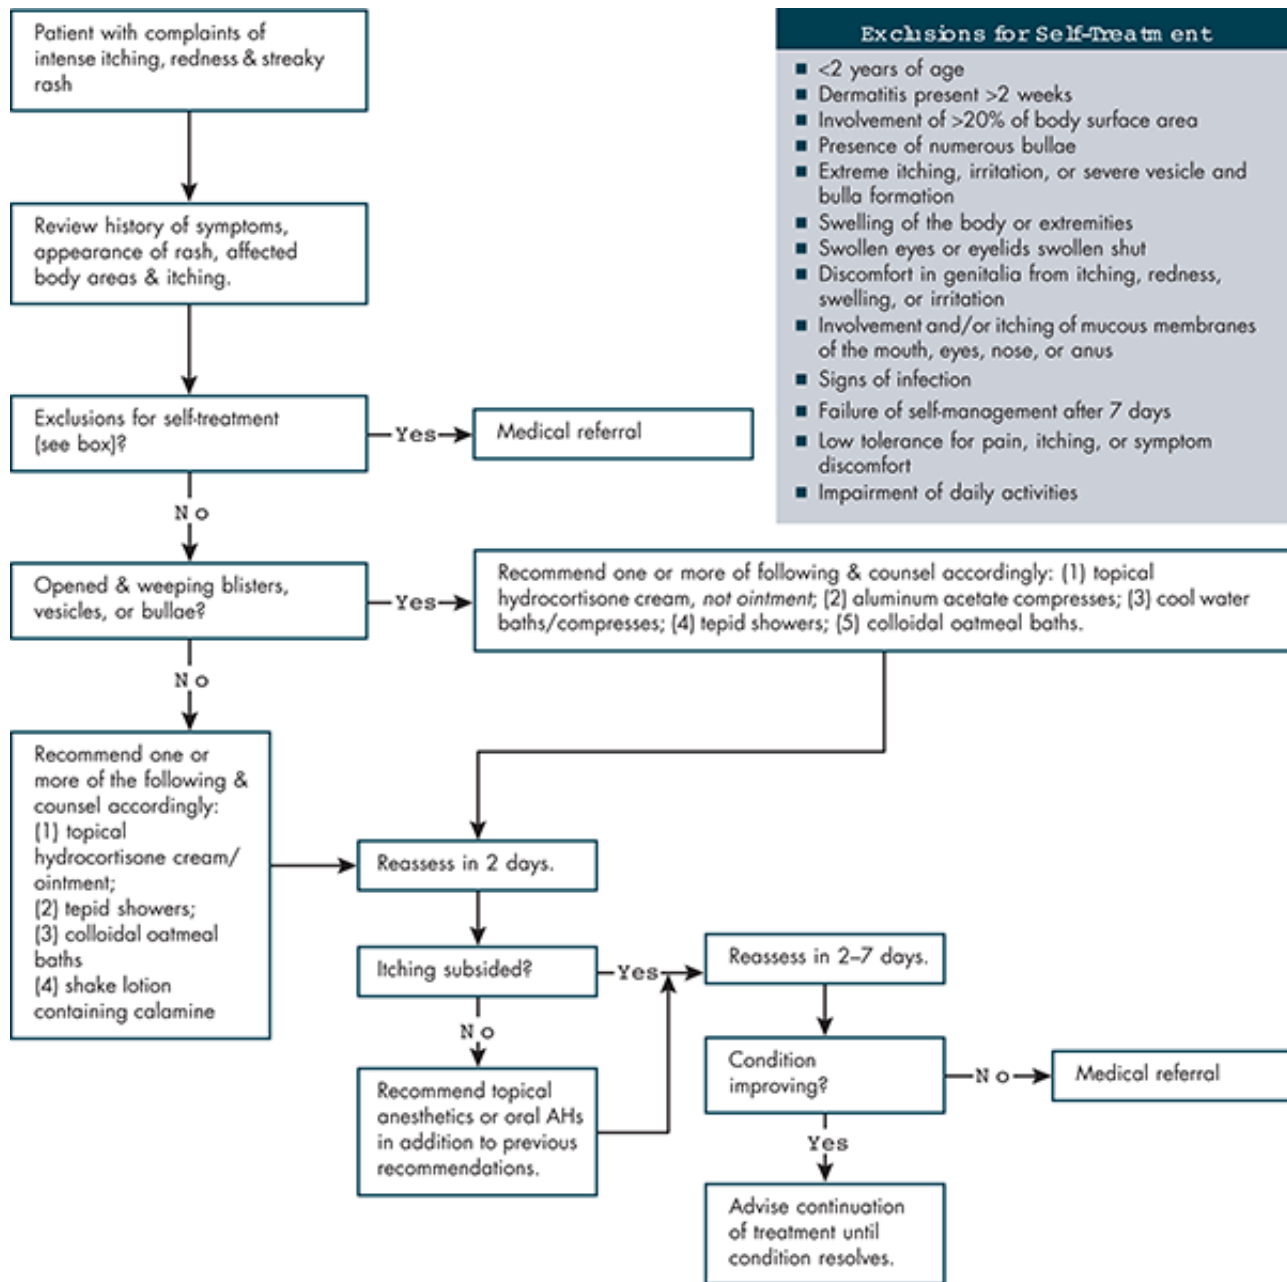

The goals of self-treating ACD are to (1) remove and avoid further contact with the offending agent, (2) treat the inflammation, (3) relieve itching and excessive scratching that may lead to open lesions and potential secondary skin infections, and (4) relieve the accumulation of debris that arises from oozing, crusting, and scaling of the vesicle fluids.

Treated or untreated dermatitis will naturally resolve in approximately 10-21 days as a result of the patient's own immune system. Topical nonprescription products may be used for symptomatic relief. Patients will seek advice on treatment because of the intensity of itching and discomfort associated with a mild localized rash, or because of the widespread nature of the dermatitis and the magnitude of symptoms.

### General Treatment Approach

Removing the known antigen from the skin as soon as possible may reduce the chance of and severity of the immune response (e.g., not wearing jewelry, switching to underwear and socks without latex, not wearing a leather watch band, washing urushiol-contaminated clothes, or showering or washing the affected area with mild soap and tepid water).

Customarily, the first several days after the initial appearance of ACD are usually the most uncomfortable for the patient. Treatment for the allergic reaction depends on the severity of the symptoms from the antigenic reaction ([Figure 34-1](#)). Hydrocortisone 1% cream may be applied to localized patches of rash that have intense pruritus and erythema. Hydrocortisone reduces the inflammation, helps relieve the itching, and as a cream, allows weeping lesions to dry. The patient also may use astringent compresses and baths to dry oozing vesicles.

Self-care of allergic contact dermatitis. Key: AH = Antihistamine.

Other potential options for areas of nonweeping lesions include products containing calamine, as well as colloidal oatmeal products. Calamine assists in the drying of poison ivy lesions. Application of products containing calamine leaves a visible pink film, which may not be esthetically pleasing for some patients. Colloidal oatmeal relieves the itching associated with rash. Care needs to be taken with the use of colloidal oatmeal because it makes the bathtub extremely slippery.

Medical referral for definitive care is appropriate for children younger than 2 years and for patients with involvement of the eyes, eyelids, and genitals or with extensive involvement of more than 20% of the skin surface. Referral is also appropriate when signs of infection or numerous large bullae are present or when self-treatment for 7 days fails to resolve the rash.

### Nonpharmacologic Therapy

#### Prevention of Urushiol-Induced ACD

Individuals at risk should familiarize themselves with descriptions and photographs of *Toxicodendron* plants. Health care providers can educate patients presenting with ACD by giving them descriptions and photographs of the plants. Patients involved in recreational or work-related outdoor activities should survey the surrounding vegetation to determine the potential risk of exposure. Table 34-4 describes preventive and protective measures for avoiding poison ivy/oak/sumac dermatitis.

#### TABLE 34-4 Preventive and Protective Measures for Poison Ivy/Oak/Sumac Dermatitis

### Preventive Measures

- Learn the physical characteristics and usual habitat of *Toxicodendron* plants. Survey the area when outdoors to assess potential risk for exposure to *Toxicodendron* plants.
- Eradicate *Toxicodendron* plants near your residence either by mechanically removing the plant and its roots or by applying an herbicide recommended by the state farm bureau or the USDA extension services. Do not burn the leaves of plants.
- Apply bentoquatam on exposed areas of the body to reduce the risk of contamination before visiting an outdoor site with high likelihood of contact with poison ivy/oak/sumac. Repeat application every 4 hours until your potential exposure has ended. This application should be followed by flushing the area with water to remove bentoquatam and any urushiol deposited on the skin surface. Bentoquatam is flammable, so avoid use near open flames.

### Protective Measures

- Wear protective clothing to cover exposed areas.
- Cover your nose and mouth with a protective mask when removing or eradicating *Toxicodendron* plants.
- Remove all clothing worn during exposure, and place the clothing directly into a washing machine, separately from other clothes.
- Wash the suspected areas of exposure as soon as possible with soap and water or with other suggested removal products.
- If thorough washing is not possible, rinse with water as soon as possible.
- At the earliest convenience, take a shower instead of a bath, using soap and water. Avoid tub baths right after exposure because oleoresin may remain in the tub and potentially affect other unexposed areas.
- Clip fingernails and meticulously clean under fingernails to avoid transferring trapped urushiol to clean skin surfaces.
- Using ordinary detergent and hot water, wash all clothing exposed to urushiol separately from other clothes in a washing machine. If clothes are dry cleaned to remove urushiol, warn cleaning personnel of the possible contamination. Put contaminated clothing in a plastic bag for transport.
- As soon as possible after use, thoroughly wash with soap and water—or with water alone—any shoes, gloves, jackets, or other protective garments; sports equipment; garden and work tools; and equipment that is capable of carrying urushiol. Wear vinyl gloves for washing contaminated objects.
- Cleanse the fur of pets after known or suspected exposures to *Toxicodendron* plants.

Accessed at [http://www.aphis.usda.gov/emergency\\_response/downloads/health/Appendix%203-6-C%20Poison%20Ivy,%20Oak%20and%20Sumac.pdf](http://www.aphis.usda.gov/emergency_response/downloads/health/Appendix%203-6-C%20Poison%20Ivy,%20Oak%20and%20Sumac.pdf), August 2, 2015; U.S. Department of Agriculture. Outsmarting poison ivy and its relatives. Accessed at <http://www.fs.fed.us/t-d/pubs/htmlpubs/htm07672313/>, August 2, 2014; and Centers for Disease Control and Prevention. Poisonous plants. Accessed at <http://www.cdc.gov/niosh/topics/plants/>, August 2, 2014.

### Use of Protective Clothing

Individuals should wear protective clothing that can be removed and washed immediately after exposure. They should use ordinary laundry detergent to wash clothes contaminated with urushiol separately from noncontaminated clothing. In addition, washing bed linens after exposure to urushiol is recommended to prevent the transfer to other parts of the body.

### Use of Barrier Products

IvyBlock lotion is the only barrier product approved by the Food and Drug Administration (FDA) to provide protection against exposure to poison ivy/oak/sumac. This product's active ingredient is an organoclay known as quaternium-18 bentonite (bentoquatam).<sup>26,27</sup> The product contains 5% bentoquatam in a lotion containing alcohol. Bentoquatam is a nonsensitizing and nonirritating organoclay that appears to possess little antigenicity or toxicity when applied topically. The mechanism by which this ingredient works is not known, but it is believed to physically block urushiol from being absorbed into the skin. It is effective in protecting patients from exposure to the urushiol common to all *Toxicodendron* plants, through both direct contact and airborne particles in smoke from burned plants.

IvyBlock lotion claims to protect when it is topically applied at least 15 minutes before exposure to *Toxicodendron*. The lotion should be shaken vigorously before generously applying it to clean dry skin. It should leave a smooth wet film of lotion where it is applied. One may determine skin coverage by looking for the faint white coating that appears when the lotion has dried. It should be reapplied once every 4 hours or as needed after the initial application to maintain effective protection. After the period of exposure has ended, the patient may remove the lotion by washing with soap and water.<sup>27</sup> This product is flammable and should not be used around the eyes or applied to an existing poison ivy rash. In addition, its use is not recommended in children younger than 6 years.

## Eradication of Toxicodendron Plants

The eradication of *Toxicodendron* plants has been suggested in situations in which extremely sensitive individuals are affected by close proximity to the plant and its oleoresin. Two methods of eradication have been recommended: either mechanically removing (hand grubbing plants and the root system using protective equipment, such as gloves and long sleeves and pants) or applying an appropriate herbicide. When considering the use of herbicides, patients should contact the U.S. Department of Agriculture's Extension Service, review information on the Web site ([www.nifa.usda.gov/Extension/index.html](http://www.nifa.usda.gov/Extension/index.html)), or contact the appropriate state or county agency to determine the recommended herbicide and prescribed methods of application to *Toxicodendron* species indigenous to the area. Patients presenting with *Toxicodendron* ACD in midwinter or during off-season periods may have recently used urushiol-contaminated objects. Urushiol is inactivated by exposure to wet environmental conditions but remains active within dead and dried parts of plants and on inanimate objects for long periods of time. An object is easily contaminated with the oleoresin. It is not unusual for objects to become contaminated in one growing season; the contaminating urushiol retains its antigenicity throughout the winter and causes rashes with each use of the object in succeeding seasons. Implicated sources of nonseasonal poison ivy rash and recurrent seasonal rashes include urushiol-contaminated shoes, boots, clothing, garden and work tools, golf clubs, baseball bats, fishing rods, other recreational equipment, and the fur of domestic pets.<sup>20</sup>

## Removal of Antigen at Time of Exposure

If preventive measures were not taken, individuals exposed to urushiol can reduce its contact with skin and transfer to other body areas by immediately washing exposed areas with mild soap and water. Urushiol is water-insoluble; however, immediate washing may avoid or reduce the severity of the rash. Once urushiol has entered the skin and attached to tissue proteins, it can no longer be removed. Washing done within 10 minutes of contact with urushiol has been shown to be the most effective.<sup>28</sup> Even up to 30 minutes postexposure, washing may remove oleoresin that remains on the skin's surface and has not entered the dermal layers. There is a misconception that a rash from urushiol spreads. The appearance of spreading is attributed to the transfer of urushiol by the hands; to additional exposure to urushiol-contaminated objects, clothing, or linens; or to the intensity of the exposure to urushiol. Washing while in the field is difficult, but using large volumes of water will assist in rinsing away much of the surface irritant and oleoresin. Historically, many home remedies included vigorous scrubbing of contaminated skin surfaces with a harsh soap or household bleach. Other cleansers and organic solvents have been used to rinse urushiol from skin surfaces, including isopropyl alcohol and hand sanitizers; however, these are not generally recommended to remove the antigen. Instead, the current recommendation is to use a mild face soap and water to wash all body areas believed to have been exposed to urushiol. Good handwashing, including meticulous cleansing under or clipping of the fingernails, is necessary to avoid contaminating additional skin surfaces.

Zanfel is marketed as a nonprescription wash to prevent or relieve the rash associated with urushiol. Two small studies suggest that Zanfel reduces the redness and blistering after urushiol exposure.<sup>29,30,31</sup> With application, Zanfel can immediately relieve pain and itching and is especially useful for spot treatments to areas that continue to itch. Anecdotally, it also has been used to clean equipment such as garden tools that are exposed to urushiol. To use Zanfel, one should wet the affected area, measure 1½ inches of the product into one palm, wet both hands and rub the product into a paste, rub both hands on the affected area (up to 3 minutes) until there is no sign of itching, and rinse the affected area thoroughly.<sup>32</sup> If itching returns after several hours, the product may be used again. Compared with other products, Zanfel is considered expensive, making cost a consideration when selecting this product. Tecnu Outdoor Skin Cleanser was originally developed as an agent to wash away radioactive matter from the skin surface of exposed individuals. This product is recommended for use after exposure to urushiol and should be rubbed into the affected area as soon after exposure as possible. Label directions indicate that it can be used up to 8 hours after exposure, with the objective of limiting exposure to other areas. The patient should cleanse the contaminated area for a minimum of 2 minutes. No water is required for the initial cleansing application. The cleanser may be wiped away with a cloth or rinsed with cool water. The manufacturer recommends using the product before eating, smoking, or using the bathroom in an effort to minimize transfer of urushiol to uncontaminated skin. A study that compared untreated urushiol exposures and exposures cleaned with Tecnu, Dial Ultra dishwashing soap, and Goop grease remover found that all three provided good protection against poison ivy rash when used to cleanse skin exposed to urushiol.<sup>29,33</sup> The difference in protective ability among the products was not significant, so cost can be a consideration in selecting a product.

## Relief of Itching

For the symptoms of ACD, the primary nondrug measure is to take cold or tepid soapless showers to temporarily relieve the pruritus. A tepid shower is approximately 90°F (32.2°C) or cooler. Hot showers, those with temperatures of 105°F (40.5°C), may cause scalding or thermal skin injuries (second-degree burns) and may intensify the pruritus. Patients can shower using hypoallergenic soap to maintain cleanliness. They should never use harsh soaps or vigorously scrub affected areas. Along with applying topical treatment, all patients should trim their fingernails to

reduce the risk of secondary bacterial skin infections from scratching.

## Pharmacologic Therapy

### Itching

Topical ointments and creams containing anesthetics (e.g., benzocaine), antihistamines (e.g., diphenhydramine), or antibiotics (e.g., neomycin) should not be used. These agents are known sensitizers and can cause a drug-induced ACD superimposed on the existing ACD.<sup>20,22</sup> Although topical antihistamines are not indicated, nonprescription, first-generation oral antihistamines can be used to assist with itching and offer sedation at night. If sedation is a concern, nonsedating antihistamines can be used. If itching is not alleviated by nonprescription oral antihistamines, patients should be referred to a primary care provider (PCP) for further care.

### Weeping

Astringents retard weeping, oozing, discharge, or bleeding from dermatitis when applied to unhealthy serous skin or mucous membranes. They decrease edema, exudation, and inflammation by reducing cell membrane permeability and by hardening the intercellular cement of the capillary epithelium. When applied as a wet dressing or compress, astringents cool and dry the skin through evaporation. They cause vasoconstriction and reduce blood flow in inflamed tissue. They also cleanse the skin of exudates, crust, and debris. Because astringents generally have low cell penetrability, their activity is limited to the cell surface and interstitial spaces. The protein precipitate that forms may serve as a protective coat, allowing new tissues to grow underneath.<sup>34</sup>

Aluminum acetate solution USP, or Burow's solution, contains approximately 5% aluminum acetate. The drying ability of aluminum acetate solution probably involves complexing of the astringent agent with proteins, thereby altering the proteins' ability to swell and hold water. The solution must be diluted 1:40 with water before use. A 1:40 dilution of Burow's solution may be prepared from prepackaged tablets or powder by adding 1 tablet or package to 1 pint of cool tap water.<sup>14</sup> The patient may soak the affected area 15-30 minutes 2-4 times daily. Alternatively, the patient may loosely apply a compress of washcloths, cheesecloth, or small towels; the compress is prepared by soaking the materials in the solution and then gently wringing them so that they are wet but not dripping. The dressings should be rewetted and applied every few minutes for 20-30 minutes, 4-6 times daily. Any remaining solution should be discarded and a fresh solution prepared for each application. Burow's solution is useful in softening and removing crusting, and it also has a mild antipruritic effect. Less expensive alternatives to aluminum acetate include isotonic saline solution (1 teaspoon of salt in 2 cups of water), tap water, diluted white vinegar (one-fourth cup per 1 pint of water), and unchlorinated water.

Hydrocortisone 1% cream will reduce weeping by treating the immune-mediated inflammation. Ointments should not be applied to open lesions because removal from the skin is more difficult. Ointments may also trap bacteria beneath the oleaginous film, leading to secondary infections.

### Inflammation

Hydrocortisone is the most effective form of topical therapy for treating symptoms of mild-moderate ACD that does not involve edema and extensive areas of the skin. Hydrocortisone is a low-potency corticosteroid capable of vasoconstriction, thereby reducing inflammation and relieving pruritus associated with ACD. It is available topically with nonprescription strengths of 0.5% and 1%. It has been approved for use in eczema, psoriasis, insect bites, seborrheic dermatitis, and allergic contact dermatitis, including poison ivy/oak/sumac. An FDA advisory panel and dermatologists believe that hydrocortisone is safe to apply to all parts of the body except the eyes and eyelids. Although systemic absorption is nominal when used on intact skin, use of topical hydrocortisone over large surface areas, prolonged use, use with an occlusive dressing, or use when skin integrity is compromised can lead to systemic absorption. Hydrocortisone cream can be applied as frequently as two to four times per day.<sup>35</sup>

Generally, topical hydrocortisone is well tolerated, with limited adverse reactions. When adverse reactions occur, they typically include burning and irritation. No dressing or bandages should be applied when hydrocortisone is used as a self-care treatment. Topical hydrocortisone should not be used on children younger than 2 years, except on a PCP's advice. Hydrocortisone should not be used if the dermatitis persists longer than 7 days, or if symptoms clear and then reappear in a few days, unless patients have consulted with a PCP.

When greater than 20% of the body is affected, systemic therapy is recommended and patients should be referred to a PCP.<sup>24</sup>

## Product Selection Guidelines

### Special Populations

Treatment of contact dermatitis in pediatric patients is similar to the approach in adults. Nondrug therapies and

pharmacologic therapies such as emollients, barrier creams, and topical corticosteroids can be used in pediatric patients as described for adults (refer to product label instructions). Use of pharmacologic products in pediatric patients younger than 2 years is discouraged without the advice of a PCP.

Topical preparations are generally considered safe for use during pregnancy, as long as they are not used for long periods of time or over extensive areas of the body. Hydrocortisone is considered a Pregnancy Category C product, but the risk is considered limited with low-potency (nonprescription) formulations.<sup>36,37</sup> Other topical preparations (e.g., calamine, colloidal oatmeal, and aluminum acetate) have an “undetermined” pregnancy category. The same precautions described for self-treatment in adults apply to pregnant women. For other treatments, pregnant patients should be referred for medical evaluation.

In geriatric patients, first-generation antihistamines (e.g., diphenhydramine) should be avoided because of sedation and other anticholinergic effects. In addition, itching is of concern in geriatric patients because scratching increases the risk for skin tears and accompanying infections.

#### Patient Factors and Preferences

Nonprescription medications for ACD are available in numerous dosage forms. The choice of dosage form depends on several factors, including the severity of the dermatitis and the presence of vesicles (dry or weeping). Ointments hold moisture within the skin and act as a reservoir for the active ingredient, keeping it on the affected site. They are also effective for use on dry or cracked skin.<sup>13</sup> However, ointments tend to hold in the heat of inflamed skin and may intensify itching in the early stages of treatment of urushiol-induced rash. Ointments should not be applied to open lesions because their removal from the skin is more difficult, and they may trap bacteria beneath the oleaginous film, leading to secondary infections. As a result, ointments are not recommended in plant-based ACD and where weeping lesions are present.

Applying a cream base allows vesicle fluid to flow freely from the blisters and does not trap bacteria because the medication is quickly absorbed into the skin. Because a cream is an oil-in-water emulsion, it tends to be drying and is best for open weeping lesions. In addition, creams are more cosmetically appealing and feel more pleasant to patients.<sup>13</sup> Gels offer ease of application and a rapid absorption of active ingredients into the skin. Some gels may contain alcohol or similar organic solvents that may cause irritation or burning when applied to open lesions. Spray products provide the easiest form of drug application. They allow even distribution to larger areas and are convenient to use. Another advantage of a spray product is that it does not require touching the area of dermatitis, which may curtail additional scratching. However, aerosol sprays may contain propellants that cause additional inflammation and/or alcohol that causes excessive drying and irritation. [Table 34-5](#) lists selected products that contain primarily colloidal oatmeal, pharmacologic treatments, or bentoquatam. (See [Chapter 36](#) for products that contain local anesthetics, hydrocortisone, or topical antihistamines.)

**TABLE 34-5 Selected Products for Poison Ivy/Oak/Sumac Dermatitis**

Aveeno Soothing Bath Treatment	Colloidal oatmeal 100%
Burow's Solution	Aluminum acetate 5%
Calamine Lotion	Calamine 8%
Cortaid	Hydrocortisone 1% or 0.5%
Domeboro Astringent Solution Powder Packets	Aluminum sulfate 1347 mg; calcium acetate 952 mg

#### Assessment of Contact Dermatitis: A Case-Based Approach

Circumstances surrounding the occurrence of the dermatitis can help determine the type of dermatitis ([Table 34-6](#)). The factors that help to distinguish ICD from ACD include (1) history of irritant or allergen exposure, (2) history of known sensitivity on previous exposure, (3) time from exposure (at home, work, or recreation) to appearance of rash, (4) distribution and appearance of the lesions, (5) severity of symptoms, and (6) improvement of the dermatitis with avoidance of irritants.<sup>2,4</sup> Much of the information distinguishing between ICD and ACD is obtained by taking the patient's history; the distribution and appearance of lesions will be the only factor directly observable at the time of the patient visit. Determining the type and success of previous treatments of similar rashes will aid in selecting the appropriate nonprescription medications.

**TABLE 34-6 Differentiation of Irritant and Allergic Contact Dermatitis**

<i>Symptom or Characteristic</i>	<i>Irritant Contact Dermatitis</i>	<i>Allergic Contact Dermatitis</i>
Itching	Yes, later	Yes, early

Stinging, burning	Early	Late or not at all
Erythema	Yes	Yes
Vesicles, bullae	Rarely or no	Yes
Papules	Rarely or no	Yes
Dermal edema	Yes	Yes
Time to reaction (rash) after exposure	Minutes to hours	Days, slower reaction
Appearance of symptoms in relation to exposures	Initial or repetitive exposures	Delayed
Causative substances	Water, urine, flour, detergents, hand sanitizers, soap, alkalis, acids, solvents, salts, surfactants, oxidizers	<i>Toxicodendron</i> plants, fragrances, nickel, latex, benzocaine, neomycin, leather
Substance concentration at exposure	Important	Less important
Mechanism of reaction	Direct tissue damage	Immunologic reaction
Common location	Hands, wrist, forearms, diaper area	Anywhere on body that comes in contact with antigen
Presentation	No clear margins	Clear margins based on contact of offending substance

Source: Adapted from references 13, 14, and 23.

Cases 34-1 and 34-2 illustrate the assessment of patients with contact dermatitis.

#### Case 34-1

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient has irritated hands and wishes to treat the condition. He works full-time as a nurse. He noticed that his hands were becoming more irritated over the past month. Patient's hands appear dry and cracked. He complains of itching and redness. No vesicles, bullae, open lesions, or signs of infection are present. Irritation is confined to the hands.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Symptoms worsened as the weather got colder and as he started working more shifts. Dryness and itching progressively increased over the last month.
c. description of the patient's efforts to relieve the symptoms	He has not tried any treatments.
d. patient's identity	John Darby

e. age, sex, height, and weight	54 years old, male, 6 ft 3 in., 210 lb
f. patient's occupation	Surgical nurse
g. patient's dietary habits	Normal diet with frequent use of alcohol
h. patient's sleep habits	Averages 8 hours per night.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Ibuprofen 600 mg by mouth every 6 hours as needed for arthritis
j. allergies	Codeine
k. history of other adverse reactions to medications	None
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	John is suffering from irritant contact dermatitis. The likely sources are the continuous use of hand sanitizers and gloves, as well as constant handwashing.
3. Identify exclusions for self-treatment (Figure 34-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer John to the appropriate health care provider. (2) Recommend self-care with a nonprescription product and/or nondrug measures. (3) Recommend self-care until John can be seen by an appropriate health care provider. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	John should take protective measures when at work to prevent irritant exposure to liquids. He should use a mild cleanser, such as Cetaphil. He should apply hand lotion frequently. He can consider wearing gloves if they are not a source of irritation.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Completely dry your hands after washing with a mild cleanser such as Cetaphil; then use a hypoallergenic hand lotion. Apply moisturizer at night and cover with cotton gloves overnight."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic	"Drying your hands will cleanse them of irritants. The hypoallergenic hand lotion will relieve dryness. The addition of cotton gloves will increase the moisture retained in your skin."

alternatives.	
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	See the box Patient Education for Contact Dermatitis.
b. maximum number of days the therapy should be employed	See the box Patient Education for Contact Dermatitis.
c. product administration procedures	See the box Patient Education for Contact Dermatitis.
d. expected time to onset of relief	See the box Patient Education for Contact Dermatitis.
e. degree of relief that can be reasonably expected	"Complete symptomatic relief is likely."
f. most common side effects	See the box Patient Education for Contact Dermatitis.
g. side effects that warrant medical intervention should they occur	See the box Patient Education for Contact Dermatitis.
h. patient options in the event that condition worsens or persists	"You should consult a primary care provider if the condition does not improve or if irritation is intolerable."
i. product storage requirements	See the box Patient Education for Contact Dermatitis.
j. specific nondrug measures	See the box Patient Education for Contact Dermatitis.
Solicit follow-up questions from the patient or caregiver.	"When should the irritation get better?"
Answer the patient's or caregiver's questions.	"You should see a difference in 1 week. If you do not see improvement, contact your primary care provider."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Ask the patient to contact you and report how he responded to the recommended therapy, or call him in a week to evaluate his treatment outcome.

Key: NA = Not applicable.

### Case 34-2

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
-------------------------------------	-------------------------------

<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of redness, swelling, and mild itching on her ears. Symptoms have worsened over the past 2 weeks.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	She notices some relief at night.
c. description of the patient's efforts to relieve the symptoms	Patient reports that no treatment has been used.
d. patient's identity	Anna Jones
e. age, sex, height, and weight	21 years old, female, 5 ft 8 in., 130 lb
f. patient's occupation	College student
g. patient's dietary habits	Normal diet with junk food
h. patient's sleep habits	5 hours a night
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Yasmin, 1 tablet by mouth daily Albuterol inhaler, 1-2 puffs as needed prior to exercising
j. allergies	Nickel
k. history of other adverse reactions to medications	NA
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Anna is suffering from an allergic reaction to a new pair of earrings. Her symptomatology (e.g., redness, swelling, and mild itching), has worsened over time as a result of continued daily exposure.
3. Identify exclusions for self-treatment ( <a href="#">Figure 34-1</a> ).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary	Options include: (1) Refer Anna to the appropriate health care provider.

problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	(2) Recommend self-care with a nonprescription product and/or nondrug measures. (3) Recommend self-care until Anna can see an appropriate health care provider. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Anna should begin self-care using hydrocortisone 1% cream.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Discontinue wearing the earrings and avoid all nickel-containing jewelry. Apply a small amount of hydrocortisone on your earlobe two times a day until symptoms resolve. The rash should resolve in 7-10 days. Contact your primary care provider if the rash worsens or persists."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Allergic contact dermatitis can be effectively treated using hydrocortisone cream."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. appropriate dose and frequency of administration	See the box Patient Education for Contact Dermatitis.
b. maximum number of days the therapy should be employed	See the box Patient Education for Contact Dermatitis.
c. product administration procedures	See the box Patient Education for Contact Dermatitis.
d. expected time to onset of relief	See the box Patient Education for Contact Dermatitis.
e. degree of relief that can be reasonably expected	"Complete symptomatic relief is likely."
f. most common side effects	See the box Patient Education for Contact Dermatitis.
g. side effects that warrant medical intervention should they occur	See the box Patient Education for Contact Dermatitis.
h. patient options in the event that condition worsens or persists	"A primary care provider should be consulted if the condition does not improve or if irritation is intolerable."
i. product storage requirements	See the box Patient Education for Contact Dermatitis.

j. specific nondrug measures	See the box Patient Education for Contact Dermatitis.
Solicit follow-up questions from the patient or caregiver.	“Can I wear any jewelry?”
Answer the patient’s or caregiver’s questions.	“Yes, you can wear earrings once the rash is resolved, as long as they do not contain nickel. Because you are allergic to nickel in earrings, you may experience the same type of rash from other jewelry or clothing items containing nickel.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Ask the patient to contact you and report if the recommended therapy resolved the rash, or call the patient in a week to evaluate her response to the therapy.

Key: NA = Not applicable.

### Patient Counseling for Contact Dermatitis

Counseling of a patient who presents with possible ICD or ACD, but who cannot identify contact with irritant chemicals, allergens, or *Toxicodendron* plants, should begin with a review of chemicals or allergens likely to cause dermatitis. Then preventive and protective measures, as well as nonprescription pharmacologic treatment options, should be explained. Counseling for nonprescription agents should include their purpose and appropriate use, their possible adverse effects, expected time to experience relief, and signs and symptoms that indicate the need for medical referral for further evaluation. The box Patient Education for Contact Dermatitis lists specific information to provide patients.

Patient Education for Contact Dermatitis

#### Irritant Contact Dermatitis

The goals in self-treating ICD are to (1) remove the offending agent and prevent future exposure to the irritant; (2) relieve the inflammation, dermal tenderness, and irritation; and (3) educate the patient on self-management to prevent and treat recurrences. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### **Nondrug Measures**

- Avoid or limit contact with common skin irritants, such as detergents, soaps, and solvents.
- Change clothing, diapers (if applicable), and gloves used for cleaning more frequently.
- Wash the affected area gently to remove the skin irritant.

#### **Nonprescription Medications**

- To help soothe the affected area, apply compresses of cool tap water or aluminum acetate for 20 minutes, 4-6 times daily.
- Use emollients liberally to restore moisture to skin.
- If itching keeps you awake at night, take a sedating oral antihistamine, such as diphenhydramine or doxylamine, and follow the label instructions. These medications can cause drowsiness that might extend to the next morning.
- Store nonprescription medications in a cool, dry place out of children’s reach.
- Rash and itching should improve within 5-7 days. If either rash or itching worsens, consult your primary care provider.
- Using nonprescription medications longer than 7 days for dermatitis without consulting a physician is not recommended.

#### **Allergic Contact Dermatitis**

The goals of self-treating ACD are to (1) remove and/or avoid further contact with the offending agent, (2) treat the inflammation, (3) relieve itching and excessive scratching that may lead to open lesions and potential secondary skin infections, and (4) relieve the accumulation of debris that arises from oozing, crusting, and scaling of the vesicle fluids. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

### **Nondrug Measures**

- Use the measures outlined in [Table 34-4](#) to prevent poison ivy/oak/sumac dermatitis.
- Take tepid, soapless showers to relieve itching.
- When cleansing the affected areas, do not use harsh cleansers or scrub vigorously.
- To avoid potential allergic reactions, use hypoallergenic cosmetics and soapless cleansers.

### **Nonprescription Medications**

- Use clean white cloths to apply cool water compresses; apply for 20-30 minutes as often as needed or desired. Use a fresh solution with each new application.
- If desired, to reduce inflammation and the itching and redness, apply topical hydrocortisone cream *only* as follows:
  - Apply a small amount to affected areas up to 2-4 times a day.
  - Avoid applying the cream around the eyes or eyelids.
- To avoid infection, do not apply ointments to open lesions.
- Apply aluminum acetate (Burow's solution) compresses to areas with vesicles, bullae, and/or weeping lesions as follows:
  - Mix a prepackaged tablet or packet of aluminum acetate with a pint of cool tap water, wet a cloth with the solution, and apply the compress to rash areas.
  - Apply compresses for 30 minutes at least 4 times a day or as needed.
  - Prepare fresh Burow's solution for each application.
- Use colloidal oatmeal baths or soaks to soothe and cleanse areas of the rash and to reduce itching:
  - Sprinkle a 30 gram packet or a cup full of milled oatmeal into fast-running bath water, and mix the water to avoid lumping of the oatmeal.
  - Soak for 15-20 minutes in the oatmeal bath at least twice a day.
  - Pat skin dry rather than wiping it.
  - Be careful; oatmeal baths can leave the tub quite slippery.
- Store nonprescription medications in a cool, dry place out of children's reach.
- Using nonprescription medications for dermatitis longer than 7 days without consulting a physician is not recommended.

### **When to Seek Medical Attention**

- Contact a primary care provider for the following situations:
  - The rash does not begin to improve in 7 days.
  - Symptoms become worse.
  - The rash spreads.
  - The rash covers large areas of the face or causes swelling of the eyelids.
  - The rash involves the genitals.

### **Evaluation of Patient Outcomes for Contact Dermatitis**

Follow-up on the patient's progress should occur after 5-7 days of treatment; that is, the patient should be encouraged to call for additional advice if the itching has not subsided significantly within 5-7 days. If, at follow-up, the rash has significantly increased in size, affects the eyes or genitals, or covers extensive areas of the face, the patient must be referred to his or her PCP. Overall, complete remission of the dermatitis may take up to 3 weeks. However, the patient should see slow but steady reduction in itching, weeping, and dermatitis after 5-7 days of therapy.

### **Key Points for Contact Dermatitis**

- The leading cause of ICD is constant unprotected exposure to wet environments that may contain irritant substances such as detergents and cleaning solutions.
- ACD is produced through sensitization to an antigenic substance.
- Many substances are antigenic. Common antigens include fragrances, metals, medications, plants, and chemicals. Urushiol from poison ivy/oak/sumac is one of the most common allergens.
- Patients who are sensitive to irritants, allergens, or urushiol should take precautions to eliminate exposure by avoiding these agents, limiting exposure time, and wearing protective clothing and equipment.
- In the case of poison ivy, avoiding geographic areas with endemic *Toxicodendron* plants is helpful. Patients should be advised to wear clothing (e.g., gloves, long sleeves, and long pants) that limits exposure of the skin to the environment. In addition, to reduce the risk of dermatitis, patients sensitive to urushiol may liberally apply bentoquatam barrier lotion every 4 hours until the exposure period is over.

- Once exposed to an irritant or antigen, the patient should bathe with mild soap and water or use large volumes of cool water immediately after exposure to reduce the risk of dermatitis.
- ACD may begin as localized streaks or patches of highly pruritic rash that with time may become more numerous or coalesce into larger plaques on exposed dermal areas. The rash may affect the eyelids or face and, in some cases, areas ordinarily considered to be protected.
- Patients should be referred for further evaluation if there is involvement of the face, genitalia, or anus; considerable edema anywhere on the body (including eyelids); or extensive lesions covering a large portion of the body.
- Treatment of localized, pruritic rash consists of a topical application of hydrocortisone cream, compresses, or baths. Weeping vesicles or bullae may be treated with aluminum acetate compresses as an astringent with soothing and drying properties.
- Irritant and allergic contact dermatitis will resolve in approximately 10-21 days with or without topical therapy. Nonprescription medications primarily relieve symptoms.

## Handbook of Nonprescription Drugs > Chapter 35. Diaper Dermatitis and Prickly Heat

### Diaper Dermatitis and Prickly Heat: Introduction

Irritant contact diaper dermatitis, commonly referred to as diaper rash, is an acute inflammation of the skin occurring in the region of the perineum, buttocks, lower abdomen, and inner thighs. Despite the common perception that diaper dermatitis is a condition occurring in infancy, it can and does occur in any population in which incontinence presents.<sup>1</sup> Given the prevalence of diaper dermatitis in the infant population, this chapter focuses primarily on infant diaper dermatitis. Information presented in this chapter may be generalized to the adult population. Readers are referred to [Chapter 49](#) for specific information regarding treatment of adult incontinence.

Prickly heat, also known as miliaria, miliaria rubra, or heat rash, is a transient inflammation of the skin that appears as a very fine, pinpoint, and usually red raised rash. It can appear on any part of the body that has sweat glands (e.g., groin, chest, and axillae). In most circumstances, neither diaper dermatitis nor prickly heat causes serious illness. These conditions typically produce discomfort, irritation, and itching. They may lead to fussiness, agitation, and irritability, especially in the infant population. Diaper dermatitis and prickly heat can also be devoid of any discomfort.

### Diaper Dermatitis

Both irritant contact and allergic contact diaper dermatitis can present in the diaper area.<sup>2</sup> This chapter focuses primarily on irritant contact diaper dermatitis, given the prevalence of this form. For ease of reading, irritant contact diaper dermatitis is referred to simply as diaper dermatitis or diaper rash throughout the chapter. Allergic contact dermatitis is also discussed briefly.

Diaper dermatitis is the most common dermatologic disorder of infancy, resulting in more than 1 million provider office visits per year.<sup>3</sup> The majority of diaper dermatitis cases appear in infants 2 years of age and younger.<sup>3,4</sup> Diaper dermatitis can present as early as 7 days after birth.<sup>4</sup> Given the common nature of diaper dermatitis, the actual incidence of the condition is likely underreported. Literature has suggested a prevalence rate of 4%-35% in the first 2 years of life.<sup>3</sup> However, a majority of children experience diaper dermatitis at least once by the time they are out of diapers. The steady decline in the number of cases of diaper rash in infants since the 1970s is attributed to the increased use of disposable diapers. The decline was accelerated in the 1980s and 1990s with improvements in diaper technology and the rise of superabsorbent core materials and breathable diaper coverings.<sup>5,6,7</sup>

### Pathophysiology of Diaper Dermatitis

Diaper dermatitis can be caused by multiple factors. Occlusion, moisture, microbes, gastrointestinal tract proteolytic enzymes and bile salts, a shift from the normal acidic skin pH (pH 4.0-5.5) to a more alkaline pH, mechanical chafing, and friction can cause skin compromise and in additive or synergistic ways present as diaper dermatitis.<sup>1,4,8,9,10,11,12,13,14,15</sup>

The skin of the infant perineal region is about one-half to one-third the thickness of adult skin. Because the perineal region is typically occluded by a diaper, this area tends to hold moisture and wetness, predisposing it to irritation and infection.<sup>16</sup> Frequent urination and defecation, combined with infrequent changing of the diaper, contributes to increased skin moisture. The typical infant begins to urinate within 24 hours after birth. Urination occurs in infants up to 20 times a day until they are approximately 2 months old; thereafter, the frequency decreases to about 8 times a day until age 8 months. Defecation occurs from 3-6 times a day up to about age 8 months. As the infant's autonomic and muscular control develops, defecation gradually declines to 1-3 times a day. In the first months of life, infants commonly need in excess of 6 diaper changes per day. Skin left in contact with wetness for long periods becomes waterlogged or hyperhydrated, which plugs sweat glands, increases susceptibility to abrasion and frictional harm, and diminishes the barrier function of the stratum corneum in the diaper area. Diminished barrier capabilities in turn make the skin more susceptible to irritation, absorption of chemicals, and opportunistic microbes.

Urine and fecal bacteria can contribute to skin breakdown. Urea-splitting bacteria from the colon are believed to convert urine contents into ammonia. Ammonia raises the pH of the skin, making it more susceptible to damage or infection. This etiologic factor has been lessened by the use of absorbent disposable diapers, which minimize mixing of urine and feces in the diaper area.<sup>5,17</sup> Mechanical irritation can also lead to epidermal breakdown, allowing other irritants (e.g., fecal bacteria) to harm the skin. Tight-fitting, stiff, or rough diapers and the use of occlusive plastic or rubberized covers or pants over cloth diapers can contribute to occlusion and mechanical friction of the skin.

Medications and foods that affect the motility or microbial flora of the gastrointestinal tract, or that hinder autonomic control of urination and defecation may contribute to diaper dermatitis. Foods high in hexitols, sorbitol, sucrose, and

fructose may induce diarrhea and predispose to diaper rash. Dairy products can also induce diarrhea, especially in the presence of lactose intolerance. Variations in infant feeding preferences can also influence prevalence of diaper dermatitis. Breast-fed infants have decreased incidences of diaper rash compared with bottle-fed infants.<sup>18</sup> The feces of breast-fed infants are less copious, less alkaline, and less caustic to the skin. Transitions in the type of food consumed (e.g., from breast milk to solid foods) can also contribute to diaper rash. Some products (e.g., antioxidants, detergent or soap residues, household cleaning products, lotions, sunscreens, insect repellents), plant materials (e.g., ragweed and thistle), and diaper product ingredients can produce an allergic contact dermatitis that resembles diaper dermatitis.<sup>19</sup> Although many of these agents commonly are not purposefully used in the diaper region, they may have an unexpected effect on skin under a diaper should they be placed in the diaper region through accident or ignorance. Chemicals used to launder reusable cloth diapers, for example, can contribute to diaper rash and skin irritation if the diapers are not adequately washed and rinsed. Harsh chemicals used to clean and sanitize the diapers may leave chemical residues that exacerbate diaper dermatitis. Allergic contact dermatitis in the diaper region routinely presents only where contact with the allergen has occurred, often sparing the inguinal skin folds. Allergic contact dermatitis should be considered when standards of care do not lead to healing in the diaper area (see [Chapter 34](#) for a discussion of allergic contact dermatitis).<sup>2</sup>

### Clinical Presentation of Diaper Dermatitis

Diaper dermatitis usually presents as red to bright red (erythematous), sometimes shiny, wet-looking patches and lesions on the skin (see Color Plates, photograph 17). Lesions may appear dusky maroon or purplish on darker skin. Generally, diaper dermatitis occurs on the skin spaces covered by the diaper, but severe cases can spread outside the diaper area. If an infant, for example, lies primarily on his or her abdomen, the rash may appear more anterior to the perineum. In the same manner, if the infant lies primarily on his or her back, the rash may appear more posterior to the perineum.

A disconcerting feature of diaper rash is that it can perceptibly present in a matter of hours, yet it can often take days to completely resolve. Most likely, the process of skin breakdown is not pronounced or visible initially, yet the skin breakdown quickly transitions from unobservable to observable. The entire process from normal to noticeably erythematous skin takes longer than the time between normal diaper changes.

Although uncommon, severe diaper dermatitis can progress to maceration, papule formation, the presence of vesicles or bullae, oozing, erosion of the skin, or ulceration. Diaper rash can also predispose infants to secondary infections and genital damage. As skin pH changes, it can foster the growth of opportunistic infections that can be bacterial (e.g., *streptococci* or *staphylococci*), fungal (e.g., yeasts), and viral (e.g., herpes simplex) in nature. If infection is a concern, visual inspection of the diaper area is beneficial for proper diagnosis. *Candida* infections, for example, can present in the diaper area secondary to diaper dermatitis. The presentation of a *Candida* infection is distinct from that of uncomplicated diaper dermatitis. The typical *Candida* superinfection presents as papular or pustular lesions around the margins of the diaper dermatitis. Pustules can also present outside the primary diaper dermatitis area (satellite lesions). Additionally, *Candida* infections in the diaper area often present in the skin folds or creases, whereas the skin folds can serve to protect areas from diaper dermatitis. Untreated or infected diaper dermatitis can progress to skin ulceration, infections of the penis or vulva, and urinary tract infections. Such developments require medical referral.

Diaper rash can also be a manifestation of other diseases, such as Kawasaki's syndrome, granuloma gluteale infantum, cytomegalovirus infection, and nutritional deficiencies. Infants born to immunocompromised mothers (e.g., those with HIV; genital herpes; other chronic, congenital, or sexually transmitted infections) should be considered at increased risk for unusual manifestations of diaper rash or diaper rash-like presentations. Primary infections of the skin can resemble diaper rash and be misdiagnosed. Inguinal swelling, fever, chills, tachycardia, blisters, vesicles, and irregular borders bounded by bumps or vesicles are indicators of infections that require medical referral.<sup>4,20</sup>

Diaper rash can exist concurrently with other skin conditions such as psoriasis and seborrhea.<sup>10</sup> Skin conditions that can occur on other parts of the body can exist in the diaper region and may be misdiagnosed as diaper dermatitis.

### Treatment of Diaper Dermatitis

#### Treatment Goals

The goals of diaper dermatitis treatment are to (1) relieve the symptoms, (2) rid the patient of the rash, (3) discourage infection, and (4) prevent recurrences.

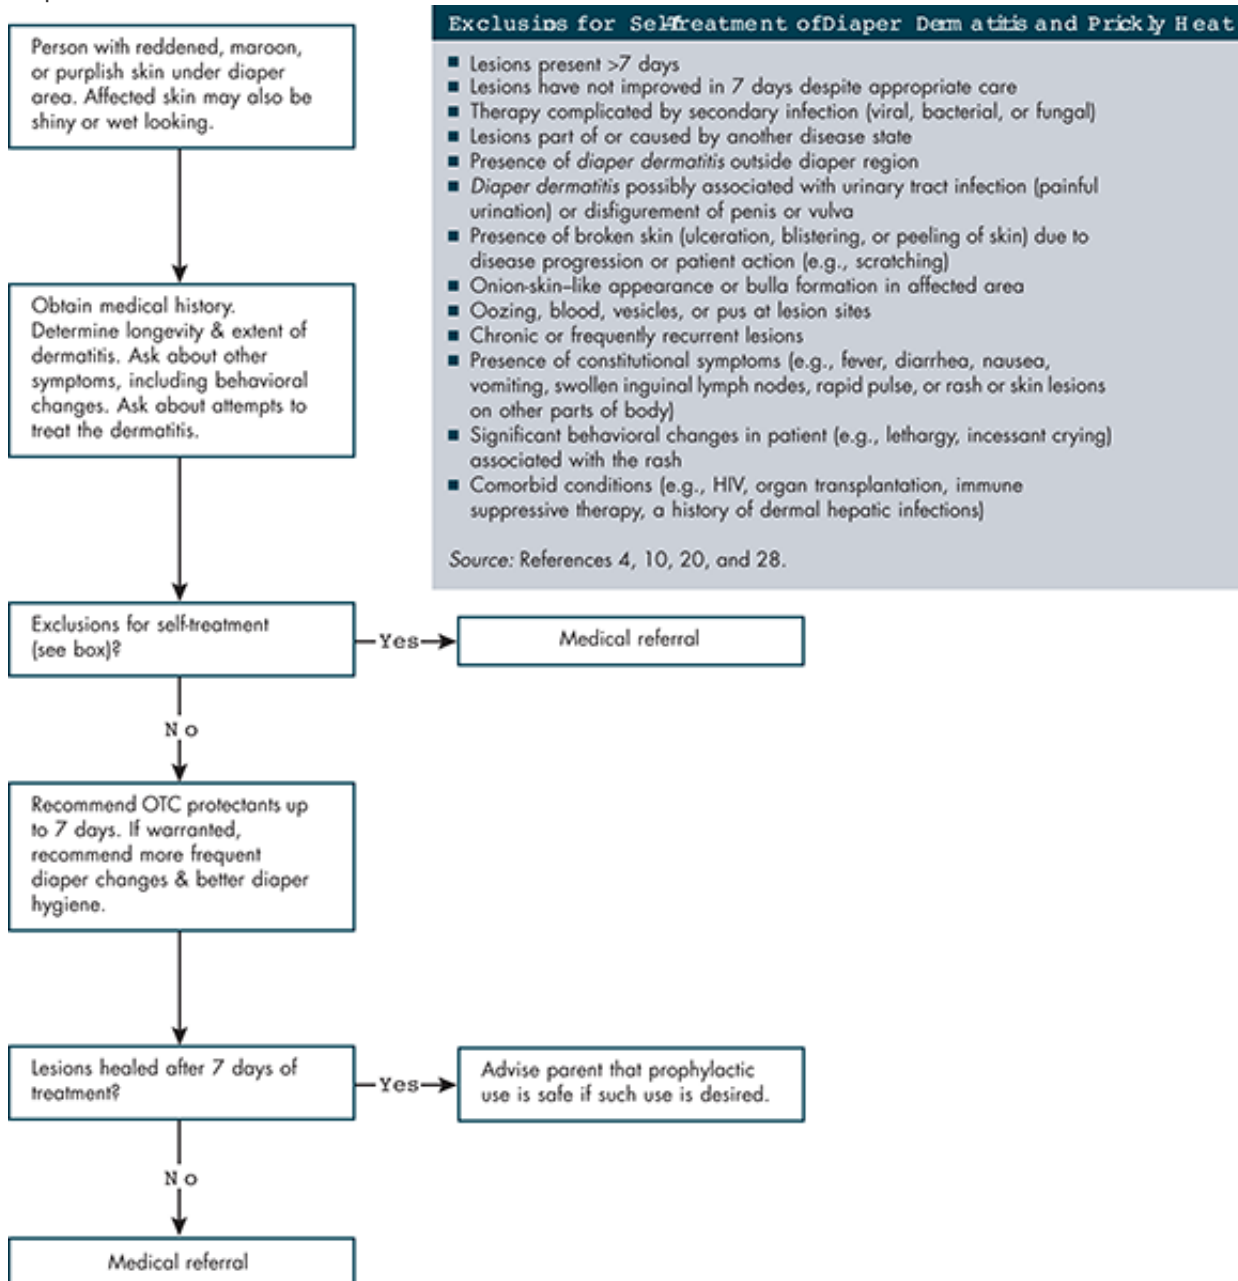

#### General Treatment Approach

The general treatment approach for diaper rash is the use of nonpharmacologic therapy or a combination of pharmacologic and nonpharmacologic therapy as outlined in [Figure 35-1](#).

The best treatment for diaper dermatitis is prevention. The ideal, yet often impractical, preventive therapy would be to

change the diaper immediately after the individual defecates or urinates. Self-treatment will often involve increased vigilance in keeping the infant dry and use of skin protectants in the diaper area. Self-treatment should be limited to diaper dermatitis that is uncomplicated (e.g., absence of comorbid conditions or symptoms) and mild-moderate (e.g., absence of oozing or blood at lesion sites, or lesions present <7 days) in presentation. Figure 35-1 presents a thorough list of characteristics of complicated and severe diaper dermatitis. Medical referral should occur when diaper dermatitis manifests one or more of the exclusions listed.

Self-care of diaper dermatitis. Key: HIV = Human immunodeficiency virus; OTC = over-the-counter.

### Nonpharmacologic Therapy

Nonpharmacologic therapy plays an integral role in the treatment of diaper dermatitis. The goals of nonpharmacologic therapy are to (1) reduce occlusion, (2) reduce contact time of urine and feces with skin, (3) reduce mechanical irritation and trauma to the inguinal and perineal skin, (4) protect the skin from further irritation, (5) encourage healing, and (6) discourage the onset of secondary infection.

Treatment of uncomplicated diaper dermatitis should be initiated with nonpharmacologic therapy. Increasing the frequency of diaper changes to a minimum of six per day is advisable. Increased vigilance in combination with increased frequency of diaper changes will often alleviate mild symptoms.

Should wiping be needed, gentle rubbing or patting with a bland, soft cloth or wipe is appropriate. Most commercially available baby wipes are now low in abrasives and chemically bland for use on diaper rash. Sensitive-skin baby wipe products are readily available to consumers. Used with finesse and gentle wiping, infant wipes are as mild as or

milder than washcloths.<sup>21</sup> Few baby wipes still contain alcohol, perfumes, soap, or other ingredients that can cause contact dermatitis or actually burn or sting the infant. Products that list such ingredients on the label should be avoided. Importantly, the unsoiled part of a diaper should not be used to clean or wipe the infant because it may harbor bacteria.

During each diaper change, careful flushing of the skin with plain water followed by gentle nonfriction drying is encouraged. One nonpharmacologic treatment modality is to let the infant's diaper area air dry prior to rediapering; however, the risk exists that the infant may have more urine or bowel contents to evacuate while air drying. Regardless of the technique used, thorough drying before rediapering is essential to good diaper-changing procedures.

As the technology of disposable diapers has improved, the disposable diaper has become a critical component of nonpharmacologic therapy for diaper rash.<sup>5,7</sup> Some disposable diapers have absorptive materials that pull moisture away from direct contact with the skin to reduce skin hyperhydration and mixing of urine with feces. Some disposable diapers have a protectant (e.g., petrolatum) already in the diaper. Research has indicated that use of disposable diapers compared with cloth diapers decreases the incidence of severe diaper dermatitis.<sup>6,22,23</sup> If cloth diapers are used, diapers should be laundered with a mild detergent and extra rinse cycles employed if sanitizing agents are used in the laundering process.

### Pharmacologic Therapy

The goals of pharmacologic therapy are to (1) protect the skin from further contact with urine and feces, (2) soothe any discomfort caused by the lesions, (3) encourage healing, and (4) discourage the onset of secondary infection.

### Skin Protectants

Protectants are the only products considered safe and effective for use in diaper dermatitis without medical referral. The Food and Drug Administration (FDA) has approved 17 ingredients, all skin protectants, for treatment of diaper dermatitis (Table 35-1).<sup>24</sup> Two or more of the approved ingredients are commonly combined in commercial products for treating diaper dermatitis. Importantly, some products contain an approved ingredient in combination with other ingredients that are unsafe or of dubious value for treating diaper rash. The other ingredients may be unsuitable or even toxic when applied to skin compromised by diaper dermatitis. Therefore, a general rule of thumb is to suggest the simplest possible products that contain FDA-approved ingredients. By law, products that contain antimicrobials, topical analgesics, and antifungals cannot claim they are for treatment of diaper dermatitis. Ingredients routinely included in skin-protectant formulations but not approved for treatment of diaper dermatitis are provided in Table 35-2.

**TABLE 35-1 FDA-Approved Skin Protectants to Treat Diaper Rash**

<i>Agent</i>	<i>Concentration (%)</i>
Allantoin	0.5-2
Calamine	1-25
Cocoa butter	50-100
Cod liver oil (in combination)	5.0-13.56
Colloidal oatmeal	≤0.007
Dimethicone	1-30
Glycerin	20-45
Hard fat	50-100
Kaolin	4-20
Lanolin	12.5-50
Mineral oil	50-100
Petrolatum	30-100
Topical cornstarch	10-98
White petrolatum	30-100

Zinc acetate	0.1-2
Zinc carbonate	0.2-2
Zinc oxide	1-25

Source: Reference 24.

**TABLE 35-2 Selected Nonmonograph Ingredients in Diaper Dermatitis Products**

Aloe	Lavender
Beeswax	Peruvian balsam
Calendula	Sodium bicarbonate
Castor oil	Sweet clover
Chamomile	Tea tree oil
Comfrey	Vitamin A
Flower extract	Vitamin D
Goldenseal	Vitamin E
Jojoba	

Of the 17 skin protectants listed in [Table 35-1](#), a select few are commonly incorporated into trade-name skin-protectant products. Useful comparative studies of the skin protectants are lacking. Zinc oxide is one of the most commonly employed semisolid skin protectants in products that treat diaper dermatitis. A major drawback of many zinc oxide ointment preparations and other hydrophobic diaper dermatitis preparations is the necessity of soap to remove the product from the skin. However, the hydrophobic nature of the preparations is beneficial in forming a protective barrier for the compromised skin. Some zinc oxide preparations are formulated to be more washable and creamlike and therefore easier to apply and remove. However, one must weigh the ease of use with the ability of the preparation to adequately protect the skin.

Petrolatum and white petrolatum are commonly used oleaginous ingredients that serve as excellent skin protectants. These products are ubiquitous ointment bases. Petrolatum may be listed as an active or inactive ingredient in skin protectant formulations. Lanolin is a bacteriostatic product obtained from a fatty substance found in wool and is also commonly used in skin-protectant products. It can be used alone or in combination with other skin protectants. Lanolin is a common contact sensitizer, and although approved for use in diaper dermatitis, risk should be noted if applied in the diaper area where the skin is inflamed and more likely vulnerable to contact allergens.

Calamine is a mixture of zinc and ferrous oxides. It has absorptive, antiseptic, and antipruritic properties and is available in numerous dosage forms. Mineral oil coats the skin with a water-impenetrable film that must be washed off with each diaper change to avoid buildup in pores and subsequent folliculitis. Mineral oil is often used in small quantities in skin protectant products. It is often listed as an inactive ingredient in formulations despite FDA approval for use as an active ingredient. Dimethicone is a silicone-based oil that repels water and soothes and counteracts inflammation. It is used in combination with other skin protectants such as petrolatum.

Topical cornstarch and talc are used almost exclusively as loose powders. Topical cornstarch is an absorbent material, whereas talc functions as a lubricant. Both products carry warnings against inhalation of the powder because of a history of injury and fatality from improper use around infants. The warning states, "Keep powder away from child's face to avoid inhalation, which can cause breathing problems."<sup>24</sup> Powders should be carefully applied with as little aerosolization as possible. Concerns about inhalation of powders have caused some health care providers to suggest pouring the powder into the hands away from the infant and gently rubbing it onto the perineal area, whereas others recommend avoiding any use of powders around infants. Talc specifically should not be applied to broken or oozing skin; it can cake on the edges of wounds and precipitate infection or retard healing. Overall, skin protectants serve as physical barriers between the skin and external irritants. Protectants also serve as lubricants in areas in which skin-to-skin or skin-to-diaper friction could aggravate diaper rash or predispose the area to diaper rash. Protectants absorb moisture or prevent moisture from coming into direct contact with skin. Protective effects of these products allow the body's normal healing processes to work. Because skin protectants are remarkably safe, their use as either treatment or prophylaxis is acceptable. Research suggests that applying a skin protectant regularly with each diaper change is one element of preventing diaper dermatitis.<sup>12</sup>

When diaper dermatitis is present and pharmacologic therapy is indicated, the provider should inform caregivers about their choices between semisolid and powdered protectants. Caregivers may be more comfortable with a

semisolid product if they are anxious about the inhalation warning on powders, or when hands-on application is not painful or uncomfortable to the child. Fortunately, the products in this category are relatively inexpensive, and socioeconomic status tends not to be a major issue in treating diaper dermatitis. [Table 35-3](#) lists selected widely available trade-name products and their active ingredients.

**TABLE 35-3 Selected Nonmonograph Ingredients in Diaper Dermatitis Products**

<i>Trade Name</i>	<i>Primary Ingredients (and selected additional ingredients)</i>
A + D Original Ointment	Petrolatum 53.4%; lanolin 15.5%
A + D Zinc Oxide Ointment	Zinc oxide 10%; dimethicone 1%
Aquaphor Healing Ointment	Petrolatum 41% (lanolin; mineral oil)
Balmex Diaper Rash Cream	Zinc oxide 11.3% (dimethicone, mineral oil)
Boudreaux's Butt Paste	Zinc oxide 16% (castor oil; mineral oil; Peruvian balsam <sup>a</sup> ; petrolatum)
Caldesene Baby Cornstarch Powder with Zinc Oxide	Talc 81% <sup>a</sup> ; zinc oxide 15%
Desitin Maximum Strength Original Paste	Zinc oxide 40% (cod liver oil; lanolin; petrolatum; talc <sup>a</sup> )
Flanders Buttocks Ointment	White petrolatum 66.2%; zinc oxide 13.4% (beeswax; castor oil <sup>a</sup> ; mineral oil; Peruvian balsam <sup>a</sup> )
Lansinoh Diaper Rash Ointment	Dimethicone 5%; lanolin 15.5%; zinc oxide 5.5% (chamomile <sup>a</sup> ; corn starch; jojoba <sup>a</sup> ; petrolatum)
Triple Paste Medicated Ointment	Zinc oxide 12.8% (corn starch; lanolin; white petrolatum)
Vitacilina Bebe Diaper Rash Ointment	Petrolatum 34.6%; zinc oxide 30%; allantoin 1% (corn starch; mineral oil; vitamin A <sup>a</sup> ; vitamin D <sup>a</sup> )

<sup>a</sup>Nonmonograph ingredients.

Skin-protectant dosing and application are straightforward. The protectant is applied liberally to the skin in the diaper area. Special attention should be paid to completely cover erythematous areas with the protectant if diaper dermatitis is already present. Overapplication (overdosage) of approved skin protectants is not a concern. Underapplication, however, can reduce the protective effectiveness of the product. The protectant should be reapplied as needed and with every diaper change. Diaper rash that does not necessitate medical referral commonly improves dramatically within 24 hours of initiating pharmacologic and nonpharmacologic treatment.

#### Contraindicated Agents

Topical nonprescription antibiotic and antifungal agents are not appropriate to use in the self-treatment of diaper dermatitis. If an infection is suspected, medical referral is advised. Topical analgesics are not recommended because they can alter sensory perception in a population that often cannot communicate perceptual changes. These agents may also excoriate macerated skin, cause pain, retard healing, and further complicate diaper dermatitis.

Hydrocortisone is indicated for minor skin irritation, but it should not be used in diaper dermatitis without supervision by a medical provider, especially in infants. Hydrocortisone can increase the risk of secondary infection via immune response suppression. Additionally, the diaper area is a significant portion of the infant's body surface area.

Hydrocortisone absorption into the skin is enhanced under occlusive conditions. When applied to macerated skin or a large surface area, absorption of hydrocortisone may lead to serum levels that interfere with the infant's pituitary-adrenal axis. Nonprescription hydrocortisone is labeled not to be used in patients younger than 2 years. (See [Chapter 34](#) for additional information on the use of hydrocortisone.)

#### Product Selection Guidelines

Whereas no particular product among the approved products possesses evidence-based advantages, personal preferences for particular product characteristics will likely determine which product caregivers use to treat diaper dermatitis. As previously mentioned, some commonly used products contain nonapproved (i.e., nonmonograph)

ingredients. These products may be used for formulation purposes, or they may be unregulated nutraceuticals listed as inactive or active ingredients. Unapproved ingredients could also be included in preparations to support marketing claims. For example, camphor may be present to provide a “medicated” fragrance; aloe may be present to appeal to the public perception that aloe is a wound-healing agent; or vitamins may be present to convey “natural” characteristics. To make the claim to treat diaper dermatitis, the product must, however, meet the FDA-published guidelines for active ingredients. Although the products used in diaper dermatitis generally have a wide margin of safety, they should not be recommended indiscriminately.

### Complementary Therapies

Complementary therapies are not recommended for use in newborns and infants because evidence is lacking regarding their safety and effectiveness in these populations. The amount and effect of systemic absorption are unknown. Appropriateness of product strength is often unknown. Although some of these agents have been used without incident in adults, no credible data exist on their safety or efficacy in infants.

### Assessment of Diaper Dermatitis: A Case-Based Approach

When a caregiver or patient consults a health care provider about a suspected diaper rash, the provider should evaluate the presentation of the diaper rash itself and determine the extent to which factors conducive to exacerbation of diaper dermatitis are present. The provider should visually inspect the diaper dermatitis if appropriate. If inappropriate, the provider should use open-ended questioning techniques to gain a description of the dermatitis. Case 35-1 illustrates assessment of patients with diaper dermatitis. If the dermatitis is deemed to be uncomplicated diaper dermatitis warranting self-care, nonpharmacologic and pharmacologic suggestions can be made by the provider. From a nonpharmacologic perspective, the caregiver should be asked what type of diaper is being used and how frequently diapers are changed. Drawing on that response, the provider must consider whether increasing the frequency of diaper changes and other nonpharmacologic measures are likely sufficient to heal the diaper dermatitis or whether pharmacologic treatment is warranted. Given minimal risk associated with pharmacologic treatment options, said options are often appropriate to suggest to the caregiver.

#### Case 35-1

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient’s symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Mr. Charles indicates that his 8-month-old daughter is quite irritable and has a rash on her “bottom.” He indicates that the rash presented this morning out of nowhere. He describes his daughter’s groin area as very red, shiny, and sensitive to touch. His daughter cries as if in pain during diaper changes when the diaper area is cleaned with a baby wipe. Mr. Charles indicates that his daughter has had this type of rash before but never so badly that it made her cry. Previous occurrences have resolved without the need to seek medical advice.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient’s symptom(s)	None noted.
c. description of the patient’s efforts to relieve the symptoms	Mr. Charles has been using a moisturizer cream on the diaper area since this morning, but he cannot remember the name of it. He bought some sensitive-skin baby wipes to see if that would cause less pain when cleaning his daughter’s diaper area.

d. patient's identity	Neva Charles
e. patient's age, sex, height, and weight	8 months old, female, 26 in., 18 lb
f. patient's occupation	NA
g. patient's dietary habits	Breast-fed 5 times daily; eats baby cereal and baby food; also eats soft table food.
h. patient's sleep habits	Normal for age
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	None
j. allergies	NKA
k. history of other adverse reactions to medications	None noted.
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate the patient's signs/symptoms and correctly identify the patient's primary problem(s).	Symptoms suggest mild-moderate diaper rash in the inguinal area. The quick presentation of the rash and the painfulness and irritability support this diagnosis.
3. Identify exclusions for self-treatment ( <a href="#">Figure 35-1</a> ).	None noted.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Neva immediately to her pediatrician or other PCP. (2) Recommend self-care until an appropriate PCP can be consulted. (3) Recommend self-care with nonprescription pharmacologic product. (4) Recommend self-care with nonpharmacologic methods. (5) Recommend both nonpharmacologic treatment and nonprescription pharmacologic treatment. (6) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Recommend that Mr. Charles use both nonprescription and nonpharmacologic modalities to treat Neva's diaper rash. Specifically recommend increased diaper changes, air drying in between diaper changes, and liberal application of Desitin Maximum Strength Original Paste with every diaper change as needed. Desitin can also be used to prevent diaper rash and can therefore be applied after Neva's current diaper rash heals.

6. Describe the recommended therapeutic approach to the patient or caregiver.	"A zinc oxide-based skin protectant such as Desitin should protect the skin and thereby allow it to heal. Nonpharmacologic therapy is just as important because it will promote healing and meet goals of treatment."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Neva meets none of the exclusion criteria that would indicate medical referral is preferred. Mild-to-moderate diaper dermatitis can be effectively managed with nonpharmacologic and nonprescription pharmacologic therapy."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	See Nondrug Measures in the box Patient Education for Diaper Dermatitis.
a. appropriate dose and frequency of administration	"Apply Desitin paste liberally with every diaper change and as needed."
b. maximum number of days the therapy should be employed	"Desitin can be applied to treat and prevent diaper rash. There is no maximum length of therapy with this medication."
c. product administration procedures	"Wash hands and clean diaper region with a soft cloth or baby wipe. Allow the area to dry thoroughly. Thereafter, apply Desitin to the diaper region liberally. A glove may be worn if preferable. Overapplication presents no danger to Neva. Change diapers every 3-4 hours as a minimum."
d. expected time to onset of relief	"Neva's diaper rash will likely be noticeably improved by tomorrow."
e. degree of relief that can be reasonably expected	"You can expect the rash to be less tender tomorrow. Application of the skin protectant will likely soothe the pain associated with the rash."
f. most common side effects	"No side effects are associated with this product."
g. side effects that warrant medical intervention should they occur	NA
h. patient options in the event the condition worsens or persists	See the box Patient Education for Diaper Dermatitis and <a href="#">Figure 35-1</a> .
i. product storage requirements	"Store away from children."
j. specific nondrug measures	See the box Patient Education for Diaper Dermatitis.

Solicit follow-up questions from the patient or caregiver.	“Should I use the creamy Desitin or the original Desitin paste?”
Answer the patient's or caregiver's questions.	“Whereas both products will help Neva's condition, I suggest the original paste because it is thicker, creates a better barrier, and may allow Neva's diaper area to heal more quickly.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Call Mr. Charles in 2 days to evaluate Neva's response to the suggested treatment regimen.

Key: N/A = Not applicable; NKA = no known allergies; PCP = primary care provider.

### Patient Counseling for Diaper Dermatitis

The health care provider should review with the caregiver proper cleaning of the diaper area. Additionally, the provider should advise the caregiver to avoid occlusion of the area, when feasible, and to avoid prolonged contact of urine or feces with the infant's skin. The provider should explain the proper methods of applying nonprescription skin protectants and should describe to the caregiver signs and symptoms that indicate the dermatitis has worsened and warrants medical attention. The box Patient Education for Diaper Dermatitis lists specific information to provide caregivers.

#### Patient Education for Diaper Dermatitis

The goals of diaper rash treatment are to (1) relieve the symptoms, (2) rid the patient of the rash, (3) discourage infection, and (4) prevent recurrences.

For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Nondrug Measures

- Change diapers frequently, at least six times a day, to prevent exposure of the infant's skin to moisture and feces.
- Do not use rubber or plastic pants over cloth diapers. Tightly covering the skin encourages skin breakdown.
- During every diaper change, use plain water to clean the diaper area. Gently dry area or allow it to air dry.
- Do not wipe the infant with any part of the diaper. Even areas that appear clean may be contaminated with fecal bacteria.
- Avoid starched or very stiff diapers.
- Avoid commercial baby wipes that contain alcohol, perfumes, and soap, which may burn or sting the skin.
- If feasible, allow the infant to go without a diaper, even for short instances, in an effort to dry the rash.

#### Nonprescription Medications

- To treat diaper rash, use a product containing one or more of the skin protectants listed in [Table 35-1](#). The product can be used even after the rash clears to prevent recurrences.
- Do not use products that contain ingredients listed in [Table 35-1](#) if they are combined with benzocaine or an antibacterial such as benzethonium chloride. Benzocaine can cause an allergic reaction; antibacterials are not suitable for use on diaper rash.
- Do not use hydrocortisone.
- Do not use topical (external) analgesics such as phenol, menthol, methyl salicylate, or capsaicin to treat diaper rash. These medications are inappropriate for use on infant skin and may cause harm.
- Powders for children or infants should be gently poured into the hands and then rubbed onto the skin, using a sufficient amount to cover the affected area. Do not vigorously shake powders near infants. Avoid infant inhalation of powders.
- Apply cream or ointment liberally, by hand or with a disposable or washable spatula, to cover the affected area.
- If using mineral oil, wash it off at every diaper change to avoid clogging skin pores.
- Throw away products that are discolored or whose expiration dates have passed. (The health care provider should point out expiration dates on the products.)

## When to Seek Medical Attention

- Consult a primary care provider if any of the exclusions in [Figure 35-1](#) apply.

## Evaluation of Patient Outcomes for Diaper Dermatitis

Treatment of diaper dermatitis should be relatively short. If 7 days of treatment have elapsed and the condition is not healed, medical referral should occur. At the conclusion of therapy, the skin should return to its pre-diaper dermatitis condition. If diaper dermatitis presents routinely or presents in a severe manner, prophylactic use of skin protectants is suggested, given the safety of preparations presented in [Table 35-1](#).

## Prickly Heat

Prickly heat, sometimes referred to as heat rash or miliaria, can occur at any age in anyone who has active sweat glands. The condition affects up to 40% of infants.<sup>25</sup> It is likely significantly underreported, given that it is less troublesome than diaper dermatitis and clears up very rapidly if left alone or if its cause is removed. Prickly heat often presents in hot working conditions and with activities in which sweating occurs (e.g., manual labor, exercise, or athletics).<sup>26,27</sup>

## Pathophysiology of Prickly Heat

Prickly heat results from blocked or clogged sweat glands.<sup>28</sup> (See [Chapter 37](#) for a review of the anatomy of the sweat gland.) The inability of sweat to escape the pores causes dilation and rupture of epidermal sweat pores, causing an acute inflammation of the dermis that may manifest as stinging, burning, or itching.

Prickly heat can arise from normal skin with little or no anatomic prodrome. The condition is most often associated with very hot, humid weather or can occur during illnesses that cause significant or profuse sweating. It also results from the inability of the skin to “breathe” because of excessive clothing, very tight clothing, or clothing that is occlusive, such as leather, polyester, or athletic protective or safety garments and devices.

## Clinical Presentation of Prickly Heat

The pinpoint-size lesions that are the hallmark of prickly heat are raised and red or maroon, forming erythematous papules (see [Color Plates](#), photograph 18). The lesions may appear in small numbers clustered together or spread over the occluded area on a pink to red field (miliaria rubra). Common sites for prickly heat dermatitis include the axillae, chest, upper back, back of the neck, abdomen, and inguinal area. The lesions often trace the pattern of the occlusion and, in uncomplicated cases, do not extend beyond the occluded area. If lesions are not resolved in a reasonable length of time (approximately 3-10 days), they can evolve into the same kinds of complications seen in diaper dermatitis (e.g., infection, pustule formation, or generalized dermatitis). Complications are extremely rare.

## Treatment of Prickly Heat

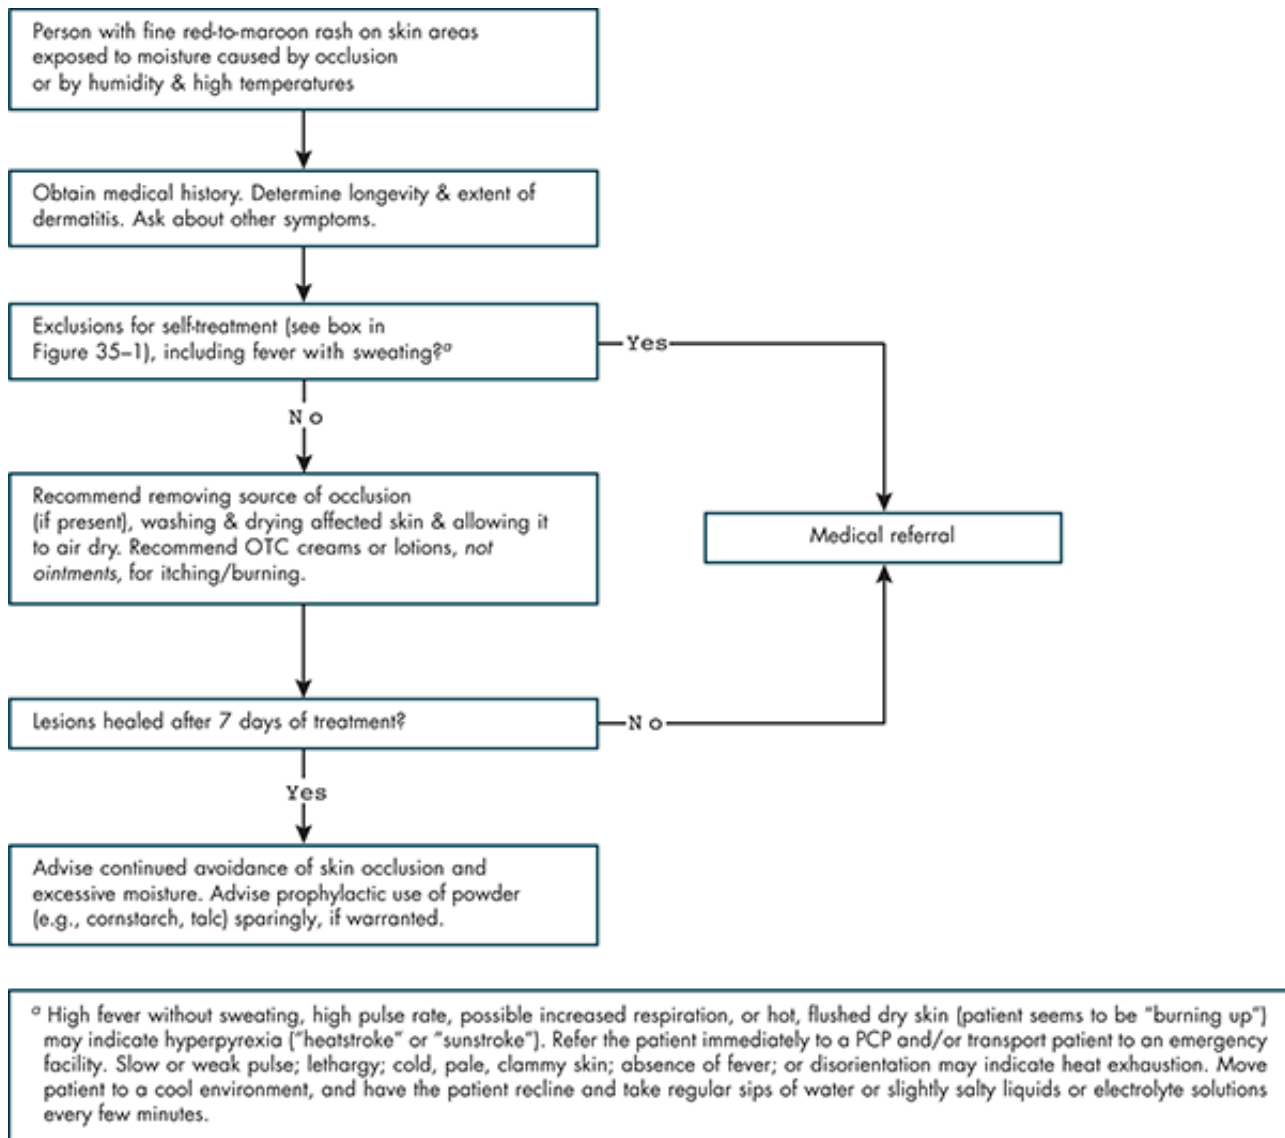

### Treatment Goals

The primary goal in the treatment of prickly heat is removal of the causative agent or agents. Lesions associated with prickly heat usually resolve without pharmacologic treatment if the cause is removed. A secondary goal in the treatment of prickly heat is alleviation of symptoms associated with the condition.

### General Treatment Approach

The nonpharmacologic treatment goals for prickly heat include (1) eliminating occlusion of skin, (2) protecting skin from further irritation, (3) promoting healing of skin, and (4) discouraging onset of secondary infection.

Pharmacologic therapy and nonpharmacologic therapy have the same goals. Pharmacologic products help (1) keep skin dry, (2) promote healing, (3) soothe any discomfort caused by lesion(s), and (4) discourage onset of secondary infection. The algorithm in [Figure 35-2](#) outlines the self-treatment of prickly heat.

Copyright © American Pharmacists Association  
All rights reserved. Any use is subject to the Terms of Use.

Self-Care of prickly heat. Key: OTC = Over-the-counter; PCP = primary care provider.

### Nonpharmacologic Therapy

Nondrug therapy for prickly heat consists of taking measures to decrease sweating and increase air flow to the affected area. If the sweating is caused by a fever, the use of internal antipyretics, if not contraindicated, is appropriate. Wearing loose, light-colored, and lightweight clothing is palliative in prickly heat and is also good prevention in that it allows airflow to the skin. Health care providers should warn patients not to apply oleaginous substances to prickly heat lesions because these substances plug pores that need to be patent.

### Pharmacologic Therapy

Nonprescription treatment of prickly heat should be limited to mild-moderate, uncomplicated cases. Affected areas should not be occluded during therapy. Overall, this disorder can be ameliorated in less time and with less total drug exposure than diaper dermatitis.

### Emollients, Skin Protectants, and Antipruritics

The choice of a drug product should be limited to one product that relieves burning and itching but does not block skin exposure to the air. Water-washable antipruritic products as well as bland emollients and protectants that soothe the skin and maintain skin moisture and texture can be used to treat the symptoms of prickly heat while the condition resolves. Colloidal oatmeal bath products and lotions have been employed for their antipruritic and soothing properties. Powders should be used only prophylactically to absorb moisture and keep skin dry, rather than as treatment of active prickly heat. (See [Table 35-4](#) for selected trade-name products and [Chapter 32](#) for a discussion of skin emollients.)

### TABLE 35-4 Selected Nonprescription Products for Prickly Heat

<i>Trade Name</i>	<i>Primary Ingredients</i>
Aveeno Daily Moisturizing Lotion	Colloidal oatmeal
Extra Strength Benadryl Itch Stopping Cream	Diphenhydramine HCl 2%; zinc acetate 0.1%
Cortizone-10 Maximum Strength Anti-Itch Cream	Hydrocortisone 1%
Eucerin Skin Calming Itch Relief Treatment	Menthol
Lubriderm Daily Moisture Lotion	Water; glycerin; mineral oil

#### Other Pharmacologic Agents

As with diaper dermatitis, hydrocortisone is contraindicated in infants. In adults, hydrocortisone may be useful if the body surface area involved is 10% or less. (See [Figure 40-4](#) for information on calculating body surface area.) Because prickly heat rapidly clears without drug therapy, the only actual use for hydrocortisone when treating prickly heat is to relieve itching. Topical antihistamines and local anesthetics (see Chapter 36) carry the risk of sensitization, but they can be employed as antipruritic agents.

#### Product Selection Guidelines

When treating prickly heat, the skin needs to dry and dissipate moisture. Therefore, only water-washable, cream-based products should be applied to prickly heat to relieve symptoms. For moisture absorption and prevention of wetness, powders are a reasonable choice. However, prolonged use or overuse of powders can lead to clogged pores and can actually precipitate prickly heat. When applied to the chest or neck, cornstarch or talc powder should be placed in the hand and applied manually to the skin with light friction. Any product that has an ingredient (e.g., phenols or boric acid) that could be toxic if absorbed through thin, compromised skin should not be recommended for use on infants. Bathing children and infants with prickly heat in colloidal oatmeal or lukewarm water may be recommended as a first option.

#### Assessment of Prickly Heat: A Case-Based Approach

Patient assessment for prickly heat involves identifying the site(s) of the lesions and potential causes of the exacerbation. If the patient is an infant, the health care provider should gather information regarding potential environmental characteristics (e.g., sleeping conditions or presence/absence of air conditioning) that could be exacerbating the condition.

Case 35-2 provides an example assessment of a patient with prickly heat.

#### Case 35-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient states he has "some sort of itchy rash" on several parts of his body, including his back and thighs. He has had the rash for about 3 days. He states that the rash is not painful.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient has had previous rashes that look identical to this rash. He tends to get the rash more often in the summer when he's working construction, but he sometimes has it in the winter months as well.
c. description of the patient's	Patient tries to prevent rash through good personal hygiene techniques (e.g.,

efforts to relieve the symptoms	taking showers more frequently) and applying a thick cream to problem areas to keep them moist; however, these measures do not always keep him from getting the rash.
d. patient's identity	C. A. Robison
e. age, sex, height, and weight	38 years old, male, 5 ft 11 in., 180 lb
f. patient's occupation	Construction worker
g. patient's dietary habits	Normal diet; minimal vegetables; 8 cups of coffee per day
h. patient's sleep habits	Averages 7 hours of sleep nightly.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	None noted.
j. allergies	Allergy to tramadol (hives)
k. history of other adverse reactions to medications	NA
l. other (describe) _____	C. A. is a very fit individual who, in addition to his job, coaches a local high school cross-country team. He often joins his students on runs.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Prickly heat secondary to sweating and possibly occlusive clothing
3. Identify exclusions for self-treatment (see <a href="#">Figure 35-1</a> ).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer C. A. to a dermatologist or his PCP. (2) Recommend self-care until an appropriate PCP can be consulted. (3) Recommend self-care with nonprescription product(s). (4) Recommend self-care with nonpharmacologic methods. (5) Recommend both nonprescription self-care products and nonpharmacologic treatment. (6) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient	Application of nonprescription hydrocortisone product would likely minimize itching associated with C. A.'s prickly heat while his condition heals. Because of the relatively large surface area (thighs and back) where the prickly heat presents, a thin layer of hydrocortisone should be applied 3-4 times per day (see

preferences.	<a href="#">Chapter 34</a> ). A powder to keep the affected areas dry could also be used judiciously. Patient education about the cause of prickly heat is important in prevention of future occurrences.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"I suggest discontinuation of the 'thick cream' because such a product can exacerbate prickly heat. A topical antihistamine will help with the itching associated with your prickly heat. It will not heal the prickly heat, but you should notice that the prickly heat heals itself in as little as 24 hours. It's important to take appropriate steps to minimize occlusion in the affected areas and to keep those areas clean and dry."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	See outcome discussion in #6.
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	"Extra Strength Benadryl Itch Stopping Cream: Apply to affected area(s) not more than 4 times daily as needed. Johnson's Baby Powder: Apply 1 time daily after showering. Do not inhale powder."
b. maximum number of days the therapy should be employed	"Both can be applied as needed; however, topical antihistamines should not be applied for more than 7 consecutive days."
c. product administration procedures	See the box Patient Education for Prickly Heat.
d. expected time to onset of relief	"Twenty-four hours or less if nonpharmacologic measures are employed as directed."
e. degree of relief that can be reasonably expected	"Itching should be minimized. Skin should return to pre-prickly heat condition."
f. most common side effects	"The cream has no common side effects. The powder can clog pores if used in excess."
g. side effects that warrant medical intervention should they occur	NA
h. patient options in the event that condition worsens or	"If condition persists after 7 days of treatment, see your primary care provider to rule out other conditions."

persists	
i. product storage requirements	“Keep product out of reach of children.”
j. specific nondrug measures	See Nondrug Measures in the box Patient Education for Prickly Heat.
Solicit follow-up questions from the patient or caregiver.	“I sometimes shower multiple times per day. Should I apply the powder after every shower?”
Answer the patient’s or caregiver’s questions.	“Applying too much powder can actually make you more likely to get prickly heat because the powder can clog the pores through which your sweat is excreted. I suggest applying the powder after the shower that will get you through the part of your day when you are most likely to sweat.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Call Mr. Robison in 2 days to evaluate his response to the suggested treatment regimen.

Key: NA = Not applicable; PCP = primary care provider.

### Patient Counseling for Prickly Heat

The health care provider should stress to the patient that prickly heat is usually easily treated by removing factors that clog skin pores, while also explaining appropriate nonpharmacologic and pharmacologic measures for healing or alleviating symptoms of prickly heat. The provider should explain that excessive use of skin protectants can exacerbate the disorder. The box Patient Education for Prickly Heat lists specific information to provide patients.

### Evaluation of Patient Outcomes for Prickly Heat

Treatment of prickly heat should be relatively short. Considerable improvement is commonly noted in as little as 24 hours after nonpharmacologic and pharmacologic treatment initiation. If the condition is not completely resolved or has worsened after 7 days of treatment, the patient should be referred for further evaluation. Monitoring of treatment success involves simple observation of lesions. At the end of therapy, skin should return to its precondition state.

### Key Points for Diaper Dermatitis and Prickly Heat

#### Diaper Dermatitis

- Diaper dermatitis is exacerbated by moisture and occlusion.
- Increasing the frequency of diaper changes (i.e., decreasing contact time between skin and excrement) plays a major role in the nonpharmacologic treatment of diaper dermatitis.
- Pharmacologic treatment should be limited to products containing FDA-approved ingredients indicated for the treatment of diaper dermatitis (Table 35-1); exotic additives and complementary therapies should be avoided.
- Apply hydrophobic skin protectants liberally to diaper dermatitis areas; overapplication should not be a concern.
- Do not use hydrocortisone in the self-treatment of diaper dermatitis.
- The majority of diaper rash cases will resolve when occlusion and wetness are adequately suppressed.
- Cases of diaper dermatitis that are still present after 7 days of treatment should be referred for further evaluation.

#### Patient Education for Prickly Heat

The objectives of self-treatment are to (1) relieve the discomfort of prickly heat and (2) eliminate its cause. For most patients, following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Nondrug Measures

- To prevent clogging skin pores, avoid excessive sweating by resting, cooling off, or going to a cool environment.
- Wear loose, light-colored, porous, and lightweight clothing to allow airflow to the skin.
- Shower, bathe, or change clothes immediately after heavy sweating, and wear loose-fitting clothes when such activity is anticipated. Remember to drink plenty of fluids and allow the body to cool down after any strenuous activity.

### Nonprescription Medications

- Unless a primary care provider advises otherwise, use systemic analgesics (e.g., aspirin, acetaminophen, or ibuprofen) to reduce a fever and the sweating it can cause. (See [Chapter 5](#) for dosing information.)
- Do not apply oily substances to prickly heat lesions because they clog skin pores.
- Use powdered skin protectants to absorb moisture and help prevent wetness ([Table 35-3](#)). Place cornstarch or talc powder in the hand, and apply to the skin with light friction. Note that prolonged use or overuse of powders can lead to clogged pores and can precipitate prickly heat.
- Do not use hydrocortisone on infants. However, it may be used to relieve itching in adult cases of prickly heat if no more than 10% of the body surface area is involved.
- Water-washable emollients applied in a thin film twice a day can help the skin return to normal (see [Chapter 32](#)).
- If redness, burning, itching, peeling, or swelling develops after a product is applied, rinse any remaining product off the skin and avoid further use.
- For older children and adults, consider using oral antihistamines for relief of itching.
- To soothe discomfort in adults or infants, wash the affected skin with bland soap or soak the skin in a colloidal oatmeal solution.
- The condition should show observable improvement in 24 hours.

### When to Seek Medical Attention

- If the condition persists after 7 days of treatment, consult a primary care provider.

### Prickly Heat

- Prickly heat is exacerbated by moisture and occlusion.
- The majority of prickly heat cases will resolve when occlusion and wetness are adequately suppressed.
- Cases of prickly heat that persist after 7 days of treatment should be referred for further evaluation.
- Pharmacologic treatment of prickly heat should be targeted at providing relief from itching or burning.
- Products containing emollients or anti-itch ingredients in water-washable dosage forms are favored in the treatment of prickly heat. Powders may be used to help dry the skin, but they must be used judiciously to prevent clogged pores.

**Handbook of Nonprescription Drugs** > Chapter 36. Insect Bites and Stings and Pediculosis**Insect Bites and Stings and Pediculosis: Introduction**

Insect bites and stings are common, and anyone who spends time outdoors is at risk. These injuries usually cause only a local reaction, but they can produce a mild allergic reaction or life-threatening anaphylaxis in patients who are sensitive. About 0.5% of the population may show signs of systemic allergic reactions to insect stings, and simultaneous multiple insect stings of 500 or more may cause death from toxicity. In the United States, more people die of insect stings than of bites from all poisonous animals combined. The exact number of people who experience systemic allergic reactions to insect bites is unknown.

Despite the potentially fatal consequences, encounters with biting and stinging insects are typically brief. Pediculosis (lice infestation) and scabies, by contrast, are parasitic infections, and the arachnids remain on the host until eradicated. Approximately 10-12 million people in the United States are affected by pediculosis each year, most of them children ages 3-12 years.

This chapter covers the stings of insects only but discusses the bites of both insects and arachnids (e.g., ticks, mites, spiders, and lice). The term *insect* is used to cover general statements about these invertebrates.

**Insect Bites**

## Pathophysiology and Clinical Presentation of Insect Bites

Bites from insects (e.g., mosquitoes, fleas, and bedbugs) and from arachnids (e.g., ticks and chiggers) are nonvenomous. Each insect has distinctive biting organs and salivary secretions that contribute to the characteristic signs and symptoms for each type of bite.

## Mosquitoes

Mosquitoes are found in abundance worldwide, particularly in humid, warm climates. After landing on the skin, mosquitoes inject an anticoagulant saliva into the victim, which causes the characteristic welt and itching. Malaria and West Nile virus are serious systemic infections that are transmitted by mosquitoes. In 2012, West Nile virus human infection was reported in 48 states in the United States.<sup>1</sup> Although most infected patients do not experience symptoms,<sup>2</sup> about 20% of infected patients experience flu-like symptoms with fever and fatigue. Symptoms can progress to muscle weakness, encephalitis, or meningitis. Controlling mosquito populations is particularly important in preventing the spread of this disease.<sup>3</sup>

## Fleas

Fleas are tiny bloodsucking insects that can be found worldwide but breed best in a humid climate. Humans are often bitten after moving into a vacant flea-infested habitat or when living with infested pets. Fleabites are usually multiple and grouped and, in humans, occur primarily on legs and ankles. Each lesion is characterized by an erythematous region around the puncture and intense itching. In addition to being annoying, fleas can transmit diseases such as bubonic plague and endemic typhus.

## Sarcoptes Scabiei

Scabies, commonly called "the itch," is a contagious parasitic skin infection caused by *Sarcoptes scabiei*, a very small and rarely seen arachnid mite. The mites burrow up to 1 cm into the stratum corneum, and the females deposit eggs in their "tunnels." Common infestation sites are interdigital spaces of fingers, flexor surfaces of the wrists, external male genitalia, buttocks, and anterior axillary folds (see Color Plates, photograph 19). Scabies infection is characterized by inflammation and intense itching. Mites are transmitted from an infected individual to others through physical contact. A scabies infection requires prescription therapy rather than nonprescription treatment.

## Bedbugs

Bedbugs usually hide and deposit their eggs in crevices of walls, floors, picture frames, bedding, folds of linens, corners of suitcases, and furniture during the day; they bite their victims at night. The increased mobility of society worldwide has heightened concern for an increased incidence of bedbug infestations in the United States in places frequented by travelers, such as hotels.<sup>4</sup> Bedbug bites typically appear along exposed areas of skin, such as the head, neck, and arms. Bites occur in clusters of twos and threes and usually in a straight line. The reaction to a

bedbug bite can range from irritation at the site to a small dermal hemorrhage, depending on the sensitivity of the individual.<sup>5</sup>

### Ticks

Ticks feed on the blood of humans and animals. During feeding, the tick's mouthparts are introduced into the skin, enabling it to hold firmly (see Color Plates, photograph 20). If the tick is removed but the mouthparts are left behind, intense itching and nodules requiring surgical excision may develop. If left attached, the tick becomes fully engorged with blood and remains for up to 10 days before dropping off. Ticks should be removed intact with fine tweezers within 36 hours. Tick removal by heating methods, such as a match or hot nail, or by painting substances onto the tick, such as nail polish or petrolatum, is not recommended because these methods can irritate the tick, causing it to secrete more saliva or even regurgitate gut contents, thereby increasing the likelihood of transmission of a tick-borne illness.<sup>6</sup>

The local reaction to tick bites consists of itching papules that disappear within 1 week. Certain species of ticks, however, can transmit systemic diseases such as Rocky Mountain spotted fever and Lyme disease. Rocky Mountain spotted fever, transmitted by wood ticks or dog ticks, is characterized by severe headache, rash, high fever, and extreme exhaustion.<sup>7</sup> Lyme disease is caused by a spirochete found in deer ticks that is transmitted into the victim after the tick is attached for 36 hours.<sup>7</sup> In 2009, Lyme disease was reported in 46 states in the United States, including the District of Columbia, with the highest number of cases in the northeast and upper Midwest.<sup>8</sup> Most acute stages of Lyme disease are heralded by skin rash and flu-like symptoms. The rash appears first as a papule at the bite site and may become an enlarged circle with a clear center called a "bull's-eye." Tender urticarial lesions appear 3-32 days after the bite and disappear spontaneously within 3-4 weeks. If left untreated, complications such as neurologic symptoms, cardiac disturbances, musculoskeletal symptoms, and arthritis may occur. Early diagnosis and prompt treatment by a health care provider are essential to prevent development of these serious manifestations.

### Chiggers

Chiggers, or red bugs, live in shrubbery, trees, and grass. After attaching to the skin, the larvae secrete a digestive fluid that causes cellular disintegration of the affected area, a red papule, and intense itching. This fluid also causes the skin to harden and form a tiny tube in which the chigger lies and continues to feed until engorged. It then drops off and changes into an adult.

### Spiders

Although all species of spiders are poisonous, most are unable to penetrate the skin because their fangs are too short or too fragile. The black widow, brown recluse, and hobo spiders are three major exceptions. Deaths from spider bites are rare, but symptoms can be serious. Reaction to black widow bites includes delayed intense pain, stiffness and joint pain, abdominal disturbances, fever, chills, and dyspnea. Brown recluse bites can cause these symptoms as well as a spreading ulcerated wound at the bite site. Hobo spider bites typically present with a moderate-severe, slow-healing wound.<sup>9</sup> If a spider bite is suspected but cannot be confirmed, the wound area should be monitored for these symptoms.

## Complications of Insect Bites

Secondary bacterial infection of insect bites can occur if skin of the affected area is abraded from scratching. Skin infections such as impetigo may be a complication of insect bites; these infections may appear as yellow crusting, purulent drainage, and/or significant redness and swelling of the skin around the bite.

## Treatment of Insect Bites

Specific nonprescription external analgesics are labeled for use in treating minor insect bites.

### Treatment Goals

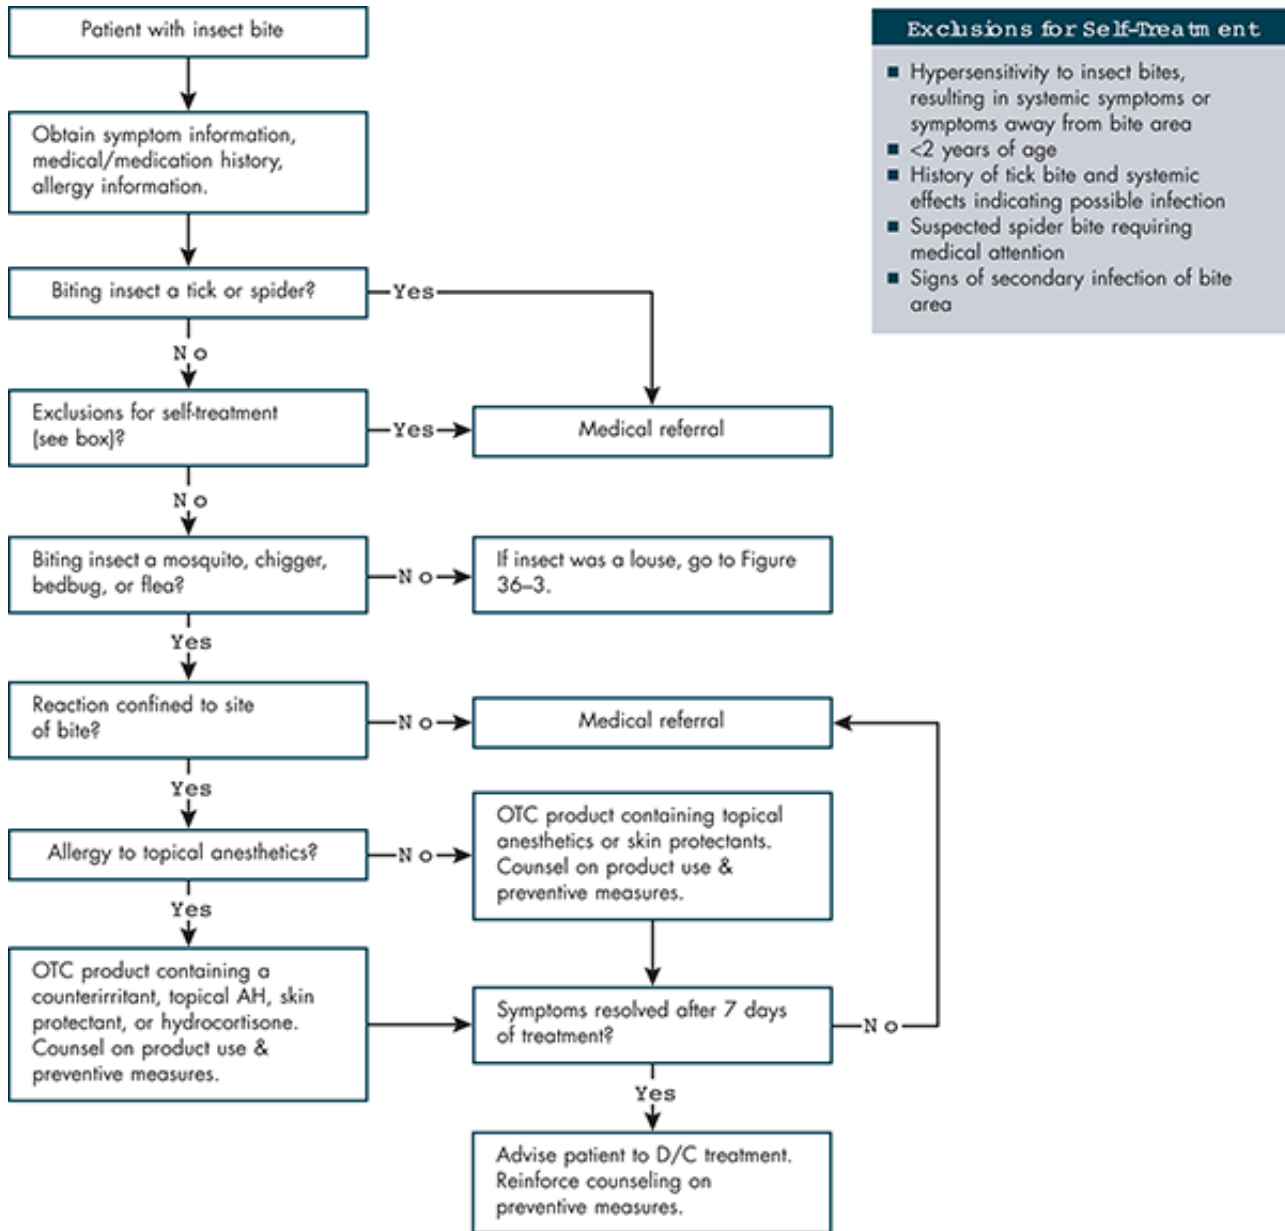

The goals of self-treating insect bites are to relieve symptoms and prevent secondary bacterial infections.

### General Treatment Approach

Application of an ice pack wrapped in a washcloth may provide sufficient relief of the pain and irritation of bites from mosquitoes, chiggers, bedbugs, or fleas; apply the ice pack to the affected area for up to 10 minutes with at least 10 minutes between applications. If this treatment does not work, applying an external analgesic to the site should relieve symptoms. Patients should be advised to avoid scratching the bite. Prevention of future insect bites is also important.

Self-treatment of insect bites with a nonprescription product is appropriate if the reaction is confined to the site and the patient is older than 2 years. No effective nonprescription product is available to treat scabies. Patients with bites from ticks and spiders require medical referral because of possible systemic effects. [Figure 36-1](#) outlines treatment of insect bites and lists exclusions for self-treatment.

Self-care of insect bites. Key: AH = Antihistamine; D/C = discontinue; OTC = over-the-counter.

### Nonpharmacologic Therapy

Nondrug measures include the two methods of preventing insect bites: avoiding insects and using repellents. Specific measures are discussed in the box Patient Education for Insect Bites.

#### Avoidance of Insects

Recommendations for avoiding insects are included in the box Patient Education for Insect Bites.

#### Use of Insect Repellents

Insect repellents are useful in preventing bites from insects such as mosquitoes, fleas, and ticks, but these products are not effective in repelling stinging insects. Selection of an insect repellent should be based on product ingredients, concentration, and the anticipated type and length of exposure. Most commercial products contain n,n-diethyl-m-toluamide, commonly called DEET; concentrations ranging from 7%-100% are available. Other ingredients that may be combined with DEET include ethylbutylacetylaminopropionate (IR3535) and dimethyl phthalate ([Table 36-1](#)).

#### **TABLE 36-1 Selected Nonprescription Insect Repellents**

<i>Trade Name</i>	<i>Primary Ingredients</i>
Cutter Skinsations Pump	DEET 7%; aloe vera; vitamin E
Cutter Advanced Sport Insect Repellent	Picaridin 15%
Deep Woods Off! For Sportsmen Insect Repellent I Pump Spray	DEET 100%
Off! Insect Repellent II Aerosol	DEET 15%
Off! Skintastic Family Formula Pump or Aerosol	DEET 7%
Off! Light and Fresh Towelettes	DEET 5.6%; aloe vera
Skin-So-Soft Bug Guard Plus IR3535 Insect Repellent Spray	IR3535 7.5%
Repel Lemon Eucalyptus Lotion	Lemon eucalyptus oil
Repel Sportsman Formula Aerosol	DEET 29%
Repel Sun and Bug Lotion	DEET 20%; ethyl hexyl-p-methoxy-cinnamate 7.5%; oxybenzone 5%
Fite Bite Permethrin Clothing Spray	Permethrin 0.5%

Key: DEET = N,N-Diethyl-m-toluamide.

#### N,N-Diethyl-M-Toluamide

The best all-purpose repellent is n,n-diethyl-m-toluamide, or DEET.

Repellents protect the skin against insect bites. The exact mechanism of action is not fully known, but DEET, like other repellents, does not kill insects. The volatile repellent, when applied to skin or clothing, releases vapors that tend to discourage the approach of insects.

Repellents, available in sprays, solutions, creams, wipes, and other forms, are applied as needed to skin or clothing according to package directions, which usually is no more frequently than every 4-8 hours. Concentrations below 30% are preferable for children, but use of DEET insect repellents on children younger than 2 months should be discouraged.<sup>10</sup> Products with DEET concentrations ranging from 10%-40% provide adequate effect and sufficient protection for adults in routine situations. Products containing 50%-100% DEET generally are promoted for adults with high exposure to insects for long periods and when high heat and humidity may decrease adherence of the product; higher concentrations of DEET may be associated with higher incidence of skin reactions.<sup>11</sup> [Table 36-2](#) provides a summary from the Environmental Protection Agency regarding the application and safe use of DEET products.<sup>12,13</sup>

Skin irritation is the most frequent DEET-related problem, with occlusion of the application area possibly contributing to skin rashes or eruptions.<sup>13</sup> Central nervous system reactions, including seizures, ataxia, hypotension, encephalopathy, and angioedema, have been reported in association with improper use or ingestion.<sup>14,15,16</sup> These products are considered safe if used appropriately, even in women who are pregnant or breast-feeding.<sup>15,16</sup> [Table 36-2](#) lists warnings and precautions for use of DEET.

#### **TABLE 36-2 EPA Guidelines for Safe Use of DEET**

- Read and follow all directions and precautions on the product label.
- Do not apply over cuts, wounds, or irritated skin.
- Do not apply to hands or near eyes and mouth of young children.
- Do not allow young children to apply this product.
- Use just enough repellent to cover exposed skin and/or clothing.
- Apply the sunscreen first, followed by the repellent, when sunscreen needs to be used in conjunction with a repellent.
- Do not use under clothing.
- Avoid overapplication of this product.
- After returning indoors, wash treated skin with soap and water.
- Wash treated clothing before wearing it again.

- Use of this product may cause skin reactions in rare cases.
- Do not spray in enclosed areas.
- To apply to face, spray on hands first, and then rub on face.
- Do not spray directly onto face.

Key: DEET = N,N-Diethyl-m-toluamide; EPA = Environmental Protection Agency.

Source: References 12 and 13.

### Other Insect Repellents

Alternative products include citronella, lemon eucalyptus oil, soybean oil, cedar oil, lavender oil, tea tree oil, garlic, thiamin, and scented moisturizers in mineral oil (e.g., Skin-So-Soft). These products generally have been found to be less effective than DEET as repellents against mosquitoes, particularly with regard to length of action. Picaridin, an alternative to DEET, is being promoted as having less odor and being less irritating to skin.<sup>14</sup> Insect repellents containing permethrin 0.5% are designed for use only on clothing and camping equipment.

### Pharmacologic Therapy

External analgesics such as local anesthetics, topical antihistamines, hydrocortisone, and some counterirritants are approved for treating pain and itching associated with insect bites. These agents are not approved for use in children younger than 2 years.

Topical skin protectant agents may be used to reduce inflammation and promote healing. First-aid antiseptics and antibiotics can help prevent secondary infections (see [Chapter 40](#)).

Systemic antihistamines often are used in treating itching related to insect bites, but this use is not a label indication. [Chapter 11](#) discusses systemic antihistamines in detail.

### Local Anesthetics

Local anesthetics such as benzocaine, pramoxine, benzyl alcohol, lidocaine, dibucaine, and phenol are approved in topical preparations for relief of itching and irritation caused by insect bites.

Local anesthetics cause a reversible blockade of conduction of nerve impulses at the site of application, thereby producing loss of sensation. Phenol exerts topical anesthetic action by depressing cutaneous sensory receptors. Topical preparations containing local anesthetics are applied in the form of creams, ointments, aerosols, or lotions. These products are generally applied to the bite area up to 3-4 times daily for no longer than 7 days.

Local anesthetics are relatively nontoxic when applied topically as directed, and systemic absorption does not typically occur with these topical products. However, allergic contact dermatitis may occur. Pramoxine and benzyl alcohol do not commonly cause adverse effects and exhibit less cross-sensitivity compared with other local anesthetics. Dibucaine, a common allergen, may cause systemic toxicity if excessive absorption occurs. Convulsions, myocardial depression, and death have been reported from systemic absorption.<sup>17</sup> Phenol solutions of greater than 2% are irritating and may cause sloughing and necrosis of skin, but the concentration of phenol in nonprescription products ranges from 0.5%-1.5%. Nonprescription products containing phenol should not be applied to extensive areas of the body, especially under compresses or bandages, because of the risk of skin damage and systemic absorption.<sup>17</sup> Products containing phenol should be avoided in pregnant patients and children.

### Topical Antihistamines

Diphenhydramine hydrochloride in concentrations of 0.5%-2% is the agent used in most products that contain a topical antihistamine.

Topical antihistamines exert an anesthetic effect by depressing cutaneous receptors and are approved for temporary relief of pain and itching related to minor insect bites.<sup>18</sup> Products are available in several topical dosage forms; they are generally applied to the bite area up to 3-4 times daily for no longer than 7 days.

Although absorption occurs through skin, topical antihistamines generally are not absorbed in sufficient quantities to cause systemic side effects, even when applied to damaged skin. Systemic absorption is of more concern when these products are used over large body areas, especially in young children. Topical antihistamines can cause photosensitivity and hypersensitivity reactions; continued use of these agents for 3-4 weeks increases the possibility of contact dermatitis.

### Counterirritants

Low concentrations of the counterirritants camphor and menthol are used in some topical analgesic products.

**Chapter 7** discusses these agents in more detail. These products generally are applied to the bite area 3-4 times daily for up to 7 days.

### Camphor

At concentrations of 0.1%-3%, camphor depresses cutaneous receptors, thereby relieving itching and irritation by exerting an anesthetic effect. However, camphor-containing products can be very dangerous if ingested. Patients should be warned to keep these products out of children's reach.

### Menthol

In concentrations of less than 1%, menthol depresses cutaneous receptors and exerts an analgesic effect. Menthol is considered a safe and effective antipruritic when applied to the affected area in concentrations of 0.1%-1%.

### Hydrocortisone

Hydrocortisone 1% topical preparations are indicated for temporary relief of minor insect bites.

A wide variety of topical hydrocortisone dosage forms are available and should be applied as directed to the bite area 3 or 4 times daily for up to 7 days. **Chapter 34** provides more information about topical hydrocortisone.

### Skin Protectants

Medications such as zinc oxide, calamine, and titanium dioxide are applied to insect bites mainly in the form of lotions, ointments, and creams. These agents act as protectants and tend to reduce inflammation and irritation. Zinc oxide works as a mild astringent with weak antiseptic properties.<sup>18</sup> Zinc oxide and calamine also absorb fluids from weeping lesions.

The Food and Drug Administration (FDA) considers nonprescription drugs containing zinc oxide and calamine to be safe and effective in concentrations of 1%-25%. Although its mechanism of action is similar to that of zinc oxide, titanium dioxide's safety and effectiveness have not been determined by FDA. These preparations should be applied to the affected area as needed. They have minimal adverse effects and are recommended for adults, children, and infants.

### Product Selection Guidelines

Sensitization, specifically contact dermatitis, can occur with local anesthetics. If these agents are preferred, pramoxine and benzyl alcohol have a low incidence of adverse effects. Dibucaine and phenol have the most potential for adverse effects, especially if systemic absorption occurs from improper application.

Adverse effects and systemic absorption generally are not a concern with short-term use of the topical antihistamine diphenhydramine hydrochloride. However, its prolonged use can cause allergic or photoallergic contact dermatitis.

Similarly, short-term use of hydrocortisone usually does not cause adverse effects or clinically significant systemic absorption. Patients with scabies, bacterial infections, or fungal infections should not use hydrocortisone without medical supervision because it can worsen or mask these disorders. Camphor-containing products can be very dangerous if ingested, making them an inappropriate choice for use in children. Patients must understand that topical antipruritics and anesthetics should not be used for longer than 7 days.

The patient's preference of dosage forms should also guide product recommendations. **Table 36-3** lists selected trade-name products in various dosage forms.

**TABLE 36-3 Selected Nonprescription External Analgesic Products for Insect Bites and Stings**

<i>Trade Name</i>	<i>Primary Ingredients</i>
<b>Local Anesthetics</b>	
Itch-X Gel/Pump Spray	Pramoxine HCl 1%; benzyl alcohol 10%
Lanacane Aerosol Spray	Benzocaine 20%
Nupercainal Ointment	Dibucaine 1%
Solarcaine Medicated First Aid Aerosol Spray	Benzocaine 20%; triclosan 0.13%
Unguentine Maximum Strength Cream	Benzocaine 5%; resorcinol 2%
<b>Topical Antihistamines</b>	

Di-Delamine Gel/Spray	Diphenhydramine HCl 1%; tripeleannamine 0.5%; benzalkonium chloride 0.15%; menthol
Maximum Strength Benadryl Cream/Spray	Diphenhydramine HCl 2%
<b>Counterirritants</b>	
Blue Star Ointment	Camphor 1.2%
Sarna Lotion	Camphor 0.5%; menthol 0.5%
<b>Corticosteroids</b>	
Cortaid with Aloe Cream/Ointment	Hydrocortisone 0.5%; aloe vera
Cortaid Intensive Therapy Cooling Spray	Hydrocortisone 1%
Cortizone-5 Cream	Hydrocortisone 0.5%
Maximum Strength Cortaid Cream/Ointment	Hydrocortisone 1%
<b>Combination Products</b>	
Aveeno Anti-Itch Cream/Lotion	Pramoxine HCl 1%; calamine 3%; camphor 0.3%
Benadryl Itch Stopping Gel Extra Strength	Diphenhydramine HCl 2%; zinc acetate 1%; camphor
Caladryl Clear Lotion	Diphenhydramine HCl 1%; zinc oxide 2%; camphor
Campho-Phenique Gel	Camphor 11%; phenol 5%; eucalyptus oil
Chigarid	Camphor 2.8%; phenol 2%; eucalyptus oil 0.5% in collodion
Medi-Quik Spray	Lidocaine 2%; benzalkonium chloride 0.2%; camphor
Sting-Kill Swabs	Benzocaine 19%; menthol 0.9%

### Assessment of Insect Bites: A Case-Based Approach

The type of insect that inflicted the patient's injury should be determined first. Patients with suspected spider or tick bites require a medical referral because of the risk of complications. For other insect bites, the seriousness of the reaction should be evaluated before a nonprescription product or nondrug measure is recommended. If a nonallergic reaction is present, the appropriate external analgesic for symptomatic relief should be recommended. Recommending a skin protectant to reduce irritation and inflammation or to prevent secondary bacterial infection is appropriate.

### Patient Counseling for Insect Bites

Counseling for insect bites includes an explanation of how to treat the injury and how to prevent recurrences. Nondrug measures and proper use of recommended nonprescription products should be explained. The explanation should include potential adverse effects of these agents, plus signs and symptoms that indicate the injury needs medical attention. Appropriate use of insect repellents to prevent further bites should also be discussed. The box Patient Education for Insect Bites lists specific information to provide patients.

#### Patient Education for Insect Bites

The objectives of self-treatment for insect bites are to (1) relieve swelling, pain, and itching; (2) prevent scratching that may lead to secondary bacterial infection; (3) monitor for infections transmitted by ticks; and (4) prevent future insect bites. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Nondrug Measures

- Apply ice pack promptly to bite area to reduce swelling, itching, and pain.
- Avoid scratching affected area; keep fingernails trimmed.
- Remove ticks with tweezers by grasping the tick's head and gently pulling; the head should be removed.

Keep the removed tick in a sealed container for future identification in case of systemic symptoms. After removal of the tick, clean the area with rubbing alcohol to disinfect the skin.

- Do not wear rough, irritating clothing over bite area.

### Preventive Measures

- To prevent exposure, cover skin as much as possible with clothing and socks and cuff clothing around ankles, wrists, and neck.
- Avoid swamps, dense woods, and dense brush that harbor mosquitoes, ticks, and chiggers.
- Keep pets free of pests.
- Remove standing water from around the home to reduce breeding areas for mosquitoes.
- Limit the amount of time spent outside at dawn and dusk.
- Use barriers such as window screens and netting.
- Apply insect repellent according to package recommendations to repel biting insects (see [Table 36-2](#)); these repellents do not deter stinging insects.
- To prevent transmission of scabies, avoid close, physical contact with infected individuals.

### Nonprescription Medications

#### *Topical Analgesics*

- Use an external analgesic to relieve pain and itching of insect bites. Choice of medications includes local anesthetics, topical antihistamines, counterirritants, and hydrocortisone.
- These products can be applied to the bite area 3-4 times daily. Do not use on children younger than 2 years. Do not use longer than 7 days.
- Note that local anesthetics can cause sensitization. If these agents are preferred, pramoxine and benzyl alcohol are less likely to cause adverse effects.
- Do not use dibucaine in large quantities, particularly over raw surfaces or blistered areas. Such use could cause myocardial depression, convulsions, or death.
- Do not apply phenol to extensive areas of the body or under compresses and bandages. Such application increases the possibility of skin damage or systemic absorption.
- Do not use topical diphenhydramine longer than the recommended 7 days. Prolonged use can cause hypersensitivity reactions or systemic effects.
- Do not use hydrocortisone on scabies, bacterial infections, or fungal infections without a medical recommendation. Hydrocortisone can mask or worsen these disorders.
- Do not allow children to ingest camphor-containing products. Camphor is toxic when ingested.

#### *Skin Protectants*

- If needed to reduce irritation or inflammation, or if bacterial infection is a concern, use a skin protectant such as zinc oxide or calamine.
- Apply protectant to affected area as needed up to 4 times daily.
- Protectants can be applied to skin of children younger than 2 years.
- Some insect bite products contain external analgesics and skin protectants.

### When to Seek Medical Attention

- Seek medical attention if the condition worsens during treatment or if symptoms persist after 7 days of topical treatment.

### Evaluation of Patient Outcomes for Insect Bites

Follow-up should occur after 7 days of self-treatment. The patient should be advised to seek medical attention if symptoms such as redness, itching, and localized swelling worsen during treatment, or if the patient develops secondary infection, fever, joint pain, or lymph node enlargement. Medical attention is also necessary if symptoms persist after 7 days of treatment.

### Insect Stings

#### Pathophysiology and Clinical Presentation of Insect Stings

Venomous insects such as bees, wasps, hornets, yellow jackets, and fire ants belong to the order Hymenoptera. They attack their victims to defend themselves or to kill other insects. The injected venom contains allergenic proteins and pharmacologically active molecules. Because venom contents vary within the Hymenoptera order, venom is discussed in general terms.

Most people will complain of pain, itching, and irritation at the site following an insect sting, but they will have no systemic symptoms. Individuals who are allergic to insect stings may experience hives, itching, swelling, and burning sensations of the skin. Although anaphylaxis is rare, those with severe allergies may experience a fall in blood pressure, light-headedness, chest tightness, dyspnea, and even loss of consciousness.

#### Wild Honeybees, Wasps, Hornets, and Yellow Jackets

Wild honeybees are most commonly found in the western and midwestern United States; they usually nest in hollow tree trunks. Because the honeybee stinger is barbed, it remains embedded in the skin, even after the bee pulls away or is brushed off, and continues to inject venom. Paper wasps, hornets, and yellow jackets are found more commonly in the southern, central, and southwestern United States. Paper wasps tend to nest in high places, under eaves of houses or on branches of high trees, whereas hornets prefer to nest in hollow spaces, especially hollow trees. Yellow jackets, considered the most common stinging culprits, usually nest in low places, such as burrows in the ground, cracks in sidewalks, or small shrubs. The stinging mechanism of wasps, hornets, and yellow jackets resembles that of the honeybee, except their stingers are not barbed. Their stingers can be withdrawn easily after venom is injected, enabling them to sting repeatedly.

#### Fire Ants

Fire ants, imported from South America early in the 20th century, are now found in the southern and western United States, live in underground colonies, and form large raised mounds. Some ants only bite, whereas others bite and sting simultaneously; however, the bite is believed to cause the reactions. Fire ant bites cause intense itching, burning, vesiculation, tissue necrosis, and anaphylactic reactions in hypersensitive persons.

### Treatment of Insect Stings

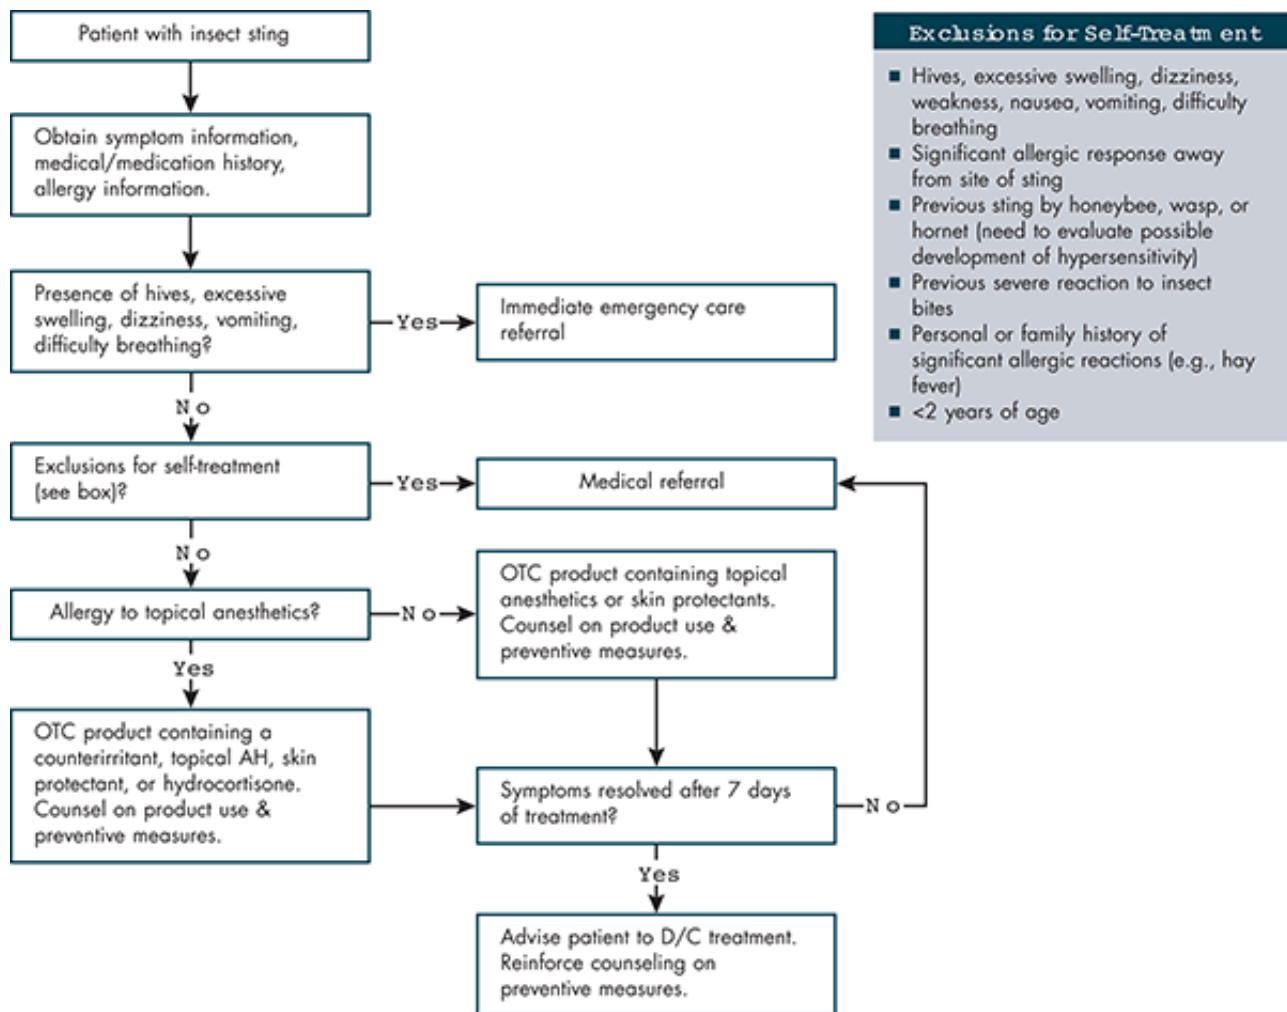

Although labeling of nonprescription products for insect-related injuries mentions only “insect bites” as an indication, it is generally accepted that FDA had intended the term to also cover insect stings.

#### Treatment Goals

The goal of self-treating insect stings is to relieve the itching and pain of cutaneous nonallergic reactions. Allergic reactions require medical referral.

#### General Treatment Approach

Removal of the stinger and application of an ice pack in 10-minute intervals are the first steps in treating insect stings. Application of a local anesthetic, skin protectant, antiseptic, or counterirritant to the sting site is appropriate if the reaction is confined to the site and if no exclusions for self-treatment apply. [Figure 36-2](#) lists exclusions for self-treatment and outlines the treatment of insect stings.

Copyright © American Pharmacists Association  
All rights reserved. Any use is subject to the Terms of Use.

Self-care of insect stings. Key: AH = Antihistamine; D/C = discontinue; OTC = over-the-counter.

Avoiding future insect stings can prevent an individual from developing allergic reactions to stings. If symptoms of an allergic reaction develop, emergency treatment should be administered, and the patient should seek medical attention. Patients with severe allergic reactions should be advised to wear a bracelet or carry a card identifying the nature of the allergy. They should also contact their primary care provider about carrying an injectable form of epinephrine.

### Nonpharmacologic Therapy

Prompt application of cold packs to the sting site in 10-minute intervals helps slow absorption and reduce itching, swelling, and pain. Removal of the honeybee's stinger and venom sac, which are usually left in the skin, is important. The patient should remove the stinger before all venom is injected; approximately 2-3 minutes are needed to empty all contents from the honeybee's venom sac. The patient should not use tweezers or squeeze the sac because rubbing, scratching, or grasping it releases more venom. Scraping away the stinger with a fingernail or the edge of a credit card minimizes the venom flow. After the stinger is removed, an antiseptic, such as hydrogen peroxide or alcohol, should be applied.

Measures to avoid attracting stinging insects are included in the Patient Education for Insect Stings box.

### Pharmacologic Therapy

The section Treatment of Insect Bites discusses the following external analgesics approved for treatment of insect bites and, by inference, insect stings: local anesthetics, topical antihistamines, counterirritants, hydrocortisone, and skin protectants.

Product labels for systemic antihistamines do not include treatment of itching associated with insect stings as an indication, even though these products are often used for this purpose.

### Complementary Therapies

Meat tenderizer has been used on insect stings to "break down" proteins in venom. Ammonia and baking soda have

been used to “neutralize” venom in insect bites. These products may affect itching. Most reports of their success are anecdotal, however, and currently their effectiveness has not been determined.

### Assessment of Insect Stings

The critical determination in assessing a patient with an insect sting is whether the patient is allergic to the venom. Patients experiencing allergic reactions should be referred immediately for emergency medical attention.

### Patient Counseling for Insect Stings

The health care provider should advise the patient that local reactions to insect stings usually are transient, but that severe reactions to insect stings can occur if sensitization to the insect venom develops with repeated exposure. The symptoms of allergic reactions should be explained. Patients who have a known hypersensitivity to insect stings should have epinephrine injection available at all times for emergency self-treatment.

For nonallergic reactions to stings, the provider should recommend one or more topical medications to manage immediate symptoms. The patient should be advised about adverse effects and any contraindications. The box Patient Education for Insect Stings lists specific information that should be provided.

#### Patient Education for Insect Stings

The objectives of self-treatment for insect stings are to (1) relieve the swelling, pain, and itching of insect stings; (2) monitor any reaction to the sting to determine whether an allergic reaction is developing; and (3) prevent future insect stings. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

### Nondrug Measures

- For honeybee stings, removing the honeybee stinger immediately is important. Scraping the stinger away with the edge of a credit card is effective. Try not to squeeze or rub the stinger; these actions will actually release more venom.
- Apply an ice pack or a cold compress promptly to the sting site to help slow absorption of the venom. This action will reduce itching, swelling, and pain.
- Avoid scratching the affected area; keep fingernails trimmed. Gloves or mittens may be used on small children during sleep to avoid unconscious scratching.
- To avoid attracting stinging insects, avoid wearing perfume, scented lotions, and brightly colored clothes; control odors in picnic and garbage areas; change children’s clothing if it becomes contaminated with summer foods such as fruits; wear shoes when outdoors; and destroy nests of stinging insects near homes.
- If you are hypersensitive to stings, wear a bracelet or carry a card showing the nature of the allergy.

### Nonprescription Medications

- For nonallergic stings, apply a topical nonprescription external analgesic such as a local anesthetic, topical antihistamine, counterirritant, or hydrocortisone to the affected site to relieve pain and itching. A skin protectant can also be recommended to prevent irritation and inflammation as well as prevent secondary bacterial infection.
- These products can be applied 3-4 times daily for up to 7 days.

### When to Seek Medical Attention

- If you have experienced previous severe reactions to insect stings, seek emergency medical care immediately. If a primary care provider has prescribed epinephrine or an oral antihistamine and you have it on your person, administer it according to the primary care provider’s instructions.
- Seek medical attention if you develop symptoms of an allergic reaction, such as hives, excessive swelling, dizziness, vomiting, or difficulty breathing.
- Seek medical attention if the pain and itching worsen during treatment or if they do not improve after 7 days of topical treatment.

### Evaluation of Patient Outcomes for Insect Stings

Follow-up for nonallergic reactions to insect stings should occur within 7 days. The patient should be advised to seek medical attention if symptoms of pain, itching, and localized swelling worsen during the treatment period or persist after 7 days of treatment. Symptoms of secondary infection or fever also warrant medical attention. Follow-up for patients who have allergic reactions should occur the same day, if possible.

Case 36-1 illustrates assessment of a patient who has an insect sting.

### Case 36-1

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	A mother comes into the pharmacy concerned after her son has just been "bitten" by something in their back yard. Her 9-year-old son had been playing all morning and suddenly ran into the house frantic and complaining of pain on his left forearm. The father had previously noticed many burrows in the backyard with what appeared to be wasps near the burrows. The son is now stating that the site has begun to itch and pain is subsiding upon coming to the pharmacy.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Mother states that she used ice on the affected area with some relief.
c. description of the patient's efforts to relieve the symptoms	The mother is aware of wasp nests in the backyard and warned her son to stay away from the burrows. In an attempt to reduce swelling and relieve pain, the mother used ice on the affected area.
d. patient's identity	Timmy Smith
e. age, sex, height, and weight	9 years old, male, 48 in., 65 lb
f. patient's occupation	4th-grade student
g. patient's dietary habits	Timmy appears to be well nourished, and proper diet is confirmed by the mother.
h. patient's sleep habits	Timmy regularly gets 8-9 hours of sleep per night.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Multivitamin, chewable
j. allergies	None
k. history of other adverse reactions to medications	None
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Patient's "bite" appears to be an insect sting, and the suspected cause is a wasp. Suspicion confirmed by multiple wasp nests in the backyard where the patient was playing prior to complaining about the sting. Patient's affected site also confirms the suspected sting with mild pain, redness, and now itching. No

	stinger appears to be present at affected area.
3. Identify exclusions for self-treatment (Figure 36-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Removal of stinger and application of an ice pack in 10-minute intervals are the first step. (2) Application of local anesthetic, topical antihistamine, counterirritant, antiseptic, or hydrocortisone including the following: a. anesthetic: Lanacane Aerosol Spray (benzocaine 20%) b. antihistamine: Maximum Strength Benadryl Cream/Spray (diphenhydramine 2%) c. counterirritant: Blue Star Ointment (camphor 1.2%) d. antiseptic: hydrogen peroxide of alcohol e. hydrocortisone: Cortizone-5 Cream (hydrocortisone 0.5%) (3) Refer Timmy to his PCP. (4) Recommend self-care until the PCP can be consulted. (5) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Because the affected area is confined to the sting site, no stinger is present, and the patient is older than 2 years, he is eligible for self-treatment. Now that the pain has subsided and the patient's chief complaint is itching at the sting site, relieving the itching is the most important therapeutic factor.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should begin application of a topical antihistamine to Timmy's affected area: - Apply a thin layer to affected area 3-4 times a day. - Ice may also be continued in 10-minute intervals to help alleviate discomfort. - If symptoms persist after 7 days of treatment, alert the child's PCP."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Because Timmy's pain is subsiding and itching is the chief complaint, topical antihistamines and ice are preferred over other therapies to relieve these symptoms."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. appropriate dose and frequency of administration	"Apply a thin layer of Maximum Strength Benadryl Cream to the affected area 3-4 times a day."
b. maximum number of days the therapy should be employed	"Apply no longer than 7 days."

c. product administration procedures	"Apply to affected areas per package insert directions."
d. expected time to onset of relief	"Product should take effect quickly."
e. degree of relief that can be reasonably expected	"Symptoms should be largely depressed, but total relief may not be achieved until the bite has completely healed in a few days."
f. most common side effects	"Photosensitivity and rash are the most common side effects."
g. side effects that warrant medical intervention should they occur	"If rash or skin irritation worsens after discontinuation, seek medical attention for the child."
h. patient options in the event that condition worsens or persists	"If signs of infection from the bite occur, seek medical attention for the child."
i. product storage requirements	"Product may be stored at room temperature."
j. specific nondrug measures	"Keep people away from wasp burrows; contact professional pesticide company for eradication of wasp nests."
Solicit follow-up questions from the patient or caregiver.	"What if my son develops an allergic reaction to the insect sting?"
Answer the patient's or caregiver's questions.	"If symptoms of an allergic reaction develop, emergency treatment should be administered, and you should seek immediate medical attention for your son. Patients with severe allergic reactions might be advised to carry a bracelet or card identifying the allergy and to carry an injectable form of epinephrine. Your son's primary care provider can prescribe the injectable epinephrine if it is needed."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Ask the mother to call to update you on her son's response to your recommendations, or you could call her in a week to evaluate his response.

Key: NA = Not applicable; PCP = primary care provider.

## Pediculosis

### Pathophysiology and Clinical Presentation of Pediculosis

Lice are irritating pests, and lice infestations in the United States are common. Three types of lice that infest humans are head lice (*Pediculus humanus capitis*), body lice (*Pediculus humanus corporis*), and pubic lice (*Phthirus pubis*).

#### Head Lice

Head lice are the most common cause of lice infestation, and outbreaks of lice infestation are common in places such as schools and day care centers. Infestations are spread through close personal contact or sharing personal items such as caps, hairbrushes, and combs. Outbreaks usually peak after the opening of schools each year, between

August and November. All socioeconomic groups are affected. Head lice create problematic infestations, but they generally do not contribute to the spread of other diseases in the United States.<sup>19</sup>

Head lice usually infest the head and live on the scalp (see Color Plates, photographs 21A and B). A lice egg or nit is about 1 mm in diameter and is typically found within 4 mm of the scalp. Once hatched, the louse must begin feeding within 24 hours or it dies. The nymph, or newly hatched, immature louse, resembles an adult and matures within 8-9 days. Without treatment, this cycle may repeat every 3 weeks.<sup>19</sup> The bite of a louse causes an immediate wheal to develop around the bite, with a local papule appearing within 24 hours. Itching and subsequent scratching may result in secondary infection. Adult lice, which are about the size of a sesame seed, are often difficult to locate because they move, but nits and nit casings generally can be spotted at the base of hair shafts when hair is parted for physical inspection. Hair inspections should focus on the crown of the head, near ears, and at the base of the neck. The grayish nits blend in well with the hair, but nit casings (hatched nits) are a lighter color and are more easily located. Nits and nit casings may be differentiated from dandruff, dirt, and so forth because of their firm attachment to the hair shaft. The presence of black powdery specks, lice feces, is also evidence of an infestation.

### Body Lice

Body lice (or “cooties”) live, hide, and lay their eggs in clothing, particularly in the seams and folds of underclothes. They periodically attack body areas for blood feedings and can transmit infections such as typhus and trench fever.<sup>20</sup> Body lice infestations generally occur in individuals who do not shower or change clothing frequently, such as the homeless.<sup>20</sup>

### Pubic Lice

Pubic lice or “crabs,” referring to their crab-like appearance, are generally transmitted through high-risk sexual contact, but they may also spread by way of toilet seats, shared undergarments, or bedding. The lice usually are found in the pubic area but may infest armpits, eyelashes, mustaches, beards, and eyebrows.<sup>21</sup>

## Treatment of Pediculosis

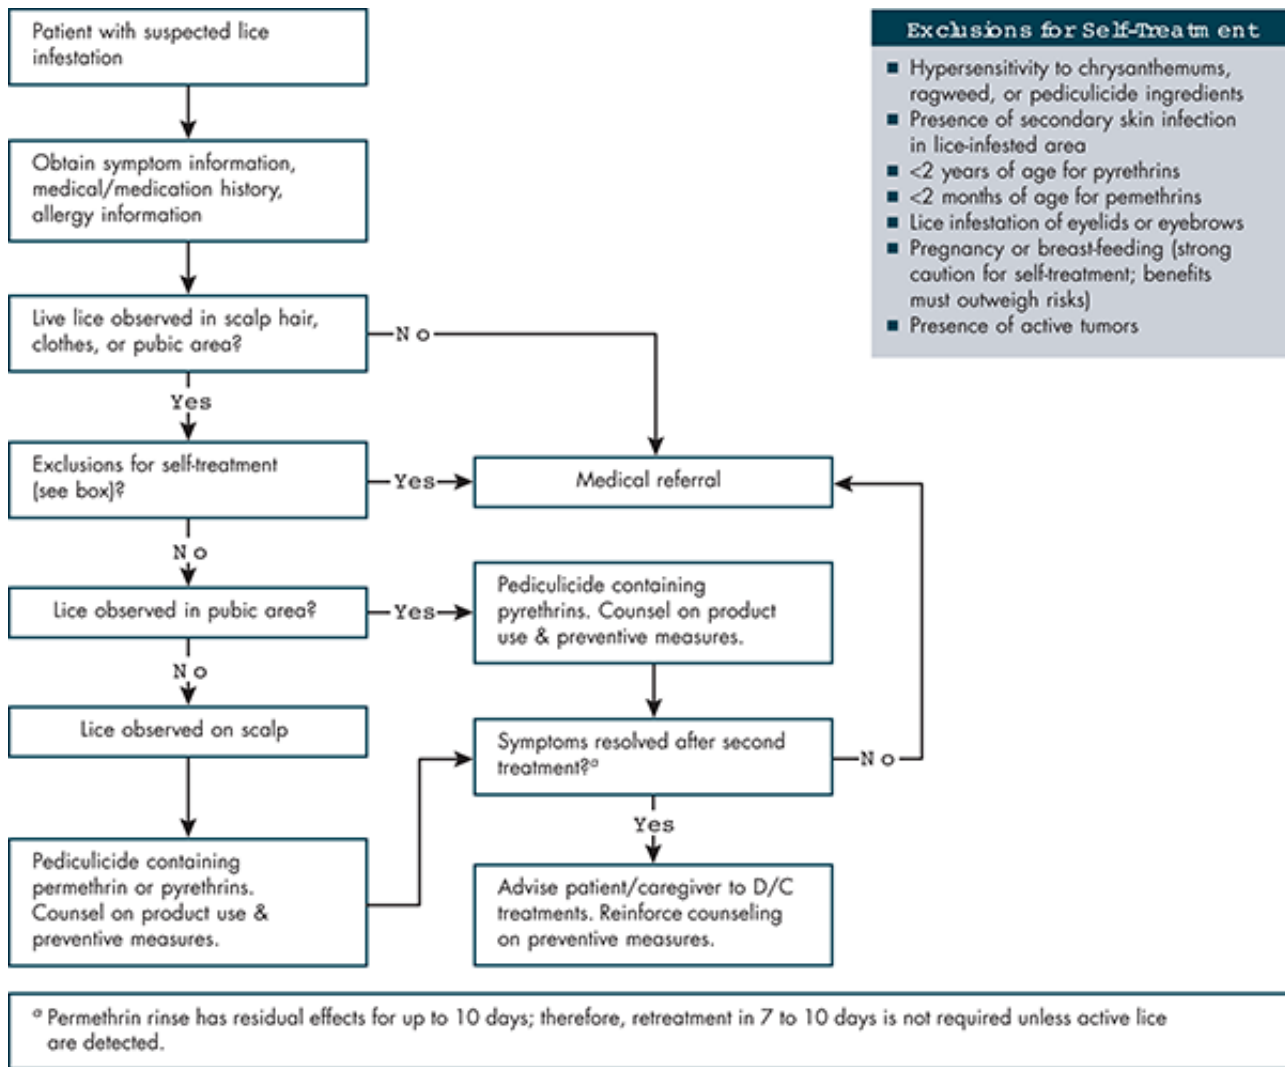

Nonprescription pediculicide agents, appropriate hair combing for nit removal, and home vacuuming and cleaning of personal items are primary treatments for lice infestation.<sup>19</sup>

### Treatment Goals

The goal of treating pediculosis is to rid the infested patient of lice by killing adult and nymph lice and by removing nits from the patient’s hair.

### General Treatment Approach

A pediculicide is applied to the infested body area for the designated amount of time to rid the patient of lice. The hair is then combed with a lice or nit comb to remove nits from the hair shaft; combing will also remove dead lice. Once rid of lice, patients should be instructed on how to avoid future infestations. [Figure 36-3](#) outlines treatment of lice infestations and lists exclusions for self-treatment.

Copyright © American Pharmacists Association  
All rights reserved. Any use is subject to the Terms of Use.

Self-care of pediculosis. Key: D/C = Discontinue.

### Nonpharmacologic Therapy

Because none of the pediculicides kills 100% of lice eggs, careful visual inspection of the hair for nits and combing with a nit comb, such as the LiceMeister comb, to remove nits are helpful in treating and controlling head lice.<sup>19</sup> Direct physical contact with an infested individual should be avoided, and articles such as combs, brushes, towels, caps, and hats should not be shared. Clothing and bedding should be washed in hot water and dried in a clothes dryer to kill lice and their nits; an alternative to washing would be to seal contaminated items in a plastic bag for 2 weeks. Hairbrushes and combs should be washed in very hot water. Carpets, rugs, and furniture should be vacuumed thoroughly and regularly.<sup>19</sup> Use of insecticidal sprays on these items is not generally recommended because lice usually survive for less than 48 hours when not in contact with a host.<sup>19</sup> Given the increasing resistance to pediculicides, some patients are choosing to use nondrug therapy exclusively; these nondrug methods, specifically combing and vacuuming, can be effective, but they are labor intensive and tedious.<sup>22</sup> Complete head shaving has also been used as a lice treatment, but the social stigma involved makes this a questionable option. Body lice are controlled by appropriate body hygiene and frequent changing and appropriate laundering of clothing and bed linens.<sup>21</sup>

### Pharmacologic Therapy

Two nonprescription pediculicide agents are available for treating pediculosis: permethrins and synergized pyrethrins. Patients should be warned about overusing these agents because of an apparent increasing trend of lice resistance to pediculicides, including the nonprescription products; the resistance may be caused by overuse, improper use, or insufficient contact time.<sup>19,23,24</sup>

### Synergized Pyrethrins

Pyrethrins are synergized by addition of piperonyl butoxide, a petroleum derivative. Pyrethrins are approved for treating head and pubic lice.

Pyrethrins block nerve impulse transmission, causing the insect's paralysis and death. Addition of piperonyl butoxide to pyrethrins synergizes their insecticidal effect through inhibition of pyrethrin breakdown, increasing insecticide levels within the louse.<sup>19,25</sup> Excessive contact time or occlusion of the scalp after product application may increase skin absorption of topical pyrethrins.

Pyrethrins, in concentrations ranging from 0.17%-0.33%, generally are used in combination with 2%-4% piperonyl butoxide. This combination is considered an effective pediculicide when applied topically as shampoos, foams, solutions, or gels. The medication is applied to the affected area for 10 minutes, and then the treated area is rinsed or shampooed as recommended. Combing with a lice comb should follow treatment. The treatment is repeated in 7-10 days to kill any remaining nits that have since hatched. The drug should not be applied more than twice in 24 hours. When applied according to directions, pyrethrins have a low order of toxicity. Most adverse reactions are cutaneous and include irritation, erythema, itching, and swelling.<sup>19,26</sup> Contact with eyes and mucous membranes should be avoided.

Individuals allergic to pyrethrins or chrysanthemums should not use this agent; ragweed-sensitive individuals risk cross-sensitivity.

### Permethrin

Permethrin, a synthetic pyrethroid, is available as a nonprescription cream rinse for treating head lice. Permethrin acts on the nerve cell membrane of lice. It disrupts the sodium channel, delaying repolarization and causing paralysis and death of the parasite.

When permethrin is applied, an estimated less than 2% is absorbed, after which the agent is metabolized.

Nonprescription permethrin is indicated for treating head lice only.

The 1% cream rinse is applied in sufficient quantities to cover or saturate washed hair and scalp. It is left on the hair for 10 minutes before rinsing; the hair is then combed with a lice comb. The rinse has residual effects for up to 10 days; therefore, retreatment in 7-10 days is not required unless active lice are detected.

Primary adverse effects, which can occur in up to 10% of the patient population, include transient pruritus, burning, stinging, and irritation of the scalp. Contact with eyes and mucous membranes should be avoided.

Permethrin is contraindicated in patients who are sensitive to pyrethrins or chrysanthemums. Permethrin should not be used on infants younger than 2 months.

### Pharmacotherapeutic Comparison

When treatment involves a single application of a pediculicide, permethrin is more effective than the pyrethrin and piperonyl butoxide combination. However, no significant difference exists in effectiveness of these agents when treatment consists of two applications.<sup>23</sup>

### Product Selection Guidelines

Preparations that contain pyrethrins may be used on children ages 2 years and older, but they should be used in pregnancy and lactation only if prescribed by a health care provider.

Pyrethrins may be recommended for treating pubic lice. For treatment of head lice, pyrethrins or permethrin may be selected on the basis of preferred dosage form, desire for single application, or patient allergies and sensitivities.

[Table 36-4](#) lists selected trade-name products containing these agents.

**TABLE 36-4 Selected Nonprescription Pediculicides**

<i>Trade Name</i>	<i>Primary Ingredients</i>
A-200 Lice Killing Shampoo	Pyrethrins 0.33%; piperonyl butoxide 3%
RID Lice Killing Shampoo, Maximum Strength	Pyrethrins 0.33%; piperonyl butoxide 4%
RID Mousse Foam, Maximum Strength	Pyrethrins 0.33%; piperonyl butoxide 4%
Nix Cream Rinse Lice Treatment	Permethrin 1%
Pronto Lice Killing Shampoo	Pyrethrins 0.33%; piperonyl butoxide 4%

### Complementary Therapies

Lice enzyme shampoos, which claim to break down the lice exoskeleton, are being promoted as an alternative to traditional pediculicides. A product containing 10% tea tree oil and 1% lavender oil applied weekly for 3 weeks was

more effective at eradicating lice than a pyrethrin/piperonyl butoxide product applied twice (1 week apart).<sup>27</sup> Tea tree oil must be used with caution because of potential significant allergic reactions and possible liver toxicity.<sup>28</sup> Other oil-based products such as petroleum jelly and mayonnaise are also being used on the basis of the theory that they impair lice respiration; however, these products are not very effective and most likely only slow the movement of lice.<sup>19,26</sup> Dangerous alternative treatments such as gasoline and kerosene should always be avoided because of their flammability and potential for toxicity.<sup>19,22</sup>

### Emerging Therapies

A new potential treatment under study is a class of products called DSP (Dry-on, Suffocation-based Pediculicide) lotions. The first DSP product to be tested, the Nuvo method, also marketed as Cetaphil cleanser, is a nontoxic lotion that “shrink wraps” lice. It is applied to hair and dried with a hairdryer to form a shrink-wrap film over hair and lice. The lotion covers breathing holes, suffocating the louse. A growing body of evidence suggests suffocation products may be more effective than pyrethrins/piperonyl butoxide.<sup>27</sup>

Dimethicone 4% lotion has also been shown to cure pediculosis while causing less irritation than traditional therapy. Furthermore, dimethicone works by coating the lice and irreversibly immobilizing them within 5 minutes of application.<sup>29</sup>

The LouseBuster is a machine that applies heat to the hair and scalp, dehydrating and killing lice and nits.

Preliminary evidence suggests this procedure kills more than 90% of nits.<sup>30</sup> Unfortunately, it is expensive and requires a certified technician to operate the machine.

### Assessment of Pediculosis: A Case-Based Approach

In many cases of pediculosis, visual inspection of the scalp will verify the presence or absence of head lice or nits. Similarly, presence of body lice can be determined by identifying adult lice and nits in seams of clothing. If a patient does not want such an inspection or if lice have not been confirmed by another health care provider, a pediculicide should not be recommended. When the disorder is confirmed, the appropriate pediculicide should be recommended. Case 36-2 illustrates assessment of a patient who has a head lice infestation.

#### Case 36-2

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	A frantic woman comes into the pharmacy asking about OTC options for head lice. She says that her 7-year-old daughter has just returned from summer camp complaining of an “itchy” scalp that started a day or so ago. Her daughter admits to sharing another girl's cap the day before leaving camp and denies any itching previously while away at camp. Upon further inspection, the woman noticed small red bumps clustered throughout the scalp and on the base of the neck. She also noticed tiny light colored “dandruff looking things” attached firmly to the hair shaft. She reports her daughter's complaints are severe itching and mild pain on scalp.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The woman explains that she has just picked up her daughter from camp when she noticed her daughter scratching her head aggressively. The mother noted that the skin had been broken in multiple locations on the scalp because of scratching; also the skin appears red and swollen in certain areas of the scalp. She inspected her daughter's scalp once they returned home and was not able to comment on any precipitating or exacerbating symptoms.

c. description of the patient's efforts to relieve the symptoms	The woman has taken all of her daughter's clothes out of her suitcase and placed them in a large plastic bag to be washed when she goes home.
d. patient's identity	Caroline Davis
e. age, sex, height, and weight	7 years old, female, 45 in., 52 lb
f. patient's occupation	Second-grade student
g. patient's dietary habits	Mother says that Caroline usually eats a well-balanced diet.
h. patient's sleep habits	Caroline usually sleeps about 9 hours per night.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	None
j. allergies	Chrysanthemums (rash), amoxicillin (rash)
k. history of other adverse reactions to medications	None
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Patient has observable nit casings and small red papules throughout the scalp and base of the neck. Patient has recently returned from summer camp and reports sharing headwear with another child, a common occurrence associated with head lice infestation.
3. Identify exclusions for self-treatment ( <a href="#">Figure 36-3</a> ).	Patient presents with broken skin caused by aggressive scratching. Signs of secondary infection appear to be present. Also, patient has documented an allergy to chrysanthemums, which would prohibit treatment with OTC synergized pyrethrins and permethrins.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Purchase nit comb for nit observation and removal. (2) Prior to nit comb use, recommend OTC pediculicide: a. A-200 Lice Killing Shampoo b. RID Lice Killing Shampoo, Maximum Strength c. RID Mousse Foam, Maximum Strength d. Pronto Lice Killing Shampoo  e. OTC permethrin products should be avoided because of chrysanthemum allergy (3) Recommend immediate medical attention.

	(4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The patient should seek medical attention because of suspected secondary infection from lice bites and scratching. Also, because of documented chrysanthemum allergy, OTC pyrethrins and permethrins cannot be used.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Your scalp shows redness, swelling, and broken skin from scratching. These are an indication of secondary infection and could possibly require antibiotic treatment."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"A suspected secondary infection and a significant allergy have been documented. You should be seen by a PCP to confirm the infection; self-treatment is not appropriate at this time."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver	"How do I avoid future contraction and spread of pediculosis?"
Answer the patient's or caregiver's questions.	"Direct physical contact with an infected individual should be avoided. Personal articles of the infected individual such as combs, brushes, towels, caps, and hats should not be shared. An infected person's clothing and bedding should be washed in hot water and dried in a clothes dryer to kill lice and nits. Once prescribed, use a pediculicide as directed. If lice are still present, this process may be repeated in 7-10 days. Do not overuse the pediculicide because overuse increases the resistance of lice to treatment."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact the patient in a day or two to ensure that she made an appointment and sought medical care.

Key: NA = Not applicable; OTC = over-the-counter; PCP = primary care provider.

### Patient Counseling for Pediculosis

Control of pediculosis requires both pharmacologic and nonpharmacologic intervention. The health care provider

should reassure parents of children with head lice that the condition is not the result of poor hygiene. Patients with confirmed head or pubic lice infestations should be counseled on which product is best for the situation and how to use the product properly; preventive measures should also be discussed. Additional information regarding patient counseling for pediculosis can be found in the box Patient Education for Pediculosis.

#### Patient Education for Pediculosis

The objectives for self-treatment of pediculosis are to (1) rid the body of lice and nits and (2) implement measures to prevent future infestations. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### **Nondrug Measures**

- Wash hairbrushes, combs, and toys of infested patients in water at a temperature of 130°F (39.4°C) or higher for 10 minutes.<sup>17</sup>
- Use water at a temperature of 130°F (39.4°C) or higher to wash the clothes, bedding, and towels of infested patients. Dry the items on the hottest dryer setting that the fabric permits.<sup>17</sup>
- Objects or clothing that cannot be washed should be sealed in plastic bags for the length of the louse's life cycle (2 weeks) so that it is unable to feed on a host.
- Avoid close physical contact with an infested patient; do not share articles such as combs, brushes, towels, caps, and hats.
- Vacuum living areas thoroughly and regularly during treatment period.
- Visually inspect the hair and scalp before, during, and after treatment for evidence of lice or nits:
  - Use a nit comb diligently to remove nits.
  - Comb the hair in segments. (Individual hairs can be trimmed if nit removal proves difficult.)

#### **Nonprescription Medications**

- Treatment of other family members should be determined on the basis of presence of lice or nits and the family members' level of contact with the infested individual; unnecessary treatment should be avoided.
- Application steps for a pyrethrin shampoo include the following:
  - Apply sufficient quantity to wet the dry hair and scalp. (Foams should also be applied to dry hair.)
  - Allow the treatment to remain for 10 minutes.
  - Work the shampoo into a lather and then rinse thoroughly. (Remove foams with shampoo or soap and water.)
  - Use a nit comb to remove dead lice and eggs as described previously.
- Application steps for a permethrin cream rinse include the following:
  - Shampoo with regular shampoo, rinse, and towel dry hair.
  - Apply sufficient cream rinse to wet hair and scalp.
  - Allow the treatment to remain for 10 minutes; then rinse and towel dry.
  - Use a nit comb as described previously.
- Avoid contact of the pediculicide with eyes and mucous membranes.
- The pediculicide can cause temporary irritation, erythema, itching, swelling, and numbness of the scalp; itching should be relieved in a few days.
- For pyrethrin products, repeat entire process in 7-10 days; permethrin products can be used again in 7-10 days if lice or nits are detected. Because of treatment resistance, proper use of these products is required and overuse must be avoided.
- If desired, contact the National Pediculosis Association at [www.headlice.org](http://www.headlice.org) or 1-781-449-6487 for information about treatment of lice infestations.

#### **When to Seek Medical Attention**

- Significant skin irritation or excessive exposure of eyes or mucous membranes to pediculicides warrants medical intervention.
- Seek medical attention if symptoms of lice infestation persist after the second treatment.

#### **Evaluation of Patient Outcomes for Pediculosis**

Follow-up of lice infestations should occur within 10 days. If signs of lice infestation persist after a second application of a pediculicide, the patient should be advised to seek medical attention. Overuse of these products should be discouraged and nonpharmacologic control measures emphasized.<sup>22</sup>

#### **Key Points for Insect Bites and Stings and Pediculosis**

- Insect stings and bites cause local irritation, inflammation, swelling, and itching; a cold pack may be applied to

reduce local symptoms.

- For relief of the itching and pain resulting from insect bites, topical nonprescription preparations that contain local anesthetics, antihistamines, hydrocortisone, or counterirritants can be used in patients ages 2 years and older.
- In hypersensitive people, anaphylactic reactions may pose serious emergency problems; these patients require immediate medical attention.
- Suspected spider bites should be referred; nonprescription treatments are not appropriate. If possible, the spider should be sealed in a container for identification.
- A tick should be removed by grasping it near the head with tweezers and gently pulling to cause the tick to release from the skin. The patient should be monitored for systemic effects such as Lyme disease and Rocky Mountain spotted fever.
- Appropriate use of insect repellents containing DEET will help prevent insect bites from mosquitoes, ticks, and chiggers.
- Exposure to mosquito bites warrants monitoring the patient for symptoms of West Nile virus.
- Nondrug measures are an important component in treatment of lice infestation.
- Available nonprescription pediculicides contain either synergized pyrethrins or permethrin.
- Pediculicides are designed for initial treatment and retreatment in 7-10 days; hair should be combed with a nit comb after treatment. Overuse should be avoided because resistance to pediculicides is a growing problem and affects the products' effectiveness.

## Handbook of Nonprescription Drugs > Chapter 37. Acne

### Acne: Introduction

Acne vulgaris (AV) is a common inflammatory skin disease of the pilosebaceous glands resulting in lesions most commonly found on the face, but also located on the neck, chest, upper back, and shoulders. More than 81%-95% of adolescent boys and 79%-82% of adolescent girls are affected.<sup>1</sup> Traditionally known as a disease affecting adolescents, AV incidence has been rising in adults, particularly in women older than 25 years.<sup>2</sup> The cause of this increase is unknown. Acne is reportedly more prevalent in male patients before 16 years of age. However, it is more prevalent in female patients after 23 years of age.<sup>3</sup> Although the peak prevalence of acne is during the adolescent years, the mean age for treatment of acne is 24 years, with roughly 10% of visits occurring between 35 and 44 years of age.<sup>3</sup> An estimated 45 million people are affected by AV in the United States.<sup>1</sup>

Many adolescents will achieve spontaneous remission of their acne, whereas some patients will experience acne into adulthood (3% of adult men and 12% of adult women) and may already have scarring by 18 years of age.<sup>2,4</sup> Although patients may tend to overestimate the severity of their acne, health care providers tend to underestimate the impact of the disease on patients. The effect of acne on patients should not be overlooked: Whether or not physical scarring exists, the potential for psychological scarring exists. Associations have been shown between acne and lower self-esteem and a negative impact on quality of life similar to that in patients with asthma or epilepsy.<sup>5</sup> In 2001, health care expenditures for acne were reported at over \$1 billion.<sup>1</sup> The direct costs related to acne are \$2.2 billion annually, and the indirect costs are \$620 million annually in the United States.<sup>6,7</sup>

A wide variety of nonprescription treatment options are available for AV. Prescription anti-acne product sales have been declining over recent years, whereas nonprescription counter sales have steadily increased.<sup>1</sup> Sales of prescription anti-acne products were estimated at \$3.3 million in 2006 and \$3.6 million in 2011.<sup>8</sup> The nonprescription market is estimated to be more than two to four times the size of the prescription market. One nonprescription medication, Proactiv, was projected to generate over \$800 billion in revenue in 2010.<sup>1</sup> Although most nonprescription acne medications are not marketed to the extent of Proactiv, their market share continues to grow. Health care providers can help patients make informed choices about their selection of acne products. This interaction also represents an opportunity for providers to introduce a new group of consumers to the value of pharmaceutical care.

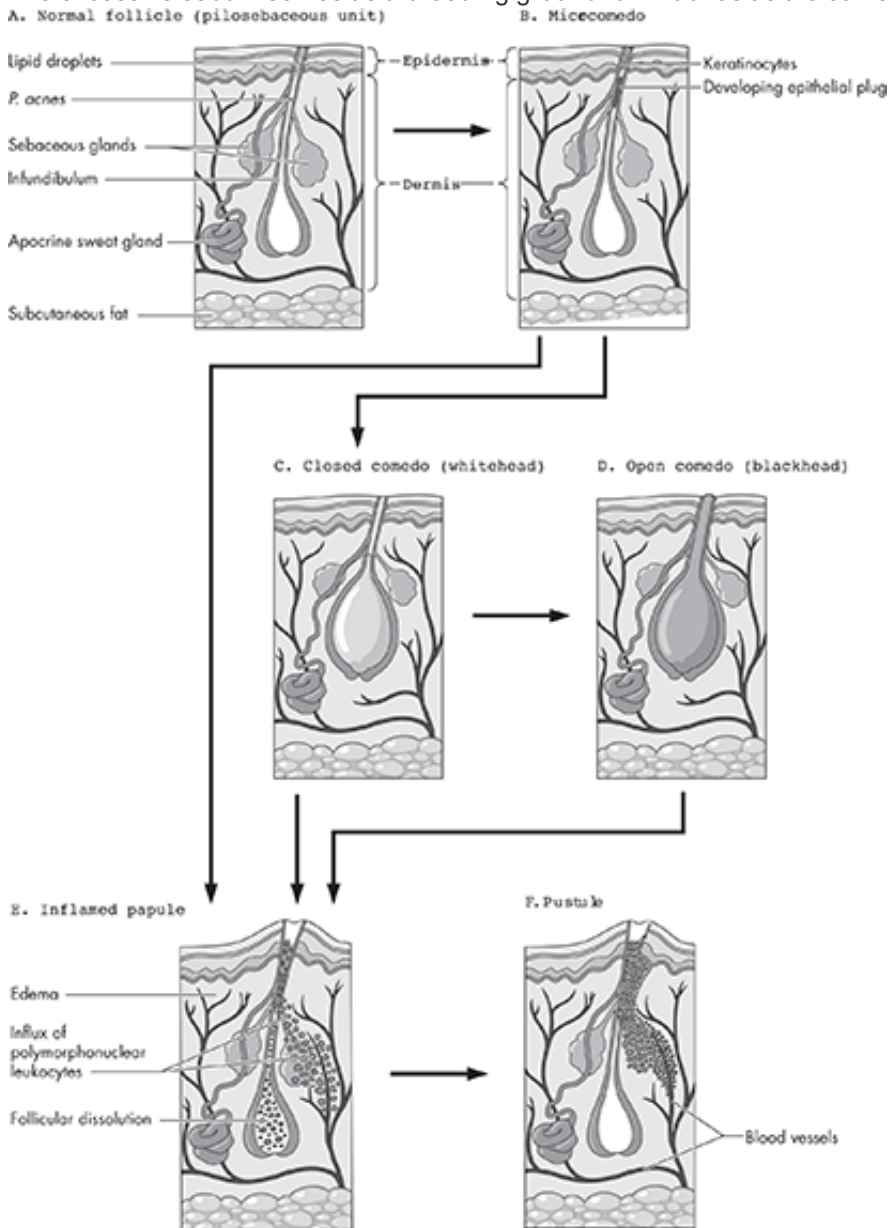

### Pathophysiology of Acne

Acne is the result of several pathologic processes that occur within the pilosebaceous unit located in the dermis, or middle layer of the skin (Figure 37-1A). These units, consisting of a hair follicle and associated sebaceous glands, are connected to the skin surface by a duct (infundibulum) lined with epithelial cells through which the hair shaft passes. The sebaceous glands produce sebum. Sebum normally functions to protect the skin from light and retain moisture. It possesses an antibacterial property that is both pro- and anti-inflammatory and is involved in the wound-healing process.<sup>9</sup> Further insight into the molecular function of the sebaceous glands has helped to further explain the role of these glands in skin function. The sebaceous gland also acts as an endocrine organ and responds to changes in androgens and hormones similar to the action of the hypothalamus-pituitary-adrenal axis. Corticotrophin-releasing hormone (CRH) influences the sebaceous glands' endocrine function.<sup>10</sup> CRH is the primary hormone involved in neuroendocrine and behavioral responses to stress. In acne-prone skin, CRH is found throughout the sebaceous glands and has been associated with the immune and inflammatory processes that lead to stress-induced acne.<sup>9</sup>

The formation of acne is multifactorial. In addition to the intricate pathophysiology, genetics and gender play an important role. Ebede et al. describe one study of 200 patients with postadolescent acne and found that 50% of patients reported at least one first-degree family relative with acne. The mean prevalence in adolescents ranges from 70%-80%. The prevalence of acne is significantly higher among women than among men in all age groups.<sup>11</sup> The pathologic factors involved in the development of acne are (1) androgenic hormonal triggers, (2) excessive sebum production, (3) alteration in the keratinization process, (4) proliferation of *Propionibacterium acnes*, and (5) resulting inflammatory responses.<sup>4,10</sup>

The rise in androgenic hormones coincides with the start of puberty and the appearance of acne. The conversion of testosterone to dihydrotestosterone stimulates an increase in the size and metabolic activity of sebaceous glands.

The excessive sebum serves as a breeding ground for *P. acnes* as the comedo develops.

Pathogenesis of acne. Key: *P. acnes* = *Propionibacterium acnes*. (Source: Adapted with permission from Fulton JE, Bradley S. *Cutis*. 1976;7:560.)

Increases in androgen levels are also partly responsible for abnormal follicular desquamation within the infundibulum. Some evidence exists in the role of sebum lipid abnormalities, such as deficiencies of linoleic acid and excesses of free fatty acids, in hyperkeratinization. Linoleic acid is an essential fatty acid that cannot be synthesized *in vivo*, only obtained through diet. Low levels of linoleic acid have been cited in patients with acne.<sup>9</sup> Sebum includes several matrix metalloproteinases that have a prominent role in inflammatory matrix remodeling and proliferative skin disorders.<sup>10</sup> Evidence also exists that follicular keratinocytes release interleukin-1, which may stimulate comedones formation. Regardless of the cause, hyperproliferation of these keratinocytes results in cell cohesion and formation of a plug that blocks the follicular orifice. This plug distends the follicle to form a micro comedo, the initial pathologic lesion of acne (Figure 37-1B). As more cells and sebum accumulate, the micro comedo enlarges and becomes visible as a closed comedo, or whitehead, that is, a small, pale nodule just beneath the skin surface (Figure 37-1C). If the contents of the plug cause distension of the pore's orifice, the plug will protrude from the pore, causing an open comedo or blackhead. The lesion is named a blackhead because of the presence of melanin and oxidation of lipids upon exposure to air. Comedones are the precursors of other acne lesions.<sup>4</sup>

Behind the plug, the buildup of sebum is an ideal habitat for proliferation of *P. acnes*. This bacterium breaks down sebum into highly irritating free fatty acids through production of lipases; *P. acnes* is also responsible for the production of pro-inflammatory mediators that induce pro-inflammatory cytokines.<sup>4</sup> As a result of the irritation and

inflammation, localized tissue destruction occurs. Toll-like receptors (TLR) are mammalian proteins that have emerged as a vital regulator of host responses to infection.<sup>10,12</sup> Research shows that cytokine induction by *P. acnes* occurs through TLR-2, which stimulates inflammatory lesions. In acne, TLR-2 invokes a significant inflammatory response as well as cellular apoptosis and tissue injury.<sup>13</sup> Redness and inflammation in and around the follicular canal constitute a papule (Figure 37-1E). A pustule (Figure 37-1F; see also Color Plates, photograph 23) possesses the same qualities as a papule but has visible purulence in the center of the lesion. Nodules result from disruption of the follicular wall and release of its contents into the surrounding dermis.<sup>14</sup> Several factors contribute to the exacerbation of existing acne and cause periodic flare-ups of acne in some patients (Table 37-1).<sup>6,10,15</sup> Recent information about the molecular function of the sebaceous glands has helped explain the role of these glands in skin function.<sup>16</sup>

**TABLE 37-1 Exacerbating Factors in Acne**

<i>Factor</i>	<i>Description of Factor</i>
Acne mechanica	Local irritation or friction from occlusive clothing, headbands, helmets, or other friction-producing devices Excessive contact between face and hands, such as resting the chin or cheek on the hand
Excoriated acne	A form of acne caused by constant picking, squeezing, or scratching at the skin. This causes the acne to look worse
Acne cosmetic	Noninflammatory comedones on the face, chin, and cheek caused by occlusion of the pilosebaceous unit by oil-based cosmetics, moisturizers, pomades, or other health and beauty products
Chloracne	An acneiform eruption caused by exposure to chlorine compounds
Occupational acne	Exposure to dirt, vaporized cooking oils, or certain industrial chemicals, such as coal tar and petroleum derivatives
Drug-induced acne	Anabolic steroids, corticosteroids, isoniazid, lithium, phenytoin
Stress and emotional extremes	May induce expression of neuroendocrine modulators and release of CRH, which play a role in centrally and topically induced stress of the sebaceous glands and possibly progression of acne <sup>6</sup>
High-humidity environments and prolonged sweating	Hydration-induced decrease in size of pilosebaceous duct orifice and prevention of loosening of comedone
Hormonal alterations	Increased androgen levels induced by medical conditions, pregnancy, or medications

Key: CRH = Corticotrophin-releasing hormone.

Source: References 6, 10, and 15.

Diet as a cause of acne flare-ups has been speculated on and dismissed in the past. However, recent research does show a link between diet and acne.<sup>10,12,17</sup> Several epidemiologic studies have correlated acne with the Western diet.<sup>18</sup> In a 2002 study with 1300 patients from two non-Western societies who had their skin examined by a general practitioner trained in diagnosing acne, no cases of acne were found. Researchers concluded that this finding must be related to the societies' diet. Several studies comparing the diets of Western civilizations to non-Westernized cultures have made similar correlations. The non-Westernized civilization had low-glycemic-load diets. These diets do not include refined cereals, chips, cookies, and bread.<sup>19</sup> Foods with a high-glycemic load elevate plasma concentrations of insulin, which regulates insulin-like growth factor-1 (IGF-1) and IGF-binding protein, promotes unregulated tissue growth, and enhances androgen synthesis. Hormones, such as androgens and IGF-1, act on sebaceous glands and keratinocytes. Dietary milk also causes a rise in IGF-1 through a high rise in blood glucose and serum insulin levels.<sup>20</sup> Newer research discusses the role of diet and medication in controlling acne.<sup>12</sup> Melnik discusses the role of mammalian target of rapamycin complex 1 (mTORC1) as a nutrient-derived signal involved in the exacerbation of acne through diet. The mTORC1 signal is activated in the presence of foods with a high glycemic load, high fat intake, high dairy intake, and high meat consumption. These foods are characteristic of

foods found in the Western diet.<sup>21</sup> The mTORC1 kinase integrates signals of cellular energy, growth factors (insulin, IGF-1), and protein-derived signals, predominantly leucine, which is provided in high amounts by milk proteins and meat with resultant increases in androgen and sebum production, respectively, which further perpetuates the pathogenesis of acne.<sup>21</sup> Melnik goes on to explain that the role of diet in acne pathogenesis is still controversial. However, the discovery of nutrient signaling pathways, like mTORC1, help explain the link between diet and acne exacerbation.

### Clinical Presentation of Acne

Acne lesions can generally be classified as noninflammatory or inflammatory. Noninflammatory lesions consist of either open or closed comedones. These lesions are often the first to manifest in the early stages of puberty and often appear initially on the forehead. With the progression of puberty and with age, especially in women, lesions tend to appear on areas of the body below the neck, such as the chest and back. Women in their 30s and 40s not uncommonly have acne that is concentrated on the chin and along the jaw line. Inflammatory lesions are further characterized as papules, pustules, or nodules. On presentation to a provider, the patient may exhibit one or more types of lesions. Acne severity is defined by the number and type of acne lesions. The Food and Drug Administration (FDA) has called on industry to develop a global grading acne system for accessing overall acne severity. FDA noted that a number of acne grading systems exist with small differences between them or inadequately defined grades of severity. [Table 37-2](#) describes the recommended comprehensive acne grading scale.<sup>22</sup>

**TABLE 37-2 Assessment of Acne Severity**

<b>Grade of Acne</b>	<b>Description</b>
0	Clear skin with no inflammatory or noninflammatory lesions
1	Almost clear; rare noninflammatory lesions with no more than one small inflammatory lesion
2	Mild severity; greater than Grade 1; some noninflammatory lesions with no more than a few inflammatory lesions (papules/pustules only, no nodular lesions)
3	Moderate severity; greater than Grade 2; up to many noninflammatory lesions and may have some inflammatory lesions, but no more than one small nodular lesion
4	Severe; greater than Grade 3; up to many noninflammatory and inflammatory lesions, but no more than a few nodular lesions

Source: Reference 22.

*Note:* The Case Report Forms for acne studies can allow for reporting by investigators of lesions worsening beyond grade 4 with treatment. It is recommended that enrollment of acne vulgaris patients not include patients with nodulocystic acne. Patients who worsen beyond grade 4 are to be described in the safety evaluation.

If acne lesions persist beyond the mid-20s or develop in the mid-20s or later, the symptoms may signal rosacea, rather than acne vulgaris. A differential diagnosis is necessary because the treatment of rosacea, although similar to that for acne, has unique elements.

Complications associated with acne include scarring and negative psychosocial impact. An acute complication of acne is postinflammatory erythema or hyperpigmentation.<sup>4</sup>

### Treatment of Acne

In most cases, acne is self-limiting and can be controlled to varying degrees. Adherence to therapeutic regimens will reduce symptoms and minimize scarring. Because acne persists for long periods, treatment must be long term, continuous, and consistent.

#### Treatment Goals

Patients and providers should identify any exacerbating factors of acne ([Table 37-1](#)). It is also imperative that patients and providers classify the acne ([Table 37-2](#)) to allow selection of the most appropriate therapeutic options.<sup>23,24,25</sup> Once the classification has been determined, treatment should be initiated and adherence to medication therapy should be encouraged.<sup>10</sup>

#### General Treatment Approach

Zaenglein and Thiboutot recommend that one or more acne treatments, either topical or topical and systemic, be combined to target a greater number of pathogenic factors.<sup>26</sup> The treatment of acne depends on the severity of the disease (Table 37-2). Patients with mild-moderate acne may self-treat with nonprescription topical products. Topical antimicrobial products are just as efficacious as oral antimicrobial agents in patients with moderate acne.<sup>27</sup> Oral antibiotics should be reserved for more severe cases of acne. Patients under the care of a provider should be instructed to avoid use of nonprescription products unless the provider recommends their use. Combining some nonprescription products with prescription acne drugs may decrease a patient's ability to tolerate prescribed topical drugs.

### Nonpharmacologic Therapy

Patients with acne should eliminate exacerbating factors of acne (Table 37-1). This measure should promote understanding and prevention of the disease as well as adherence to therapy. Patients seeking self-care options should cleanse the skin with a mild soap or nonsoap cleanser twice daily. The use of abrasive products and excessive cleansing may worsen the acne. Self-care options should also include staying well hydrated. Dehydration may increase the inflammatory chemicals in the cell and may cause dysfunction in the natural desquamation process of the stratum corneum. Decker and Graber explain that the normal skin has a pH of 5.3-5.9. Washing the face with harsh soaps that can increase the pH by at least 2.0 units can cause skin dryness and create an environment for growth of *P. acnes*.<sup>1</sup> Patients should also consider dietary changes by eliminating or cutting back on high-glycemic-load foods to determine whether the acne improves or remains the same.<sup>12</sup>

### Physical Treatments

Physical treatments have increased in popularity (Table 37-3).<sup>1,28</sup> A wide range of self-applied, acrylate glue-based material strips can aid in the extraction of impacted comedones. These products are a better alternative to picking the acne, which can result in scarring.<sup>29</sup> Professional comedo extraction is a useful adjunct to the overall acne regimen and often results in immediate improvement; the risks include tissue damage or scarring if these procedures are not done correctly. In addition, FDA has approved several light-based therapies for the treatment of acne. These treatments target reduction of *P. acnes* and disruption of sebaceous gland function. *P. acnes* produce porphyrin compounds during normal metabolism. Porphyrins absorb visible light at a variety of wavelengths, which excites the porphyrin compound, causing oxygen and free radicals. The oxygen radicals are thought to destroy *P. acnes* by damaging lipids in the cell wall of the organism.<sup>10</sup> For now, light therapy is considered a device to be used in conjunction with traditional pharmacologic therapy for acne.<sup>17</sup> More well-designed trials that include light therapy as a standard of treatment are needed.<sup>10,17</sup>

### Pharmacologic Therapy

Topical therapy is the standard of care in acne treatment.<sup>30</sup> Health care providers should be familiar with the several nonprescription products available for treatment of acne.

#### Benzoyl Peroxide

Many are familiar with benzoyl peroxide (BP), the most common topical antibiotic acne product available both with and without a prescription. BP has keratolytic, comedolytic, and antibacterial properties against skin *P. acnes*. BP kills bacteria by introducing oxygen into the environment, thereby killing *P. acnes*, which can thrive only in an oxygen-free environment.

BP has been the mainstay of treatment for type I acne since the 1930s.<sup>1</sup> In March 2010, FDA issued a final rule for topical acne drug products that included BP as a generally recognized as safe and effective (Category I) active ingredient in nonprescription topical acne product. BP had been classified as Category III since 1995 because of concern about benzoyl's weak mutagenic effect in vitro and BP's tumor promotion potential. FDA concluded that BP in concentrations of 2.5%-10% should be switched from class III to class I based on animal studies that suggest BP is not carcinogenic or photocarcinogenic.<sup>31</sup>

BP has the ability to prevent or eliminate the development of treatment resistance by *P. acnes*, which has increased with the use of conventional antibiotics (macrolides and tetracyclines) over the last three decades.<sup>16,30</sup> Resistant strains have been found in 50% of acne patients who had close contact with a resistant organism.<sup>16</sup> *Close contact* is defined as those individuals living in the same household with family members with acne. The use of BP in combination with antibiotics has been recommended to minimize *P. acnes* resistance.<sup>16</sup> BP is often used in combination with other oral or topical antibiotics. In a recent literature review, BP was more effective than topical antibiotics such as clindamycin and erythromycin. In addition, BP in combination with either of these antibiotics was

more effective and better tolerated than either of the antibiotics alone.<sup>16</sup>

**TABLE 37-3 Description of Physical Treatments**

<i>Implement</i>	<i>Treatment</i>
Scrubs	Abrasion opens closed comedones and prevents their progression. However, the abrasive nature of this action could damage the integrity of the skin.
Cleansing cloth	Cloths are less abrasive than scrubs while providing conditioning and exfoliation of the skin.
Cosmetic adhesive pads	Pads were developed to remove adherent corneocytes, dirt, oil, or loosen open comedones from the skin.
Brushes	Oscillating motion of the brush is used to deeply cleanse the skin while removing makeup. The impact of this treatment has not been clinically evaluated.
Heating devices	Heating devices are marketed to directly treat AV by contacting the lesion. The device is thought to treat acne through heat and phototherapy.
Light therapy	Use of limited-spectrum wavelength, such as blue light (peak at 415 nm) and mixed blue and red light (peak at 415 and 660 nm) has been found to be effective in reducing acne lesions after 4-12 weeks.

Source: References 1 and 28.

Nonprescription formulations of BP are available in concentrations of 2.5%-10%. Higher strengths of BP have the same antibacterial effects as the lower strengths.<sup>1</sup> Higher strengths may cause more skin irritation.<sup>17</sup> All new users of nonprescription acne products should test the product by applying it sparingly to one or two small affected areas over the first 3 days. If discomfort does not occur, the product should be used according to label directions.<sup>31</sup> Avoidance of contact with clothes or hair is advised because this product may cause bleaching. In addition, avoidance of excessive sun exposure and use of a sunscreen product are recommended. Minor improvement may occur with daily application of BP; the number of applications can be increased or decreased until a mild peeling occurs. Some patients may experience only mild erythema and scaling during the first few days, which usually subside within 1 or 2 weeks. Allergic contact dermatitis reactions, characterized by a sudden onset of erythema and vesiculation, are considered rare and occur in a minority of the population (1 in 500).<sup>1</sup> A 2014 FDA Drug Safety Communication reported rare but serious allergic reactions to BP and salicylic acid that ranged from symptoms of local irritation to local and systemic hypersensitivity, including anaphylaxis.<sup>32</sup> FDA has not determined if the products active ingredients, inactive ingredients, or both are responsible for these reactions. Use of BP products should be discontinued when an allergic reaction such as itching or hives occurs. Medical attention should be sought for hypersensitivity reactions such as throat tightness; difficulty breathing; feeling faint; or swelling of the eyes, face, lips, or tongue. The box Patient Education for Acne lists other precautions for use of BP. Other FDA-approved topical anti-acne ingredients include hydroxy acids in various strengths, sulfur 3%-10% (in single-ingredient products), and a combination of sulfur 3%-8% with either resorcinol 2% or resorcinol monoacetate 3%.<sup>33,34</sup>

#### Patient Education for Acne

The goal of self-treatment is to control mild acne, thereby preventing more serious forms from developing. Acne usually goes away without treatment. Symptoms can usually be managed with diligent and long-term treatment. The best approaches to controlling acne are using cleansers and medications to keep the pores open and avoiding situations that worsen acne. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Disease Information

- Acne is the result of several pathologic processes that occur within the pilosebaceous unit located in the dermis, or middle layer of the skin.
- Acne can be controlled by using certain medications, but it cannot be cured.

#### Nondrug and Preventive Measures

- Cleanse skin thoroughly but gently twice daily to produce a mild drying effect that loosens comedones. Use a mild, oil-free cleanser and warm water.
- To prevent or minimize acne flare-ups, avoid or reduce exposure to environmental factors such as dirt, dust,

petroleum products, cooking oils, or chemical irritants.

- To prevent friction or irritation that may cause acne flare-ups, do not wear tight-fitting clothes, headbands, or helmets; avoid resting the chin on the hand.
- To minimize acne related to cosmetic use, do not use oil-based cosmetics and shampoos.
- To prevent excessive hydration of the skin, which can cause flare-ups, avoid areas of high humidity. In addition, do not wear tight-fitting clothes that restrict air movement.
- Avoid stressful situations when possible and practice stress-management techniques. Stress can worsen existing acne.
- Do not pick or squeeze pimples, which can further irritate skin and possibly lead to worsening of acne and scarring.
- Note that sexual activity plays no role in the occurrence or worsening of acne, although the onset of sexual activity and occurrence of acne may be simultaneous or take place within the same time span.

### Nonprescription Medications

- Most common available nonprescription products contain BP, salicylic acid, or sulfur, and they come in a variety of formulations (e.g., cleansers, creams, gels, and astringents).
- BP is the most effective and widely used nonprescription medication for treating acne.

### **Benzoyl Peroxide**

- BP inhibits the growth of *Propionibacterium acnes*, the bacteria involved in acne development; it also helps unclog pores by causing a mild peeling effect.
- Do not use BP if you have very sensitive skin or are sensitive to BP.
- When using this product, avoid unnecessary sun exposure and use a sunscreen.
- Avoid contact of BP with eyes, lips, mouth, and nose, as well as cuts, scrapes, and other abrasions, to avoid possible excessive irritation.
- Avoid contact of BP with hair and dyed fabrics, which may be bleached by this product.
- Skin irritation, characterized by redness, burning, itching, peeling, or possibly swelling, may occur with the recommended treatment regimen. Irritation may be reduced by using the product less frequently or in a lower concentration.
- Note that use of other acne medications with this product may cause excessive dryness and peeling. Do this only as directed by a health care provider.
- After the initial 1-2 weeks of treatment, applications can be increased up to 2-3 times per day over a period of 2-3 days, as tolerated.
- Slight improvement may be noticed in as little as a few days, but maximum effectiveness may take up to 4-6 weeks of continued use.
- If treatment is tolerated, but the problem persists, the strength may be increased to 5% after 1 week and to 10% after 2 weeks, if necessary.
- Continue the treatment regimen even after lesions have cleared to prevent the formation of new ones.

### **Salicylic Acid**

- Salicylic acid helps unclog pores by causing slight peeling.
- This medication is less effective than BP.
- Salicylic acid can be used once or twice daily as a cleanser or as a topical gel.
- Gel formulations should be applied to only the affected area.
- If excessive peeling occurs, limit use to once daily or every other day.
- Salicylic acid may cause sun sensitivity, so use a sunscreen (see the previous section Benzoyl Peroxide).
- Maximum effectiveness and duration of use are similar to those of BP.
- Lack of response after 6 weeks is an indication of need for medical referral.

### **Sulfur**

- Sulfur is believed to work by inhibiting the growth of *P. acnes*.
- This medication can be applied 1-3 times daily, but its use is limited by its chalky yellow color and characteristic unpleasant odor.
- Use of sulfur is mostly adjunctive; it is not as effective as BP.
- Do not use in patients with allergy to sulfa drugs.

### **When to Seek Medical Attention**

- If severe skin irritation or sensitivity develops, stop use of BP and sunscreen, and see a health care provider.

- If improvement has not occurred after 6 weeks of treatment with BP, seek medical evaluation.
- If you experience tightness in the throat; breathing problems; feeling faint; or swelling of the eyes, face, tongue, or lips with use of either BP or salicylic acid, seek emergency medical attention.

## Hydroxy Acids

Keratolytic agents such as alpha hydroxy acids (AHAs) and beta hydroxy acids (BHAs) are also common nonprescription acne products. Hydroxy acids are considered less potent and are often used when patients cannot tolerate other topical acne products.<sup>30</sup> Some hydroxy acids have comedolytic properties and are moderately effective in the treatment of acne.<sup>16</sup>

AHAs are natural exfoliating acids that occur in sugar cane, milk products, and fruits; the most common AHAs are glycolic, lactic, and citric acids, respectively.<sup>1</sup> AHAs are not able to penetrate the pilosebaceous unit to cause a comedolytic effect. AHAs are available in several nonprescription formulations in concentrations of 4%-10% or through dermatologists at higher concentrations. In a study comparing BP with AHAs, BP demonstrated a superior effect at 8 weeks. However, once acne is controlled, a light chemical peel with AHAs may be useful to help correct scarring and hyperpigmentation.<sup>16</sup>

Polyhydroxyl acids are a new category of AHA that has fewer side effects such as irritation and stinging. They are marketed for patients with more clinical sensitivity. They are also said to have moisturizing and humectant properties.<sup>1</sup> Lactobionic acid has been said to inhibit the breakdown of matrix metalloproteinase enzymes that occurs because of sun exposure. This reduces the appearance of photoaging on the skin.<sup>1</sup>

Salicylic acid, often described as a BHA, is a comedolytic agent available in various nonprescription acne products in concentrations of 0.5%-2%.<sup>1,17</sup> The comedolytic effect is concentration dependent. Higher concentrations are used for prescriptions and chemical peels.<sup>1</sup> Salicylic acid provides a milder, less-effective alternative to prescription agents such as topical retinoids.<sup>17</sup> In cleansing preparations, salicylic acid is considered adjunctive treatment. This agent is a phytohormone and is chemically similar to the active component of aspirin. Salicylic acid is lipid soluble and able to penetrate the pilosebaceous unit to produce a comedolytic effect.<sup>17</sup> Salicylic acid products also offer protection from the sun by inhibiting ultraviolet radiation B (UVB)-induced formation of sunburn cells that occurs after the cell has been exposed to UVB rays that cause an irreversible damage the cell's DNA and by increasing the removal of UVB-induced dimers (premutagenic lesions) in living skin equivalents.<sup>17</sup> However, patients using these products should continue to wear a broad-spectrum sunscreen to protect skin from further skin damage. BHA products are contraindicated in diabetic patients or patients with poor blood circulation. Use of these products should be limited to the affected area. Use of the products over a large area for prolonged periods could result in toxicity. Signs of salicylate toxicity include nausea, vomiting, dizziness, loss of hearing, tinnitus, lethargy, hyperpnea, diarrhea, psychic disturbances, toxic inner ear damage, hypoglycemia, and hypersensitivity.<sup>17</sup> In 2014, FDA warned of potentially life-threatening hypersensitivity reactions for nonprescription acne products containing salicylic acid or BP (see section Benzoyl Peroxide).<sup>32</sup>

## Sulfur

Sulfur, precipitated or colloidal, is included in acne products as a keratolytic and antibacterial in concentrations of 3%-10%.<sup>1,34</sup> It is generally accepted as effective in promoting the resolution of existing comedones but, on continued use, may have a comedogenic effect. Alternative forms of sulfur such as sodium thiosulfate, zinc sulfate, and zinc sulfide are not recognized as safe and effective.

Side effects with these products are rare but include the noticeable odor and dry skin, depending on the formulation used.<sup>17</sup> Sulfur is usually combined with other topical nonprescription agents such as resorcinol.<sup>1</sup>

## Sulfur/Resorcinol

Combinations of sulfur 3%-8% with resorcinol 2% or resorcinol monoacetate 3%, which enhances the effect of sulfur, are available in nonprescription acne products.<sup>17,34</sup> The products function primarily as keratolytics, fostering cell turnover and desquamation. Resorcinol is not effective when used as a monotherapy. However, it is believed to have antibacterial, antifungal, and keratolytic effects when used with other anti-acne products such as sulfur.<sup>1</sup> Resorcinol produces a reversible, dark brown scale on some darker-skinned individuals.<sup>17</sup>

## Pharmacotherapeutic Comparison

Table 37-4 provides a comparison of the therapeutic properties of the major acne products.<sup>1,24,34,35</sup>

### TABLE 37-4 Comparison of Nonprescription Topical Acne Agents

	<b><i>Benzoyl Peroxide</i></b>	<b><i>Hydroxy Acids</i></b>	<b><i>Sulfur</i></b>	<b><i>Resorcinol</i></b>
Bactericidal	Yes	No	No	Yes (also has antifungal properties)
Keratolytic	Yes	Yes	Yes	Yes
Comedolytic	Yes	Yes (BHAs)	Yes	No
Concentration	2.5%-10%	0.5%-2%	3%-10%	2% 3%-8% (in combination with sulfur)

Key: BHA = Beta hydroxy acid.

Source: References 1, 24, 34, and 35.

### Product Selection Guidelines

Skin cleansers and topical acne products are available in a variety of vehicles and strengths. Medicated cleansing products (bars and liquids) are not of much value; they leave little active ingredient residue on the skin. Generally, gels are the most effective formulations because they are astringents and remain on the skin the longest. Gels and solutions have a drying effect that may sometimes cause contact dermatitis. However, these dosage forms are not greasy and may be more beneficial in patients with oily skin. Creams and lotions are generally less irritating to the skin compared with gels and solutions. Lotions and creams with a low fat content are intended to counteract drying (astringent effect) and peeling (keratolytic effect).<sup>36</sup> They are acceptable alternatives to the more-effective gels and are recommended for dry or sensitive skin and for use during dry winter weather. Ointment vehicles are not used because they are occlusive and tend to worsen acne. Patients should start with the lowest strength available and gradually increase the concentration to minimize the irritating effects of the product. Table 37-5 lists selected nonprescription trade-name acne products in these and other formulations.

Many patients will use nonprescription medications in combination with prescription products to manage acne. Product selection is important for the successful treatment and management of acne. It is important that patients seek medical referral for proper diagnosis and grading of acne. For example, women who experience acne related to hormonal imbalance may benefit more from correction of the imbalance with hormone therapy such as oral contraceptives, whereas a peripubertal teenager or young adult may benefit more from consultation on avoidance of comedogenic products and adherence with nonprescription products such as BP.<sup>29</sup>

### Special Populations

Pregnant patients may have problems with acne because of hormonal imbalances. In most cases, if pregnancy occurs during treatment with any acne medication, the medication should be discontinued and the obstetrician should be advised of current or previous product use because of the potential for teratogenic effects. Topical BP, sulfur, and hydroxy acids are all Pregnancy Category C.<sup>1,37</sup>

Acne occurs in all age groups, including the pediatric population. This population comprises neonates, infants, and young children. Most infantile and neonatal acne is self-limiting; however, differential diagnoses by appropriate health care providers, which may include a pediatric endocrinologist, are needed for treatment recommendations. The first detailed evidenced-based clinical guidelines by the American Acne and Rosacea Society were endorsed by the American Academy of Pediatrics and published in May 2013.<sup>38</sup>

### Complementary Medicine, Vitamins, and Vitamin Analogues

Tea tree oil is widely known for its antibacterial and antifungal properties. *Staphylococcus aureus*, a common pathogen found on the skin, is sensitive to tea tree oil. Tea tree oil also has anti-inflammatory properties.<sup>1</sup> Terpen-4-ol, the active ingredient in tea tree oil, has been postulated to suppress production of inflammatory mediators and inflammation.<sup>1</sup>

Oral zinc may be considered an alternative to tetracyclines.<sup>16,17</sup> Zinc is bacteriostatic against *P. acnes*, inhibits chemotaxis, and has shown effectiveness against severe acne. One study found that zinc was 17% less effective than minocycline but that zinc could be used as an alternative to tetracycline therapy, especially in the summer, because it does not cause phototoxicity. However, zinc's adverse effects of nausea, vomiting, and diarrhea have made it a less attractive therapy. Poor patient compliance as a result of these side effects has limited its use.

### TABLE 37-5 Selected Nonprescription Acne Products

<b>Benzoyl Peroxide Products</b>	
Proactiv Repairing Treatment	Benzoyl peroxide 2.5%
ZAPZYT Maximum Strength 10% Benzoyl Peroxide Acne Treatment Gel	Benzoyl peroxide 10%
PanOxyl Acne Foaming Wash 10% Benzoyl Peroxide	Benzoyl peroxide 10%
<b>Salicylic Acid Products</b>

<b>Physical Treatments</b>	
Olay Pro-X Advanced Cleansing System, Brush	Acne brush
Garnier Skin Care Clean+ Refreshing Remover Cleansing Towelettes, cleansing cloth	Cleansing cloth
Zeno Heat Treat Blemish Prevention Kit	Heat therapy
Bioré Deep Cleansing Pore Strips	Comedone extraction strip
Proactiv Clearzone Acne Clearing Device	Light therapy

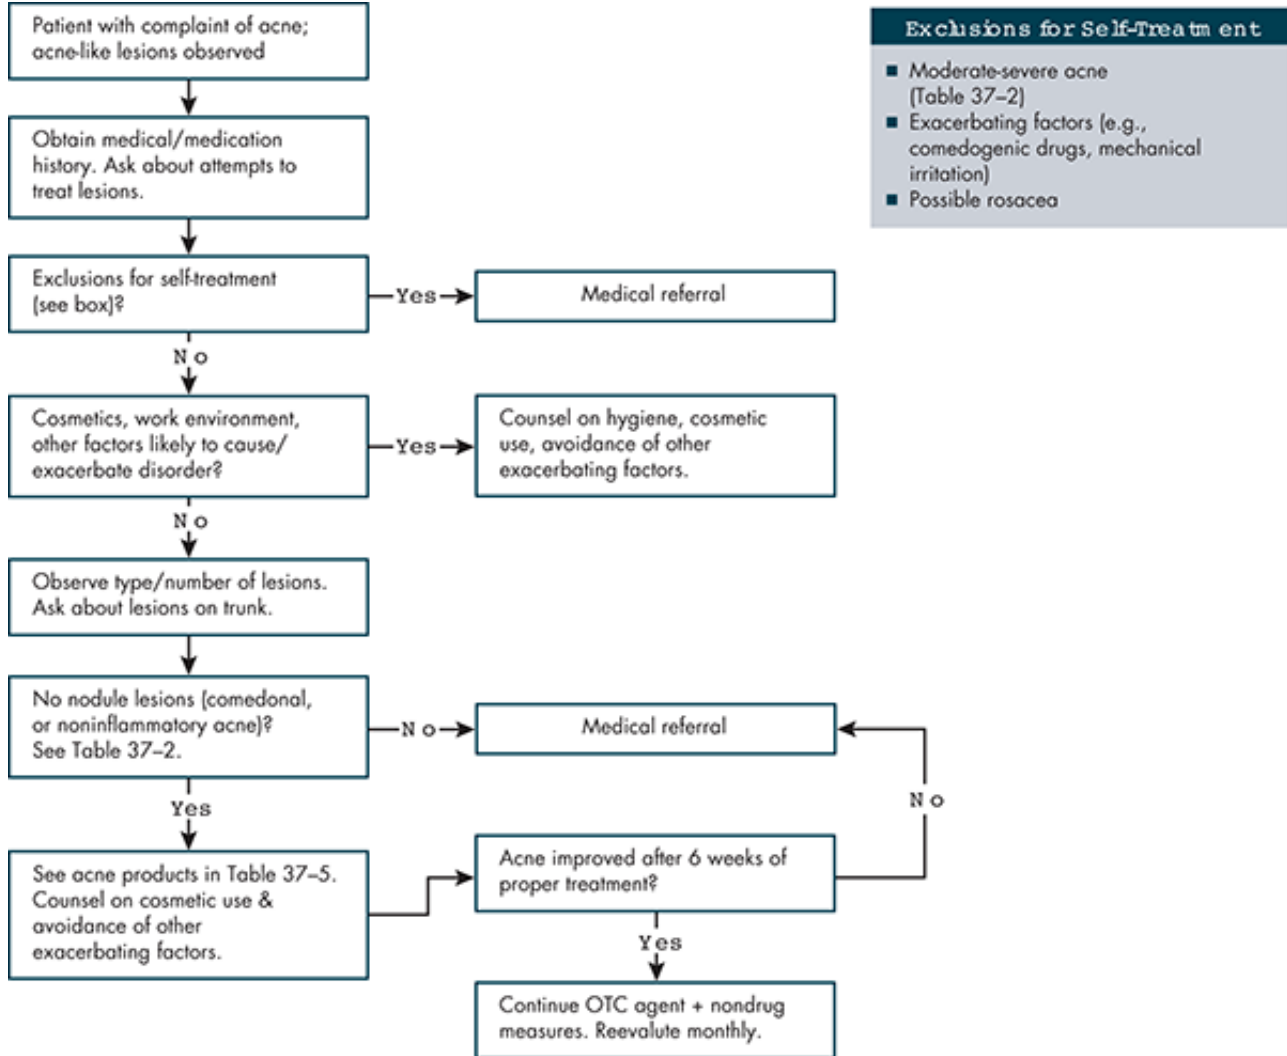

Vitamin A is naturally occurring and is a retinol. Vitamin A is transformed into several metabolites. One metabolite, retinoic acid, is used in cosmetics to help eliminate wrinkles and fine lines. Theoretically, retinol should also work against acne. However, few studies exist to validate this claim. Oral vitamin A or retinol may be beneficial in acne in doses up to 300,000 units daily for women and 500,000 daily for men. Common adverse effects include xerosis and cheilitis. Nicotinamide is used both orally and topically for AV. Nicotinamide is an active form of niacin and has been postulated to have several roles in the treatment of acne. It is an anti-inflammatory that improves the texture of photoaged skin and decreases sebum production.<sup>39</sup> Data on nicotinamide's role in acne are still limited, and more research needs to be facilitated to assess the role of nicotinamide in acne.

### Assessment of Acne: A Case-Based Approach

Patient assessment begins with asking questions to define the condition. Physical assessment, which involves observing the affected area and questioning the patient further, is the next step in evaluating the disorder. This evaluation helps determine whether the condition is acne vulgaris or another dermatologic condition with similar signs and symptoms. Physical assessment also determines whether the severity of the condition precludes self-

treatment (Figure 37-2). Before self-care is recommended, an assessment of current medication use (prescription and nonprescription) is necessary to reveal prescribed treatments for the disorder or use of medications known to cause acne (Table 37-1).

Cases 37-1 and 37-2 are examples of assessment of patients presenting with acne.

Copyright © American Pharmacists Association  
 All rights reserved. Any use is subject to the Terms of Use.

Self-care of acne. Key: OTC = Over-the-counter.

**Case 37-1**

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient has come into the pharmacy complaining of breakouts on the forehead over the last 3 weeks. He describes them as small bumps on his forehead.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	He complains that this started once it got warm outside. He started baseball season and needs to wear his uniform and hat. He noticed the acne about 3 weeks ago, and he cannot seem to get a handle on his breakouts.

c. description of the patient's efforts to relieve the symptoms	He says that he is now washing his face with soap and water about 4 or 5 times a day to keep it clean, but the acne seems worse.
d. patient's identity	Dylan McGhee
e. age, sex, height, and weight	16 years old, male, 6 ft 1 in., 185 lb
f. patient's occupation	Student and baseball player
g. patient's dietary habits	Eats healthy for dinner. Usually eats whatever he has time to eat for breakfast and lunch.
h. patient's sleep habits	Stays up late studying.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	NA
j. allergies	NKDA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Exacerbation of acne could be caused by patient's baseball cap that is worn during baseball season. Patient also washes his face very often and uses a soap that could be very drying, hence contributing to his worsening acne.
3. Identify exclusions for self-treatment (Figure 37-2).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Dylan to an appropriate health care provider. (2) Recommend self-care with an OTC product and nondrug measures. (3) Recommend self-care until Dylan can see an appropriate health care provider. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Recommend self-care options to Dylan.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Try a self-care option that includes nondrug measures and an OTC product."
7. Explain to the patient or	"Your acne could be caused by the baseball cap. The cap may occlude your skin

caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	and cause your pores to clog with sweat and oil. Try removing your cap or wearing a looser cap during games. You should remove your cap when you are not in the sun. You could also try benzoyl peroxide 2.5% to treat the existing acne and prevent new acne. I also recommend that you wash your face twice a day with a mild cleanser. Soap may be too drying for your skin and could make your acne worse.” “In addition, although your diet is typical of young adults your age, you may want to consider a healthier diet for breakfast and lunch to see if your acne improves with dietary changes as well. Research has shown a link between diet and acne. The findings are still controversial, but some patients may find that changing their diet helps improve their acne symptoms.”
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	See the box Patient Education for Acne.
b. maximum number of days the therapy should be employed	See the box Patient Education for Acne.
c. product administration procedures	See the box Patient Education for Acne.
d. expected time to onset of relief	See the box Patient Education for Acne.
e. degree of relief that can be reasonably expected	“Slight improvement may be noticed in as little as a few days, but maximum effectiveness may take up to 6 weeks of continued use.”
f. most common side effects	See the box Patient Education for Acne.
g. side effects that warrant medical intervention should they occur	“If severe irritation or sensitivity develops, stop use of BP and sunscreen, and see a health care provider.”
h. patient options in the event that condition worsens or persists	“If your acne worsens, see a health care provider.”
i. product storage requirements	See the box Patient Education for Acne.
j. specific nondrug measures	See the box Patient Education for Acne.
Solicit follow-up questions from the patient or caregiver.	“Can I use the higher strength of benzoyl peroxide to get rid of the acne faster?”

Answer the patient's or caregiver's questions.	"Studies have shown that lower strengths of benzoyl peroxide are just as effective as higher strengths. You should start with the lowest strength first to avoid irritation of your skin."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact the patient in 3 weeks to see if he has noticed any improvement in his acne symptoms. Ask him to call in 6 weeks to discuss whether his acne symptoms are controlled.

Key: BP = Benzoyl peroxide; NA = not applicable; NKDA = no known drug allergies; OTC = over-the-counter.

### Case 37-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient has come into the pharmacy for advice on recurrent facial acne.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	She always had occasional acne that coincided with her menstrual cycle. However, now that she is pregnant, her acne seems out of control.
c. description of the patient's efforts to relieve the symptoms	She has not really tried anything yet.
d. patient's identity	Daphne Turner
e. age, sex, height, and weight	28 years old, female, 5 ft 5 in., 145 lb
f. patient's occupation	Teacher
g. patient's dietary habits	Normal healthy diet with a recent occasional increase in cravings for ice cream
h. patient's sleep habits	Sleeps well. Her bedtime is 10:30 pm.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Prenatal vitamin once a day
j. allergies	Penicillin

k. history of other adverse reactions to medications	None
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Patient's acne may have flared because of pregnancy and fluctuation in hormones.
3. Identify exclusions for self-treatment (Figure 37-2).	Pregnancy
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Daphne to an appropriate health care provider. (2) Recommend self-care with an OTC product and nondrug measures. (3) Recommend self-care. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Refer Daphne to an appropriate health care provider.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Most over-the-counter and prescription drugs for acne may not be safe for you to use during pregnancy."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"You should talk to your health care provider for recommendations on how to treat your acne. Most over-the-counter drugs used for acne are a Pregnancy Category C drug. You will need to talk with a health care provider to determine which drugs may be safe for you during pregnancy."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"Can I use some of the acne towelettes on my skin?"
Answer the patient's or caregiver's questions.	"You should still consult your health care provider because some of the towelettes have medication on them that could be absorbed by your skin."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact the patient in 3 days to see whether she was able to set up

an appointment with her health care provider.

Key: NA = Not applicable; OTC = over-the-counter.

## Patient Counseling for Acne

The success of the treatment regimen depends largely on the patient. Therefore, it is crucial that the provider educate the patient on the causes of acne, correct any misconceptions, and clearly explain the rationale for treatment. Patient buy-in will facilitate adherence and increase the likelihood of a successful outcome. The provider must also evaluate the patient's maturity and willingness to comply with a skin care program that involves a continued daily regimen of washing affected areas and applying medication. Reassurance and emotional support are often necessary to reduce patient concern because acne cannot be cured—only controlled. The box Patient Education for Acne lists specific information to provide patients.

**TABLE 37-6 Selected Web Sites for Acne Information**

<b>Organizations</b>	<b>Web Site</b>
Acne.com	<a href="http://www.acne.com">www.acne.com</a>
Acne.org	<a href="http://www.acne.org">www.acne.org</a>
Food and Drug Administration	<a href="http://www.fda.gov">www.fda.gov</a>

The Internet lists supplemental information about acne in lay language, including discussions of acne, nonprescription drugs used to treat it, and treatment expectations. Selected sites that appear to provide accurate information are listed in [Table 37-6](#). If not copyrighted, these materials can be printed and given to the patient during the consultation. If the material is copyrighted, the provider should instead give the patient the Web site address.

## Evaluation of Patient Outcomes for Acne

Although the patient may expect complete resolution of the acne, an improvement in the disorder, as defined by a decrease in both the number and severity of lesions, is a more realistic expectation for effective self-treatment. The provider should determine whether patients whose acne shows no improvement after 6 weeks of self-treatment or 6 months with diet change are following the recommended regimen. If they have been adherent, medical referral is appropriate. Patients who have not diligently followed the regimen should be encouraged to do so. The provider should again explain the expected results and the rigor with which treatment must be pursued. If some improvement is evident, the provider may suggest monthly follow-up to check for improvement in the condition and potential adjustment of the maintenance regimen.

## Key Points for Acne

- Acne cannot be cured, but it may be controlled enough to improve cosmetic appearance and prevent development of severe acne with resultant scarring.
- Adherence to any regimen to treat acne is a crucial factor in achieving a successful outcome.
- Minimizing environmental and physical factors that exacerbate acne can help limit the extent of the condition.
- Pharmacologic and nonpharmacologic therapies should be tailored to the patient.
- According to current guidelines, medical referral is the preferred initial step before implementing nonprescription therapy.
- Some people have chronic acne into adulthood and must care for their skin for a long time before improvement will occur.
- If given proper counseling, including empathy and reassurance, patients with acne may understand that the condition may not exist forever.

**Handbook of Nonprescription Drugs** > Chapter 38. Prevention of Sun-Induced Skin Disorders

**Prevention of Sun-Induced Skin Disorders: Introduction**

Current research has demonstrated that exposure to ultraviolet radiation (UVR) is cumulative and can produce serious, long-term problems. The most common skin problem caused by excessive UVR exposure is sunburn. However, other conditions either are directly caused or exacerbated by exposure to UVR, including premature aging, skin cancers, cataracts, and photodermatoses.

Long-term UVR exposure and damage can result in histopathologic changes in the skin, resulting in premature aging of the skin or photoaging. These changes may result in wrinkling of the skin, discolorations, and other signs of skin damage. [Chapter 39](#) provides an in-depth discussion of photoaging and its treatment.<sup>1-5</sup>

Photodermatoses can be defined as a heterogeneous group of skin disorders that are induced or exacerbated (photoaggravated) by radiation of varying wavelengths. More than 20 disorders are classified as photodermatoses ([Table 38-1](#)). The common factor in the development of a photodermatosis is the onset or exacerbation of signs and symptoms after exposure to UVR. In addition to the idiopathic photodermatoses, UVR can precipitate or exacerbate many photoaggravated dermatologic conditions, including herpes simplex labialis (cold sores), systemic lupus erythematosus (SLE) and associated skin lesions, and melasma, which may affect pregnant women and women taking oral contraceptives.<sup>1-3</sup>

**TABLE 38-1 Common Photodermatoses**

<b>Idiopathic Disorders</b>
Actinic prurigo
Chronic actinic dermatitis
Hydroa vacciniforme
Polymorphous light eruption
Solar urticaria
<b>Photoaggravated Dermatoses</b>
Atopic dermatitis
Chronic actinic dermatitis
Cutaneous T-cell lymphoma
Dermatomyositis
Disseminated superficial actinic porokeratosis
Drug-induced photosensitivity
Erythema multiforme
Herpes simplex labialis
Lichen planus actinicus
Pellagra
Pemphigus
Porphyrias
Psoriasis
Reticular erythematous mucinosis
Rosacea

Systemic lupus erythematosus

The most serious skin disorder caused by UVR is skin cancer. Cumulative exposure from childhood to adulthood, even without serious sunburn, may predispose a person to develop precancerous and cancerous skin conditions. Epidemiologic studies conducted since the 1950s demonstrate a strong relationship between chronic, excessive, and unprotected sun exposure and human skin cancer. Nonmelanoma skin cancers are the most common type of cancer malignancy in the United States. In the United States in 2006, an estimated 2 million people were treated for basal and squamous cell carcinomas (nonmelanoma skin cancers, NMSC). An estimated 76,250 people were diagnosed with malignant melanoma in 2012. Although skin cancers are a significant cause of morbidity and mortality associated with UVR exposure, most NMSCs can be cured, and melanoma is highly treatable if detected early.<sup>3-5</sup>

Avoiding excessive exposure to UVR through the use of sunscreens and other sun protection measures will reduce the incidence of the sun-induced skin disorders: sunburn, premature aging of the skin, photodermatoses, skin cancer, and other long-term dermatologic effects. Education about the safe and effective use of sunscreen and suntan products is a public health need. To perform this function, health care providers should be aware of the hazards of UVR and the criteria for selecting and properly using sunscreen products. Providers are encouraged to become involved in educational efforts to help minimize the morbidity and mortality associated with UVR exposure.<sup>4,5</sup>

### Pathophysiology of Sun-Induced Skin Disorders

#### Ultraviolet Radiation

The UV spectrum is divided into three major bands: ultraviolet C (UVC), ultraviolet B (UVB), and ultraviolet A (UVA); all three cause or exacerbate sun-induced skin disorders. Because most UVC radiation (wavelength between 200 and 290 nm) is screened out by the ozone layer of the upper atmosphere, little of it reaches Earth; however, UVC is emitted by some artificial sources of UVR. Most of the UVC that strikes the skin is absorbed by the dead cell layer of the stratum corneum.

UVB (wavelength between 290 and 320 nm) is the most active UVR wavelength for producing erythema, which is why it is called sunburn radiation. The intensity of UVB radiation reaching the Earth is the highest from 10:00 am to 4:00 pm.

UVB is considered the primary inducer of skin cancer; however, its carcinogenic effects are believed to be augmented by UVA. UVB is also primarily responsible for wrinkling, epidermal hyperplasia, elastosis, and collagen damage. The only true therapeutic effect of UVB exposure is vitamin D<sub>3</sub> synthesis in the skin.<sup>5-8</sup> The amount of UVB needed for vitamin D production is dependent on both patient and environmental factors (e.g., location, altitude, cloud cover, time of year, skin pigmentation, and age). However, with the wide availability of vitamin D supplementation in foods and the availability of vitamin D supplements, the need for UVB exposure to increase vitamin D production is not necessary. The American Academy of Dermatology position statement on vitamin D states that UV radiation exposure should not be used as a source of vitamin D because of the risks associated with UV radiation.<sup>7-9</sup>

Previously, only UVB was believed to produce premature aging effects on the skin and increase skin cancer risk; however, evidence now exists that UVA radiation (wavelength between 320 and 400 nm) is involved in suppression of the immune system and damage to DNA, which result in premature photoaging and skin cancers.<sup>5,6</sup> In addition, UVA can produce photosensitivity reactions in patients who have ingested or applied photosensitizing agents. Although approximately 20 times more UVA than UVB reaches Earth at noon (30 times more in winter), erythemogenic activity is relatively weak in the UVA band.<sup>10</sup>

The Food and Drug Administration (FDA) sets standards for sunlamp products and UV lamps. However, these regulations do not include any specified limits on the amount of UVA and UVB emitted from tanning devices. The only requirement is that the ratio of UVB to UVA must not exceed 0.05 (5%). Most tanning beds or devices use UVR sources that emit more than 96% UVA and less than 4% UVB, a different mix of UVR than that obtained from natural sunlight. Tanning bed use has been associated with an increased risk of skin cancers.<sup>6,11-13</sup> Health care providers should advise parents and patients about the long-term hazards related to tanning devices; in addition, providers should explain that tanning devices currently provide no accepted health benefits.

Many factors contribute to the amount of UVR exposure received. Contrary to popular opinion, cloud cover filters very little UVR; 70%-90% of UVR will penetrate clouds, depending on the clouds' density. However, clouds tend to filter out the infrared radiation that contributes to the sensation of heat, creating a false sense of security against a burn.<sup>14</sup>

White or light-colored surfaces (e.g., snow or sand) reflect the UVR that strikes them.<sup>15</sup> Also, the irradiance of UVB increases by 4% for every 1000-foot increase in altitude. These factors all contribute to the overall radiation received, and severe sunburn may result even if the person is sitting in the shade or if there is cloud cover.<sup>16,17</sup> Water reflects no more than 5% of UVR, allowing the remaining 95% to penetrate and burn the swimmer. Therefore, time in the water, even if the swimmer is completely submerged, should be considered part of the total time spent in the sun. Dry clothes reflect almost all UVR; however, if light passes through dry clothing when held up to the sun, UVR will also penetrate the clothing. Tightly woven material offers the greatest protection.<sup>15,17</sup> Wet clothes allow transmission of approximately 50% of UVR.

Although UVB does not penetrate window glass, UVA does. Most automobile windshields are made from laminated glass that filters most of the UVA. However, side windows are not made from laminated glass; therefore, a significant amount of UVA may pass through to persons in the vehicle. Therefore, patients sensitive to UVA (e.g., those with photodermatoses or those taking photosensitizing drugs) should use appropriate sunscreens even when driving with the windows closed.<sup>18</sup>

The Environmental Protection Agency has developed a UV index that uses a scale to rate the amount of skin-damaging UV radiation that reaches the earth's surface at any instance in time (Table 38-2). As the rating increases, the risk of exposure increases. When a UV index is given in the United States, it typically is given for noon; however, the UV index changes throughout the day. Factors that influence the UV index are time of day (UVR exposure is greater at midday than in the early morning or late afternoon); ozone (limited amounts of ozone increase the amount of UVR exposure); altitude (higher altitudes receive greater UVR exposure); season (spring and summer have greater UVR exposure); surface (reflective surfaces increase UVR exposure); latitude (UVR exposure increases closer to the equator); and land cover (less tree cover increases UVR exposure).<sup>19</sup>

**TABLE 38-2 Global Solar UV Index**

<i>Rating Number</i>	<i>Interpretation of UVR Exposure Risk</i>
1-2	Low
3-5	Moderate
6-7	High
8-10	Very high
11+	Extreme

Key: UV = Ultraviolet; UVR = ultraviolet radiation.

Source: Reference 19.

### Sunburn and Suntan

The degree to which a person will develop a sunburn or a tan depends on several factors, including type and amount of radiation received, thickness of the epidermis and stratum corneum, skin pigmentation, skin hydration, and distribution and concentration of peripheral blood vessels. Most UVR that strikes the skin is absorbed by the epidermis.

A sunburn involves a number of mediators, including histamine, lysosomal enzymes, kinins, and at least one prostaglandin. These mediators produce peripheral vasodilatation as the UVR penetrates the epidermis; then an inflammatory reaction involving a lymphocytic infiltrate develops. Swelling of the endothelium and leakage of red blood cells from capillaries will also occur. Although the exact mechanism is not fully understood, UVB radiation is believed to produce erythema by first causing damage to cellular DNA. The intensity of the UVB-induced erythema peaks at 12-24 hours after exposure.<sup>14</sup>

A tan is produced when UVR stimulates the melanocytes in the skin layers to generate more melanin, and when UVR oxidizes the melanin already in the epidermis. Both processes serve as protective mechanisms to diffuse and absorb additional UVR. However, tanning does not protect an individual from developing skin cancer, photodermatoses, premature photoaging, or other UVR-related negative health risks. Tanning also does not protect against future sunburns. Although UVA and UVB both contribute to the tanning process, they induce pigmentation by different mechanisms. UVA produces a tan by inducing an immediate pigment darkening, resulting from photooxidation of existing melanin and redistribution of melanocytes. The pigment darkening begins to be visible rapidly after exposure and may last for 2 hours after UVR exposure. UVB acts by stimulating melanocyte activity and increasing the number of melanocytes in the skin. This delayed tanning of the skin becomes visible 3-4 days after exposure to UVR and will

last from 10 to 30 days depending on skin type and amount of UVR exposure.<sup>14</sup>

### Photodermatoses

Photodermatoses can be classified into 4 main categories: immunologically-mediated reactions; drug- or chemical-induced photosensitivity; defective DNA disorders; and photoaggravated disorders. The exact pathologic mechanism for the development of these abnormal reactions to UVR is unknown. UVB most often is responsible for the reactions; however, UVA and some visible light may also cause photodermatoses.

Photosensitivity encompasses two types of conditions: photoallergy and phototoxicity. Drug photoallergy (a relatively uncommon immunologic response) involves an increased, chemically induced reactivity of the skin to UVR and/or visible light. UVR (primarily UVA) triggers an antigenic reaction in the skin. This reaction, which is not dose related, usually is seen after at least one prior exposure to the involved chemical agent or drug.

Like photoallergy, phototoxicity is an increased, chemically induced reactivity of the skin to UVR and/or visible light. However, phototoxicity is not immunologic. It is often seen on first exposure to a chemical agent or drug, is dose related, and usually exhibits no drug cross-sensitivity. Some drugs associated with phototoxicity are listed in [Table 38-3](#). This type of reaction is not limited to drugs but is also associated with plants, cosmetics, and soaps.<sup>2</sup>

## Skin Cancer

The majority of NMSCs occur on the most exposed areas of the body (the face, head, neck, and backs of the hands). The two most common types of NMSC are basal cell carcinoma (BCC) and squamous cell carcinoma (SCC). BCC is often an aggressive, invasive disorder of the epidermis and dermis that can cause serious damage to the skin and underlying tissue. However, it rarely metastasizes. SCC is found in epithelial keratinocytes and grows very slowly. The pathophysiology of melanoma differs from that of the NMSCs. Although most melanomas come from normal skin, about 30% arise from existing nevi (moles). Some of the risk factors for skin cancer include a family or personal history of melanoma; sun sensitivity (e.g., difficulty tanning or burning easily); large numbers of atypical nevi; a previous history of SCC or BCC; tanning bed use; and a history of excessive sun exposure and sunburns.

Regardless of risk factors, skin cancer may develop in all individuals with increased exposure to UVR.<sup>5</sup> A growing amount of evidence supports the supposition that sun exposure plays a role in the development of all types of skin

cancers.<sup>20</sup>

## Clinical Presentation of Sun-Induced Skin Disorders

### Sunburn

Sunburn is, in fact, a burn. It most often is seen as a superficial burn with a reaction that ranges from mild erythema to tenderness, pain, and edema (see Color Plates, photograph 24). Severe reactions to excessive UVR exposure can sometimes produce burns that range in severity from superficial partial-thickness to full-thickness with the development of vesicles (blisters) or bullae (many large blisters), as well as fever, chills, weakness, and shock. Shock caused by heat prostration or hyperpyrexia can lead to death. (See [Chapter 40](#) for treatment of sunburn.)

### Drug Photosensitivity

Drug photoallergy presents similar to allergic contact dermatitis (e.g., poison ivy) and is characterized by pruritus with erythematous papules, vesicles, bullae, and/or urticaria (see Color Plates, photograph 25). Phototoxicity is most likely to appear as exaggerated sunburn with pruritus,<sup>1</sup> but urticaria may also occur (see Color Plates, photograph 26).

### Photodermatoses

Each photodermatosis has a unique morphology. Polymorphous light eruption alone can have multiple morphologic presentations of pruritus with papules, vesicles, plaques, and/or urticaria.

### Premature Aging

This condition is characterized by wrinkling and yellowing of the skin. Conclusive evidence reveals that prolonged exposure to UVR results in elastosis (degeneration of the skin due to a breakdown of the skin's elastic fibers). Pronounced drying, thickening, and wrinkling of the skin also may result. Other physical changes include cracking, telangiectasia (spider vessels), solar keratoses (growths), and ecchymoses (subcutaneous hemorrhagic lesions).<sup>2,5,14</sup> (See [Chapter 39](#) for measures for reversing photoaging.)

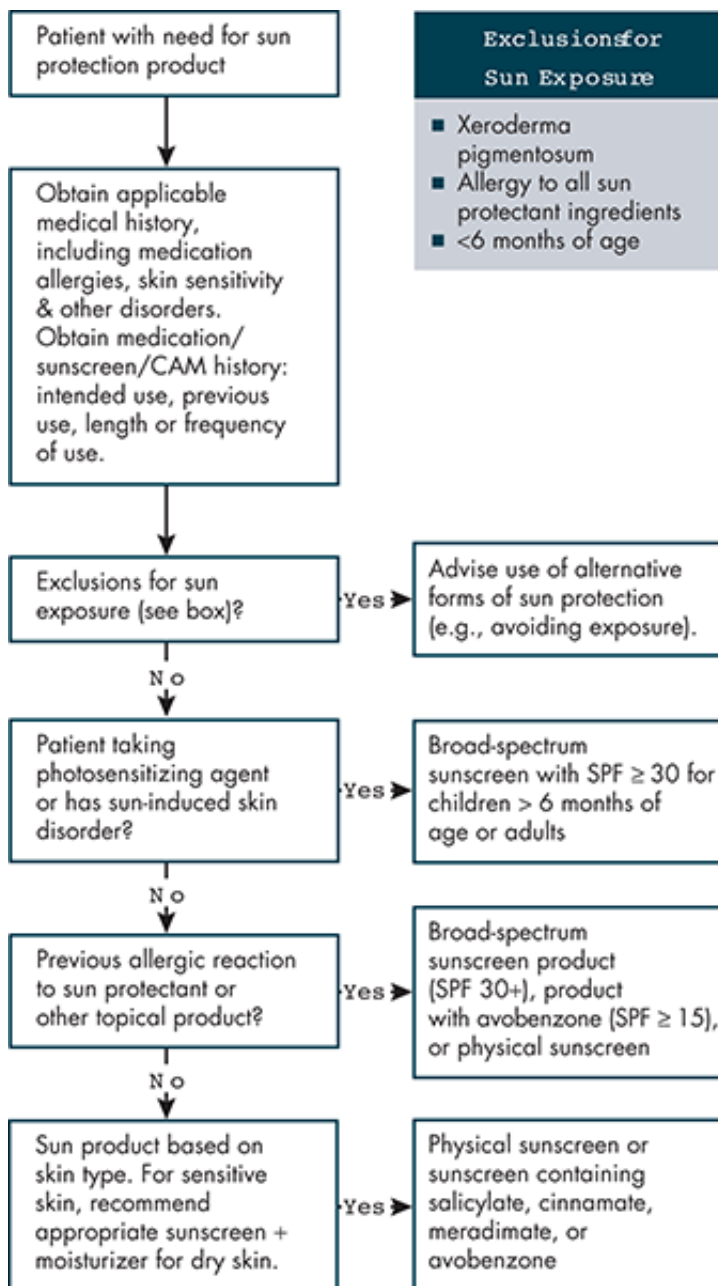

### Skin Cancer

BCC is a translucent nodule with a smooth surface. It is usually firm to the touch and may be ulcerated or crusted. It is generally found as an isolated lesion on the nose or other parts of the face, although multiple lesions are sometimes found. SCC, on the other hand, is a slow-growing, isolated papule or plaque on sun-exposed areas of the body. Self-examination for melanoma uses four factors (A-B-C-D) for evaluation: Asymmetric shape; Border irregularity or poorly defined border; Color variation within the same mole or a change in color; and Diameter larger than 6 mm. A mole with these characteristics and any new growth or change in appearance of the skin (including the lips) should be evaluated by a dermatologist.<sup>17</sup>

## Prevention of Sun-Induced Skin Disorders

The short-term goals in preventing sun-induced skin disorders are relatively simple: avoid or minimize sunburn, photosensitivity reactions, and UVR-induced or -exacerbated photodermatoses. The expected long-term outcomes are prevention of skin cancer and avoidance of premature aging of the skin.

UVR-induced skin disorders can be prevented by minimizing exposure to UVR and by using sunscreen agents. The sunscreen product selected and the degree of protection will vary, depending on the patient's intended use for the product and the conditions under which the product will be used ([Figure 38-1](#)).

Copyright © American Pharmacists Association  
All rights reserved. Any use is subject to the Terms of Use.

Self-care for sun protection. Key: CAM = Complementary and alternative medicine; SPF = sun protection factor.

The greater the risk a patient has of developing a UVR-induced skin disorder, the greater the need to avoid sun exposure. However, most people do not spend warm, sunny afternoons sitting inside, nor do they go to the beach or pool wearing lots of clothing. Providers can assist the patient in striking a balance between completely avoiding sun exposure, wearing protective clothing, and using sunscreen products. If, however, the patient suffers from a UVR-induced skin disorder (e.g., SLE), few options are available. With regard to preventing sunburn, the patient's natural skin type will be the primary factor in determining the sun protection factor (SPF) of the sunscreen product to be used. The lighter the natural skin color (and the more *quickly* a burn develops), the higher the SPF required for the sunscreen product to prevent sunburn.

#### Avoidance of Sun Exposure

Although unrealistic, complete avoidance of UVR is often the best approach for patients who have the physical characteristics or history listed in [Table 38-4](#). For people who refuse to stay indoors or who must be outdoors for extended periods, wearing protective clothing (e.g., a hat with a 4-inch brim, long pants, and a long-sleeved shirt) should be recommended. In situations in which the patient is unwilling or unable to avoid the sun or to wear protective clothing, the next best choice is to use a sunscreen product.<sup>21</sup>

**TABLE 38-4 Patient Risk Factors for the Development of UVR-Induced Problems**

- Fair skin that always burns and never tans

- A history of one or more serious or blistering sunburns
- Blonde or red hair
- Blue, green, or gray eyes
- A history of freckling
- A previous growth on the skin or lips caused by UV exposure
- The existence of a UV-induced disorder
- A family history of melanoma
- Current use of an immunosuppressive drug
- Current use of a photosensitizing drug
- Excessive lifetime exposure to UVR, including tanning beds and booths
- History of an autoimmune disease

Key: UV = Ultraviolet light; UVR = ultraviolet radiation.

Source: Reference 17.

## Measures of UVR Protection

### SPF

Purchasers of sunscreens are usually familiar with SPF, which is one parameter for determining a sunscreen's effectiveness for UV protection. Another parameter, minimal erythema dose (MED), is used to calculate a sunscreen's SPF. The MED is defined as the "minimum UVR dose that produces clearly marginated erythema in the irradiated site, given as a single exposure."<sup>20,21</sup> It is a dose of radiation, not a grade of erythema. Generally, two MEDs will produce a bright erythema; four MEDs, a painful sunburn; and eight MEDs, a blistering burn. However, because of variations in thickness of the stratum corneum, different parts of the body may respond differently to the same MED. Furthermore, the MED for heavily pigmented blacks is estimated to be 33 times higher than that for lightly pigmented whites.

The important measure for sunscreens is the SPF, which is derived by dividing the MED on protected skin by the MED on unprotected skin. For example, if a person requires 25 mJ/cm<sup>2</sup> of UVB radiation to experience 1 MED on unprotected skin and requires 250 mJ/cm<sup>2</sup> of radiation to produce 1 MED after applying a given sunscreen, the product would be given an SPF rating of 10. The higher the SPF, the more effective the agent is in preventing sunburn. If 60 minutes of sun exposure normally is required for someone to experience two MEDs (a bright erythematous sunburn), a sunscreen with an SPF of 6 will allow that person to stay in the sun 6 times longer (or 6 hours) before receiving the same degree of sunburn (assuming the sunscreen is reapplied at the recommended intervals). The SPF is product specific, because it is calculated on the basis of the final formulation of the product and cannot be determined on the basis of the active ingredient alone.<sup>18,19</sup> A product with an SPF of 15 blocks 93% of UVB. Raising the SPF to 30 increases UVB protection to only 96.7%, and an SPF of 40 blocks 97.5%.<sup>19</sup> A hypothetical SPF of 70 would increase UVB protection to only 98.6%.<sup>21,22</sup>

### Measures of UVA Protection

With concern growing about the long-term adverse effects of UVA, the utility of the SPF value in measuring photoprotection from UVA has been questioned. FDA has concluded that both UVA and UVB radiation protection can be assessed effectively by the SPF test in combination with a new broad-spectrum in vitro test. Products that pass the new test will offer higher protection against both UVA and UVB, and they will be labeled as broad-spectrum sunscreens.<sup>23</sup>

### Use of Sunscreens

On June 17, 2011, FDA announced new requirements for nonprescription sunscreens. These changes are outlined in four regulatory documents: a final rule, a proposed rule, an advanced notice of proposed rulemaking, and a draft guidance for industry.<sup>23-27</sup> These regulations became effective in June 2012.

The final rule mandates that all sunscreens labeled as broad spectrum must pass FDA's new, standardized broad-spectrum procedure that measures a product's UVA protection relative to its UVB protection. This procedure is in addition to the standardized sun protection factor test mandated previously. Only broad-spectrum sunscreens with an SPF value of 15 or higher will be able to claim to reduce the risk of skin cancer and early skin aging if they are used as directed along with other skin protection measures. Broad-spectrum sunscreens with an SPF value between 2 and 14 and products that protect against only UVB (not broad spectrum) can claim only to help prevent sunburn. Products that are not broad spectrum must carry a label warning: "Skin Cancer/Skin Aging Alert: Spending time in the sun

increases your risk of skin cancer and early skin aging. This product has been shown only to help prevent sunburn, not skin cancer or early skin aging.<sup>23</sup>

A sunscreen's efficacy is also related to its substantivity—that is, its ability to remain effective during prolonged exercising, sweating, and swimming. This property can be a function of the active sunscreen, the vehicle, or both. Generally speaking, products with cream-based (water-in-oil) vehicles appear more resistant to removal by water than those with alcohol bases. The final rule prohibits “waterproof,” “sweatproof,” and “sunblock” claims, because these terms overstate product effectiveness. Further, water-resistance claims on the front label must indicate whether the sunscreen remains effective for either 40 or 80 minutes while swimming or sweating. These times are based on the standard testing procedure. Products that are not water resistant must instruct consumers to wear a water-resistant product while swimming or sweating. Finally, all sunscreen products must include standard “Drug Facts” labeling on the back or side of the container.<sup>23</sup>

The final rule limited the maximum SPF value on sunscreen levels to “50+.” This rule is based on the lack of sufficient evidence that products with SPF values higher than 50 provide more protection than products with SPF values of 50.<sup>24,25</sup>

The application dosage forms eligible for review and inclusion in the final monograph are oils, lotions, creams, gels, butters, pastes, ointments, sticks, and sprays. Other application dosage forms (e.g., towelettes and wipes) are not considered in the final monograph.<sup>26-28</sup>

The draft guidance for industry is an enforcement guide for manufacturers of sunscreens. It provides information to help manufacturers understand how to label and test their products in light of the new final rule, proposed rule, and advance notice of proposed rulemaking.<sup>27</sup>

## Types of Sunscreens

According to the therapeutic definitions, topical sunscreens can be divided into two major subgroups: chemical sunscreens and physical sunscreens. Chemical sunscreens work by absorbing and thus blocking the transmission of UVR to the epidermis. An active ingredient absorbs at least 85% of the radiation in the UV range at wavelengths from 290 to 320 nm, but the agent may or may not allow transmission of radiation to the skin at wavelengths longer than 320 nm. Physical sunscreens are generally opaque and act by reflecting and scattering UVR, rather than by absorbing it. An opaque sunscreen active ingredient reflects or scatters all light in the UV and visible ranges at wavelengths from 290 to 777 nm. The sunscreen thereby minimizes suntan and sunburn.

The final monograph (FM) for sunscreens includes 15 chemical agents and 2 physical agents as safe and effective for use as sunscreens. Table 38-5 lists these agents, their UVR absorbance range, and their maximum concentrations. Because the SPF is product-specific and does not depend on the sunscreen's active agent alone, the FM has eliminated a required minimum strength for sunscreens that contain a single active ingredient.<sup>28-30</sup>

**TABLE 38-5 Sunscreens Considered Safe and Effective**

<i>Sunscreen Agent</i>	<i>UV Spectrum Activity</i>	<i>Maximum Range (nm)</i>	<i>Approved Maximum Concentration (%)</i>
<b>ABA and Derivatives</b>			
Aminobenzoic acid (PABA)	UVB	288.5	15
Padimate O	UVB	310	8
<b>Anthranilates</b>			
Meradimate	UVA II	340 <sup>a</sup>	5
<b>Benzophenones</b>			
Dioxybenzone	UVB, UVA II	282 <sup>b</sup>	3
Oxybenzone	UVB, UVA II	290 <sup>c</sup>	6
Sulisobenzone	UVB, UVA II	285 <sup>d</sup>	10
<b>Cinnamates</b>			
Cinoxate	UVB	310	3
Octocrylene	UVB, UVA II	303	10

Octinoxate	UVB	308-310	7.5
<b>Dibenzoylmethane Derivatives</b>			
Avobenzonone <sup>e</sup>	UVA I	360	3
<b>Salicylates</b>			
Homosalate	UVB	306	15
Octisalate	UVB	305	5
Trolamine salicylate	UVB	298	12
<b>Miscellaneous</b>			
Ensulizole	UVB	302	4
Ecamsule (terephthalylidene dicamphor sulfonic acid)	UVB, UBA	345	2
Titanium dioxide <sup>f</sup>	290-770	—	25
Zinc oxide <sup>f</sup>	290-770	—	24

Key: ABA = Aminobenzoic acid; UVA = ultraviolet A; UVB = ultraviolet B.

<sup>a</sup> Values are achieved when used in combination with other sunscreen agents.

<sup>b</sup> Second peak occurs at 217 nm.

<sup>c</sup> Second peak occurs at 329 nm.

<sup>d</sup> Second peak occurs at 324 nm.

<sup>e</sup> Agent is currently marketed through a new drug application.

<sup>f</sup> Agent scatters (rather than absorbs) radiation in the 290-770 nm range.

### Aminobenzoic Acid and Derivatives

Aminobenzoic acid (formerly para-aminobenzoic acid [PABA]), once was the most widely used sunscreen agent; however, it has been replaced by other agents, because it is a major sensitizer. Because of the continuing confusion about the name of this common sunscreen agent, the FM requires that product labels list it as “aminobenzoic acid”; in addition, each time this name appears on product labeling, it must be followed by “(PABA)” so patients know which chemical entity they are using.

Aminobenzoic acid is an effective UVB sunscreen, especially when formulated in a hydroalcoholic base (maximum of 50%-60% alcohol). The SPF of such formulations increases proportionally as the concentration of aminobenzoic acid increases from 2% to 5%. One advantage of this agent is its ability to penetrate into the horny layer of the skin and provide lasting protection. Its substantivity on sweating skin is significant but is reduced on skin that is immersed in water. The only recommended derivative of aminobenzoic acid is padimate O.

The disadvantages of alcoholic solutions of aminobenzoic acid include contact dermatitis, photosensitivity, stinging and drying of the skin, and yellow staining of clothes on exposure to the sun. Products containing padimate O will not cause staining of the clothing, which may offer an advantage over aminobenzoic acid-containing products. Patients who have experienced a photosensitivity reaction to a sunscreen product containing aminobenzoic acid or any of its derivatives should avoid using these products. [10,21,22,30](#)

### Anthranilates

The anthranilates are ortho-aminobenzoic acid derivatives. Meradimate, the menthyl ester of anthranilic acid, is a

weak UV sunscreen with maximal absorbance in the UVA range. It is usually found in combination with other sunscreen agents to provide broader UV coverage.<sup>10,21,22,30,31</sup>

### Benzophenones

The benzophenone group comprises three agents: dioxybenzone, oxybenzone (benzophenone-3), and sulisobenzene (benzophenone-4). As a group, these agents are primarily UVB absorbers, with maximum absorbance between 282 and 290 nm. However, their absorbance extends well into the UVA range (up to 350 nm with oxybenzone, and up to 380 nm with dioxybenzone). Because of the possibility of allergic reactions to aminobenzoic acid and its derivatives and their broad spectrum of action, many sunscreen products now contain benzophenones in their formulations. Oxybenzone, also found in some cosmetic formulations, is a significant sensitizing agent among sunscreens. As the use of these agents has increased, reports of sensitivity to the benzophenones have also increased.<sup>10,21,22,30</sup>

### Cinnamates

Cinnamates include cinoxate, octinoxate, and octocrylene. As shown in [Table 38-5](#), cinoxate and octinoxate have similar absorbance ranges and maximum absorbances. Octocrylene, however, has an absorbance range of 250-360 nm, well into the UVA range. Octocrylene is currently found in more commercial sunscreen preparations than it was in the past, possibly reflecting its broader spectrum of absorbance. It is also an effective photostabilizer. Octocrylene can decrease the rate that other sunscreens degrade when they are exposed to sun. It is often combined with other sunscreens to improve their stability.<sup>29</sup>

Unfortunately, cinnamates do not adhere well to the skin and must rely on the vehicle in a given formulation for their substantivity.<sup>10,21,22,30,31</sup>

### Dibenzoylmethane Derivatives

Avobenzone (butyl methoxydibenzoylmethane, originally known as Parsol 1789) is the first of a new class of sunscreen agents effective throughout the entire UVA range (320-400 nm; full spectrum). It has maximum absorbance at approximately 360 nm. Although avobenzone absorbs UVR throughout the UVA spectrum, its absorption capacity falls off sharply at 370 nm. Therefore, reactions from photosensitive drugs and chemicals that are highly reactive in the 370-400 nm range could still occur. Avobenzone, however, offers the best protection in the UVA range compared with the other chemical sunscreens on the market. It is commonly included in sunscreen products to increase UVA coverage. Avobenzone is easily degraded by exposure to sunlight; it is found in newer sunscreen products combined with octocrylene, salicylates, methylbenzylidene camphor, and micronized zinc oxide and/or titanium dioxide to enhance stability of the product and to extend the product's spectrum of coverage through the UVA and UVB spectrum.<sup>10,21,22,30</sup>

### Salicylates

Salicylic acid derivatives are weak sunscreens and must be used in high concentrations. They do not adhere well to the skin and are easily removed by perspiration or swimming.<sup>10,30,31</sup>

### Other Chemical Sunscreens

Ensulizole does not fit into any of the above classes. It is a pure UVB sunscreen with an absorbance range of 290-320 nm. Ecamsule (terephthalylidene dicamphor sulfonic acid) is a new molecule that FDA approved in 2006. It is a water-resistant broad-spectrum sunscreen. Ecamsule is often combined with octocrylene to increase its stability to light.<sup>10,31</sup>

### Physical Sunscreens

Physical sunscreens (zinc oxide and titanium dioxide) are considered broad-spectrum UV protectants. They are used most often on small and prominently exposed areas by patients who cannot limit or control their exposure to the sun (e.g., lifeguards). Earlier formulations of these agents were opaque and had an undesirable sticky or gritty sensation. Current formulations contain micro- or nano-sized particles of the agent. These formulations are transparent, which improves their cosmetic appeal. Because titanium dioxide increases the effective SPF of a product and extends the spectrum of protection well into the UVA range, the number of commercial products containing this agent has increased. The FM allows zinc oxide to be used alone or in combination with any of the other sunscreen agents except avobenzone; the exception results from a lack of data on effectiveness.<sup>10,21,22,30</sup>

### Combination Products

FDA has not recommended limits on the number of sunscreen agents that may be used together. However, each sunscreen agent must contribute to the efficacy of a product and must not be included merely for marketing promotion purposes. Therefore, the FM requires that each active ingredient contribute a minimum SPF of not less than 2; in addition, the finished product must have a minimum SPF of not less than the number of sunscreen active ingredients used in the combination multiplied by 2.<sup>22</sup>

### Dosage and Administration Guidelines

The two major causes of poor sun protection with sunscreen use are application of inadequate amounts and infrequent reapplication. Although many sunscreen products that prevent burning of the lips (or nose) are available, the lips are often neglected. Products for the lips differ in ingredients and in the UVA and UVB spectrum, but they carry most of the same labeling used on sunscreen lotions (including the SPF). The SPF of these products is usually at least 15. Studies have shown that lip protection not only helps prevent drying and burning of the lips, but that it also helps prevent the development of cold sores or fever blisters triggered by the herpes simplex virus in patients who are susceptible to recurrent outbreaks.

For maximum effectiveness, sunscreens must be applied liberally to all exposed areas of the body and reapplied at least as often as the label recommends. FDA-approved labeling recommends that sunscreens be applied 15-30 minutes before UV exposure and at least every 2 hours thereafter. Reapplication after every episode of swimming, towel drying, or excessive sweating is also recommended.<sup>33</sup>

The FDA standard for application of sunscreens is 2 mg/cm<sup>2</sup> of body surface area. This standard means that, for sufficient protection, the average adult in a bathing suit should apply nine portions of sunscreen of approximately one-half teaspoon each, or approximately 4 and one-half teaspoons (22.5 mL) total. The sunscreen should be distributed as follows:

- Face and neck: one-half teaspoon.
- Arms and shoulders: one-half teaspoon to each side of body.
- Torso: one-half teaspoon each to front and back.
- Legs and tops of feet: 1 teaspoon to each side of body.

Because of the cost of sunscreen products and the need to apply them often and in sufficient amounts, people may use far less sunscreen than is necessary to provide adequate protection. Exposure to UVR should be within the limits of the SPF value of the sunscreen for the individual using the sunscreen. A higher SPF may be needed for longer or more intense exposure to UVR. The final rule requires that the sunscreen label recommend the following with regard to sunscreen application: Regardless of the water resistance of the product, it should be applied 15 minutes before sun exposure. Non-water-resistant products should be reapplied at least every 2 hours. Water-resistant products should be reapplied every 2 hours, after 40 or 80 minutes of swimming or sweating (as designated on the label), and immediately after towel drying.<sup>23</sup>

### Safety Considerations

The development of a rash, vesicles (blisters), hives, or exaggerated sunburn after use of the sunscreen product is most likely a sign of either a photosensitivity or allergic reaction.<sup>1-3</sup> Product labels must state the following: "Stop use if skin rash occurs."<sup>22</sup> The patient should be referred for medical evaluation of the situation. The degree of the reaction will determine what type of medical intervention (if any) is necessary.

If a patient has experienced a prior reaction to a sunscreen product, the product's name and ingredients should be identified, if possible. This action may be difficult, because product formulations change frequently. Photosensitivity and contact dermatitis are more likely to occur with aminobenzoic acid and its derivatives, although the benzophenones, cinnamates, homosalate, avobenzone, and meradimate have also been reported to produce both conditions. In a French study of contact dermatitis, 15.4% of patients were found to have an allergy to sunscreens, with almost one-half attributed to oxybenzone.<sup>34</sup> Although no evidence exists of significant effects from eye contact, FDA requires the label warning "Keep out of eyes."

### Additional Product Considerations

#### Sunscreens in Cosmetic Products

The FM addresses a gray area that has allowed the proliferation of cosmetics claiming to offer sun protection. It stipulates that sunscreen products will be classified as drugs rather than cosmetics, because consumers expect that sunscreens will protect them from some of the sun's damaging effects. However, cosmetics that contain sunscreen agents will be classified as cosmetics as long as no therapeutic claims are made and the sunscreen is intended for a nontherapeutic, nonphysiologic purpose. If the cosmetic makes a claim for use as a sunscreen product, it will have to

include the appropriate labeling. Under the directions for use, the optional statement “for sunscreen use” may be added.<sup>22,23</sup>

## Product Selection Guidelines

Two primary factors will determine the best product for a given patient: the intended use of the product and specific patient characteristics. The decision of which sunscreen product to use must be based on the information obtained from both categories.

### Intended Use

Some patients may want to use sunscreens to prevent sunburn or the photoaging effects of UVR or to protect themselves from skin cancer. Others may need protection from sun exposure because they are taking photosensitive drugs or they suffer from a photodermatosis.

The higher the SPF of the sunscreen product, the greater the protection it provides against sunburn and tanning.

Studies have shown that sunscreens can protect against the long-term hazards of skin cancer.<sup>10,21</sup> Considerable research is currently being conducted on all aspects of UVR and its effects. However, experts are debating whether low-SPF products protect individuals from UV skin damage or allow them to receive dangerously high levels of UVR over extended periods of time. Because of the known hazards associated with UVR, FDA and other organizations such as the American Academy of Dermatology recommend the use of sunscreen products of at least SPF 15. Generally, if a product is to be used to prevent skin cancer, reduce the chances of a photosensitivity reaction, or reduce the risk of triggering a skin disorder induced or aggravated by UVR, a broad-spectrum SPF value of 15 or higher is recommended.

### Patient Factors

For patients not concerned with photosensitivity, photodermatoses, or prevention of skin cancer, product selection is much simpler. The following factors can serve as a guide in selecting products with the appropriate properties for a patient’s particular situation.

The most important factors in product selection are the individual’s natural skin type and tanning history. An SPF product of 30+ should be used by people who burn easily and tan minimally at best. If the individual plans to swim, participate in vigorous activity (e.g., sand volleyball), or work outdoors, the sunscreen product must be able to adhere to the skin more substantially than if the individual just lies on the beach. The expected duration of the physical activity can also help to determine which sunscreen to use. Water-resistant products are usually effective for at least 40 or 80 minutes when used during the above activities.<sup>23</sup>

At least one-third of the current commercial products are labeled “noncomedogenic,” “fragrance-free,” and “hypoallergenic.” Noncomedogenic products do not plug the pores and, therefore, do not exacerbate acne. This property is especially important for teenagers, who usually spend more time outdoors than other age groups and generally would prefer not to use comedogenic sunscreens. Many patients are sensitive to various ingredients (e.g., fragrances, emulsifiers, and preservatives). These patients should try to choose fragrance-free formulations or those that are hypoallergenic. In a randomized, placebo-controlled study of adverse reactions to sunscreens, 16% of subjects developed a local reaction to the topically applied product.<sup>35</sup> Of these subjects, 53% agreed to patch testing and photopatch testing. None of this subset showed an allergic sensitivity to the sunscreen agents. Instead, all the reactions were found to be caused by formulation ingredients, such as fragrances and preservatives. This finding reinforces the belief that most sensitivity may be caused by ingredients other than sunscreens. Although it may not be possible to figure out which specific ingredient a patient is sensitive to, patients who have a history of sensitivity to certain types of ingredients would do well to use a fragrance-free, hypoallergenic product.

Some patients have normally dry skin; sunbathing can further exacerbate this problem. These patients should avoid ethyl and isopropyl alcohols, which are included in a number of commercial sunscreen products and can further dry the skin.

### Use in Special Populations

Absorptive characteristics of human skin in children younger than 6 months differ from those of adult skin. The metabolic and excretory systems of infants are not fully developed to handle any sunscreen agent absorbed through the skin. Therefore, only patients older than 6 months are considered to have skin with adult characteristics. FDA requires that sunscreen products be labeled with the statement “children under 6 months of age: ask a doctor.” Caregivers should be extremely wary regarding sun exposure in children, especially infants. Although the evidence is not yet conclusive, researchers and providers agree that use of an SPF-15 product starting after 6 months of age and continuing throughout one’s lifetime can reduce the incidence of long-term skin damage due to UVR. A product with an SPF of 30+ may result in even higher reductions in sunburn, premature skin aging, skin cancer, and other skin problems. No special consideration is needed for the use of sunscreen-containing products in the elderly or in

pregnant or lactating women.<sup>23-28,36</sup>

### Assessment of Sun-Induced Skin Disorders: A Case-Based Approach

The approach to UVR-induced skin disorders differs from that used in most self-care situations. These disorders are addressed from a preventive, rather than a treatment, standpoint.

Consequently, assessment of the patient should focus on the *intended use* of the product. Clinical providers' interventions with patients occur in two primary situations. The first situation occurs when a patient requests a recommendation for a sunscreen product to prevent a burn and/or to allow development of a tan. The second situation is initiated by the provider when a patient is placed on a drug that can produce a photosensitivity reaction. In this second scenario, no real patient assessment is needed, because prevention of exposure to UVR is the standard approach.

Cases 38-1 and 38-2 illustrate the assessment of patients with sun-induced skin disorders.

#### Case 38-1

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient would like help picking out a sunscreen to take with her on vacation to the Bahamas. She is concerned that she could get a bad sunburn because she will be out in the sun for several hours most days. She has light skin and usually burns before she tans. She typically uses a product with an SPF of 12. She has a history of multiple sunburns (ranging from mild to severe) on her face and exposed areas.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Staying completely out of the sun has been the only thing she has found that keeps her from getting burned, but she doesn't want to have to spend this vacation indoors.
c. description of the patient's efforts to relieve the symptoms	She has tried using sunscreens with an SPF of 25 in the past. She applied them while she was outside in the sun, and usually only one time.
d. patient's identity	Cecelia Jones
e. age, sex, height, and weight	30 years old, female, 5 ft 2 in., 130 lb
f. patient's occupation	Paralegal
g. patient's dietary habits	Tries to eat a well-balanced diet.
h. patient's sleep habits	Typically gets 6-8 hours of sleep per night.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Allergic rhinitis: loratadine 10 mg daily; contraception: Yasmin 1 tablet by mouth daily

j. allergies	NKA
k. history of other adverse reactions to medications	None
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	The patient desires a sunscreen product that will allow her to spend time in the sun while on vacation.
3. Identify exclusions for sun exposure (Figure 38-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Use an OTC sunscreen product regularly while in the sun. (2) Avoid sun exposure by staying in the shade or indoors. (3) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Regularly using a sunscreen product while outdoors will allow the patient to enjoy the outdoor activities she would like to do on vacation.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Use a sunscreen product of SPF 15 or greater that provides both UVA and UVB coverage. A product that is water resistant will be a better choice if you plan to be in the water during the day. Apply the product liberally to all sun-exposed areas of the body."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Correct use of a sunscreen product will allow you to enjoy time outdoors without getting a sunburn. With past burns, you may not have applied an appropriate amount of sunscreen or the right type: a broad spectrum sunscreen that provides both UVA and UVB coverage."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Apply the sunscreen product every day 15-30 minutes prior to going out into the sun. Reapply non-water resistant sunscreen at least every 2 hours and every 40 or 80 minutes as directed on the product label if sweating or in the water. You will need to apply the sunscreen as follows: <ul style="list-style-type: none"> <li>• Face and neck: one-half teaspoon.</li> <li>• Arms and shoulders: one-half teaspoon to each side of body.</li> <li>• Torso: one-half teaspoon each to front and back.</li> <li>• Legs and tops of feet: 1 teaspoon to each side of body.</li> </ul>
Solicit follow-up questions from the	"What sunscreen should I choose? Is there a specific one I should get?"

patient or caregiver.	
Answer the patient's or caregiver's questions.	"There are many sunscreens that are effective. The most important thing to look for is a broad-spectrum sunscreen that blocks both UVA and UVB. Also, you should use a water-resistant product if you will be in the water or sweating."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	NA

Key: NA = Not applicable; NKA = no known allergies; OTC = over-the-counter; SPF = sun protection factor; UVA = ultraviolet A; UVB = ultraviolet B.

### Case 38-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient has a history of psoriasis, and she has noticed that her condition and medication for the psoriasis make her more sensitive to the sun. Any sunburn will exacerbate her psoriasis. She would like something to help her worsening psoriasis symptoms. She noticed a worsening of her psoriasis when in the sun for too long this weekend, and she got a sunburn. Her psoriasis symptoms have gotten much worse since the sun exposure.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Sun exacerbates her psoriasis symptoms. So far, nothing has helped relieve her exacerbation.
c. description of the patient's efforts to relieve the symptoms	She used sunscreen prior to being in the sun, but she failed to reapply it throughout the day.
d. patient's identity	Sarah-Anne Smith
e. age, sex, height, and weight	25 years old, female, 5 ft 8 in., 145 lb
f. patient's occupation	Teacher
g. patient's dietary habits	She eats at home for most meals and tries to eat a healthy diet. Occasionally (1-2 meals per week) she eats out or picks up fast food.
h. patient's sleep habits	She gets between 7-8 hours of sleep a night.
i. concurrent medical conditions, prescription and nonprescription	Psoriasis: topical triamcinolone 0.5% cream applied 3 times daily.

medications, and dietary supplements	
j. allergies	Penicillins
k. history of other adverse reactions to medications	None
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Patient with history of psoriasis that is exacerbated by sunburns or excessive sun exposure.
3. Identify exclusions for sun exposure (Figure 38-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Avoidance of additional sun exposure until her psoriasis symptoms improve. (2) Use of a sunscreen product in future sun exposures. (3) Referral to her dermatologist.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Because the patient has had a worsening of her psoriasis secondary to sun exposure, she should follow up with her dermatologist to assess her symptoms. In the future, she should use sunscreen regularly when exposed to the sun.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should see your dermatologist for treatment of your worsening psoriasis symptoms. In the future, apply a sunscreen at least 15 minutes prior to sun exposure, and reapply it every 2 hours during sun exposure for non-water-resistant products. Also, you should consider wearing a long-sleeved shirt and a hat with a 4-inch brim prior to sun exposure, and you should avoid sunburns."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Psoriasis is commonly aggravated by sun exposure."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.

Solicit follow-up questions from the patient or caregiver.	"Is there any sunscreen that only needs to be used once a day?"
Answer the patient's or caregiver's questions.	"No. All sunscreens, even water-resistant ones, must be reapplied."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	NA

Key: NA = Not applicable.

### Patient Counseling for Sun-Induced Skin Disorders

Health care providers can provide a great service by counseling patients about the suntanning process and about properly selecting and using sunscreens. One study reported that among the participants, 13% of children and 9% of adults had experienced a sunburn during the previous week; in addition, the study found a relationship between sunburn and a parental attitude that tanning is healthy.<sup>29</sup>

One simple way to find out whether a patient is using a sunscreen properly is to ask how long the current bottle has lasted. When applied properly, according to the suggested dosing guidelines and in accordance with the appropriate substantivity of the product, a sunbather could easily use about 1 ounce every 80-90 minutes. This use would amount to several ounces a day and several bottles per week. Incredibly, many frequent sunbathers use only one bottle in an entire season. This diminished usage demonstrates the importance of individuals' receiving adequate counseling to get the protection they desire. The box Patient Education for Protection from Sun Exposure lists specific information to provide patients.

Patients should also be advised to wear sunglasses to protect their eyes from sun-induced damage. The box A Word about Sun-Induced Ocular Damage describes the categories of available sunglasses and their UVR filtration properties.<sup>31</sup>

#### Patient Education for Protection from Sun Exposure

The objectives of self-treatment depend on a patient's specific goal or health status. Protection from sun exposure can prevent sunburn or tanning, photosensitivity reactions in susceptible persons, or exacerbation of sun-induced photodermatoses. The primary long-term benefits are to prevent skin cancer and premature aging of the skin. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Avoiding/Minimizing Sun Exposure

- Avoid exposure to the sun and other sources of ultraviolet radiation (UVR), such as tanning beds/booths and sunlamps.
- The sun's rays are the most direct and damaging between 10:00 am and 4:00 pm. Avoid sun exposure as much as possible during this time of day.
- Sunburn can occur on a cloudy or overcast day; 70%-90% of UVR penetrates clouds.
- Wear protective clothing (e.g., long pants, a long-sleeved shirt, and a hat with a brim). Tightly woven fabrics that do not allow light to pass through will provide the most protection.
- Use a beach umbrella or other protection to reduce UVR.
- Water and wet clothing allow significant transmission of UVR. Even if the body is completely submerged, consider time in the water as part of the total time spent in the sun.

#### Use of Sunscreens

- An SPF of 15 or greater provides the greatest protection against sunburn and other UVB-induced skin problems.
- A broad-spectrum sunscreen product (e.g., avobenzone used in combination with padimate O and/or octocrylene, meradimate, titanium dioxide, or one of the benzophenones) provides optimal protection against UVA and UVB sun exposure. This type of sunscreen is especially recommended if you have a sun-induced disorder, if you are taking photosensitizing drugs, or if you just want to reduce sun exposure as much as possible to prevent long-term effects.
- Apply first dose 15 minutes before exposure.
- Apply approximately 1 ounce of sunscreen over the exposed areas of the body, avoiding contact with the eyes. The sunscreen should be distributed as follows: 1/2 teaspoon to the face and neck area, 1/2 teaspoon

to the arms and shoulders, 1/2 teaspoon to the front and back each, and 1 teaspoon to each side on the leg and top of the foot.

- Use the most substantive sunscreen available; water-resistant sunscreens are recommended if you will be in water or perspiring excessively.
- Reapply the sunscreen according to the label instructions, usually every 40 minutes or 80 minutes (as directed on the label) for water-resistant sunscreens while swimming or sweating or after towel drying. Apply every 2 hours for non-water-resistant products or for water-resistant products if you are not swimming or sweating.
- Always check the expiration date on the sunscreen product. Sunscreens can lose their effectiveness.
- Higher altitudes and lower latitudes increase the amount of UVR to which an individual is exposed. Take proper precautions (e.g., use a sunscreen with a high SPF) to protect skin from UVR.
- Snow and sand reflect UVR. Take proper precautions to protect exposed skin (e.g., wear sunglasses and use high SPF sunscreens).
- Keep sunscreen out of direct sun, which can reduce its potency.
- Continue to use a sunscreen as long you are taking a photosensitizing drug or exhibiting signs and symptoms of photodermatitis.
- Avoid sunscreens containing aminobenzoic acid derivatives, benzophenones, cinnamates, or meradimate if you have had a prior allergic reaction to a sunscreen product.
- Stop using the sunscreen if redness, itching, rash, or exaggerated sunburn occurs.

Key: SPF = Sun protection factor; UVA = ultraviolet A; UVB = ultraviolet B.

#### A Word About Sun-Induced Ocular Damage

Recent studies have demonstrated a relationship between both UVA and UVB in cataract formation. UVR has been shown to cause temporary injuries such as photokeratitis (a painful type of snow blindness associated with highly reflective surfaces). Another concern involves an increase in the incidence of uveal (iris plus ciliary body) melanoma. These concerns are even more serious because of the erroneous belief that all sunglasses screen out UVR. In response, the Sunglass Association of America, working with FDA, has developed a voluntary labeling program. Abbreviated information concerning sunglasses' UVR-screening properties is directly attached to each pair, and brochures describing the appropriate use of each type of lens are available at outlets selling the sunglasses.<sup>37</sup>

According to its UVR filtration properties, each pair of sunglasses is placed in one of the following three categories:

1. Cosmetic sunglasses block at least 70% UVB and 20% UVA. They are recommended for activities in nonharsh sunlight (e.g., shopping).
2. General-purpose sunglasses block at least 95% UVB and 60% UVA. With shades that range from medium to dark, they are recommended for most activities in sunny environments (e.g., boating, driving, flying, or hiking).
3. Special-purpose sunglasses block at least 99% UVB and 60% UVA. They are recommended for activities in very bright environments (e.g., ski slopes and tropical beaches).<sup>37</sup>

Key: FDA = Food and Drug Administration; UVA = ultraviolet A; UVB = ultraviolet B; UVR = ultraviolet radiation.

#### Evaluation of Patient Outcomes for Sun-Induced Skin Disorders

The short-term outcomes for sunscreen use are readily apparent. Twenty-four hours after use, there will be no obvious sunburn, photosensitivity reaction, or eruption of photodermatosis. This success indicates that the appropriate sunscreen agents and/or SPF were used. However, the long-term effects of UVR (e.g., skin cancer or premature aging of the skin) may take up to 20-30 years to become evident.

#### Key Points for Sun-Induced Skin Disorders

- UVR (UVA and UVB) triggers a variety of photodermatoses and causes sunburn, photosensitivity, skin cancer, premature aging of the skin, cataracts, and a variety of other medical problems.
- There is no safe form of UVR exposure. Tanning and use of tanning beds can result in negative health effects.
- The effects of UVR are cumulative over one's lifetime.
- The best protection against UVR is avoidance. The next best approach is to wear a hat, long sleeves, pants, and UV-protective sunglasses.
- Maximum protection is provided by using a broad-spectrum sunscreen of SPF 15+.
- Because broad-spectrum sunscreens provide added UVA protection, they are the best sunscreen for preventing long-term effects, regardless of the patient's history.

Providers need to appreciate sunscreen products as therapeutic agents rather than cosmetics. Unfortunately, most patients have the latter view. This perception makes good patient counseling even more important. Reinforcing the need for proper selection of the appropriate sunscreen product and correct use of these products are key to

educating the public and reducing the risks of UVR exposure.

## Handbook of Nonprescription Drugs > Chapter 39. Skin Hyperpigmentation and Photoaging

### Skin Hyperpigmentation and Photoaging: Introduction

Photoaging of the skin is directly related to exposure to ultraviolet radiation (UVR). Skin hyperpigmentation may result from serious or benign medical conditions. This chapter focuses on the treatment of hyperpigmentation and photoaging once they have occurred. Nonprescription products used to minimize sun exposure are discussed in [Chapter 38](#).

Hydroquinone, a skin-bleaching agent, can be used for self-treatment of hyperpigmentation. However, this may soon change if the Food and Drug Administration (FDA) rules to remove this product from the market. Alpha hydroxy acids (AHAs), promoted as nonprescription treatments for photoaging, are used to treat both disorders.

### Skin Hyperpigmentation

Hyperpigmentation, manifested as an area of skin darker than the surrounding skin, is usually a benign phenomenon. Hyperpigmentation may be perceived by the patient as a disfigurement, especially when the altered pigmentation occurs on the face and neck and is in noticeable contrast to the surrounding normal skin color. Although products used to treat hyperpigmentation serve a cosmetic function, it is important to emphasize that they are drugs with potential toxicity and side effects. Pigment disorders may also present with both hypo- and hyperpigmented skin or skin that may appear mottled.

### Pathophysiology of Skin Hyperpigmentation

Systemic as well as localized skin diseases may cause pigment cells to become overactive (resulting in skin darkening) or underactive (resulting in skin lightening). Endocrine imbalances caused by Addison's disease, Cushing's disease, or hyperthyroidism and conditions such as pregnancy are capable of altering skin pigmentation. Metabolic alterations affecting the liver, as well as certain nutritional deficiencies, can be associated with diffuse melanosis. Inflammatory dermatoses (e.g., contact dermatitis from poison ivy or acne lesions) or physical trauma to the skin (e.g., thermal burn) may cause prolonged postinflammatory hyperpigmentation. In addition, certain drugs ([Table 39-1](#)) have an affinity for melanin and may cause hyperpigmentation. Skin hyperpigmentation resulting from these conditions may occur as a result of increased melanin, increased melanocytes, or deposits of other darkening chemicals in the skin.<sup>1-3</sup> Melanocytes (pigment cells) produce melanosomes, pigment granules that contain the protein melanin, a brown-black pigment. These cells can be viewed as tiny one-celled glands with long projections used to pass pigment particles into the keratinocytes, from which the particles migrate upward to the skin surface. The human epidermis has about 800-1000 melanocytes per square millimeter. The melanocyte density is the same in all races. However, the proportion and distribution of these cells throughout the epidermis differ. The melanocyte is believed to provide protection from UVR. Dark skin usually has more active melanocytes compared with light skin, which explains why UVR-induced skin cancers of all types are less common in dark skin than in light skin.<sup>4-6</sup>

**TABLE 39-1 Medications That May Cause Hyperpigmentation**

Amiodarone
Anticonvulsants (e.g., phenytoin, phenobarbital, carbamazepine)
Antimalarial agents (e.g., chloroquine, hydroxychloroquine)
Antineoplastic agents (e.g., cyclophosphamide, daunorubicin, doxorubicin, fluorouracil, busulfan)
Clofazimine
Heavy metals (e.g., gold compounds, arsenic, mercury, silver, bismuth)
Hormone replacement therapy
Minocycline
Oral contraceptives
Phenothiazines (e.g., chlorpromazine, thioridazine, imipramine, clomipramine)

Tricyclic antidepressants (e.g., imipramine, desipramine, amitriptyline)
Zidovudine

*Source:* Adapted from references 1, 2, and Dermatologic drug reactions and common skin conditions. In: Dippiro JT, Talbert RL, Yee GC, et al., eds. *Pharmacotherapy: A Pathophysiologic Approach*. 8th ed. New York, NY: McGraw-Hill Professional; 2011:1661-72.

Three types of hyperpigmentation may be self-treated with topical nonprescription agents: ephelides, solar lentigines, and melasma.<sup>7</sup> Ephelides, or freckles, are spots of uneven skin pigmentation that first appear in childhood, are exacerbated by the sun, and tend to fade with reduced sun exposure. Melasma (also called chloasma), a condition in which macular hyperpigmentation appears, usually on the face or neck, is often associated with pregnancy (“the mask of pregnancy”) or the use of oral contraceptives, as well as with sun exposure. Solar or “senile” lentigines (age spots or liver spots) appear on exposed skin surfaces, particularly in fair-skinned people, and are induced by UVR.

### Clinical Presentation of Skin Hyperpigmentation

Depending on the etiology of hyperpigmentation, patients can present with varying signs and symptoms. Most notably, patients complain of persistent macular discoloration on the face or other sun-exposed areas. Discoloration typically consists of a more intense brown coloration than that of surrounding normal skin and may range from dark to faint in appearance. Clinical evidence of hyperpigmentation and photoaging, as well as response to treatment, is not easily quantifiable by standard light photography or by routine clinical evaluation. Fluorescence photography is used to detect subtle but significant decreases in diffuse and mottled hyperpigmentation after topical treatment, which helps to clinically evaluate and effectively assess the efficacy of topical products.<sup>8</sup>

### Treatment of Skin Hyperpigmentation

#### Treatment Goals

The goal of treating skin hyperpigmentation is to diminish the degree of pigmentation of affected areas so the skin tone of these areas is consistent with surrounding normal skin.

#### General Treatment Approach

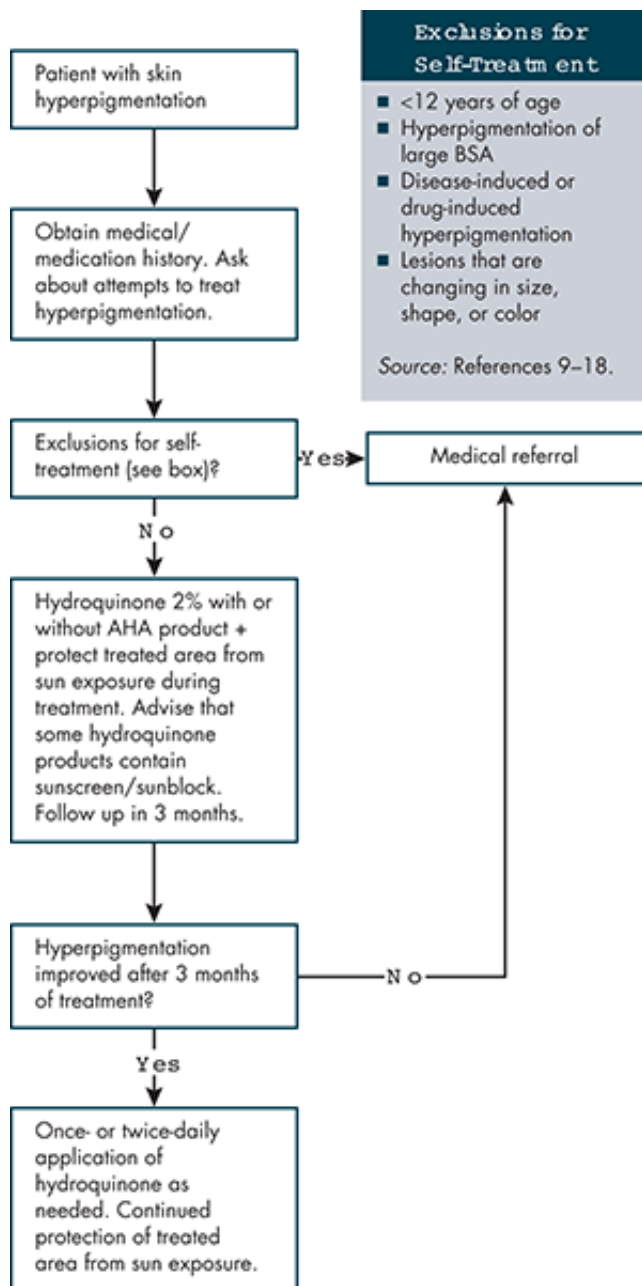

The approaches to treat hyperpigmentation have expanded significantly within the past 10 years. The treatment generally falls into two categories: stopping the skin cells from overproducing melanin (the cells responsible for giving the skin its pigment) and physically removing the top few layers of the skin’s surface through chemical or mechanical exfoliation. Although good results can be achieved using either approach, the best results are accomplished through a combination of the two.

Exfoliation used to treat hyperpigmentation involves physically buffing away surface-layer skin (microdermabrasion) and applying chemical agents (e.g., AHAs). Although microdermabrasion is a routine procedure in salons, the recommendation is to seek an experienced practitioner. Because of the risk of microdermabrasion tearing the skin, chemical peeling is a better option for sensitive skin. Abrading skin may also cause irradiation and burning.

Skin-bleaching agents diminish hyperpigmentation by inhibiting melanin production within skin.<sup>9</sup> As discussed in the section Treatment of Photoaging, the combination of hydroquinone with an antioxidant and exfoliant is considered efficacious, giving patients acceptable outcomes with minimal adverse effects.<sup>3,9-11</sup>

To prevent negation of the effects of treatment, patients must avoid even minimal exposure to UVR, and they must use sunscreen agents and protective clothing on an ongoing basis, even after discontinuing the bleaching agent.

The algorithm in [Figure 39-1](#) outlines the self-treatment of skin hyperpigmentation.<sup>9-18</sup>

Copyright © American Pharmacists Association  
All rights reserved. Any use is subject to the Terms of Use.

Self-care of skin hyperpigmentation. Key: AHA = Alpha hydroxy acid; BSA = body surface area.

### Pharmacologic Therapy

Management of hyperpigmentation as directed by a primary care provider may include topical prescription agents composed of ingredients known to cause lightening of the skin, such as tretinoin (retinoic acid), azelaic acid, hydroquinone, and corticosteroid, and may include laser therapy. Combination products or laser therapy may sometimes be effective for postinflammatory hyperpigmentation that is resistant to nonprescription treatment.<sup>12</sup> A number of nonprescription agents have been used in skin-bleaching preparations. These agents have included hydroquinone 2%, ascorbic acid, *N*-acetyl glucosamine, glycolic acid, vitamin C, licorice extract, niacinamide, and kojic acid. Newer products are being formulated with synthetic oligopeptide, rucinol, tranexamic acid, deoxyarbutin, dioic acid, and aloesin.<sup>3,13</sup> However, only preparations containing hydroquinone were submitted to the FDA Advisory Review Panel on Over-the-Counter Miscellaneous External Drug Products, and products containing this agent remain the most effective nonprescription skin-bleaching products available. Table 39-2 lists selected trade-name products.

**TABLE 39-2 Selected Nonprescription Skin Bleaching/Fading Products**

Trade Name	Primary Ingredients
Clinicians Complex 6% Skin Bleaching Cream	Hydroquinone 2%; kojic acid 2%

La Roche-Posay Mela-D Skin Lightening Daily Lotion	Hydroquinone 2%
Topix HQS-2 Skin Lightening Cream	Hydroquinone 2%; benzophenone 1.5%
DDF Fade Gel 4	Hydroquinone 2%; kojic acid; azelaic acid; salicylic acid
Glymed Plus Derma Pigment Bleaching Fluid	Hydroquinone 2%
SkinCeuticals Pigment Regulator	Kojic acid 2%; emblica extract 2%; glycolic acid
Murad Age Spot and Pigment Lightening Gel	Hydroquinone 2%; glycolic acid
Exuviance Brighten Up Kit	Hydroquinone 2%; glycolic acid; PHA/kojic acid complex
Alpha Hydrox Spot Light Skin Lightener	Hydroquinone 2%; glycolic acid 10%; vitamin E
Lumixyl	Synthetic oligopeptide 0.1%
Philosophy Miracle Worker Dark Spot Corrector	Niacinamide
Shiseido White Lucent Intensive Spot Targeting Serum	Tranexamic acid
Noreva IKLEN Depigmenting Serum	Rucinol

Key: PHA = Polyhydroxy acids.

Hypopigmentation treatment options are often limited. Treating hypopigmentation may involve the use of topical products, light or laser treatment, or surgical skin grafting. Nonprescription skin-staining products such as Dy-O-Derm or Chromelin Complexion Blender, which contain dihydroxyacetone (the active ingredient in self-tanning products and treatment for vitiligo), may be used to adjust color in lightened skin areas to approximate natural darker tones in mixed hypo- and hyperpigmented disorders.<sup>14</sup> Once the desired skin color is attained, applications may be decreased from daily to every fourth to seventh day to maintain the desired outcome. These products have a higher concentration of dihydroxyacetone compared with self-tanning products and are not intended for widespread application over the body.

### Hydroquinone

Hydroquinone (*p*-dihydroxybenzene) in concentrations of 1.5%-2% is currently available for nonprescription use for the treatment of skin hyperpigmentation.<sup>7</sup> It is considered to be the mainstay and gold standard of hyperpigmentation therapy.<sup>3,10,13</sup> However, the safety of bleaching creams that contain hydroquinone continues to be reviewed in the literature.<sup>14-15</sup> In 2006, FDA proposed withdrawing the tentative final monograph approving skin-bleaching creams to replace it with a final rule stating that all drug products (including hydroquinone) used for skin lightening in nonprescription products are no longer generally recognized as safe and effective owing to the potential increased risk of cancer and ochronosis. If this final monograph is published, hydroquinone products will be removed from the nonprescription marketplace. In December 2009, a nomination was approved for additional studies to be conducted by the National Toxicology Program (NTP) to determine if the use of hydroquinone poses a risk to humans.<sup>17</sup> At the time this book went to press, the NTP review process was still ongoing.<sup>17</sup> In the interim, FDA believes that hydroquinone should remain available as a nonprescription OTC drug product.

Hydroquinone and its derivatives act by reducing conversion of tyrosine to dopa and, subsequently, to melanin by inhibiting the enzyme tyrosinase. Other possible mechanisms of action include destruction of the melanocyte or melanosomes.<sup>9-10</sup> The 2% concentration is safer and produces results equivalent to those of higher concentrations.<sup>15</sup> Exfoliants such as topical glycolic acid (an AHA) or topical tretinoin are sometimes combined with hydroquinone to increase efficacy compared with hydroquinone monotherapy.<sup>18</sup> Hydroquinone 2% should be rubbed gently but thoroughly into affected areas twice daily. The agent should be applied to clean skin before application of moisturizers or other skin care products. It should not be applied to damaged skin or near the eyes. If no improvement is seen within 2 months, its use should be discontinued and a primary care provider should be consulted.<sup>9,19</sup> Once the desired benefit is achieved, hydroquinone can be applied as often as needed in a once- or twice-daily regimen to maintain lightening of the skin. Because of the lack of safety data, hydroquinone is not recommended for children younger than 12 years. Contraindications to the use of hydroquinone include hypersensitivity to the product. Although not directly contraindicated, it should be used during pregnancy only if absolutely needed.<sup>19</sup>

Adverse effects, such as tingling or burning on application, are mild with low concentrations of topical

hydroquinone.<sup>11</sup> Patients may want to apply the agent to a small test area and check for signs of irritation after 24 hours. Higher concentrations frequently irritate the skin and, if used for prolonged periods, may cause side effects, including epidermal thickening, ochronosis, and colloid milium.<sup>11,19</sup>

The effectiveness of hydroquinone varies among patients. Results are best on lighter skin and lighter lesions. In dark skin, the response to hydroquinone depends on the amount of pigment present. Although treatment may not lead to complete disappearance of hypermelanosis, the results are often satisfactory enough to reduce self-consciousness. A disadvantage of treatment with hydroquinone is that it tends to overshoot the intended degree of lightening and may produce treated areas that are lighter than the surrounding normal skin color. Therefore, the patient must carefully observe the degree of lightening as the treatment progresses and must subsequently decrease applications when sufficient lightening has occurred.

A decrease in skin color usually becomes noticeable in about 4 weeks; however, the time of onset varies from 3 weeks to 2 months. The reduced pigmentation lasts for 2-6 months but can be reversed by exposing skin to UVR. Although sunscreens may help to prevent repigmentation, even visible light may cause some darkening. Therefore, a sunscreen containing opaque ingredients, such as zinc oxide or titanium dioxide, is preferable for sun protection.<sup>2</sup> Some nonprescription hydroquinone products are formulated to include a sunscreen.

In some cases, lesions become slightly darker before fading. A transient inflammatory reaction may develop after the first few weeks of treatment. Inflammation makes subsequent lightening more likely, although inflammation can occur without subsequent depigmentation. Mild inflammation is not an indication to stop therapy except when the reaction increases in intensity, at which point a patch test for allergy to hydroquinone can be done. Most reactions, however, are irritant rather than allergic in nature. Topical hydrocortisone may be used temporarily to alleviate the inflammatory reaction. A few cases of reversible brown discoloration of nails after application of hydroquinone have been reported.<sup>20</sup>

## Alternative Agents

### Synthetic Oligopeptide

A clinical trial demonstrated that synthetic oligopeptide 0.01% produced improvement in hyperpigmentation. The oligopeptide's mechanism of action, inhibiting tyrosinase, is similar to that of hydroquinone. The study found that the product was well tolerated and less toxic than hydroquinone. This agent is currently available only in the nonprescription product Lumixyl. It has not been approved by FDA as a skin-bleaching product. A pea-size amount should be applied twice daily, with results expected in 8-16 weeks.<sup>21-23</sup>

### Kojic Acid

Kojic acid, a product derived from certain species of fungus (e.g., *Acetobacter*, *Aspergillus*, and *Penicillium*), can be found in cosmetic products promoted for the treatment of hyperpigmentation. This product is usually found in combination with AHAs, with or without hydroquinone. It is dosed and applied according to the product type (e.g., cream, soap, lotion, and drops). Kojic acid works by inhibiting the production of tyrosinase. Adverse effects associated with this product include contact dermatitis and erythema. One study comparing the combination of kojic acid and glycolic acid with that of hydroquinone and glycolic acid demonstrated similar results between the two therapies.<sup>3,10-12</sup>

### Rucinol

Rucinol is a resorcinol derivative that has a unique mechanism of action that inhibits both tyrosinase and tyrosinase-related protein-1 (TRP-1), which is an enzyme used in melanin synthesis.<sup>10,13</sup> Several studies have demonstrated that rucinol serum or cream, applied twice daily, improved pigmentation within 8-12 weeks and was tolerated well.<sup>10,13,23</sup>

### Tranexamic Acid

Tranexamic acid (trans-4-aminomethylcyclohexanecarboxylic acid) is an agent that has been available for many years but is receiving more attention as a result of the hydroquinone controversy. It works by inhibiting plasmin.<sup>9,13,24</sup> Plasmin indirectly leads to decreased tyrosinase activity in melanocytes. Although some studies have shown no benefit, a few have shown improvement within 12 weeks of beginning use.<sup>24</sup> Studies have evaluated topical, intravenous, and oral dosage forms. The most common side effects of the topical form were irritation to the applied area. Currently, tranexamic acid can be found as an adjunct ingredient in some nonprescription serums.

### Mandelic Acid

Mandelic acid is one type of AHA and is derived from almonds. It is used in the treatment of several skin conditions, including hyperpigmentation. When combined with salicylic acid and administered as a peel, it has fewer side effects than a glycolic peel and has demonstrated better efficacy.<sup>25</sup>

### Niacinamide

Niacinamide is a form of vitamin B<sub>3</sub>. Although most pharmacologic treatments of hyperpigmentation disrupt tyrosinase activity, niacinamide instead works by preventing the transfer of melanin to keratinocytes. Another form of

vitamin B<sub>3</sub>, niacin, has been shown to significantly decrease hyperpigmentation and is associated with only mild side effects.<sup>26-27</sup>

### Product Selection Guidelines

Product selection should be based on a suitable dosage form (e.g., cream, lotion, or gel) for the patient's skin type (dry, normal, or oily) and anatomic site (face or neck). For example, an emollient cream-based product may be more suitable for dry skin, whereas a gel-based preparation may be preferable for an oily skin type.

### Assessment of Skin Hyperpigmentation: A Case-Based Approach

Assessment should involve evaluating the affected areas to determine whether they are characteristic of freckles, melasma, or lentiginos. The patient's medication history and health status are important factors in pinpointing possible causes of the hyperpigmentation.

Case 39-1 is an example of the assessment of a patient with skin hyperpigmentation.

#### Case 39-1

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient has been experiencing darkening areas of skin on her forehead, which first appeared 6 months ago.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient says that she has been on an oral contraceptive for 2 years. The skin areas appear darker when the patient spends more time in sunlight.
c. description of the patient's efforts to relieve the symptoms	The patient has tried topical moisturizing lotions and hydroquinone 2% per the pharmacist's recommendation 3 months ago, but she has seen little improvement. Patient inquires about trying Lumixyl next.
d. patient's identity	Judy Blume
e. age, sex, height, and weight	20 years old, female, 5 ft 6 in., 160 lb
f. patient's occupation	Full-time college student
g. patient's dietary habits	Diet is well balanced. She drinks wine and beer occasionally.
h. patient's sleep habits	She averages 5 hours per night during the week and 10 hours on the weekend.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Birth control: Yaz 1 tablet every day; headaches or menstrual cramps: ibuprofen 200 mg as needed; polycystic ovaries: Glucophage XR 500 mg daily
j. allergies	None

k. history of other adverse reactions to medications	None
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	The patient has hyperpigmentation on her forehead, which appeared 6 months ago. Patient started taking an oral contraceptive agent 2 years ago, which may have contributed to the hyperpigmentation. The areas turn darker when exposed to sunlight, but they have not really changed since they appeared.
3. Identify exclusions for self-treatment (Figure 39-1).	The patient has tried OTC products, including hydroquinone, unsuccessfully for 3 months.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Judy to a health care provider or dermatologist for further evaluation. (2) Discontinue oral contraceptive. (3) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Patient should be referred to a health care provider or dermatologist because the OTC treatment has been unsuccessful.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Because you have tried self-treatment unsuccessfully for 3 months, you should see a health care provider or dermatologist for further evaluation."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Continuing treatment with the current product or trying another OTC option will most likely not provide any benefit. A health care provider or dermatologist can evaluate your condition and suggest other treatments."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"A friend told me about Lumixyl. Can't I try it first?"
Answer the patient's or caregiver's questions.	"Lumixyl is not FDA approved yet. Hydroquinone is currently the best OTC product available, and because you tried it for 3 months with no improvement, I would recommend that you be seen for further evaluation."
<b>Evaluation of Patient Outcomes</b>	

9. Assess patient outcome.

Contact the patient in a couple of days to ensure that she made an appointment for further evaluation.

Key: FDA = Food and Drug Administration; NA = not applicable; OTC = over-the-counter.

### Patient Counseling for Skin Hyperpigmentation

The types of hyperpigmentation that are self-treatable should be explained to the patient, and the importance of avoiding sun exposure during and after treatment should be stressed. The product instructions should be reviewed with the patient to ensure a successful therapeutic outcome. The box Patient Education for Skin Hyperpigmentation lists specific information to provide patients.

#### Patient Education for Skin Hyperpigmentation

The objective of self-treatment with skin-bleaching products is to diminish the degree of pigmentation in affected areas. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Hydroquinone

- Use hydroquinone to lighten only limited areas of hyperpigmented skin that show brownish discoloration.
- Do not use these products on nevi (moles) or reddish or bluish areas, such as port wine discoloration.
- Time to initial response averages 6-8 weeks, but it may take up to 3 months to see noticeable results.
- Test for possible irritant reactions to the product by applying it to a small test area and by checking the area for redness, itching, or swelling after 24 hours.
- Do not apply the product near the eyes or to damaged skin.
- Apply a thin layer of the product to clean, dry skin in the affected area only. Rub product into the skin gently but thoroughly.
- If moisturizers or other topical agents are being used at the same time, apply the hydroquinone first.
- When you are outdoors for even a short time, apply an opaque sunblock or broad-spectrum sunscreen (see Chapter 38) to the affected area after applying the hydroquinone, unless the product already contains a sunscreen in the formulation.
- Once the desired lightening of skin is reached, apply the hydroquinone once or twice daily to prevent hyperpigmentation from recurring. Continue to protect the treated area from sun exposure.

#### When to Seek Medical Attention

- Consult a primary care provider if:
  - No improvement is seen after 3 months of using hydroquinone.
  - Skin pigmentation becomes darker during treatment with hydroquinone.

#### Evaluation of Patient Outcomes for Skin Hyperpigmentation

Follow-up on the patient's progress should occur after 3 months of therapy. Follow-up can be achieved through a telephone call or a scheduled visit. If the pigmented area shows no improvement, the patient should consult a primary care provider or a dermatologist. If the desired outcome has been achieved, the patient should continue applying the agent once or twice daily to maintain lightening of the skin.

#### Photoaging

Photoaging, also referred to as premature aging or dermatoheliosis, is the pattern of characteristic skin changes associated with sun exposure. Most fair-skinned Americans will have some signs of photodamaged skin by 50 years of age. A variety of therapies are available to treat photodamaged skin; these therapies range from use of topical products and cosmetics to more invasive procedures such as face-lifts, botulinum toxin A injections, and laser resurfacing. Although some products are available by prescription only, many others are nonprescription, with AHAs being widely used to combat photoaged skin.<sup>28</sup>

#### Pathophysiology of Photoaging

Aging skin results from a combination of intrinsic and extrinsic factors. Clinical and histologic changes that occur intrinsically include genetically controlled skin and muscle changes, expression lines, sleep lines, and hormonal changes. The second component, extrinsic aging, relates to environmental influences such as UVR, smoking, wind, and chemical exposure.<sup>29-31</sup> Medications known to induce photosensitivity can contribute to photoaging by making the skin sensitive to UVR (see Chapter 38).

Prematurely aged facial skin, with creases and wrinkles, dry texture, and blotchy hyperpigmentation, is largely attributed to cumulative UVR, or photoaging. Exposure to ultraviolet B (UVB) (290-320 nm) is primarily responsible for photoaging, although the longer ultraviolet A (UVA) wavelengths (320-400 nm) also contribute to damage. The amount of UVA present in sunlight is 10 times that of UVB, which allows greater amounts of skin exposure. UVA can penetrate into the deeper dermal layer and can work synergistically with UVB to cause photodamage and skin cancers.

Microscopically, sun-damaged skin shows dysplasia (abnormal tissue development), atypical keratinocytes, and occasional cell necrosis. Irregularity of epidermal cell alignment is also common. Loss of collagen and elastin is seen deeper in the dermal layer.<sup>29-31</sup>

### Clinical Presentation of Photoaging

Clinical signs of photoaging include changes in color, surface texture, and functional capacity (Table 39-3). Photoaged skin may have a sallow yellow color with discoloration and may show telangiectasias (visible distended capillaries). Textural changes include loss of smoothness, loss of subcutaneous tissue around the mouth, and epidermal thinning around the lips. As sebaceous glands hypertrophy, the skin begins to show coarse texture with increased pore size. In addition, fine vellus hairs can develop into unwanted terminal hairs. Other manifestations of photoaged skin may include development of precancerous (actinic keratosis) and cancerous (basal cell, squamous cell, and melanoma) tumor development.<sup>28-31</sup> Cosmetically, patients may notice freckling, discolorations, or “crow’s feet” (small parallel lines around the eyes). Postmenopausal skin is susceptible to reduced estrogen receptor stimulation of dermal metabolism and undergoes significant changes in collagen and moisture content. These changes lead to signs of skin aging, as evidenced by diminished elasticity and wrinkles.<sup>32</sup>

**TABLE 39-3 Glogau Classification of Photoaging**

Type I (Mild)	No wrinkles, early photoaging, mild pigment changes 20-30 years of age
Type II (Moderate)	Wrinkles in motion, early-to-moderate photoaging, keratoses palpable 30-40 years of age
Type III (Advanced)	Wrinkles at rest, advanced photoaging, obvious dyschromia and keratoses ≥50 years of age
Type IV (Severe)	Only wrinkles, severe photoaging, yellow-gray skin ≥60 years of age

Source: Glogau RG. Aesthetic and anatomic analysis of the aging skin. *Semin Cutan Med Surg.* 1996;15(3):134-8.

### Treatment of Photoaging

#### Treatment Goals

The first goal is to prevent or minimize the likelihood of skin photoaging by using appropriate sun protection, including sunscreens.<sup>33</sup> The goals of treating photoaging are to (1) reverse cumulative skin damage with prescription and nonprescription products and (2) maintain the skin and protect it from further extrinsic damage by making lifestyle changes and, most important, protecting the skin from further and prolonged sun exposure.

#### General Treatment Approach

The first step in preventing and treating photoaged skin is for the patient to commit to daily sun protection. Broad-spectrum sunscreens (UVA and UVB coverage) with a sun protection factor (SPF) of 15 or greater can minimize further photodamage during UVR exposure<sup>29</sup> (see Chapter 38).

Proper cleansing of the skin removes bacteria, dirt, desquamated keratinocytes, cosmetics, sebum, and perspiration. However, excessive use of soap leads to xerosis, eczematous dermatitis, and other skin conditions.<sup>34</sup>

#### Pharmacologic Therapy

Within the vast array of available nonprescription products for skin care, the division of categories is blurred. Cosmetics and moisturizers are not pharmaceuticals, whereas antiperspirants and sunscreens are considered nonprescription pharmaceuticals. Although “cosmeceuticals” are an undefined category of products recognized by providers and dermatologists, no final regulatory guidance is currently available for these products from FDA. Many

cosmeceutical ingredients, such as AHAs, function as active pharmaceuticals that are known to have a sustained effect on the skin.<sup>35</sup>

Various topical products are being used to treat aging skin. These products include coenzyme Q10, *N*-furfuryladenine (Kinerase), AHAs, and beta hydroxy acids (BHAs). Of the vitamins, only A, C, B<sub>3</sub>, and E have the most evidence supporting their use in treatment and/or prevention of photoaging.<sup>36</sup>

### Alpha and Beta Hydroxy Acids

Current labeling on AHA cosmetic products includes recommendations for melasma, acne, solar lentigines, and fine wrinkling of photoaging.<sup>10</sup> The AHAs are used in various concentrations and in a wide array of available products. Most AHAs are sold as cosmeceuticals; however, some are sold as cosmetics, and yet others are sold as pharmaceuticals through a primary care provider. These products range in concentration from 2% to 20% (as nonpeeling AHAs). As peeling agents (as used by estheticians or dermatologists), they come in concentrations greater than 20%.

Of the available nonprescription products, AHAs currently play a major role in reliably reversing and cosmetically improving aging skin.<sup>10,37</sup> Many types of AHAs are available, with the most common being lactic and glycolic acids (Table 39-4). The Cosmetic Ingredient Review Expert Panel, the cosmetic industry's self-regulatory body, concluded that use of AHAs in cosmetic products is safe if (1) concentrations are less than or equal to 10%, (2) the final pH is greater than or equal to 3.5, and (3) the product is formulated with a sunscreen or includes directions to use a sunscreen.<sup>38</sup>

**TABLE 39-4 Selected Nonprescription Products for Photoaged Skin**

<i>Trade Name</i>	<i>Active Ingredients</i>
<b>Alpha Hydroxy Acid Products</b>	
DermaQuest Skin Therapy	Glycolic acid 5%; azelaic acid 2.5%; salicylic acid 2%
Dr. Michelle Copeland AHA Face Cream	Glycolic acid 10%
M.D. Forte Facial Cleanser III	Glycolic acid 20%
Alpha Hydrox AHA Enhanced Anti-Wrinkle Crème	Glycolic acid 10%
Aqua Glycolic Hand and Body Lotion	Glycolic acid 14%
Peter Thomas Roth Glycolic Acid Hydrating Gel	Glycolic acid 10%
DDF Glycolic Exfoliating Oil Control Gel	Glycolic acid 10%
Reviva Labs Glycolic Acid Cream Exfoliation and Cell Renewal	Glycolic acid 10%
Alpha Hydrox AHA Souffle	Glycolic acid 12%
Peter Thomas Roth Glycolic Acid Moisturizer	Glycolic acid 10%
<b>Beta Hydroxy Acid Products</b>	
Paula's Choice Exfoliating 2% BHA Lotion	Salicylic acid 2%
Peter Thomas Roth Beta Hydroxy 2% Acne Wash	Salicylic acid 2%

Of the BHAs, salicylic acid is used widely, even as a chemical peel.<sup>39-40</sup> Compared with AHA products, BHAs are more lipophilic and demonstrate keratolytic effects. Products containing BHAs as the active ingredients may be beneficial to acne-prone skin.

Polyhydroxy acids are the new generation of AHAs that appear to have results similar to those of the alpha and beta hydroxy products, but with less irritation.<sup>33</sup>

Used appropriately, AHA products act as exfoliants by causing detachment of keratinocytes, resulting in a smoother, nonscaly skin surface with eventual normalization of keratinization. The effect of the AHA product depends on the concentration and pH.<sup>33</sup> The lower the pH, the more effective the product, and the higher the AHA concentration, the more deeply it affects the stratum corneum. By improving skin elasticity, AHAs have been shown to make skin more

flexible and less vulnerable to cracking and flaking. Long-term use has led to an increase in skin collagen and elastin.<sup>33,37</sup> Regular application of AHAs results in smoother skin texture, lessening of fine lines, and normalization of pigmentation.<sup>37</sup>

Guidelines for treatment with AHAs include identification of patient factors such as medications, prior procedures, and medical history, all of which may affect treatment outcome and realistic patient expectations.<sup>41</sup> Care should be taken to apply AHAs to completely dry skin, with an estimated wait time of 10-15 minutes after cleansing the face. It is also prudent to begin application gradually, starting every other night for approximately 1 week and then increasing as tolerated to a maximum of twice-daily application. AHA products may make the skin more sensitive to sun exposure. Patients should be advised to use daily sunscreen or sunblock with an SPF of 15 or greater during use of AHAs and after their discontinuation.<sup>29</sup>

Common adverse effects of AHA and BHA products include mild, transient stinging, burning, pruritus, skin lightening, and dryness. BHA products may be less irritating. Many of these effects can be ameliorated if products are used with caution and proper counseling. Patients should also note that other topically applied products, both medications and cosmetics, may contain active ingredients capable of exacerbating irritation (e.g., AHA, BHA, and hydroquinone).

### Retinol and Retinaldehyde

Retinol has been incorporated into many skin care products. It is very unstable and, with light exposure, easily degrades to biologically inactive forms.<sup>33</sup> Retinol is transformed into retinaldehyde and then into retinoic acid with a two-step enzymatic process involving dehydrogenase in human keratinocytes. Topical retinaldehyde not only is well tolerated by human skin but has also been shown to have several effects identical to that of tretinoin.

### Ascorbic Acid (Vitamin C)

Ascorbic acid (vitamin C) is a plentiful antioxidant in the skin.<sup>33</sup> It neutralizes reactive oxygen species caused by UV irradiation and functions as a scavenger of free radicals. Ascorbic acid could be used topically for the prevention and correction of human skin aging. Several studies with human volunteers have appeared in the literature in the past few years that suggest some anti-aging potential after topical ascorbic acid application. It is also reported that ascorbic acid has at least some photoprotective properties.

### Idebenone

Ubiquinone (ubidecarenone; coenzyme Q10) is a lipophilic antioxidant that is synthesized by all mammalian cells and is critical for the protection of mitochondrial membranes.<sup>33</sup> Idebenone is a synthetic derivative of ubiquinone that is more soluble and has potent antioxidant properties. It has been suggested that by quenching free radicals in the epidermis, it has a beneficial effect on preventing and/or reversing photoaging. These products are often found in cosmetic creams and lotions promoted as anti-aging and/or antioxidant products.

### Product Selection Guidelines

Skin type should determine the product type chosen. Creams are appropriate for drier skin types, lotions are best for combination or normal skin, and gels or solutions are useful for oilier skin. Use of products with higher concentrations and a lower pH may produce faster results. However, the patient should be warned that these products may also cause greater skin irritation.

There are limited data on the safety of AHAs in special populations, such as pregnant or lactating women and pediatric and geriatric populations. AHA products appear to be safe when used topically in adults.<sup>42</sup>

### Assessment of Photoaging: A Case-Based Approach

If visual inspection of the patient's skin indicates photoaging, the patient should be questioned about his or her history of UVR (sunlight as well as artificial light) exposure. Knowing whether the patient's current occupational or recreational habits require excessive exposure is useful not only in determining the cause of the skin disorder but also in developing a treatment plan. It is important to assess for a history of diseases or medications that may predispose the patient to premature photodamage or photosensitivity. The patient's health status, lifestyle practices, and daily skin maintenance regimen are other pertinent assessment criteria.<sup>28</sup>

Case 39-2 is an example of assessment of a patient with photoaging.

### Case 39-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>

<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of observable photoaging on her skin, which includes increased pore size, wrinkles, dry skin, and dark skin pigmentation.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	These skin changes have been occurring over the past several years and are progressively becoming more noticeable.
c. description of the patient's efforts to relieve the symptoms	She uses daily moisturizer but wants to "clean up her face" with something stronger.
d. patient's identity	Dora Norris
e. age, sex, height, and weight	50 years old, female, 5 ft 4 in., 145 lb
f. patient's occupation	Executive assistant
g. patient's dietary habits	Patient eats fast food often while running errands for her boss. She denies drinking alcohol.
h. patient's sleep habits	Normal sleep schedule; she averages 7 hours per night.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Asthma: Advair 250/50 mcg 1 puff twice daily, Ventolin HFA as needed; osteoporosis prevention: calcium 600 mg + vitamin D 400 international units
j. allergies	None
k. history of other adverse reactions to medications	None
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	The patient has increased pore size, wrinkles, dry skin, and hyperpigmented areas on her face caused by photoaging.
3. Identify exclusions for self-treatment.	The patient has no exclusions for self-treatment.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or	Options include: (1) Refer Dora to a health care provider or dermatologist for further evaluation. (2) Recommend a 2-month trial of an OTC AHA product and use

Share this information with the patient or caregiver.	(2) Recommend a 2-month trial of an OTC AHA product and use of daily sunscreen. (3) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The patient would like to try an OTC product.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Apply chosen AHA product, such as Thomas Roth Glycolic Acid Hydrating Gel, to clean, dry face. Wait about 10 minutes after cleansing face to apply. Start out applying every other night for 1 week, and increase as tolerated to a maximum of twice daily."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Seeing a dermatologist may not be necessary with proper use of this product. Wrinkles will not be completely removed because they are part of the natural aging process."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	"AHA product should be applied to a clean, dry face. Wait 10-15 minutes after drying face before applying product. Start out gradually with 1 application every other day, and increase to a maximum of twice daily as tolerated."
b. maximum number of days the therapy should be employed	"Improvement may be seen in as little as 4 weeks but may take as long as 2 months."
c. product administration procedures	"The product should be applied after cleansing the face."
d. expected time to onset of relief	"Improvement is usually seen in 1 month."
e. degree of relief that can be reasonably expected	"Fine lines may be reduced, pore size may decrease, and dryness should be improved. All signs of wrinkles, however, may not completely disappear."
f. most common side effects	"Mild irritation may occur. In addition, the areas being treated may appear to be lighter than surrounding skin."
g. side effects that warrant medical intervention should they occur	"If the treated areas of skin become severely irritated or darken significantly, you should see your health care provider or a dermatologist."
h. patient options in the event that condition worsens or persists	"If no improvement is seen within 2 months, you should see your health care provider or a dermatologist."

i. product storage requirements	“When not in use, the product should be stored at normal room temperature and tightly closed.”
j. specific nondrug measures	“This product may make the skin more sensitive to sun exposure. A sunscreen with an SPF of at least 15 should be applied daily while using this product and for up to a week afterward.”
Solicit follow-up questions from the patient or caregiver.	(1) “May I use this product more than twice a day?” (2) “Should I always wear sunscreen or only when I am using this product?”
Answer the patient’s or caregiver’s questions.	(1) “No. This product should be used a maximum of twice daily.” (2) “This product will increase the overall sensitivity of your skin to the sun. In addition because you are in the car often during your workday, it is advisable to use a daily moisturizer or foundation with an SPF of at least 15.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Ask the patient to call you to update you on her response to your recommendation; or you could call her in a month to evaluate response.

Key: AHA = Alpha hydroxy acid; NA, = not applicable; OTC = over-the-counter; SPF = sun protection factor.

### Patient Counseling for Photoaging

Patients should be advised that premature wrinkling, creases, dry texture, and blotchy hyperpigmentation are not inevitable.<sup>30</sup> The provider should be proactive in identifying and recommending products that are appropriate for a specific patient. The box Patient Education for Photoaging lists specific information to provide patients.

#### Patient Education for Photoaging

The objectives of self-treatment are to (1) reverse skin damage by using available nonprescription products and (2) protect the skin from further damage by making lifestyle changes and protecting skin from sun exposure. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Alpha Hydroxy Acids

- Protect the skin from sun exposure by covering it with clothing. FDA recommends advising patients to wear long-sleeved clothing and hats with brims of at least 4 inches. Patients should also use a sunblock or sunscreen product with an SPF of 15 or greater during use of alpha hydroxy acids (AHAs) and regularly in the future to prevent further damage.
- To prevent dry skin, cleanse the skin with a mild soap or a soap-free liquid cleanser. Do not cleanse skin more often than twice daily. Apply a pea-sized amount of an AHA product to clean, dry skin.
- To minimize transient mild tingling and stinging, wait 10-15 minutes after cleansing the face to apply an AHA product.
- Excessive skin dryness or irritation warrants decreased application.
- Note that AHA products contain an active ingredient and that the use of other products, including cosmetics, could result in skin irritation, including mild stinging, burning, or erythema.
- Do not apply the product too close to the eyes or mucous membranes.
- Begin applying this product once at bedtime every other day for approximately 1 week. Gradually increase application to twice a day.
- Use a daily moisturizer with sunscreen after applying the AHA product to minimize dry skin and maintain the antiphotaging effect.
- Store this product in a cool dry place out of children’s reach.
- Discontinue the AHA product if severe irritation, such as redness or excessive dryness, or a rash occurs.

## Evaluation of Patient Outcomes for Photoaging

Patients treated with nonprescription products for photoaging should set a reasonable goal. Obviously, these preparations cannot “erase wrinkles.” The provider should monitor the progress of the treatment and be sensitive to issues that may require medical referral.

### Key Points for Skin Hyperpigmentation and Photoaging

- Photoaging and hyperpigmentation are cosmetically unacceptable skin conditions. Patients who have reasonable expectations should be able to achieve even skin tone and to minimize appearance and occurrence of fine wrinkling with the use of nonprescription products.
- Hydroquinone is the only FDA-approved nonprescription skin-bleaching product. Patients should apply a 2% concentration to skin up to twice daily, as tolerated.
- Patients younger than 12 years, those with large areas of hyperpigmentation or disease- or drug-induced hyperpigmentation, or those with lesions that have changed in size, shape, or color should consult their primary care provider.
- Patients should be referred to a primary care provider if no improvement occurs within 3 months or if skin darkens during treatment of hyperpigmentation.
- Patients should avoid applying hydroquinone-containing products near the eye area or on damaged skin areas.
- Patients using AHAs to reduce photoaging should be advised to apply AHAs up to twice daily to dry skin. Patients who do not see a desired improvement in skin appearance in 2 months or who experience excessive irritation or drying of the skin should contact their primary care provider.
- Patients who use products to prevent photoaging or hyperpigmentation should be instructed to protect their skin from daily sun exposure by using a sunscreen with SPF 15 or greater to maintain results.

**Handbook of Nonprescription Drugs > Chapter 40. Minor Burns, Sunburn, and Wounds****Minor Burns, Sunburn, and Wounds: Introduction**

Pharmacists often provide guidance to consumers needing treatment for minor burns and wounds. A quick assessment helps to identify appropriate products and procedures to manage cuts, burns, and scrapes and to speed the healing process. Burn and wound care management can be quite resource intensive, with much of the cost related to fees for emergency department visits and the expense of the medications and supplies used for wound healing. Thousands of people seek medical treatment for skin injuries each year. For example, approximately 450,000 patients per year are estimated to receive burn injuries that require medical treatment.<sup>1</sup> Because patients commonly use self-care in burn and wound management, a thorough knowledge of skin injuries and how they heal is essential. Although the skin is well adapted to heal minor burns and wounds over time, use of the proper dressing and appropriate use of antiseptics and antibiotics will facilitate healing, minimize scar formation, and prevent secondary bacterial skin infections. All health care providers must perform an accurate assessment of the injury to determine whether self-care or referral for further evaluation is appropriate.

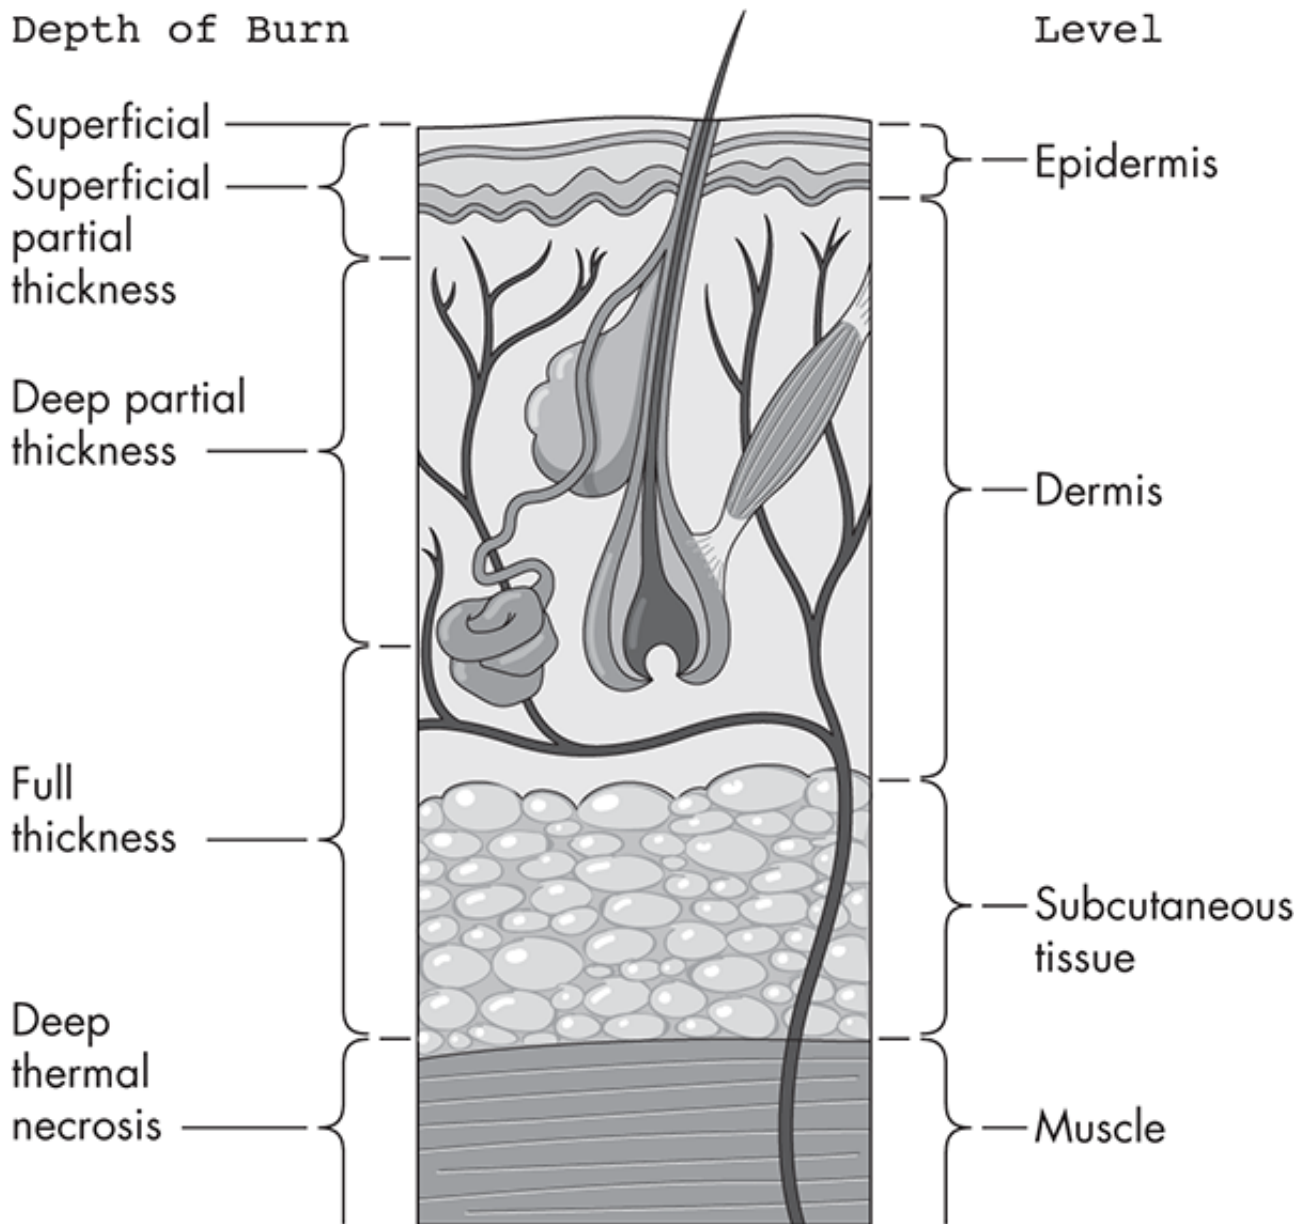

**Pathophysiology of Minor Burns, Sunburn, and Wounds**

Skin injuries are described according to the cause and depth of damage. Acute wounds include burns, abrasions, punctures, and lacerations. These wounds are typically caused by trauma, and with proper care, tend to heal within 1 month in healthy adults. On the other hand, any wound that does not heal properly through the normal stages of wound healing is considered a chronic wound and requires triage with more intense medical care. Chronic wounds will not be discussed in this chapter.

*Burns* are wounds caused by thermal, electrical, chemical, or ultraviolet radiation (UVR) exposure.

*Thermal burns* result from skin contact with flames, scalding liquids, or hot objects (e.g., irons, oven broiler elements, hot pans, curling irons, or radiators) or from the inhalation of smoke or hot vapors. [Figure 40-1](#) shows a cross-section of the anatomy of the skin and the depths of injury caused by thermal burns. (See [Chapter 32](#) for further discussion of skin anatomy and physiology.)

Cross-section of skin showing depth of burns.

*Chemical burns* occur secondary to exposure to corrosive or reactive chemicals that cause tissue damage, ulceration and sloughing. The necrotic tissue often acts as a reservoir allowing continued absorption of the chemical. This may result in prolonged cutaneous damage and tissue injury.<sup>2</sup> If not adherent to the skin, clothing that has been exposed to chemicals should be removed to prevent continued burn insult to the affected skin. The provider should refer all patients with chemical burns to the emergency department for evaluation.

*Sunburn* is caused by too much exposure to ultraviolet A (UVA) and ultraviolet B (UVB) light produced from natural sunlight and by commercial tanning beds and tanning lamps. (see Color Plates, photograph 24).<sup>3</sup> (See [Chapter 38](#) for a discussion of UVR bands.) Photosensitive reactions (phototoxicity and photoallergy) are related to the coadministration of drugs and chemicals but are often mistaken as sunburn (see Color Plates, photographs 25 and 26). The clinical presentation of phototoxicity includes erythema that resembles sunburn, which desquamates (peels) within several days.<sup>4</sup>

*Abrasions* usually result from a rubbing or friction injury to the epidermal portion of the skin and extend to the uppermost portion of the dermis. *Punctures* usually result from a sharp object that has pierced the epidermis and may reach into the dermis or deeper tissues. *Lacerations* result from sharp objects cutting through the various layers of the skin.<sup>5</sup>

Self-treatment of acute wounds such as abrasions, lacerations, punctures, and burn wounds that do not extend beyond the dermis is generally deemed appropriate.

Understanding the physiology of wound healing is just as important as understanding the pathology of the wound itself. Skin integrity depends on a delicate balance between structure and function. When a burn or wound disturbs this balance, prompt restoration is required to ensure body homeostasis and proper wound healing. Wound healing

begins immediately after injury and consists of three overlapping phases: inflammatory, proliferative, and maturation (remodeling).<sup>6</sup>

The *inflammatory phase* is the body's immediate response to injury. This phase, which lasts approximately 3-4 days, is responsible for preparing the wound for subsequent tissue development and consists of two primary parts: hemostasis and inflammation. Hemostasis is initiated by the release of thromboplastin from injured cells to form a clot to stop bleeding and allow healing to proceed. Later in the inflammatory phase, debris and bacteria are removed from the wound bed. Collagen is formed to stimulate wound healing, and epithelial cells migrate to cover the wound bed and provide the initial (one-cell-thick) layer of new skin that will cover the wound.<sup>6</sup>

In the next phase of healing, the *proliferative phase*, the wound is filled with new connective tissue and covered with new epithelium. This phase starts on about day 3 and continues for about 3 weeks. It involves the formation of granulation tissue, which is a collection of new connective tissue (fibroblasts and newly synthesized collagen), new capillaries, and inflammatory cells.<sup>6</sup>

The final phase of healing is known as the *maturation or remodeling phase*. This is the longest phase, beginning at about week 3, when the wound is completely closed by connective tissue and resurfaced by epithelial cells. It involves a continual process of collagen synthesis and breakdown, replacing earlier, weak collagen with high-tensile-strength collagen; this process peaks approximately 60 days after the injury occurred.<sup>6</sup>

Several local and systemic factors can affect how efficiently and to what extent a wound will heal. Local factors include tissue perfusion and oxygenation, infection, and wound characteristics. The most important systemic factors that can affect the healing process are poor vascularization, bacterial contamination, inadequate nutrition, coexisting medical conditions, and medications.

Poor vascularization delays wound healing. The resulting poor oxygenation leads to impaired leukocyte activity, decreased production of collagen, decreased epithelialization, and reduced resistance to infection. Common disorders that may cause decreased perfusion include diabetes, severe anemia, hypotension, peripheral vascular disease, and congestive heart failure.<sup>7</sup>

Wound infection occurs when there is deposition and multiplication of organisms in tissue with an associated host reaction. Some wound infections are caused by fungi and protozoa, but most minor wound infections are caused by bacteria, especially *Streptococcus pyogenes*, *Enterococcus faecalis*, and *Staphylococcus aureus*. When the number of bacteria is excessive, wounds can become infected. Localized infection in the wound delays collagen synthesis and epithelialization, prolongs the inflammatory phase, and causes additional tissue destruction.<sup>8</sup>

Adequate nutrition provides the building blocks for wound repair. Protein, carbohydrates, vitamins, and trace elements are needed for collagen production and cellular energy.<sup>9</sup> Vitamin supplements are commonly used to manage wound healing. Vitamin C has many roles in wound healing, and a deficiency in this vitamin has multiple effects on tissue repair. Vitamin C deficiencies result in impaired healing and have been linked to decreased collagen synthesis and fibroblast proliferation, decreased angiogenesis, and increased capillary fragility. Also, vitamin C deficiency leads to an impaired immune response and increased susceptibility to wound infection. Vitamin E also has anti-inflammatory properties and has been suggested to have a role in decreasing excess scar formation in chronic wounds. Animal experiments have indicated that vitamin E supplementation is beneficial to wound healing and topical vitamin E has been widely promoted as an antiscarring agent.<sup>10</sup>

It is commonly recognized that, in healthy older adults, the effect of aging causes a temporal delay in wound healing but not an actual impairment in terms of the quality of healing.<sup>11</sup> Patients who are obese have problems with poor perfusion (adipose tissue lacks blood flow) and tend to have delayed wound healing.<sup>12</sup>

Poorly controlled diabetes is usually associated with reduced collagen synthesis, impaired wound contraction, delayed epidermal migration, and reduced polymorphonuclear leukocyte chemotaxis and phagocytosis. Strict professional attention should be given to wounds in patients with diabetes because of these inherent difficulties.<sup>13</sup>

Some medications have the capacity to affect wound healing, such as those that interfere with clot formation or platelet function or with inflammatory responses and cell proliferation. Glucocorticosteroids inhibit wound repair through global anti-inflammatory effects and suppression of cellular wound responses, including fibroblast proliferation and collagen synthesis. Systemic steroids cause wounds to heal with incomplete granulation tissue and reduced wound contraction. In addition, chemotherapeutic drugs delay cell migration into the wound, decrease early wound matrix formation, lower collagen production, impair proliferation of fibroblasts, and inhibit contraction of wounds.<sup>12</sup> Patients who are taking these medications should be carefully followed by a wound care specialist to ensure that proper healing occurs.

Local features that may impair wound closure include poor oxygenation resulting from inadequate perfusion, with chronic hypoxia and inflammation largely secondary to infection; the presence of necrotic tissue, eschar (i.e., scab), or foreign bodies (e.g., glass and dirt); inadequate moisture; and infection.<sup>14</sup> Providers who are aware of and can recognize problems associated with these local factors can provide more effective wound care management instructions to ensure faster wound healing.

### Clinical Presentation of Minor Burns, Sunburn, and Wounds

The clinical presentation of burns, sunburn, and wounds is largely determined by the depth of skin damage. For simplification, this depth classification (Figure 40-2) has been divided into four descriptive stages.

Copyright © American Pharmacists Association  
All rights reserved. Any use is subject to the Terms of Use.

Stages of wounds. **A: Stage I**, Nonblanchable erythema of intact skin with warmth and redness. **B: Stage II**, Superficial lesions with partial-thickness skin loss involving the epidermis with or without the dermis involved. **C: Stage III**, Full-thickness skin loss with damage to subcutaneous tissue. **D: Stage IV**, Full-thickness skin loss with extensive tissue necrosis and damage to underlying muscle, tendon, and bone.

*Stage I* skin injuries (i.e., minor sunburn and superficial burn) involve only the epidermis, with no loss of any skin layers, and consist primarily of reddened, nonblanching unbroken, nonblistering skin. Minor sunburn causes a superficial burn injury characterized by erythema and slight dermal edema that results from an increase in blood flow to the affected skin. The increased blood flow begins approximately 4 hours after exposure, peaking between 12 and 24 hours after exposure. Other superficial burns usually result from a brief exposure to low heat, causing a painful area of erythema similar to sunburn but without significant damage to epithelial cells. Avoidance of additional injury and symptomatic relief of pain and fever are usually the only treatment required. The majority of superficial burns can be managed through self-care or ambulatory care centers and will heal within 3-6 days.<sup>15</sup>

*Stage II* skin injuries (i.e., severe sunburn, abrasions, superficial lacerations and punctures, superficial partial-thickness burns, and deep partial-thickness burns) include blistering or partial-thickness skin loss that involves all the epidermis and part of the dermis. Because the injury involves a break in the skin, drainage from the wound area may occur, in addition to pain, edema, and erythema. Severe sunburns fall into this category and result in blisters that will desquamate or “peel” over a period of several days. There is a slight chance of bacterial infection because of the loss of the outer skin barrier (see Color Plates, photograph 24). Pain, edema, and skin tenderness accompany erythema. Systemic symptoms such as vomiting, low-grade fever, chills, weakness, and shock may be seen in patients in whom a large portion of the skin surface has been affected. After exfoliation and for several weeks thereafter, the skin will be more susceptible than normal to sunburn.<sup>15</sup> In addition to sun exposure, stage II burns result from higher levels of

heat or longer exposures than in superficial burns. Damage to the epidermis and dermis layers produces painful blistering and can be superficial partial-thickness or deep partial-thickness burns. These burns often occur from a splash or spill of hot liquid, brief contact with a hot object, flash ignition, chemical contact, and exposure to a flame. Stage II burns are painful and sensitive to temperature and air. In addition, blanching occurs, indicating loss of blood vessels to the area. The burn's appearance may be a patchy white-to-red area, and large blisters may be present. Pain may be more intense than in superficial burns because of the irritation to nerve endings, although some areas may lack sensation. Wound resurfacing can occur because of surviving nests of epithelial cells that line the hair follicles and sweat glands. In this case, healing may be slow and scarring is likely to occur.

Stage II burns are prone to infection because of the loss of barrier function and vasculature. Infection will worsen the severity of a burn injury or its depth, or both. If the damage does not involve the deeper proliferating area of the epidermis (e.g., superficial partial-thickness burns), rapid regeneration of a normal epidermis usually results within 2-3 weeks, with minimal or no scarring. If more of the dermis is involved (e.g., deep partial-thickness burns), the wound will take longer to heal (up to 6 weeks) and may cause thick scar formation (hypertrophic scarring or cheloid), as well as contractures of the skin and underlying tissues that can affect use of the involved areas.

Small stage II burns on 1%-2% of body surface area (BSA) can usually be managed through self-care. However, superficial partial-thickness burns that occur on a child or a patient with multiple medical problems or that cover more than 10% of BSA require hospitalization with fluid restoration. All stage II burns that fail to heal within 2-3 weeks or those that exhibit pain, redness, exudate formation, fever, odor, or malaise that persists days or weeks after the initial injury should be referred for medical evaluation. Finally, patients with deep partial-thickness burns should be examined in a hospital's emergency department. These burn injuries can convert to full-thickness injuries if not properly and promptly managed.<sup>15</sup>

*Stage III* skin injury (i.e., full-thickness burns and deep lacerations and punctures) includes full-thickness skin loss with damage to the entire epidermis, dermis, and dermal appendages and may involve subcutaneous tissue. Heat exposure that is more extensive than deep partial-thickness burns will cause death of the full thickness of skin in the affected area, resulting in a dry, leathery area that is painless and insensate. Deep punctures and lacerations can be quite painful. Deep lacerations bleed profusely, and underlying tissue layers may be visible in the wound bed. The body attempts to heal these wounds by sloughing off the dead layer and contracting the wound. Hospitalization is normally required for treatment of full-thickness burns.<sup>15</sup> Patients suffering from deep lacerations or punctures should seek emergency care as soon as possible.

*Stage IV* skin injury is an extension of *Stage III* stage III but also involves the subcutaneous tissue and underlying muscle, tendon, and bone.<sup>5</sup> Understanding these stages helps in selecting appropriate dressings for proper wound closure.

Figures 40-1 and 40-2 illustrate the depth and associated stages of skin injury.

## Treatment of Minor Burns, Sunburn, and Wounds

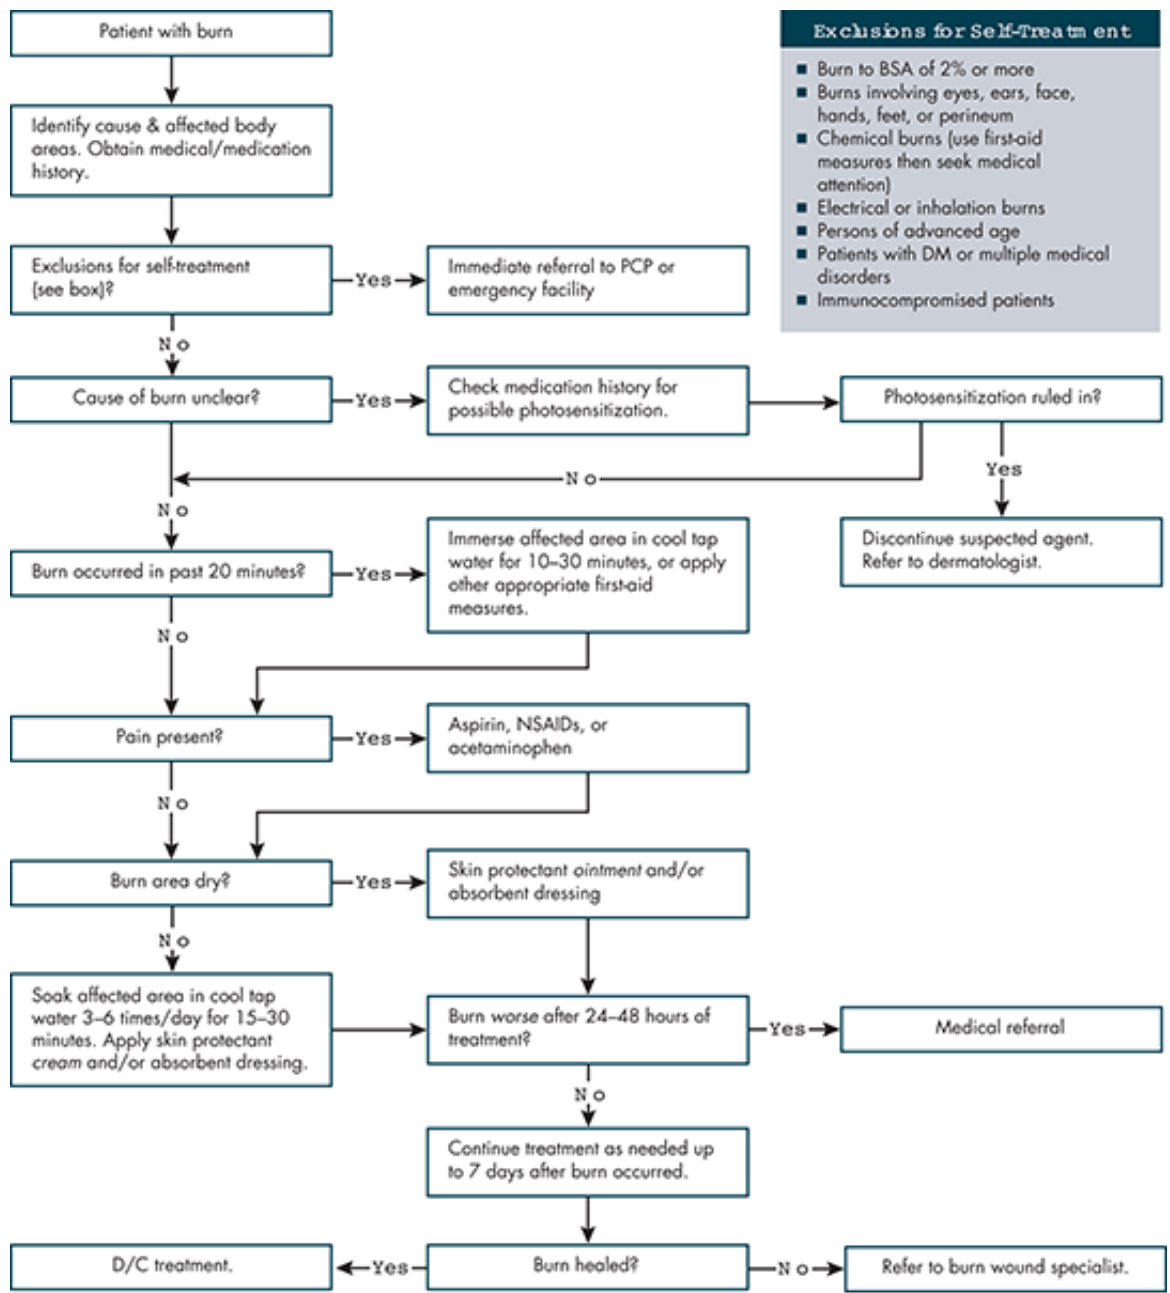

### Treatment Goals

The goals in treating acute, minor skin injury are to relieve symptoms, to promote healing by protecting the burn or wound from infection and further trauma, and to minimize scarring. Treatment should include a stepwise approach that involves cleansing the damaged area, selectively using antiseptics and antibiotics, and closing or covering with an appropriate dressing.

### General Treatment Approach

The extent and depth of stage I and II burns should be assessed for self-treatment, both initially and again in 24-48 hours. The inflammatory response to a burn injury evolves over the first 24-48 hours; therefore, the initial appearance of the injury often leads to an underestimation of its actual severity. If the patient has none of the exclusions for self-treatment listed in Figure 40-3, the provider should treat the patient (or guide the patient's treatment) using the treatment approach outlined in the algorithm. If the burned area is 2% of BSA or larger and consists of superficial partial-thickness or greater injury, medical attention is needed. Figure 40-4 illustrates the rule-of-nine method for estimating the percentage of BSA. Stage III and IV skin injury (e.g., animal or human bites, puncture wounds, and severe burns) require immediate medical evaluation. Specifically, these injuries require primary care provider consultation to assess the need for systemic or topical prescription antibiotics and a tetanus booster to prevent infection from the tetanus toxin occasionally found in dust, soil, and animal waste.

**Exclusions for Self-Treatment**

- Burn to BSA of 2% or more
- Burns involving eyes, ears, face, hands, feet, or perineum
- Chemical burns (use first-aid measures then seek medical attention)
- Electrical or inhalation burns
- Persons of advanced age
- Patients with DM or multiple medical disorders
- Immunocompromised patients

Uncontaminated acute skin injuries at stages I and II (Figure 40-2), such as minor cuts, scrapes, and burns, require only basic supportive measures, including irrigation with saline or water for removal of debris from the damaged area and use of a wound dressing to keep the area moist and to prevent entry of bacteria into the affected area. Topical nonprescription antibiotic and antiseptic preparations can also be useful in preventing secondary infection, especially when debris or other foreign particulate matter that increases the risk of infection is present. Figure 40-5 outlines the triage and treatment of acute skin injuries.

Self-care of acute skin wounds. Key: PCP = Primary care provider.

### Nonpharmacologic Therapy

Nonpharmacologic therapy used in the treatment of stage I and II skin injuries primarily involves first-aid measures to relieve pain, prevent contamination, and promote healing. The approach involves steps to remove exposure to the offending agent, stop bleeding and weeping from exudates, cool a burn, provide pain relief, decrease infection risk, and protect the area from further trauma.

Wound irrigation is often necessary to clean the wound surface by removing dirt and debris. Normal saline or water is sufficient for irrigation; however, mechanical removal of debris with clean gauze is sometimes appropriate. Minor abrasions and lacerations should be cleansed with water or sterile saline to remove any debris. They should then be covered with an appropriate wound dressing.

The patient or provider should inspect puncture wounds to ensure that no foreign bodies are retained and update tetanus prophylaxis, if necessary. If no debris is present, the wound should then be cleansed with either water or sterile saline. The wounds should be left open and soaked with soapy water for 30 minutes, at least 4 times a day initially, to allow for proper healing.<sup>11</sup> The wound should then be covered with an appropriate wound dressing. Specific first-aid measures for the care of burns are described in [Figure 40-3](#). Reducing further trauma to the site of skin injury caused by burns is done by immediately removing the source of heat and actively cooling the burn wound with cool tap water (lavage, soaks, compress or immersion). Continuous cooling for the first 10 minutes dissipates heat, reduces pain, delays onset and minimizes the extent of burn edema by decreasing the histamine release from

the skin mast cells. Cooling beyond 10 minutes may provide pain relief to the patient. It is best to avoid the application of ice or ice-cold water because this may cause numbness and intense vasoconstriction, resulting in further tissue damage. Chemical burns should be irrigated with copious amounts of water to reduce the size and extent of the injury.<sup>16</sup>

A nonadherent, hypoallergenic dressing may be applied to the wound to protect the damaged area and speed wound healing (Table 40-1). Minor skin injuries usually heal without additional treatment. Patients should be advised not to pull at loose skin or peel off burned skin because viable skin may be removed in the process, thereby delaying healing.

**TABLE 40-1 Options in Wound Dressing**

<i>Description (Trade Name)<sup>a</sup></i>	<i>Uses/Indications</i>	<i>Advantages</i>	<i>Disadvantages</i>
<b>Gauze Dressings</b>			
Nonocclusive fiber dressing with loose, open weave (Bulky Bandage, Conform, Kerlix Rolls and Sponges, Kling)	Stages II-IV Minimal to heavy exuding wounds/topicals Debridement Wound rehydration May use with semioclusive dressings	Readily available in many sizes Deep wound packing May use with infected wounds/topicals Nonocclusive Conformable	Wound bed may desiccate if dressing is dry Nonselective debridement May cause bleeding/pain on removal Need secondary dressing Frequent dressing changes
<b>Nonadherent (Gauze-Type) Dressings</b>			
Nonadherent, porous dressings lightly coated (Adaptic, Nexcare Pads, Release, Telfa, Vaseline Gauze)	Skin donor sites Stage II, shallow stage III Staple/suture lines Abrasions Lacerations Punctures May use with semioclusive dressings	Readily available Less adherent than plain gauze Lightly coated dressings allow exudate to flow through	Need secondary dressing May cause bleeding/pain on removal Some impregnated dressings may delay healing May require frequent dressing changes Some may cause exudate pooling
<b>Foams</b>			
Semipermeable, nonwoven, absorptive, inert polyurethane foam dressings (Allevyn, EPIGARD, Epi-Lock, Hydrasorb, Lyofoam; Figure 40-6C)	Stage II, shallow stage III Minimal-to-moderate drainage First- and second-degree burns Contraindicated in third-degree burns	Most are nonadhesive Some can be used with infected wounds/topicals Thermal insulation Reduce pain Nonocclusive Moist environment Conformable	Most require secondary dressing May require cutting May cause wound desiccation May be difficult to determine wound contact surface

		Less frequent dressing changes Trauma-free removal Absorbent	
<b>Alginates</b>			
Hydrophilic, nonwoven dressings composed of calcium-sodium (percentages vary) alginate fibers. Alginates are processed from brown seaweed into pad or twisted fiber form. Exudate transforms fibers to gel at wound interface (AlgiDERM, Algosteril, Band-Aid Brand Quick Stop Adhesive Bandages, Kaltostat, Sorbsan)	Light-to-heavy exuding wounds Stages II, III, IV Skin donor sites	Absorptive Reduce pain Nonocclusive Moist environment Conformable Easy, trauma-free removal Can use on infected wounds Accelerate healing time Less frequent dressing changes Potential to aid in control of minor bleeding	Require secondary dressing Characteristic odor May need wound irrigation May desiccate May promote hypergranulation
<b>Carbon-Impregnated (Odor-Control) Dressings</b>			
Dressings with an outer layer of carbon for odor control (Carboflex, Lyofoam C)	Malodorous wounds	Control odor	Require appropriate seal or odor may escape Carbon is inactivated when it becomes wet
<b>Composite/Island Dressings</b>			
Nonadherent, absorptive center barrier with adhesive at perimeter (Allevyn Island, Lyofoam A, Nu-Derm, Viasorb)	Stages II, III Moderate-to-heavy exuding wounds	Nonadherent over wound Semioclusive Autolysis Suture/staple lines Protective and reduce pain No secondary dressing required Impermeable to fluids/bacteria	May cause periwound trauma on removal
<b>Hydrocolloids</b>			
Wafer dressings composed of hydrophilic particles in an adhesive form covered by a water-resistant film or foam (Band-Aid Brand Advanced Healing Strips, Comfeel Plus, Cutinova, DuoDERM CGF Dressing, Exuderm, Tegasorb, ULTEC; <a href="#">Figure 40-6D</a> )	Stages I, II, shallow stage III Clean, granular wounds Autolysis Minimal-to-	Occlusive Manage exudate by particle swelling Autolysis Long wear time	For uninfected wounds only May cause periwound trauma on removal

	<p>moderate exuding wounds Can use with absorption products and alginates</p>	<p>Self-adherent Impermeable to fluids/bacteria Conformable Protective Thermal insulation Reduce pain Moist environment</p>	<p>Difficult wound assessment Characteristic odor Impermeable to gases Some may leave residue on skin or in wound</p>
<b>Transparent Adhesive Films</b>			
<p>Semiocclusive, translucent dressings with partial or continuous adhesive composed of polyurethane or copolyester thin film (BIOCLUSIVE, Blisterfilm, CarraFilm, OpSite, Suresite, Tegaderm; <a href="#">Figure 40-6E</a>)</p>	<p>Stages I, II, shallow stage III Clean granular wounds Minimally exuding wounds Autolysis Can use with absorption products and alginates Can be used in conjunction with some enzymatic debriders</p>	<p>Semiocclusive Gas permeable Easy inspection Autolysis Protective Impermeable to fluids/bacteria Comfortable Self-adherent Reduce pain Moist environment Shear resistant</p>	<p>For uninfected wounds only Not absorptive May cause periwound trauma on removal With continuous adhesive, may reinjure wound on removal With large amounts of exudate, maceration may occur</p>
<b>Hydrogels/Gels</b>			
<p>Nonadherent, nonocclusive dressings with high moisture content that come in the form of sheets and gels (Aquasite, Bioflex RX 1267P, Elasto-Gel, FlexiGel, New Skin Burn Relief Dressings, 2nd Skin Hydrogel Moist Gel Pads, Vigilon; <a href="#">Figure 40-6F</a>)</p>	<p>Stages II, III, some approved for stage IV Granular or necrotic wound beds Autolysis Some used on partial- and full-thickness burns Punctures</p>	<p>Nonadherent Most are nonocclusive Trauma-free removal Varying absorption capabilities Conformable Some can be used in conjunction with topicals Thermal insulation Reduce pain Moist environment</p>	<p>Most require secondary dressings May macerate periwound skin Some products may dehydrate Slow-to-minimal absorption rate in most Most require frequent/daily dressing change</p>
<b>Antimicrobial</b>			
<p>Dressings that contain an antimicrobial agent to reduce bacterial contamination (Acticoat, Actisorb Silver 200, Avance, Aquacel, Iodoflex)</p>	<p>Stages II, III, and IV All locally infected wounds</p>	<p>Nonadherent Absorbent Reduce infection</p>	<p>Use caution in patients with thyroid disease because of increased iodine absorption Skin allergy</p>

<sup>a</sup> The trade names listed for each type of wound dressing are given as examples of available products; however,

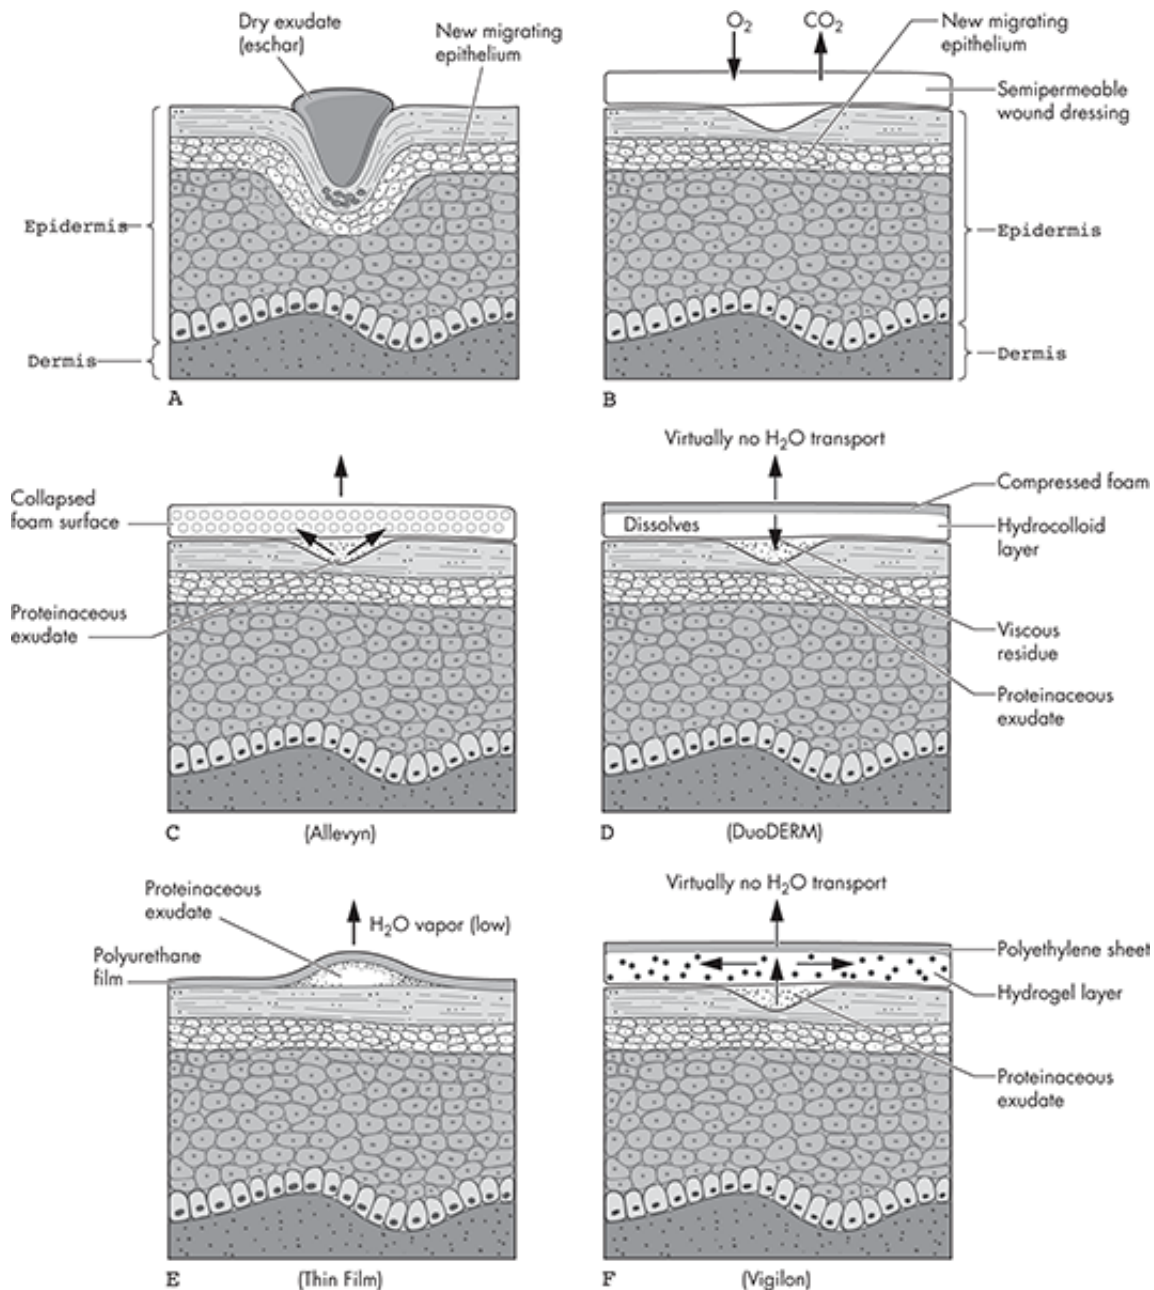

these products do not constitute an all-inclusive list of available wound-dressing products.

*Source:* Adapted with permission from an unpublished document prepared by McIntosh A, Raheer E. Silver Cross Hospital, Joliet, IL; 1991.

In the case of chemical burns, the patient should immediately remove any clothing on or near the affected area. The affected area should then be washed with tap water for at least 15 minutes or longer until the offending agent has been removed. This treatment, however, should not delay transport to a hospital emergency department. If the eye is involved, the eyelid should be pulled back and the eye irrigated with tap water for at least 15-30 minutes. The irrigation fluid should flow from the nasal side of the eye to the outside corner to prevent washing the contaminant into the other eye. The area poison control center should be contacted immediately at 800-222-1222 for treatment recommendations. Referral for further evaluation is frequently encouraged for eye injuries, and medical attention should be sought as soon as possible.

### Wound Dressing

Traditional wound management involves leaving the wound open to air or covering it with a nonocclusive textile dressing (gauze). However, this type of management leads to eschar (i.e., scab) formation, which impedes reepithelialization of wounds and creates unwanted scars (Figure 40-6A). Wound dehydration with delayed healing and increased risk of bacterial entry into the wound may also occur. Removal of gauze dressings often tears away not only the eschar but also the new tissue under the eschar. These cumulative problems have led primary care providers and nurses to develop new treatment strategies that are based on creating a moist wound environment (Figure 40-6B). Providing a moist wound environment reduces the loss of protein, electrolytes, and fluid from the wound to help to minimize pain and infection.<sup>17</sup> Providers should still recommend the use of gauze and gauze-type adhesive dressings under certain circumstances; for example, gauze pads may be used with more advanced semioclusive dressings such as foams for better exudate absorption. Gauze dressings also assist with the removal of eschar and necrotic tissue when wound debridement is necessary. In addition, gauze-type adhesive bandages may be used for stage I skin injuries for which the possible removal of excess granulation tissue is not a concern.

Mechanisms by which semipermeable wound dressings create a moist environment for wound healing. **A**, Regenerating epidermal cells are forced to "tunnel" below the dry wound eschar to attain wound closure. This tunneling delays wound closure. **B**, Semipermeable wound dressings prevent formation of eschar by maintaining optimal moisture level at the wound bed. Unhindered by the presence of a dry eschar, migrating epithelial cells are able to migrate and close the wound. **C**, Mechanism of action of a hydrophilic polyurethane foam dressing (Epi-Lock). **D**, Mechanism of action of a hydrocolloid wound dressing (DuoDERM). **E**, Mechanism of water vapor transmission in thin films. **F**, Mechanism of action of a hydrogel wound dressing (Vigilon). (Source: Adapted with permission from Syzcher M, Lee SJ. Modern wound dressings: a systemic approach to wounds. *J Biomater Appl.* 1992;7:142-213.)

### Selection Criteria for Wound Dressings

Choosing the right dressing depends on proper assessment of skin injury and of characteristics of the wound bed. Healing requires the appropriate type and amount of moisture in the wound bed to enhance healing. The role of a wound dressing is to provide the right environment to enhance and promote wound healing. A moist healing environment stimulates cell proliferation and encourages epithelial cells to migrate. Moisture-retentive dressings also act as a barrier against bacteria and absorb excess wound fluid, creating opportune conditions for healing. Today's wound dressings can also help decrease or eliminate pain, reduce the need for dressing changes, and provide autolytic debridement. Used appropriately, they are also cost-effective.<sup>18</sup>

Understanding the potential use and function of specific wound dressings should guide the provider in proper product selection. Also, wound dressing requirements may change with each healing phase. In terms of promoting moist wound healing, the wound dressing may be used to absorb excess moisture, maintain optimal moisture, or provide moisture where it is lacking. [Table 40-1](#) and [Figure 40-7](#) describe the major categories of available wound

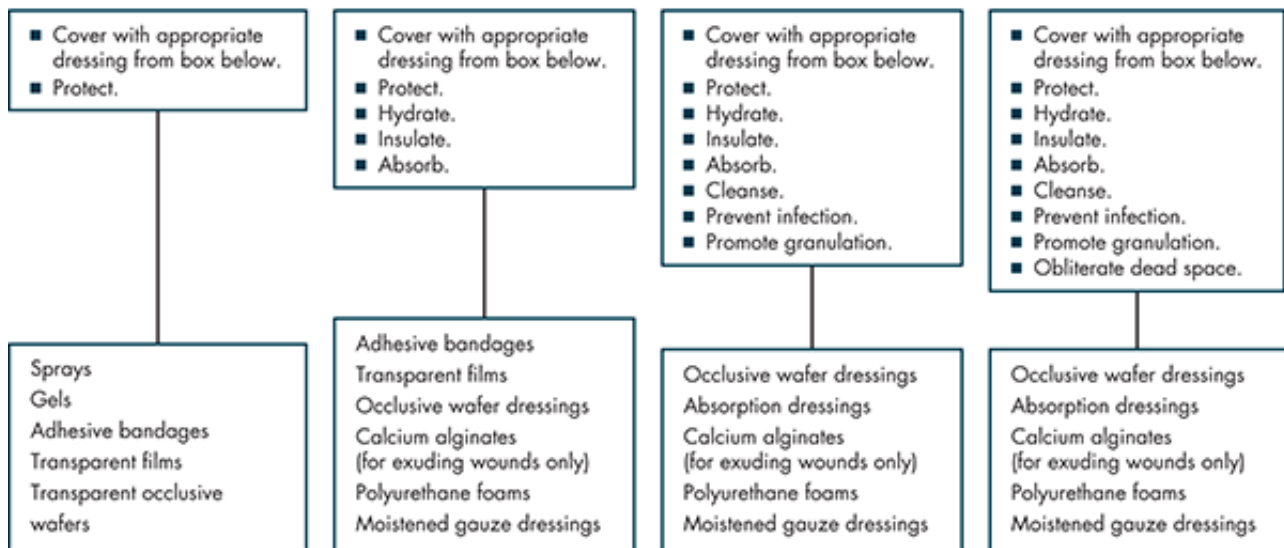

care products and give an overview of their indications, advantages, and disadvantages.<sup>18,19</sup>

Stage I: Reddened unbroken skin (stage I ulcer)

Stage II: Blister or partial-thickness skin loss (abrasion, puncture wound, stage II ulcer)

Stage III: Full-thickness skin loss [deep puncture wound, laceration, stage III ulcer]

Stage IV: Full-thickness skin loss (involving muscle/tendon/bone) [deep puncture wound, deep laceration, stage IV ulcer]

## Types of Wound Dressings

### Gauze

Gauze is available in a variety of forms and is generally used to care for minor burns and wounds that are draining or those requiring debridement. It is available in woven and nonwoven forms and can be impregnated with nonadherent products such as petrolatum as well as with antiseptics and antimicrobials. Some advantages of gauze are that it is readily available in many sizes and forms, it is affordable, and it can be combined with other topical products. Disadvantages of gauze are that it must be held in place by a second agent, its fibers may adhere to the wound bed, and it must be changed often (preferably several times a day) to prevent the wound from drying out. In addition, gauze alone is not recommended for moist wound treatment. Examples of gauze products include Kerlix, Kling, and Conform.<sup>18</sup>

### Antimicrobial

Antimicrobial dressings contain products like silver and iodine and are often used in the management of wounds that are colonized or infected. As exudates from the wound bed are slowly absorbed, silver and iodine are gradually released to decrease the bacterial load within the wound bed. Examples include Acticoat, Actisorb, and Iodoflex.<sup>20</sup>

### Specialty Wound Dressings

Often the practitioner must maintain a delicate balance of moisture and wound healing.<sup>18</sup> Specialty dressings are available that absorb excess moisture (e.g., foams, alginates), maintain moisture (e.g., hydrocolloid and transparent film dressings), or provide moisture where it is lacking (e.g., hydrogels).

*Dressings that absorb moisture* are beneficial early in the inflammatory phase of healing. The wound tissue may be overly moist as a result of the accumulation of fluid evaporated by exposed damaged tissue and from blood and serous drainage. A wound that is "too wet" may result in maceration of the tissue.<sup>21</sup> A wound that exudes moderate-to-high levels of drainage requires an absorbent dressing (e.g., foam, alginates, carbon-impregnated, and composite dressings). These dressings offer the benefit of requiring fewer dressing changes compared with nonabsorbent dressings, enabling undisturbed wound healing. Examples include Kaltostat, Repel, Mepilex, and Actisorb.

*Dressings that maintain moisture* are preferred as healing moves to the proliferative phase, with the formation of new connective tissue. Dressings that maintain natural moisture, such as hydrocolloid and transparent film dressings, are preferred in this phase.<sup>18,19</sup> Examples include Exuderm and Suresite.

*Dressings that provide moisture* are preferred when a dry wound that is covered with dead tissue needs to be rehydrated before optimal healing can occur. Providing moisture will soften and remove the dead tissue while promoting autolytic debridement, which facilitates the migration of newly formed epithelial tissue to the wound bed. A wound dressing must contain water to effectively add moisture to a wound and promote healing. Hydrogel dressings can consist of 80%-99% water on a nonadherent, cross-linked polymer, and they have varying absorptive

properties.<sup>19,22,23</sup> Examples include AquaSite and FlexiGel.

### Adhesive Bandages

Most superficial wounds (minor abrasions and lacerations) may simply require the application of adhesive gauze-type bandages such as regular Band-Aid brand bandages. Recognition of the importance of the moist wound-healing method has led to the development and marketing of more moisture retaining hydrocolloid-based bandages that promote wound healing (e.g., Band-Aid Brand Advanced Healing Strips and New Skin). Alternatives to conventional bandages are cyanoacrylate tissue adhesives, also known as liquid adhesive bandages (e.g., Liquiderm), which are used for small cuts and abrasions. These bandages are preferred for either cosmetic purposes (i.e., when a wound is located on the face) or when a more flexible dressing product is needed (i.e., when a wound is located on the finger or elbow). Adhesive bandages are often preferred by patients because they are waterproof, require no needles for wound closure, and have antimicrobial properties against gram-positive organisms.<sup>24</sup>

### Surgical Tape

As the name implies, surgical tape is primarily used to hold in place bandages that cover a wound or surgical incision. The tape should be chosen on the basis of its adhesive properties, but it should be easy to remove. To minimize skin irritation, paper and cloth tapes should not contain latex and should be hypoallergenic. The most adherent, and potentially irritating, tape is clear surgical tape. Thus, it should be reserved for wounds that do not require frequent dressing changes (e.g., to secure IVs or surgical drains). Examples include Blenderm, Medipore, and Micropore.

### Pharmacologic Therapy

Various products are useful in treating minor burns, sunburn, and wounds. Some agents cleanse the area and/or relieve pain, swelling, and/or inflammation. Others either protect the damaged area from infection or otherwise aid in healing the skin.

### Systemic Analgesics

An initial step in treating the patient with a minor skin injury is to recommend short-term administration of a systemic analgesic, preferably one with anti-inflammatory activity, such as the NSAIDs (e.g., aspirin, naproxen, or ibuprofen). As prostaglandin inhibitors, NSAIDs may decrease erythema and edema in the injured area. NSAIDs may be especially beneficial in the patient with mild sunburn, especially in the first 24 hours after overexposure to UVR. Their use has been shown to decrease inflammation caused by exposure to UVR. However, this effect has been found to last only about 24 hours,<sup>25</sup> possibly because the initial inflammation of sunburn is mediated by prostaglandins, whereas the later inflammation is associated primarily with leukocytes. For patients who cannot tolerate NSAIDs, acetaminophen can provide pain relief, although it is a weak prostaglandin inhibitor and is not an anti-inflammatory agent. (See [Chapter 5](#) for discussion of dosages and safety considerations for systemic analgesics.)

### Skin Protectants

The Food and Drug Administration (FDA) has recognized the skin protectants in [Table 40-2](#) as safe and effective for the temporary protection of minor burns and abrasions.

**TABLE 40-2 Skin-Protectant Ingredients Used in Treatment of Minor Burns and Sunburn**

<i>Ingredient</i>	<i>Proposed Concentrations (%)</i>
Allantoin	0.5-2
Cocoa butter	50-100
Petrolatum	30-100
Shark liver oil	3
White petrolatum	30-100

*Source:* U.S. Food and Drug Administration. Skin protectant drug products for over-the-counter human use. Final rule. *Federal Register*. 2003;68:33377.

Skin protectants benefit patients with minor skin injuries by making the damaged area less painful. They protect the area from mechanical irritation caused by friction and rubbing, and they prevent drying of the stratum corneum. Products that prevent dryness and provide lubrication should be selected. Generally, the patient may apply a skin protectant as often as needed. If the skin injury has not improved in 7 days or if it worsens during or after treatment,

the patient should seek medical attention promptly.

### Topical Anesthetics

The pain of minor burns, wounds, and sunburn can be attenuated by the judicious use of topical anesthetics. Agents proposed as safe and effective in providing temporary relief of pain specifically associated with minor burns are listed in [Table 40-3](#).

**TABLE 40-3 Nonprescription Topical Analgesic Ingredients for Treatment of Minor Burns and Sunburn**

<i>Agent</i>	<i>FDA-Approved Concentrations (%)</i>
<b>Amine and Caine-Type Local Anesthetics</b>	
Benzocaine	5-20
Butamben picrate	1
Dibucaine	0.25-1
Dibucaine hydrochloride	0.25-1
Dimethisoquin hydrochloride	0.3-0.5
Dyclonine hydrochloride	0.5-1
Lidocaine	0.5-4
Lidocaine hydrochloride	0.5-4
Pramoxine hydrochloride	0.5-1
Tetracaine	1-2
Tetracaine hydrochloride	1-2
<b>Antihistamines</b>	
Diphenhydramine hydrochloride	1-2
Tripelennamine hydrochloride	0.5-2

Source: *Federal Register*. 1983;48:6820-33.

Topical anesthetics relieve pain by inhibiting the transmission of pain signals from pain receptors. Relief is short lived, lasting only 15-45 minutes.<sup>26</sup>

Benzocaine (0.5%-20%) and lidocaine (2%-5%) are the two anesthetics most often used in nonprescription drug preparations. Dibucaine (0.25%-1%), tetracaine (0.5%-2%), butamben (1%), and pramoxine (0.5%-1%) are also found in external anesthetic preparations. The higher concentrations of the topical anesthetics are appropriate for skin injuries in which the skin is intact. Lower concentrations are preferred when the skin surface is not intact because drug absorption is enhanced. These agents should be applied only to small areas of no more than 1%-2% of BSA to avoid systemic toxicity.<sup>26,27</sup>

Topical anesthetics should be applied no more than 3 or 4 times daily. Because their duration of action is short, continuous pain relief cannot be obtained with these agents. Increasing the number of applications increases the risk of a hypersensitivity reaction and, more important, the chance for systemic toxicity.

Benzocaine produces a hypersensitivity reaction in about 1% of patients, a higher incidence than that seen with lidocaine. In contrast, benzocaine is essentially free of systemic toxicity, whereas the systemic absorption of lidocaine can lead to a number of side effects. However, systemic toxicities caused by lidocaine are rare if the product is used on intact skin, on localized areas, and for short periods.<sup>26</sup>

### First-Aid Antiseptics

Antiseptics are chemical substances designed for application to intact skin up to the edges of a damaged skin area for disinfection purposes. When effective antiseptics are combined with proper skin injury care technique, including gentle handling of tissue, the infection rate is low. Ideally, antiseptics should exert a sustained effect against all microorganisms, without causing tissue damage. However, even therapeutic concentrations of antiseptics can harm tissue. For example, alcohol-containing preparations should not be used within the wound bed because they

dehydrate the area and also cause pain and cell damage. Therefore, antiseptics should be used to disinfect only intact skin surrounding the wound after the removal of all organic matter.

Antiseptic active ingredients recognized as safe and effective for use include hydrogen peroxide topical solution USP, ethyl alcohol (48%-95%), isopropyl alcohol (50%-91.3%), iodine topical solution USP, iodine tincture USP, povidone/iodine complex (5%-10%), and camphorated phenol (Tables 40-4 and 40-5).<sup>27</sup>

**TABLE 40-4 Nonprescription First-Aid Antiseptic Ingredients**

<b>Antiseptic Agents</b>	<b>Concentration (%)</b>
Ethyl alcohol	48-95
Isopropyl alcohol	50.0-91.3
Hydrogen peroxide topical solution	USP
Iodine tincture	USP
Iodine topical solution	USP
Phenol	0.5-1.5
Povidone/iodine complex	5-10
Quaternary ammonium compound	0.13

Antiseptics and germicides. Drug Facts and Comparisons eFacts. Accessed at <http://online.factsandcomparisons.com/MonoDisp.aspx?monoid=fandc-hcp10207&book=DFC>, July 28, 2014.

### Hydrogen Peroxide

Hydrogen peroxide 3% topical solution USP is a widely used antiseptic. Enzymatic release of oxygen occurs when the hydrogen peroxide comes in contact with the skin, causing an effervescent, mechanical cleansing action. Hydrogen peroxide should be used where released gas can escape; therefore, it should not be used in abscesses, nor should bandages be applied before the compound dries. Because of the limited bactericidal effect and the risk of tissue toxicity, hydrogen peroxide has little benefit over soapy water for antiseptics.

### Ethyl Alcohol

Alcohol has good bactericidal activity in 20%-70% concentrations. Caution must be used, however, when applying it to the intact skin surrounding the injured area, given that inadvertent, direct application of alcohol to the wound bed can cause tissue irritation. Ethyl alcohol may be used 1-3 times daily, and the wound may be covered with a sterile bandage only after the washed area has dried.<sup>27</sup>

### Isopropyl Alcohol

Compared with ethyl alcohol, isopropyl alcohol 70% aqueous solution has somewhat stronger bactericidal activity

and lower surface tension. Isopropyl alcohol is generally used for its cleansing and antiseptic effects on intact skin. It should not be used to clean open wound beds because of possible cytotoxic effects and higher reported infection rates. Isopropyl alcohol also has a greater potential for drying the skin (astringent action) because its lipid solvent effects are stronger than those of ethyl alcohol. Similar to ethyl alcohol, isopropyl alcohol is flammable and must be kept away from a flame.<sup>27</sup>

### Iodine

An iodine solution USP of iodine 2% and sodium iodide 2.5% is used as an antiseptic for superficial skin injuries. An iodine tincture USP of iodine 2%, sodium iodide 2.5%, and alcohol (approximately 50%) is less preferable than the aqueous solution because the tincture is irritating to the tissue. Strong iodine solution (Lugol's solution) must not be used as an antiseptic. In general, bandaging should be discouraged after iodine application to avoid tissue irritation. Iodine solutions stain skin, may be irritating to tissue, and may cause allergic sensitization in some people. Iodine products are recommended if patients have chlorhexidine allergy.<sup>28</sup>

### Povidone/Iodine

Povidone/iodine is a water-soluble complex of iodine with povidone. It contains 9%-12% available iodine, which accounts for its rapid bactericidal activity. Povidone/iodine is nonirritating to skin and mucous membranes. However, when used as a wound irrigant, povidone/iodine is absorbed systemically; the extent of iodine absorption is related to the concentration used and the frequency of application. The final serum level also depends on the patient's intrinsic renal function. When severe burns and large wounds are treated with povidone/iodine, iodine absorption through the skin and mucous membranes can result in excess systemic iodine concentrations, possibly causing transient thyroid dysfunction, clinical hyperthyroidism, and thyroid hyperplasia.<sup>28</sup>

### Camphorated Phenol

Oily solutions of phenol and camphor are often used as nonprescription first-aid antiseptics. These products contain relatively high concentrations of phenol (4%) and must be used with caution. If oleaginous phenolic solutions are applied to moist areas, the phenol is partitioned out of the vehicle into water, resulting in caustic concentrations of phenol on the skin. These damaging effects can be avoided by applying these products only to dry, intact skin. Wounds treated with camphorated phenol should not be bandaged because the moisture would result in tissue damage.<sup>29</sup>

### First-Aid Antibiotics

Nonprescription first-aid antibiotics available in the United States consist of the active ingredients bacitracin, neomycin, and polymyxin B sulfate (Table 40-6).<sup>30</sup> These topical agents help prevent infection in minor cuts, wounds, scrapes, and burns. They are especially beneficial if the wound contains debris or foreign matter. Topical and, in some cases, oral antibiotics are indicated in contaminated wounds that have a moderately high risk of infection. However, clean wounds free of contamination have a low infection rate and do not warrant the use of prophylactic antibiotics. If questions arise concerning the degree of contamination and the need for oral antibiotics, the patient should seek medical attention.

**TABLE 40-6 Selected Nonprescription Antibiotic Products**

<i>Trade Name</i>	<i>Primary Ingredients</i>
Betadine First Aid Antibiotics + Moisturizer Ointment	Polymyxin B sulfate 10,000 U/g; bacitracin zinc 500 U/g
Q-tips Treat & Go	Cotton swabs containing bacitracin 500 U/g
Gold Bond First Aid Antibiotic Ointment	Bacitracin zinc 500 U/g; polymyxin B sulfate 10,000 U/g; neomycin base 3.5 mg/g; pramoxine HCL 10 mg
Neosporin Ointment	Polymyxin B sulfate 5000 U/g; bacitracin zinc 400 U/g; neomycin base 3.5 mg/g
Neosporin Plus Pain Relief Ointment	Bacitracin zinc 500 U/g; polymyxin B sulfate 10,000 U/g; neomycin base 3.5 mg/g; pramoxine HCL 10 mg
Neosporin Plus Pain Relief Cream	Polymyxin B sulfate 10,000 U/g; neomycin base 3.5 mg/g; pramoxine HCL 10 mg
Polysporin Ointment/Powder	Polymyxin B sulfate 10,000 U/g; bacitracin zinc 500 U/g

Source: Wolters Kluwer Health, Inc. Antiinfectives-topical. Antibiotic agents. Drug Facts and Comparisons eFacts. Accessed at <http://online.factsandcomparisons.com/MonoDisp.aspx?monoid=fandc-hcp10163&book=DFC>, July 28,

2014.

Topical antibiotic preparations should be applied to the wound bed after cleansing and before applying a sterile dressing. Special caution should be taken when applying these preparations to large areas of denuded skin, however, because the potential for systemic toxicity can increase. Prolonged use of these agents may result in the development of resistant bacteria and secondary fungal infection. If significant signs of improvement are not seen within 7 days, the patient should seek medical attention.

### Bacitracin

Bacitracin is a polypeptide bactericidal antibiotic that inhibits cell wall synthesis in several gram-positive organisms. The development of resistance in previously sensitive organisms is rare. Minimal absorption occurs with topical administration. The frequency of allergic contact dermatitis (erythema, infiltration of macrophages, papules, edematous, or vesicular reaction) is approximately 2%. Topical nonprescription preparations usually contain 400-500 U/g of ointment and are applied 1-3 times a day.<sup>30</sup>

### Neomycin

Neomycin is an aminoglycoside antibiotic; it exerts its bactericidal activity by irreversibly binding to the 30S ribosomal subunit to inhibit protein synthesis in gram-negative organisms and some species of *Staphylococcus*. Neomycin has been demonstrated to decrease the severity of clinical infection 48 hours after treatment in tape-stripped wounds. Resistant organisms may develop. Neomycin applied topically produces a relatively high rate of hypersensitivity; reactions occur in 3.5%-6% of patients. Although neomycin is not absorbed when applied to intact skin, application to large areas of denuded skin may cause systemic toxicity (ototoxicity and nephrotoxicity). It is most frequently used in combination with polymyxin and bacitracin in a concentration of 3.5 mg/g to prevent the development of neomycin-resistant organisms. Applications are made 1-3 times a day.<sup>30</sup>

### Polymyxin B Sulfate

Polymyxin B sulfate is a polypeptide antibiotic that is effective against several gram-negative organisms because it alters the bacterial cell wall permeability. Topical preparations may be compounded in either a solution or ointment base, and numerous prepackaged antibiotic combinations containing polymyxin B are available. Applications are usually made 1-3 times a day.<sup>30</sup>

## Product Selection Guidelines

If a topical anesthetic is to be used, the provider should recommend the most appropriate product formulation. These products are available as ointments, creams, solutions (lotions), and sprays (aerosols).

Ointments are oleaginous-based preparations. They provide a protective film to impede the evaporation of water from the wound area, which helps keep the skin from drying. However, if the skin is broken, an ointment may not be appropriate because of its impermeability. The presence of excessive moisture trapped beneath the ointment may promote bacterial growth or maceration of the skin, thereby delaying healing. Ointments are more appropriate for minor burns and wounds in which the skin is intact. Creams are emulsions that allow some fluid to pass through the film and are best for broken skin. Generally, it is easier to apply and remove creams than ointments. To prevent contamination of the preparation, the patient should not apply ointments and creams directly from the container onto the burn or wound. A preferred technique is to apply the topical product to a clean or gloved hand or gauze and then apply it directly to the injury site.

Lotions spread easily and are easier to apply when the burn or wound area is large. However, lotions that produce a powdery cover should not be used on a wound bed because they tend to dry the area, are difficult (and possibly painful) to remove, and provide a medium for bacterial growth under the caked particles.

Generally, aerosol and pump sprays are more costly than other topical dosage forms. Sprays offer the advantage of precluding the need to physically touch the injured area, so there is less pain associated with applying the medication. Proper application requires holding the container approximately 6 inches from the wound and spraying for 1-3 seconds. This method decreases the chances of chilling the area. However, sprays are not usually protective in that the aerosol is typically water or alcohol based and will evaporate. In addition, alcohol-based sprays can irritate and dehydrate the wound bed.

[Table 40-7](#) lists selected trade-name topical products appropriate for treating minor burns, sunburn, and wounds.

**TABLE 40-7 Selected Nonprescription Topical Products for Minor Burns, Sunburn, and Wounds**

<i>Trade Name</i>	<i>Primary Ingredients</i>
<b>Skin Protectants</b>	
A + D Original Ointment	Petrolatum 80.5%; lanolin 15.5%; cod liver oil (contains vitamins A and D)
Zinc oxide, Desitin Ointments	Zinc oxide 20% or 25%; white petrolatum

<b>Local Anesthetics</b>	
Americaine Aerosol	Benzocaine 20% ointment
ELA-Max 4%	Lidocaine 4%
Dermoplast Pain-Relieving Spray	Benzocaine 20%; menthol 0.5%
Dibucaine Topical Ointment	Dibucaine 1%
Itch-X Spray/Gel	Pramoxine HCl 1%; benzyl alcohol 10%
Solarcaine Aloe Extra Burn Relief Gel/Spray	Lidocaine 0.5%
Xylocaine Ointment	Lidocaine 2.5%
<b>Local Anesthetics/Antiseptics</b>	
Bactine First Aid Antiseptic Spray	Lidocaine HCl 2.5%; benzalkonium chloride 0.13%
Dermoplast Antibacterial Spray	Benzocaine 20%; benzethonium chloride 0.2%
Lanacane Maximum Strength Anti-Itch Cream	Benzocaine 20%; benzethonium chloride 0.1%
Bicozene	Benzocaine 6%; resorcinol 2%

Drug Facts and Comparisons eFacts. Accessed at <http://online.factsandcomparisons.com/MonoDisp.aspx?monoid=fandc-hcp10282>, July 28, 2014.

Normal saline is the preferred choice for effective wound irrigation. The issue of which is the best antiseptic solution to use remains unresolved. When choosing an antiseptic product, one must consider tissue toxicity and costs of the different ingredients.

A topical antibiotic applied 1-3 times a day to a contaminated wound is effective in eradicating bacteria and producing faster wound healing when the agent is combined with appropriate cleansing of the wound and the use of proper dressings.

#### Complementary Therapies

Natural products such as honey, *Calendula officinalis*, *Aloe vera*, *Garcinia morella*, and *Datura metol* are said to have healing properties.<sup>31,32</sup> (See Chapter 51 for a more in-depth review of natural products for skin.)

Aloe vera gel is obtained from the mucilaginous center of the leaf of the aloe vera plant. It has been used for many centuries and is the major ingredient in various commercial skin and wound-care products. The aloe vera gel contains vitamins A, B, C, and E; enzymes; polysaccharides; amino acids; sugars; and minerals. In the management of acute and chronic wounds, several reports of studies using aloe vera have demonstrated variable results.<sup>31</sup> *Calendula officinalis* has been widely used in homeopathic medicine for the treatment of many diseases. It is thought to promote wound healing by its reported anti-inflammatory and antibacterial properties. Results of one study indicate the effectiveness of *C. officinalis* extract for enhancing the antioxidant defense mechanism, thereby decreasing burn injury in a group of rats exposed to burn injury.<sup>32</sup>

The use of honey in wound management dates back many centuries. Honey consists of approximately 40% fructose, 30% glucose, 5% sucrose, and 20% water. It also contains several amino acids, antioxidants, vitamins, minerals, glucose oxidase (which produces hydrogen peroxide), and gluconic acid. Honey is highly viscous and delivers a moist wound healing environment. Also, because of the hyperosmolarity of honey, it is able to absorb the exudates from the wound and enable the wound to heal in a moist environment. Honey also has antibacterial, anti-inflammatory, and antifungal properties.<sup>33</sup>

One prospective randomized trial of honey versus silver sulfadiazine (SSD) for superficial burns demonstrated that honey dressings showed greater efficacy over SSD cream for treating superficial and partial-thickness burns; however, honey dressings are not advocated by burn centers.<sup>34</sup>

#### Assessment of Minor Burns, Sunburn, and Wounds: A Case-Based Approach

The assessment approach for burns differs slightly from the approach for wounds. When a patient presents with a burn, the severity of the burn should be immediately assessed by determining the depth of the injury and the percentage of BSA involved. The percentage of the adult body that has been burned can be estimated by the rule-of-nine method (Figure 40-4). The total BSA is divided into 11 areas, each accounting for 9% or a multiple of 9. An easy way to estimate the percentage of burned BSA is to use the back of the hand as 1% of BSA. The rule of nine is reliable for adults but inaccurate for children and patients with small body surfaces.

Case 40-1 is an example of the assessment of a patient with a minor burn.

When a patient presents with a minor wound, the type, depth, location, and degree of contamination should be assessed. Visual inspection of the affected area usually provides an accurate evaluation of these factors. The wound should also be assessed for signs of infection, including whether drainage of yellow or greenish fluid (pus) is present or whether the skin around the wound has become increasingly erythematous, swollen, and painful. Because noninfectious processes such as drug-induced eruptions could be involved, the patient's health status and current medication use should also be determined. Antimicrobial agents should generally be recommended when secondary infection is present or might occur.

Case 40-2 is an example of the assessment of a patient with a minor wound.

### Case 40-1

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient describes intense pain and a dark pink burn on her right arm. She says that she accidentally touched the oven door when reaching in to retrieve a baked dish 2 days ago. The lesion is approximately 1 inch by 3 inches with nonraised edges.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The patient says that the pain is worse when she moves her right arm and when she showers.
c. description of the patient's efforts to relieve the symptoms	The patient has not tried anything other than keeping the area dry to "help it heal faster."
d. patient's identity	Gena Davies
e. age, sex, height, and weight	42 years old, female, 5 ft 5 in., 160 lb
f. patient's occupation	Bus driver
g. patient's dietary habits	Eats a regular diet filled with meats and potatoes.
h. patient's sleep habits	At least 7 hours nightly
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Hyperlipidemia: pravastatin 20 mg daily; hypothyroidism: levothyroxine 125 mcg daily
j. allergies	Aspirin

k. history of other adverse reactions to medications	None
l. other (describe) _____	The patient uses her arms a lot when driving the bus route 5 days a week. She also likes to do garden work regularly.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Gena is suffering from a first-degree superficial thermal burn secondary to coming into contact with a hot oven.
3. Identify exclusions for self-treatment (Figure 40-3).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Gena to an appropriate health care provider. (2) Recommend self-care with a nonprescription skin protectant and nondrug measures. (3) Recommend self-care until Gena can see an appropriate provider. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Gena should use a nonprescription skin protectant or topical analgesic along with nondrug measures to treat her problem.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Cleanse the area with water and a mild soap. Apply a skin protectant ointment such as cocoa butter or petrolatum to the burn area several times a day to reduce pain, keep the wound area moist, and protect the wound from mechanical irritation. Cover the burn with a transparent film dressing to provide additional protection."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Minor burns can be properly managed with nonprescription skin protectants and nondrug measures as long as there are no exclusions for self-treatment, as in your case."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	See the box Patient Education for Minor Burns and Sunburn.
b. maximum number of days the therapy should be employed	See the box Patient Education for Minor Burns and Sunburn.

c. product administration procedures	See the box Patient Education for Minor Burns and Sunburn.
d. expected time to onset of relief	"You should experience relief in about 7 days."
e. degree of relief that can be reasonably expected	"The burn can be healed by using a skin protectant and recommended nondrug measures properly."
f. most common side effects	See the box Patient Education for Minor Burns and Sunburn.
g. side effects that warrant medical intervention should they occur	See the box Patient Education for Minor Burns and Sunburn.
h. patient options in the event that condition worsens or persists	See the box Patient Education for Minor Burns and Sunburn.
i. product storage requirements	"Store in a cool, dry place out of children's reach."
j. specific nondrug measures	See the box Patient Education for Minor Burns and Sunburn.
Solicit follow-up questions from the patient or caregiver.	"Will the burn heal faster if I 'dry it out'?"
Answer the patient's or caregiver's questions.	"Drying the burn area leads to scab formation, which can delay wound healing and possibly lead to unwanted scarring. Providing a moist wound environment is ideal to aid in healing."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	"If you provide me with your phone number, I will give you a call in 7-10 days to see how your wound is healing."

**Case 40-2**

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient approaches the pharmacy counter asking for "something for a swollen tongue that hurts really bad." Upon questioning, she says she had her tongue pierced four days ago, and it's been hurting and swollen ever since. She grimaces and slowly opens her mouth to reveal a tongue with a swollen dark yellow-brownish center that has a red tear in the middle.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	She says the pain that now extends to her jaws and neck keeps her from eating and drinking. Nothing has relieved the discomfort at this point other than keeping her mouth closed as much as possible. The pain is getting worse.

c. description of the patient's efforts to relieve the symptoms	The patient has tried liquid Tylenol with little relief.
d. patient's identity	Kim Summers
e. age, sex, height, and weight	27 years old, female, 5 ft 5 in., 160 lb
f. patient's occupation	Hair stylist
g. patient's dietary habits	Vegetarian
h. patient's sleep habits	6-8 hours a night
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Norethindrone and ethinyl estradiol 777, 1 per day
j. allergies	NKA
k. history of other adverse reactions to medications	None
l. other (describe) _____	None
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Patient is suffering from inflammation and pain from a possible wound infection.
3. Identify exclusions for self-treatment (Figure 40-5).	Involvement of mucous membrane
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer patient to an appropriate health care provider. (2) Recommend self-care with a nonprescription analgesic and nondrug measures. (3) Recommend self-care until patient can see an appropriate health care provider. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Patient should consult a health care provider.
6. Describe the recommended	"You should consult a health care provider for treatment because self-

therapeutic approach to the patient or caregiver.	treatment is not recommended.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“Seeing a health care provider is best because your problem is severe and debilitating. You may also have a bacterial infection that requires a prescription antibiotic. Finally, you are at high risk for serious foot problems because you have diabetes.”
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	“Is there anything I can put on my tongue to help stop the pain?”
Answer the patient’s or caregiver’s questions.	“Yes. There is a viscous lidocaine solution that your prescriber may recommend.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact the patient in a day or two to ensure that she made an appointment and sought medical care.

Key: NKA = No known allergies.

### Patient Counseling for Minor Burns, Sunburn, and Wounds

Once a burn is assessed as self-treatable, the patient’s immediate concern, relieving the pain and swelling, should be addressed. Some patients may not realize the potential complications of even minor burns; therefore, advice on how to protect the injury is vital in preventing possible infection and minimizing scarring.

After a 24- to 48-hour follow-up evaluation of the burn, either continuation of self-treatment or referral for further evaluation should be recommended. If self-treatment continues, the patient needs to know how long healing of the burn will take, as well as the signs and symptoms that indicate worsening of the injury. Burned skin is more susceptible to sunburn for several weeks after initial injury, so avoiding sun exposure and using sunscreen agents during this period are recommended. The box Patient Education for Minor Burns and Sunburn lists specific advice for successful treatment of these injuries.

#### Patient Education for Minor Burns and Sunburn

The objectives of self-treatment are to (1) relieve the pain and swelling, (2) protect the burned area from further physical injury, and (3) avoid infection and scarring of the burned area. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Nondrug Measures

- Treat superficial burns with no blistering as follows:
  - Immerse the affected area in cool tap water for 10-30 minutes.
  - Cleanse the area with water and a mild soap.
  - Apply a nonadherent dressing or skin protectant to the burn.
- For small burns with minor blistering, follow the first two steps above, but use a hydrocolloid dressing to protect the burn.
- If possible, avoid rupturing blisters.
- For sunburns, avoid further sun exposure and follow the previous procedures according to whether blistering is present.

#### Nonprescription Medications

- For superficial burns (including sunburn) with unbroken skin, treat the affected area with thin applications of skin protectants or topical anesthetics using a tissue to reduce the risk of infection from the fingertips.
- If the skin is broken, use topical antibiotics to prevent infection.
- If nutritional status is poor, take supplements for vitamins A, B, and C.
- Do not apply camphor, menthol, or ichthammol to the burn.
- For temporary relief of pain, take aspirin, acetaminophen, ibuprofen, or naproxen (see [Chapter 5](#) for dosage guidelines and safety considerations).

### When to Seek Medical Attention

- If a skin rash, weight gain, swelling, or blood in the stool occurs while taking pain relievers, report these side effects to a primary care provider.
- Report immediately to a primary care provider any redness, pain, or swelling that extends beyond the boundaries of the original injury.
- If the burn seems to worsen or is not healed significantly in 7 days, see a primary care provider for further treatment.

When assessing a wound, the provider should remember that minor cuts and abrasions may be self-treated, whereas chronic and more severe acute wounds or those that appear infected should first be evaluated by a primary care provider ([Figure 40-5](#)). Irrigation with soapy water or normal saline is generally recommended if a wound is dirty. Patients should be instructed to change the dressing only when it is dirty or not intact. The provider should ensure that the patient understands the basic steps in wound care, especially the selection of appropriate wound dressings. An explanation of basic skin physiology and the wound-healing process will enhance patient compliance. The box Patient Education for Acute Wounds lists specific information to provide patients. The patient should be referred for further treatment if the wound does not show signs of healing after 7 days of self-treatment.

#### Patient Education for Acute Wounds

The objective of self-treatment is to promote healing by protecting the wound from infection or further trauma. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

- Position the wound above the level of the heart to slow bleeding and relieve throbbing pain.
- If the wound is dirty, irrigate it with tepid tap water or normal saline solution, which is not toxic to cells. Use antiseptic solutions selectively and cautiously. Any inflammation should subside within 12-24 hours.
- When cleansing with soapy water, wash hands, apply mild liquid soap (e.g., Dove soap) to a wet cotton ball, and gently wash the wound area; rinse the wound under running warm water and gently pat the area dry.
- Cover the wound with a dressing that will keep the wound site moist. Make sure the dressing is the appropriate size and contour for the affected body part.
- Continue using a wound dressing until the wound bed has firmly closed and signs of inflammation in surrounding tissue have subsided. This process usually takes 2-3 weeks. Failure to keep the wound covered may delay healing.
- Avoid disrupting the dressing unnecessarily; change it only if it is dirty or is not intact. Most dressings should be changed every 3-5 days. Frequent changes may remove resurfacing layers of epithelium and slow the healing process. Change dressing if excessive fluid is released.
- Use a mild analgesic to control pain.
- All wound dressings should be kept in their original packaging and stored away from moisture.
- Observe the wound for signs of infection. Redness, swelling, and exudate are a normal part of healing; foul odor is not.

### When to Seek Medical Attention

- Consult a primary care provider if infection is suspected or the wound does not show signs of healing after 7 days of self-treatment.

### Evaluation of Patient Outcomes for Minor Burns, Sunburn, and Wounds

Burn should be reassessed after 24-48 hours because the full extent of skin damage may not be initially apparent. If the burn has progressed or worsened, the patient should be referred to an appropriate health care provider for further evaluation.

Minor wounds should exhibit decreased redness during healing. Signs that indicate the need for further evaluation include cellulitis or tissue infection, such as increasing redness, pain, and swelling that extend beyond the boundaries of the original wound, and contact dermatitis from topical treatment.

The patient's progress should be checked after 7 days to assess the healing process; therefore, a scheduled visit to see the provider is preferable. If the wound shows no signs of healing or has worsened (i.e., foul odor, worsened

inflammation), the patient should be referred for more aggressive therapy.

### Key Points for Minor Burns, Sunburn, and Wounds

- Minor burns and sunburn can often be treated with self-care. However, deeper burn injuries or burns affecting more than 1%-2% of BSA require medical attention.
- Burn injuries may increase in severity over the first 24-48 hours, so reassessment is always necessary.
- Patient complaints usually focus on pain. Skin protectants and dressings should be recommended, and aspirin or NSAIDs are often helpful if not contraindicated. The type of dressing or skin protectant used depends on whether the wound is dry or weeping. Blisters should not be ruptured. Topical hydrocortisone or anesthetics may provide additional relief in some patients but should be used sparingly on broken skin. Counterirritants such as camphor, menthol, and ichthammol should be avoided.
- Vitamins, whether systemic or topical, are generally of no value unless the patient is malnourished.
- Photosensitization reactions can often be assessed by reviewing the patient's history and must be distinguished from ordinary sunburns.
- Self-treatment of minor acute wounds is appropriate.
- First-aid antibiotics are used to prevent infection.
- Moist wound healing is now considered the standard of care.
- Proper selection of first-aid products, including appropriate wound dressing, is essential.

## Handbook of Nonprescription Drugs &gt; Chapter 41. Fungal Skin Infections

## Fungal Skin Infections: Introduction

Fungal skin infections, or dermatomycoses, are among the most common cutaneous disorders.<sup>1</sup> Dermatomycoses are often referred to as ringworm because their characteristic lesions are ring shaped with clear centers and red, scaly borders. However, these lesions can vary from the ring form and may present as single or multiple lesions that range from mild scaling to deep granulomas (inflamed, nodular lesions).

Fungal infections are usually superficial and can involve the hair, nails, and skin. The term *tinea* refers exclusively to dermatophyte infections. Most often, tinea infections are named according to the area of the body that is affected (e.g., scalp [tinea capitis], groin [tinea cruris], body [tinea corporis], feet [tinea pedis], and nails [tinea unguium]). These infections are generally caused by three genera of fungi. Species of *Candida* and other yeasts may also be involved<sup>2</sup>; however, currently available nonprescription antifungals are not indicated for self-management of cutaneous infections secondary to yeasts.<sup>3</sup>

Although many pathogenic fungi exist, the overall prevalence of actual superficial fungal infections is remarkably low. An estimated 10%-20% of the U.S. population suffer from a tinea infection at any one time.<sup>4,5</sup> Many degrees of susceptibility, from instantaneous "takes" by a single spore to severe trauma with massive exposure, produce a clinical infection. Trauma to the skin, especially trauma that produces blisters (e.g., from wearing ill-fitting footwear), appears to be significantly more important than simple exposure to the offending pathogens to the occurrence of human fungal infections.<sup>5</sup> Other predisposing factors for the development of tinea infections include diabetes mellitus and other diseases associated with immune system depression, use of immunosuppressive drugs, impaired circulation, poor nutrition and hygiene, occlusion of the skin, and warm, humid climates.<sup>5,6</sup>

The most prevalent cutaneous fungal infection in humans is tinea pedis (dermatophytosis of the foot, or athlete's foot). Tinea pedis afflicts approximately 26.5 million people in the United States every year; 7 of every 10 sufferers are male. Approximately 45% will suffer with tinea pedis episodically for more than 10 years. When exposure to infectious environments is equal, the incidence of tinea pedis infections in women approaches that in men.<sup>4,5,7,8</sup>

Tinea pedis is rare among blacks but common in whites, particularly whites who live in urban tropical areas.<sup>9</sup> An estimated 70% of people will be afflicted with tinea pedis in their lifetime. Although tinea pedis may occur at all ages, it is more common in adults, presumably because of their increased opportunities for exposure to pathogens.<sup>5</sup>

The risk for development of tinea pedis is greater in individuals who use public pools or bathing facilities than in the general population. However, tinea pedis may be acquired in the home if one or more members of the household are already infected. High-impact sports that cause chronic trauma to the feet (e.g., long-distance running) also predispose athletes to tinea pedis.<sup>10-12</sup> The trauma affords infecting fungi the opportunity to invade the outer layers of the skin. In addition, wearing socks and shoes exacerbates the problem by impeding the dispersion of heat and the evaporation of moisture, both of which facilitate fungal growth. In contrast, individuals who most often use footwear that allows the feet to remain cool and dry (e.g., sandals) are less likely to develop tinea pedis.

Tinea unguium (ringworm of the nails or onychomycosis) causes about half of all nail disorders and is sometimes associated with tinea pedis. The estimated prevalence of tinea unguium is between 2% and 8% percent, depending on the population.<sup>13</sup> The Food and Drug Administration (FDA) has not approved self-treatment of onychomycosis with topical nonprescription antifungals. Rather, the affected nail must be treated with systemic drug therapy (e.g., terbinafine or itraconazole) or removed surgically to rid the area of the offending fungus.

The next two most common infections are tinea corporis and tinea cruris. Tinea corporis, also called ringworm of the body, is most common in prepubescent individuals. It is frequently transmitted among children in day care centers and among child participants in contact sports, such as wrestling. However, it is also more common in adults and children who live in hot, humid climates. Individuals who are under stress or overweight are also at increased risk to develop tinea corporis.<sup>14,15</sup>

Tinea cruris, or jock itch, is most common during warm weather, but it can occur at any time of the year if the skin in the groin area stays warm and moist for long periods. For example, sweating or prolonged contact with wet clothing provides an ideal environment for the growth of fungi. Tinea cruris occurs more often in men than in women and rarely affects children. Close indirect or direct physical contact between infected males and noninfected females does not mitigate the higher prevalence of tinea cruris in males. For example, females who live in the same household with infected males do not develop infections at the same rate as noninfected males in the same household.<sup>5</sup>

Although its true incidence is unknown, tinea capitis, or ringworm of the scalp, occurs most often in children because they are more likely to have contact with infected individuals and because they are less attentive than adults to

personal hygiene. Compared with black males and white children, black female children are infected more often, possibly because of the hair care products and practices (e.g., occlusive hair dressings and tight braiding) that are unique to this population.<sup>5,14</sup>

Tinea capitis can be spread by direct contact with an infected person, but it is often spread by contact with infected fomites (e.g., using infected combs, hats, toys, or telephones; wearing infected clothing; using infected towels; or sleeping on infected linens). In some instances, tinea capitis is spread through contact with other infected individuals or with infected cats or dogs.<sup>16</sup> As with onychomycosis, tinea capitis cannot be managed with topical nonprescription antifungals.

### Pathophysiology of Fungal Skin Infections

Tinea infections are caused by three genera of pathogenic fungi: *Trichophyton*, *Microsporum*, and *Epidermophyton*. Tinea pedis and tinea cruris are caused by species of *Epidermophyton* and *Trichophyton*. Species of *Trichophyton* and *Microsporum* cause ringworm of the scalp. *Trichophyton* species also cause ringworm of the nails or onychomycosis. All species of the three genera can cause tinea corporis.<sup>5</sup> Fungal transmission can occur through contact with infected people, animals, soil, or fomites. Dermatophytes are classified according to their habitat: anthropophilic (humans), zoophilic (animals), and geophilic (soil). Most tinea infections are caused by person-to-person contact with individuals infected with anthropophilic dermatophytes.<sup>14</sup>

In addition to specific fungi, other environmental factors such as climate and social customs contribute to dermatophytosis development. Footwear is a key variable, as illustrated by the incidence of tinea pedis in any population that wears occlusive footwear, especially in the summer and in tropical or subtropical climates. Nonporous shoe material increases temperature and hydration of the skin, which interferes with the barrier function of the stratum corneum. Similarly, sweating or wearing wet clothing for long periods of time can predispose individuals to the development of tinea corporis and tinea cruris.

Chronic health problems and medications that weaken or suppress the immune system can also increase the risk for development of tinea infections. For example, patients with diabetes or human immunodeficiency virus and elderly persons taking medications such as glucocorticoids should be instructed to monitor themselves for signs and symptoms of tinea infections. They should also be instructed about the importance of proper hygiene and diet for the prevention of tinea infections and other health problems.

After a dermatophyte is inoculated into the skin under suitable conditions, a tinea infection progresses through several stages. The stages include periods of incubation and then enlargement, followed by a refractory period and a stage of involution. During the incubation period, the dermatophyte grows in the stratum corneum, sometimes with minimal signs of infection. After the incubation period and once the infection is established, two factors appear to play a role in determining the size and duration of the lesions: the growth rate of the organism and the epidermal turnover rate.<sup>17</sup> The fungal growth rate must equal or exceed the epidermal turnover rate, or the organism will be quickly shed.

Dermatophytid infestations remain within the stratum corneum. Resistance to the spread of infection seems to involve both immunologic and nonimmunologic mechanisms. For example, the presence of a serum inhibitory factor (SIF) appears to limit the growth of dermatophytes beyond the stratum corneum. SIF is not an antibody but a dialyzable, heat-labile component of fresh sera. It appears that SIF chelates the iron that dermatophytes need for continued growth.<sup>17</sup> Once in the stratum corneum, dermatophytes produce keratinases and other proteolytic enzymes that cause allergic reactions when they reach living epidermis.<sup>5</sup>

The major immunologic defense against fungal skin infections is the type IV delayed-hypersensitivity response. The refractory period precedes complete development of this cell-mediated immunity. The fungal growth rate typically exceeds epidermal turnover, and inflammation and pruritus are at their peak. After development of an adequate immune response, symptoms of superficial fungal infections diminish, and the infection may clear spontaneously during the involution period. Patients with chronic infections typically present with much less inflammation. This presentation may be caused by a suppressed hypersensitivity response, which in turn reduces the inflammatory response.<sup>2</sup>

### Clinical Presentation of Fungal Skin Infections

The clinical spectrum of tinea infections ranges from mild itching and scaling to a severe, exudative inflammatory process characterized by denudation, fissuring, crusting, and/or discoloration of the affected skin. Individuals experiencing their first tinea infection and patients with infections secondary to zoophilic fungi tend to present with greater inflammation.<sup>14</sup> Table 41-1 summarizes key differences between fungal skin infections, contact dermatitis, and bacterial skin infections to distinguish the underlying cause of a patient's symptoms from other conditions that may have a similar clinical presentation.

#### Tinea Pedis

Clinically, tinea pedis has four accepted variants; two or more of these types may overlap. The most common is the chronic intertriginous type,<sup>5</sup> characterized by fissuring, scaling, or maceration in the interdigital spaces; malodor; pruritus; and/or a stinging sensation on the feet (see Color Plates, photograph 27). Typically, the infection involves the lateral toe webs, usually between either the fourth and fifth or the third and fourth toes. From these sites, the infection may spread to the sole or instep of the foot but rarely to the dorsum. Warmth and humidity aggravate this condition; consequently, hyperhidrosis (excessive sweating) becomes an underlying problem and must be treated along with the dermatophyte infestation.<sup>5</sup>

Normal resident aerobic diphtheroids may become involved in the tinea pedis process. After initial invasion of the stratum corneum by dermatophytes, enough moisture may accumulate to trigger a bacterial overgrowth. Increased moisture and temperature then lead to the release of metabolic products that diffuse easily through the underlying horny layer already damaged by fungal invasion. In more severe cases, gram-negative organisms intrude and may exacerbate the condition, causing skin maceration, white hyperkeratosis, or erosions with increased patient symptomatology.<sup>5</sup>

The second variant of tinea pedis foot is known as the chronic papulosquamous pattern.<sup>5</sup> It is usually found on both feet and is characterized by mild inflammation and diffuse, moccasin-like scaling on the soles of the feet. Tinea unguium of one or more toenails may also be present and may continue to fuel the infection. The toenails must first be cured with oral drug therapy, such as itraconazole, ketoconazole, or terbinafine, or they must be removed surgically to rid the area of the offending fungus.

**TABLE 41-1 Differentiation of Fungal Skin Infections and Skin Disorders with Similar Presentation**

<b>Criterion</b>	<b>Fungal Skin Infections</b>	<b>Contact Dermatitis</b>	<b>Bacterial Skin Infection</b>
Location	On areas of the body where excess moisture accumulates, such as the feet, groin area, scalp, and under the arms	Any area of the body exposed to the allergen/irritant; hands, face, legs, ears, eyes, and anogenital area involved most often	Anywhere on the body
Signs	Presents either as soggy malodorous, thickened skin; acute vesicular rash; or fine scaling of affected area with varying degrees of inflammation; cracks and fissures may also be present	Presents as a variety of lesions: raised wheals, fluid-filled vesicles, or both	Presents as a variety of lesions from macules to pustules to ulcers with redness surrounding the lesion; lesions are often warmer than surrounding, unaffected skin
Symptoms	Itching and pain	Itching and pain	Irritation and pain
Quantity/severity	Usually localized to one region of the body but can spread	Affects all areas of exposed skin but does not spread	Usually localized to one region of the body but can spread
Timing	Variable onset	Variable onset from immediately after exposure to 3 weeks after contact	Variable onset
Cause	Superficial fungal infection	Exposure to skin irritants or allergens	Superficial bacterial infection
Modifying factors	Treated with nonprescription astringents, antifungals, and nondrug measures to keep the area clean and dry	Treated with topical antipruritics, skin protectants, astringents, and nondrug measures to avoid reexposure	Treated with prescription antibiotics

The third variant of tinea pedis is the vesicular type, usually caused by *Trichophyton mentagrophytes* var. *interdigitale*.<sup>5</sup> Small vesicles or vesicopustules are observed near the instep and on the mid-anterior plantar surface. Skin scaling is seen on these areas as well as on the toe webs. This variant is symptomatic in the summer and is clinically quiescent during the cooler months.

The acute ulcerative type is the fourth variant of tinea pedis. It is often associated with macerated, denuded, weeping ulcerations on the sole of the foot. Typically, white hyperkeratosis and a pungent odor are present. This type of infection, which is complicated by an overgrowth of opportunistic, gram-negative bacteria such as *Proteus* and *Pseudomonas*, has been called a “dermatophytosis complex,” and it may produce an extremely painful, erosive, purulent interspace that can impede the patient’s ability to walk.<sup>5</sup>

### Tinea Unguium

Nails affected by tinea unguium gradually lose their normal shiny luster and become opaque. If left untreated, the nails become thick, rough, yellow, opaque, and friable. The nail may separate from the nail bed if the infection progresses secondarily to subungual hyperkeratosis. Ultimately, the nail may be lost altogether. Subungual debris also provides an excellent medium for the growth of opportunistic bacteria and other microorganisms, which can lead to further infectious complications.<sup>5</sup>

### Tinea Corporis

Tinea corporis may have a diverse clinical presentation. Most often, the lesions, which involve glabrous (smooth and bare) skin, begin as small, circular, erythematous, scaly areas. The lesions spread peripherally, and the borders may contain vesicles or pustules. Infected individuals may also complain of pruritus.<sup>18</sup>

Tinea corporis can occur on any part of the body. However, the location of the infection can provide clues to the type of infecting dermatophyte. For example, zoophilic dermatophytes often infect areas of exposed skin such as the neck, face, and arms. In contrast, infections secondary to anthropophilic dermatophytes often occur in occluded areas or in areas of trauma.<sup>5</sup>

### Tinea Cruris

Tinea cruris is more common in males and occurs on the medial and upper parts of the thighs and the pubic area. The lesions have well-demarcated margins that are elevated slightly and are more erythematous than the central area; small vesicles may be seen, especially at the margins. Acute lesions are bright red, and chronic cases tend to have more of a hyperpigmented appearance; fine scaling is usually present. This condition is generally bilateral with significant pruritus; however, the lesions usually spare the penis and scrotum. This characteristic can help to distinguish tinea cruris from candidiasis, which also causes lesions in these areas.<sup>19</sup> Pain may also be present during periods of sweating or when the skin becomes macerated or infected by a secondary microorganism.<sup>4,5</sup>

### Tinea Capitis

Clinically, tinea capitis may present as one of four variant patterns, depending on the causative dermatophyte. In noninflammatory tinea capitis, lesions begin as small papules surrounding individual hair shafts. Subsequently, the lesions spread centrifugally to involve all hairs in their path. Although there is some scaling of the scalp, little inflammation is present (see Color Plates, photograph 28). Hairs in the lesions are a dull gray color and usually break off above the scalp level.<sup>5</sup>

The inflammatory type of tinea capitis produces a spectrum of inflammation, ranging from pustules to kerion formation. Kerions are weeping lesions whose exudate forms thick crusts on the scalp.<sup>8</sup> In addition to fever and pain, individuals with this type of tinea capitis may experience a higher degree of pruritus. Regional lymph nodes may also be enlarged.<sup>5</sup>

The black dot variety of tinea capitis was named for the appearance of infected areas of the scalp. The location of arthrospores on the hair shaft causes hairs to break off at the level of the scalp, leaving black dots on the scalp surface. Hair loss, inflammation, and scaling with this type of tinea capitis range from minimal to extensive. Therefore, this variant is especially challenging to diagnose.<sup>5,20,21</sup>

The favus variant of tinea capitis typically presents as patchy areas of hair loss and scutula (yellowish crusts and scales). Ultimately, these lesions can coalesce to involve a major portion of the scalp. If left untreated, this condition can lead to secondary bacterial infections, scalp atrophy, scarring, and permanent hair loss.<sup>5</sup>

## Treatment of Fungal Skin Infections

### Treatment Goals

The goals of treating fungal skin infections are to (1) provide symptomatic relief, (2) eradicate existing infection, and (3) prevent future infections.

### General Treatment Approach

In many instances, patients can effectively self-treat tinea pedis, tinea corporis, and tinea cruris with nonprescription topical antifungals and nonpharmacologic measures. However, individuals with tinea unguium or tinea capitis should be referred to a primary care provider for treatment.

Patients who want to improve the appearance of the nail during prescription treatment of tinea unguium can use Fungal Nail Revitalizer to reduce nail discoloration and to smooth out the thick, rough nail. This product contains calcium carbonate (a strong alkali) and urea (a protein denaturant) to debride nail tissue. The patient should apply the cream over the entire surface of the infected nail, scrub this area for at least 1 minute with the provided nailbrush, and then wash and dry the nail completely. For optimum results, this procedure should be performed daily for 3 weeks. Patients should be advised that this product will improve only the appearance of the nails and that it will not treat the tinea infection.

Before recommending therapy, the provider must be reasonably sure that the lesions are consistent with a tinea infection. Their appearance should conform to the descriptions provided in Clinical Presentation of Fungal Skin Infections, and photographs 27 and 28 of tinea lesions (see Color Plates) should be consulted for comparison. Furthermore, the lesions should not resemble any other skin conditions covered in this text. When in doubt about the true cause of a condition, the patient should be advised to consult a primary care provider or dermatologist. [Figure 41-1](#) outlines the appropriate self-treatment options for fungal skin infections.

A number of topical antifungals are available in a variety of dosage forms for self-treatment of fungal skin infections. The selection of a particular product depends on the type of infection and on individual patient characteristics and preferences. For example, in acute, inflammatory tinea pedis, characterized by reddened, oozing, and vesicular eruptions, the inflammation must be counteracted with solutions of astringent aluminum salts before antifungal therapy can be instituted.

A critical determinant of the outcome of therapy is the patient's ability to adhere to the recommended therapy for the appropriate length of time. Adherence may be difficult because these conditions may take between 2 and 4 weeks to resolve. Patients may be tempted to terminate therapy when their symptoms subside but before the infection has been eradicated. Another determinant of therapeutic outcome relates to the patient's adherence to the nonpharmacologic measures intended to complement the effects of nonprescription antifungals and to prevent future infections. These measures include keeping the skin clean and dry, avoiding the sharing of personal articles, and avoiding contact with infected fomites or persons who have a fungal infection.

#### Nonpharmacologic Therapy

The box Patient Education for Fungal Skin Infections located at the end of the chapter describes nonpharmacologic measures intended to complement the effects of nonprescription antifungals and to prevent future infections. The patient should follow these measures during and after treatment of the infection.

#### Pharmacologic Therapy

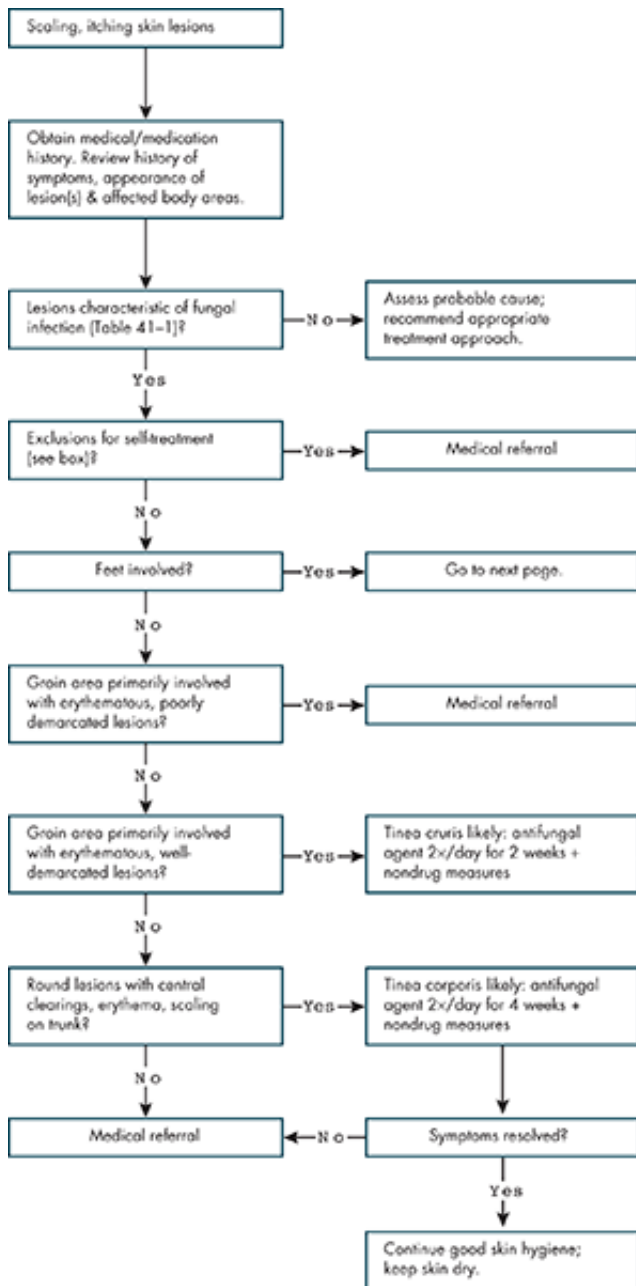

An antifungal ingredient must have at least one well-designed clinical trial that demonstrates its effectiveness in treating tinea infections before FDA will classify it as a monograph antifungal.<sup>22</sup> Butenafine hydrochloride, clioquinol, clotrimazole, haloprogin, miconazole nitrate, terbinafine hydrochloride, tolnaftate, and various undecylenates are considered safe and effective for nonprescription use in the treatment of fungal skin infections.<sup>3</sup> These agents are labeled for treatment of athlete's foot, jock itch, and body ringworm. The recommended treatment period is a minimum of 1-4 weeks.

#### Clotrimazole and Miconazole Nitrate

Topical clotrimazole and miconazole nitrate are imidazole derivatives that demonstrate fungistatic/fungicidal activity (depending on concentration) against *Trichophyton mentagrophytes*, *Trichophyton rubrum*, *Epidermophyton floccosum*, and *Candida albicans*.

These agents act by inhibiting the biosynthesis of ergosterol and other sterols and by damaging the fungal cell wall membrane, thereby altering its permeability and resulting in the loss of essential intracellular elements. These drugs have also been shown to inhibit the oxidative and peroxidative enzyme activity that results in intracellular buildup of toxic concentrations of hydrogen peroxide; this toxicity may then contribute to the degradation of subcellular organelles and to cellular necrosis. In *C. albicans* infections, these drugs have been shown to inhibit the transformation of blastospores into the invasive mycelial form that causes infection.

FDA classifies clotrimazole 1% and miconazole nitrate 2% as safe and effective for topical nonprescription use in treating tinea pedis, tinea cruris, and tinea corporis. Clotrimazole and miconazole nitrate are applied once in the morning and once in the evening. For athlete's foot and ringworm, these drugs should be applied twice daily for 4 weeks; for jock itch they should be applied twice daily for 2 weeks.

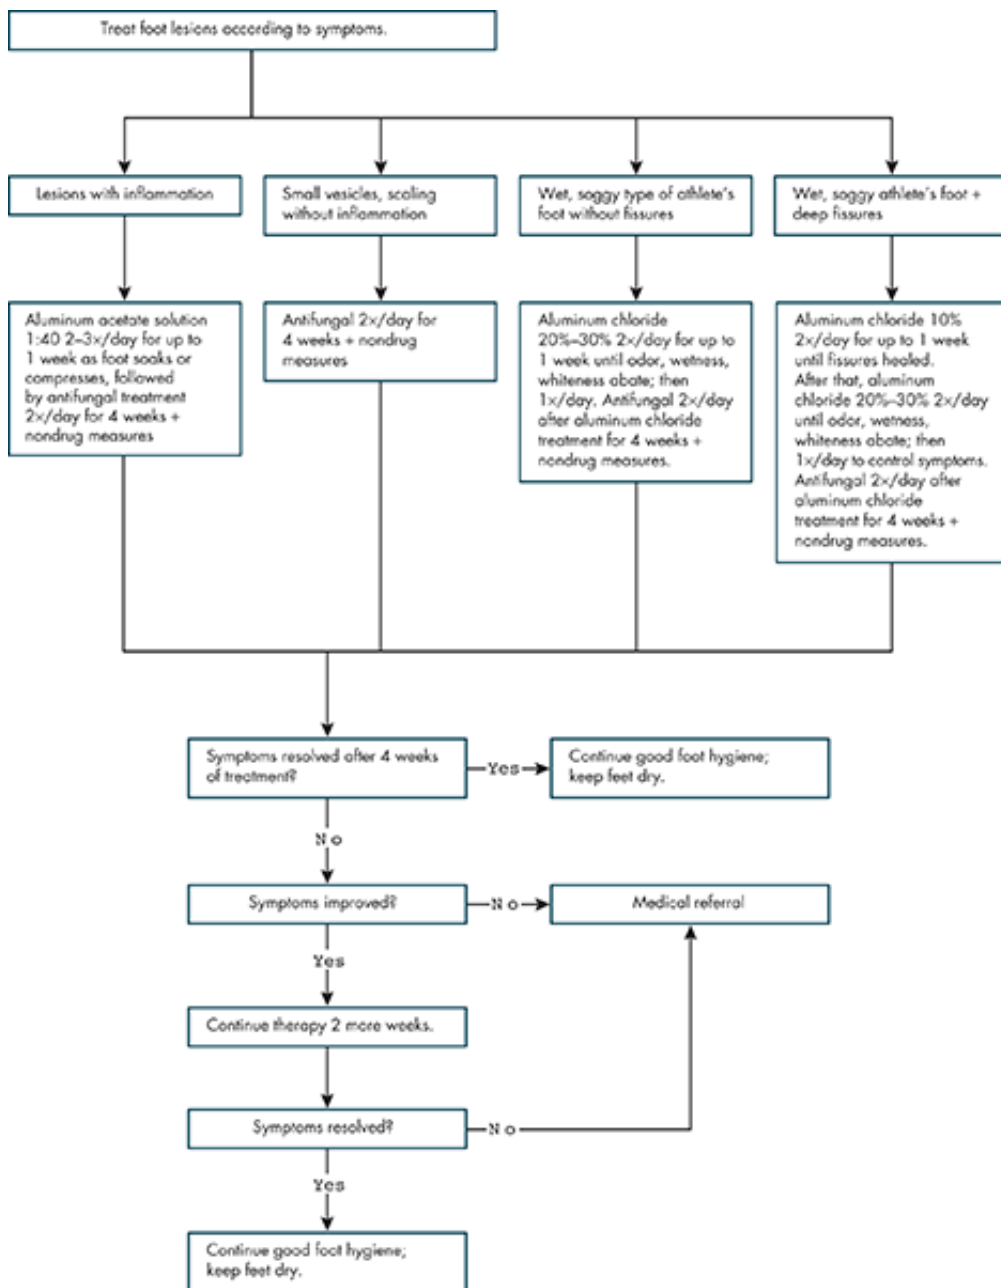

**Exclusions for Self-treatment**

- Causative factor unclear
- Unsuccessful initial treatment, or worsening of condition
- Nails or scalp involved
- Face, mucous membranes, or genitalia involved
- Signs of possible secondary bacterial infection (oozing purulent material)
- Excessive and continuous exudation
- Condition extensive, seriously inflamed, or debilitating
- Diabetes, systemic infection, immune deficiency
- Fever, malaise, or both

Self-care of fungal skin infections.

Rare cases of mild skin irritation, burning, and stinging have occurred with use of nonprescription topical antifungals. No drug-drug interactions have been reported with topical use of clotrimazole and miconazole nitrate for up to 4 weeks.<sup>3</sup>

### Terbinafine Hydrochloride

Topical terbinafine hydrochloride 1% was reclassified as a nonprescription medication in 1999.

This antifungal agent inhibits squalene epoxidase, a key enzyme in fungi sterol biosynthesis. This action results in a deficiency in ergosterol and a corresponding accumulation of squalene within the fungal cell, causing fungal cell death.

Terbinafine hydrochloride is indicated for interdigital tinea pedis, tinea cruris, and tinea corporis caused by *E. floccosum*, *T. mentagrophytes*, and *T. rubrum*. Similar to miconazole and clotrimazole, terbinafine hydrochloride should be applied sparingly to the affected area twice daily.

In clinical trials, this drug demonstrated that it could cure tinea pedis with 1 week of treatment. However, complete resolution of symptoms may require up to 4 weeks of treatment. For athlete's foot between the toes, patients should apply terbinafine twice a day for 1 week. For athlete's foot on the bottom or sides of the foot, it should be applied twice a day for 2 weeks. For jock itch and ringworm, patients should apply terbinafine once a day for 1 week or as directed by a primary care provider.

Clinical trials to date have demonstrated a low incidence of side effects for terbinafine hydrochloride. These side

effects include irritation (1%), burning (0.8%), and itching/dryness (0.2%).<sup>23,24</sup> No drug-drug interactions have been reported with topical use of this agent.

### Butenafine Hydrochloride

Topical butenafine hydrochloride 1% was reclassified as a nonprescription medication in 2001. Like terbinafine, this antifungal agent is a squalene epoxidase inhibitor. This action results in a deficiency in ergosterol, a corresponding accumulation of squalene within the fungal cell, and eventually cell death.

Butenafine hydrochloride is indicated as a cure for tinea pedis between the toes, tinea cruris, and tinea corporis caused by *E. floccosum*, *T. mentagrophytes*, and *T. rubrum*. Similar to other nonprescription topical antifungals, butenafine hydrochloride also relieves the itching, burning, cracking, and scaling that can accompany these conditions. This agent's effectiveness on infection of the bottom or sides of the foot is unknown.

Patients suffering from tinea pedis should be advised to apply a thin film to affected skin between and around toes twice daily for 1 week, once a day for 4 weeks, or as directed by a primary care provider. Patients with tinea cruris or tinea corporis should apply a thin film to the affected area once daily for 2 weeks or as directed by a primary care provider.

Effective treatment rates of butenafine for interdigital tinea pedis with 1-week and 4-week application durations are reported to be approximately 38% and 74%, respectively. In clinical trials, Lotrimin Ultra kept users free of tinea pedis for up to 3 months.<sup>25</sup> To date, clinical trials demonstrate a low incidence of side effects for this agent. Further, no drug-drug interactions have been reported with its topical use.

### Tolnaftate

Topical tolnaftate has demonstrated clinical efficacy since its commercial introduction in the United States in 1965. In addition, it was the standard against which the efficacy of other topical antifungals was compared for many years. Although tolnaftate's exact mechanism of action has not been reported, it is believed that tolnaftate distorts the hyphae and stunts the mycelial growth of the fungi species. Tolnaftate is the only nonprescription drug approved for both preventing and treating tinea infections.<sup>3</sup> It acts on fungi that are typically responsible for tinea infections, including *T. mentagrophytes*, *T. rubrum*, and *E. floccosum*.

Tolnaftate is valuable primarily in the dry, scaly lesions. Relapse of superficial fungal infections has occurred after tolnaftate therapy has been discontinued. Relapse may be caused by inadequate duration of treatment, patient nonadherence with the medication, or use of tolnaftate when an oral antifungal should have been used.

As a cream, tolnaftate is formulated in a polyethylene glycol 400/propylene glycol vehicle. The 1% solution is formulated in polyethylene glycol 400 and may be more effective than the cream. The solution solidifies when exposed to cold but liquefies with no loss in potency if allowed to warm. These vehicles are particularly advantageous in superficial antifungal therapy because they are nonocclusive, nontoxic, nonsensitizing, water miscible, anhydrous, easy to apply, and efficient in delivering the drug to the affected area.

The topical powder formulation of tolnaftate uses cornstarch/talc as the vehicle. The two agents combined absorb excess moisture in the affected area that allows fungus to thrive. The topical aerosol formulation of tolnaftate includes talc, alcohol, and the propellant vehicle.

Tolnaftate (1% solution, cream, gel, powder, spray powder, or spray liquid) is applied sparingly twice daily. Effective therapy usually takes 2-4 weeks, although some individuals (patients with lesions between the toes or on pressure areas of the foot) may require treatment lasting 4-6 weeks. Tolnaftate is well tolerated when applied to intact or broken skin, although it usually stings slightly when applied. Delayed hypersensitivity reactions to tolnaftate are extremely rare. No drug-drug interactions have been reported with topical use of tolnaftate.

### Clioquinol/Haloprogin/Undecylenic Acid

Although FDA has approved clioquinol 3%, haloprogin 1%, and undecylenic acid and undecylenate salts for nonprescription use, no commercially available nonprescription topical antifungals currently contain these agents.

### Salts of Aluminum

Because aluminum salts do not have any direct antifungal activity, these drugs were not included in the FDA final monograph for topical antifungal drug products. Rather, they are approved for the relief of inflammatory conditions of the skin, such as tinea pedis. However, their effectiveness as astringents and their possible use in treating tinea pedis merit their inclusion in this chapter. Historically, aluminum acetate has been the foremost astringent used for both the acute, inflammatory type and the wet, soggy type of tinea pedis. Aluminum chloride is also used to treat the wet, soggy type of infection.

Aluminum salts do not cure athlete's foot entirely but are useful when combined with other topical antifungal drugs. Application of aluminum salts merely shifts the disease process back to the simple dry type of athlete's foot, which can then be controlled with other agents, such as tolnaftate or an imidazole.

The action and efficacy of aluminum salts appear to be two pronged. First, these compounds act as astringents. Their drying ability probably involves complexing of the astringent agent with proteins, thereby altering the proteins' ability to swell and hold water. Astringents decrease edema, exudation, and inflammation by reducing cell membrane permeability and by hardening the intercellular cement of the capillary epithelium. Second, aluminum salts in concentrations greater than 20% possess antibacterial activity, which may help to prevent the development of secondary bacterial infections. Aluminum chloride solution (20%) may exhibit that activity in two ways: by directly killing bacteria and by drying the interspaces. Solutions of 20% aluminum acetate and 20% aluminum chloride demonstrate equal in vitro antibacterial efficacy.

Aluminum acetate for use in tinea pedis is generally diluted with about 10-40 parts of water. Depending on the situation, the whole foot may be immersed in the solution for 20 minutes up to 3 times a day (every 6-8 hours), or the solution may be applied to the affected area in the form of a wet dressing.

For patient convenience, aluminum acetate solution (Burow's solution) or modified Burow's solution (which includes dextrin, polyethylene glycol and sodium bicarbonate as inactive ingredients) is available for immediate use in solution or in forms to be dissolved in water (powder packets, powder, and effervescent tablets) (see [Chapter 34](#)). Aqueous solutions of 20%-30% aluminum chloride have been the most beneficial for the wet, soggy type of athlete's foot.<sup>7</sup> Twice-daily applications are generally used until the signs and symptoms (odor, wetness, and whiteness) abate. After that, once-daily applications may control the symptoms. In hot, humid weather, the original condition may return within 7-10 days after the application is stopped.

Because aluminum salts penetrate the skin poorly, their toxicity is low. However, a few cases of irritation have been reported in patients with deep fissures. Therefore, the use of concentrated aluminum salt solutions on severely eroded or deeply fissured skin is contraindicated. In this case, the salts must be diluted to a lower concentration (10% aluminum chloride) for initial treatment.

Solutions of aluminum acetate or aluminum chloride have the potential for misuse (e.g., accidental childhood poisoning by ingestion of the solutions or the solid tablets), so precautions must be taken to prevent this misuse. Products containing these ingredients are intended for external use only and should not be applied near the eyes. Prolonged or continuous use of aluminum acetate solution may produce tissue necrosis. In the acute inflammatory stage of tinea pedis, this solution should be used less than 1 week. The provider should instruct the patient to discontinue its use if inflammatory lesions appear or worsen.

#### Pharmacotherapeutic Comparison

All the topical antifungals approved for treating cutaneous fungal infections have demonstrated effectiveness. The allure of butenafine hydrochloride and terbinafine hydrochloride is their ability to cure athlete's foot in some patients after 1 week. However, a close analysis of the data demonstrates that the number of patients achieving complete resolution of the problem is low, and that the effectiveness of these agents parallels that of other antifungals previously approved for nonprescription use (e.g., clotrimazole and miconazole nitrate).<sup>26</sup>

Controlled studies have demonstrated the efficacy of clotrimazole and miconazole nitrate for tinea pedis and other kinds of fungal infections (see [Chapter 8](#)). Both agents would be expected to demonstrate efficacy comparable to that of tolnaftate for tinea infections. If patient factors (e.g., nonadherence or improper foot hygiene) can be ruled out as a cause of treatment failure, both can be suggested as alternative treatment modalities.

#### Product Selection Guidelines

Cutaneous antifungals are available as ointments, creams, powders, and aerosols ([Table 41-2](#)). Creams or solutions are the most efficient and effective dosage forms for delivery of the active ingredient to the epidermis. Sprays and powders are less effective because often they are not rubbed into the skin. They are probably more useful as adjuncts to a cream or a solution or as prophylactic agents in preventing new or recurrent infections.

Patient adherence is influenced by product selection. Therefore, the provider should recommend a drug and dosage form that are likely to cause the least interference with daily habits and activities, without sacrificing efficacy. For example, elderly patients may require a preparation that is easy to use. Obese patients, in whom excessive sweating may contribute to the disease, should sprinkle talcum powder on the feet and in the shoes as adjunctive therapy to keep the feet dry. Under certain circumstances, the provider may need to instruct the caregiver instead of the patient in the proper use of foot products.

Before recommending a nonprescription product, the provider should review the patient's medical history. For example, patients with diabetes should have their blood glucose levels under control because increased glucose in perspiration may promote fungal growth. Patients with allergic dermatitides often have a history of asthma, hay fever, or atopic dermatitis; therefore, they are extremely sensitive to many oral and topical agents. Acquiring a good medical history may aid in distinguishing a tinea infection from atopic dermatitis and may avoid the recommendation of a product that might cause further skin irritation.

In addition, product line extensions that carry the same brand name do not necessarily have the same active ingredient(s). For example, the cream and solution formulations of Lotrimin AF contain clotrimazole 1%, whereas the

topical spray and powder formulations contain miconazole nitrate 2%. Indeed, Lotrimin Ultra, the newest line extension, contains butenafine hydrochloride. It is economically prudent for the manufacturer to create a line extension with a different active ingredient for an already-approved brand name. Filing New Drug Applications (NDAs) for new brand names of antifungal products with different active ingredients would be prohibitively expensive. Similarly, Desenex spray liquid and spray powder formulations contain miconazole nitrate 2%, whereas these products formerly contained undecylenic acid and zinc undecylenate in a 25% concentration. In addition, Desenex Max Antifungal Cream now contains terbinafine 1%.

### Complementary Therapies

Bitter orange, tea tree oil, and garlic have been used with some success in the management of fungal skin infections, with few or no side effects. None of the studies that examined these ingredients included more than 60 patients, but the results suggest that further investigation of each complementary therapy is warranted.

**TABLE 41-2 Selected Nonprescription Topical Antifungal Products**

<i>Trade Name</i>	<i>Active Ingredient</i>	<i>Directions for Use</i>
Cruex Antifungal Spray Powder	Miconazole 2%	Spray a thin layer over affected area twice daily for 2 weeks.
Desenex Antifungal Liquid Spray	Miconazole 2%	Spray a thin layer over affected area twice daily for 4 weeks.
Lamisil AT Antifungal Gel,	Terbinafine HCl 1%	For athlete's foot between the toes, apply once a day for 1 week. For jock itch and ringworm, apply once a day (morning or night) for 1 week.
Lamisil AT Cream	Terbinafine HCl 1%	For athlete's foot between the toes, apply twice a day (morning and night) for 1 week. For athlete's foot on the bottom or sides of the foot, apply twice a day (morning and night) for 2 weeks. For jock itch and ringworm, apply once a day (morning or night) for 1 week.
Lotrimin AF Clotrimazole Cream	Clotrimazole 1%	For athlete's foot and ringworm, use twice daily for 4 weeks. For jock itch, use daily for 2 weeks.
Lotrimin AF Antifungal Jock Itch Powder Aerosol Spray	Miconazole nitrate 2%	For athlete's foot and ringworm, use twice daily for 4 weeks. For jock itch, use twice daily for 2 weeks.
Lotrimin Ultra Antifungal Cream	Butenafine 1%	For athlete's foot between the toes, apply to affected skin between and around the toes twice a day for 1 week (morning and night), or once a day for 4 weeks. For jock itch and ringworm, apply once a day to affected skin for 2 weeks.
Micatin Antifungal Cream	Miconazole nitrate 2%	For athlete's foot and ringworm, use twice daily for 4 weeks. For jock itch, use twice daily for 2 weeks.
Tinactin Athlete's Foot Cream	Tolnaftate 1%	For athlete's foot and ringworm, use daily for 4 weeks. For jock itch, use daily for 2 weeks.
Tinactin Powder Spray	Tolnaftate 1%	For athlete's foot and ringworm, spray twice daily for 4 weeks. For prevention, spray 1-2 times daily.

Bitter orange has the least evidence of safety and efficacy. However, in one controlled trial, topical application of oil of bitter orange 3 times daily demonstrated benefit in most patients with tinea corporis, tinea cruris, or tinea pedis in 1-4 weeks. The only reported side effect was mild, local irritation.<sup>27</sup>

Investigations into the efficacy of tea tree oil for tinea pedis have yielded mixed results. In one study that compared tolnaftate 1% cream with tea tree oil 10% cream, both agents were equally effective in relieving the scaling, inflammation, itching, and burning, but neither agent was more effective than placebo in achieving mycologic cure.<sup>28</sup> Results of two other studies suggest that tea tree oil 25% and 50% appear to result in both symptomatic and

mycologic cure of tinea pedis. However, the mycologic cure rates were inferior to those for butenafine and clotrimazole.<sup>29,30</sup>

Research relative to the efficacy of topical garlic for the management of tinea infections has been positive. For example, application of a garlic gel containing 0.6% ajoene (i.e., a constituent of garlic believed to have antifungal activity) was demonstrated to be as effective as terbinafine 1% cream in a study of subjects with either tinea corporis or cruris.<sup>31</sup> In another study, the use of ajoene 0.4% as a cream resulted in clinical and mycologic cure of all research subjects after 2 weeks of use.<sup>32</sup> In the most recent study, researchers reported evidence that ajoene 1% cream produces a higher mycologic cure rate than that of ajoene 0.6% and terbinafine 1% creams.<sup>33</sup> (For an in-depth discussion of garlic, see [Chapter 51](#).)

### Assessment of Fungal Skin Infections: A Case-Based Approach

Fungal skin infections must be differentiated from bacterial skin infections and noninfectious dermatitis. If possible, the provider should examine the affected area to determine whether the disorder's manifestation is typical of a fungal infection ([Table 41-1](#)).<sup>34</sup> The only true determinant of a fungal infection is a clinical laboratory evaluation of tissue scrapings from the affected area.

The provider should question the patient thoroughly regarding the condition and its characteristics to determine symptoms, extent of disease, previous patient adherence with medications, and any compounding disorders (e.g., diabetes or obesity) that might render the patient susceptible. Patients with diabetes, for example, may present with a mixed dermatophytid and monilial infection. In general, it is appropriate to inspect the affected area if privacy and sanitary conditions allow. Inspection is especially appropriate for patients with diabetes.

Cases 41-1 and 41-2 are examples of the assessment of patients with a fungal skin infection.

The most common complaint of patients with a cutaneous fungal infection is pruritus. However, if fissures are present, particularly between the toes, painful burning and stinging may also occur. If the area is abraded, denuded, or inflamed, weeping or oozing may be present in addition to pain. Some patients may merely remark on the bothersome scaling of dry skin, particularly if the infection involves the soles of the feet. In other instances, small vesicular lesions may combine to form a larger bullous eruption marked by pain and irritation, or the only symptoms may be brittleness and discoloration of a hypertrophied nail.

The provider should seek to distinguish a tinea infection from diseases with similar symptoms, such as bacterial infection, irritant contact dermatitis, allergic contact dermatitis, and atopic dermatitis. For this reason, the manifestation of these disorders is briefly discussed here. In children, peridigital dermatitis or atopic dermatitis is more common than tinea pedis. Shoe dermatitis is perhaps the most common form of allergic contact dermatitis from clothing. Therefore, the provider should inquire about the type of footwear worn by the patient and about recent footwear changes. Since 1950, the increased use of rubber and adhesives in footwear has paralleled the increase in reports of shoe dermatitis in the dermatologic and podiatric literature. Contact allergy to accelerators (the chemical compounds used to speed the processing of rubber used in sponge-rubber insoles for tennis shoes) has also been reported.<sup>35</sup> In addition to accelerators, antioxidants have been implicated as major chemical allergens, and various phenolic resins used in adhesives are also troublesome. The patient is usually unaware that his or her footwear may be causing the problem.

Hyperhidrosis of interdigital spaces and of the sole of the foot is common, as is infection of the toe webs by gram-negative bacteria. In hyperhidrosis, tender vesicles cover the sole of the foot and toes, and these areas may be quite painful. The skin generally turns white, erodes, and becomes macerated. This condition is accompanied by a foul foot odor. A soggy wetness of the toe webs and the immediately adjacent skin characterizes infection by gram-negative bacteria; the affected tissue is damp and softened. The last toe web (adjacent to the little toe) is the most common area of primary or initial involvement because it is deeper and extends more proximally than the web between the other toes. Furthermore, abundant exocrine sweat glands, a semioclusive anatomic setting, and the added occlusion provided by footwear enhance development of the disease at this site. The provider must be careful not to confuse this condition with soft corns, which also appear between the fourth and fifth toes.

### Patient Counseling for Fungal Skin Infections

The proper application technique for topical antifungals and required duration of therapy should be described to the patient to prevent over- or undermedication. The patient should be told to apply the medication regularly throughout a complete course of therapy. Information that will help to control or eradicate the infection and that will minimize the likelihood of recurrent infections may also be provided. This information should address proper care of the infected skin site, appropriate laundry techniques and products, minimal use of occlusive clothing, and avoidance of habits or behavior that may lead to recurring infections. The patient should also be told which conditions indicate the need to consult a primary care provider (e.g., the development of a secondary bacterial infection). The box Patient Education for Fungal Skin Infections lists specific information to provide patients.

### Patient Education for Fungal Skin Infections

The objectives of self-treatment are to (1) relieve itching, burning, and other discomfort; (2) inhibit the growth of fungi and cure the disorder; and (3) prevent recurrent infections. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

### **Nondrug Measures**

- To prevent spreading the infection to other parts of the body, either use a separate towel to dry the affected area or dry the affected area last.
- Do not share towels, clothing, or other personal articles with household members, especially when an infection is present.
- Launder contaminated towels and clothing in hot water, and dry them on a hot dryer setting to prevent spreading the infection.
- Cleanse skin daily with soap and water, and thoroughly pat dry to remove oils and other substances that promote growth of fungi.
- If possible, do not wear clothing or shoes that cause the skin to stay wet. Wool and synthetic fabrics prevent optimal air circulation.
- If needed, allow shoes to dry thoroughly before wearing them again. Dust shoes with medicated or nonmedicated foot powder to help keep them dry.
- If needed, place odor-controlling insoles in casual or athletic shoes. These insoles also provide some support and cushioning for the feet. Change insoles routinely every 3-4 months or more often if their condition warrants. Take care that the shoe fit is not compromised by the insoles.
- As with all topical medications, discontinue the use of an antifungal if irritation, sensitization, or worsening of the skin condition occurs.
- Avoid contact with people who have fungal infections. Wear protective footwear (e.g., rubber or wooden sandals) in areas of family or public use, such as home bathrooms or community showers.

### **Nonprescription Medications**

- Ask a health care provider for assistance in picking the appropriate antifungal agent and dosage form for your infection.
- Available agents include butenafine, clotrimazole, miconazole nitrate, terbinafine, and tolnaftate.
- It usually takes 2-4 weeks to cure tinea infections. Some cases may require 4-6 weeks of treatment.
- Apply the antifungal to the clean, dry affected area as directed (in the morning or evening if once daily, or both times if twice daily). Massage the medication into the area. Note that creams and solutions are easier to work into the skin; therefore, they are probably more effective treatment forms.
- Avoid getting the product in your eyes.
- Wash hands thoroughly with soap and water before and after applying the product.
- Topical antifungals themselves may cause itching, redness, and irritation.
- Tolnaftate may sting slightly upon application.
- When the medication is to be applied to pressure areas of the foot, where the horny skin layer is thicker, apply a keratolytic agent (e.g., Whitfield's ointment) to the affected area first to help the antifungal penetrate the skin.
- If oozing lesions are present, apply aluminum acetate solution (1:40) to the area before applying the antifungal:
  - Soak the area in an aluminum acetate solution for 20 minutes up to 3 times a day (every 6-8 hours), or apply the solution to the affected area in the form of a wet dressing.
  - Note that aluminum acetate solution (Burow's solution) or modified Burow's solution is available for immediate use as a solution or as forms to be dissolved in water (powder packets, powder, and effervescent tablets).
  - Avoid getting the product in your eyes.
  - To avoid skin damage, use the solution for no more than 1 week. Discontinue use of the solution if inflammatory lesions appear or worsen.
- For the wet, soggy type of athlete's foot, apply to or soak foot in aluminum acetate solution (1:40) before applying the antifungal:
  - Soak feet with aluminum acetate solution (1:40) twice daily until the odor, wetness, and whiteness are gone. After that, soak once daily to control the symptoms.
  - If deep fissures are present in the skin, use a more dilute solution of aluminum acetate for initial treatment.

### **When to Seek Medical Attention**

- Discontinue use of the product and contact a primary care provider if itching or swelling occurs, or if the infection worsens.
- Consult a primary care provider if the infection worsens or persists beyond the recommended length of

therapy.

**Case 41-1**

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient presents to the pharmacy with redness in the shape of eyeglasses on her nose and around both eyes. Scaling and weeping vesicles on both eyelids extend into both eyebrows. The patient has an open sore on the bridge of her nose that she admits she caused by scratching the area. She also complains of intense itching. Her symptoms began about a month ago, right after she started to swim competitively at school.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	She says that the itching is worse after she removes her swim goggles.
c. description of the patient's efforts to relieve the symptoms	She has tried hydrocortisone ointment with no relief.
d. patient's identity	Sara Lansbury
e. age, sex, height, and weight	21 years old, female, 5 ft 6 in, 128 lb
f. patient's occupation	College student
g. patient's dietary habits	Patient is a vegetarian.
h. patient's sleep habits	Number of hours that patient sleeps each night varies.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Seasonal allergies: Claritin D in the spring and fall
j. allergies	Ragweed and maple trees
k. history of other adverse reactions to medications	None
l. other (describe) _____	Patient has a history of ringworm during swim season.
<b>Assessment and Triage</b>	

2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s) (Table 41-1).	Patient is suffering from inflammation, weeping, denudation, and intense itching on her face, secondary to ringworm.
3. Identify exclusions for self-treatment (Figure 41-1). <sup>36</sup>	Severe symptoms, eye involvement, eyebrow involvement
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer patient to an appropriate health care provider. (2) Recommend self-care with a nonprescription antifungal and nondrug measures. (3) Recommend self-care until patient can see an appropriate health care provider. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Patient should consult a health care provider.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should consult a health care provider for treatment."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"This option is best because your problem is severe and is affecting skin near your eyes. You will need oral medication that is available only by prescription to treat your condition."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"One of my teammates said that I should suffocate the ringworms by applying clear nail polish on the itchy spots. Does this really work?"
Answer the patient's or caregiver's questions.	"Ringworm is not actually caused by worms. It is caused by a fungus that lives in the superficial skin layers. Nail polish will have no effect on your symptoms. It can, however, cause severe irritation if you get it in your eyes."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact the patient in a day or two to ensure that she made an appointment and sought medical care.

**Case 41-2**

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient describes intense itching and a red, scaly rash on and between the third, fourth, and fifth toes of each foot. He says that the symptoms began a week ago, soon after he began his summer job at a lawn maintenance service.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The patient says that the itching is worse after he gets home from work in the evening.
c. description of the patient's efforts to relieve the symptoms	The patient has not tried anything other than scratching the affected area when the itching becomes unbearable.
d. patient's identity	Robert Grees
e. age, sex, height, and weight	17 years old, male, 5 ft 11 in., 175 lb
f. patient's occupation	Lawn maintenance worker
g. patient's dietary habits	Eats fast food for breakfast and lunch.
h. patient's sleep habits	6-7 hours nightly
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	None
j. allergies	None
k. history of other adverse reactions to medications	None
l. other (describe) _____	NA
<b>Assessment And Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s) ( <a href="#">Table 41-1</a> ).	Robert is suffering from a scaling red rash and itching secondary to athlete's foot. He likely contracted this problem from mowing lawns.
3. Identify exclusions for self-treatment	None

(Figure 41-1). <sup>36</sup>	
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Robert to an appropriate health care provider. (2) Recommend self-care with a nonprescription antifungal and nondrug measures. (3) Recommend self-care until Robert can see an appropriate provider. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Robert should use a nonprescription antifungal and nondrug measures to treat his problem.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Regular use of any of the commercially available nonprescription antifungals in any dosage form except a spray or powder should alleviate the problem. However, for the medication to be optimally effective, you will have to take several measures to keep the affected area clean and dry."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Athlete's foot can be effectively managed with nonprescription antifungals and nondrug measures (keeping the area clean and dry) as long as there is no evidence of secondary infection or preexisting medical conditions that would preclude self-treatment, as in your case. Sprays and powders are less effective because they often are not rubbed into the skin."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	See the box Patient Education for Fungal Skin Infections.
b. maximum number of days the therapy should be employed	See the box Patient Education for Fungal Skin Infections.
c. product administration procedures	See the box Patient Education for Fungal Skin Infections.
d. expected time to onset of relief	"Itching may be relieved somewhat within a few days, but eradication of the causative microorganism may take up to 4 weeks."
e. degree of relief that can be reasonably expected	"Athlete's foot can be cured if you use the antifungal and nondrug measures properly."
f. most common side effects	See the box Patient Education for Fungal Skin Infections.
g. side effects that warrant medical	See the box Patient Education for Fungal Skin Infections.

intervention should they occur	
h. patient options in the event that condition worsens or persists	See the box Patient Education for Fungal Skin Infections.
i. product storage requirements	“Store in a cool, dry place out of children’s reach.”
j. specific nondrug measures	See the box Patient Education for Fungal Skin Infections.
Solicit follow-up questions from the patient or caregiver.	“Why do I have this? I am not an athlete.”
Answer the patient’s or caregiver’s questions.	“Your feet are sweating more than usual now because you are working outside. As a result, the skin on your feet remains damp until you remove your shoes and socks after work. Moisture helps the fungus that causes ringworm to thrive.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Ask the patient to call to update you on his response to your recommendations. Or you could call him in a week to evaluate the outcome.

Key: NA = Not applicable.

### Evaluation of Patient Outcomes for Fungal Skin Infections

In general, the patient should begin to see some relief of the itching, scaling, and/or inflammation within 1 week. If the disorder shows improvement within this time frame, continuing treatment for 1-3 weeks (depending on the type of tinea infection and medication being used) should be recommended. If the disorder has not improved or has worsened, referring the patient to a primary care provider for more aggressive therapy is appropriate. Recurrent skin infections may be a sign of undiagnosed diabetes, immunodeficiency, or another organic problem that requires medical evaluation.

### Key Points for Fungal Skin Infections

- Tinea corporis, tinea cruris, and tinea pedis can be treated with nonprescription drugs. Clotrimazole, miconazole nitrate, terbinafine hydrochloride, butenafine hydrochloride, tolnaftate, and undecylenic acid and its derivatives are efficacious for this purpose.
- The effectiveness of topical antifungals will be limited unless the patient eliminates other predisposing factors to tinea infections.
- These drugs are effective in all their delivery vehicles, but the powder forms should be reserved only for extremely mild conditions or as adjunctive therapy.
- Because solutions and creams can spread beyond the affected area, they should be used sparingly.
- When recommended for suspected or actual dermatophytosis, these topical antifungals should be used twice daily (morning and night). Treatment should be continued for 2-4 weeks, depending on the symptoms. After that time, the patient and/or provider should evaluate the effectiveness of the therapy.
- To minimize nonadherence, the provider should advise patients that alleviation of symptoms will not occur overnight. Patients should also be cautioned that frequent recurrence of any of these problems is an indication that they should consult a primary care provider.
- Immunocompromised patients and those with diabetes or circulatory problems should be treated by a primary care provider.

## Handbook of Nonprescription Drugs > Chapter 42. Warts

### Warts: Introduction

Warts, or verrucae, are a common skin disorder caused by human papillomaviruses (HPVs).<sup>1-12</sup> Approximately 7%-10% of the general population has warts. This percentage does not include nongenital warts.<sup>1</sup> Approximately 70% of warts are common warts.<sup>2-4</sup> Warts occur more frequently in children and adolescents than in infants and adults, with the peak incidence among 12- to 16-year-olds.<sup>1,2,5</sup> Warts are a benign condition and often go away without treatment. Approximately 23% of warts regress within 2 months, 30% within 3 months, and 65%-78% within 2 years.<sup>1,6,11</sup> This chapter discusses treatments for common and plantar warts that are found on areas of the body and are amenable to self-treatment.

High-quality, consistent data on warts are limited. Several risk factors exist for the development of warts, such as having previous or existing warts; having a depressed immune system; going barefoot, especially on wet surfaces; using swimming pools and public showers; working in a meat handling occupation; and biting one's fingernails.<sup>1-3,5</sup> HPV infection occurs via person-to-person contact, autoinoculation, or fomites found on contaminated surfaces.<sup>1,3,7</sup> When minor skin abrasions are present, HPV may enter the epidermal layer and infect the basal keratinocytes.<sup>1</sup> HPV infection is limited to the epidermal tissues and does not spread systemically.<sup>11</sup> Although different types of HPV are not found exclusively in specific areas of the body, different types do preferentially infect nonkeratinized mucous membranes rather than keratinized stratified squamous epithelium.<sup>1</sup> The incubation period may be long (i.e., 8 months).<sup>2</sup> The manifestation of warts may depend on the immune response of the infected individual. How quickly warts are cleared is influenced by factors such as viral type, patient immune status, and the extent and duration of time the warts have been present.<sup>1</sup>

*Editor's Note:* This chapter is based on the 17th edition chapter of the same title, written by Nicholas G. Popovich and Gail D. Newton.

### Pathophysiology of Warts

HPVs are double-stranded DNA viruses.<sup>1-6,8</sup> More than 150 related viruses and more than 200 subgroups have been identified through DNA sequencing.<sup>2</sup> Warts may affect skin and mucous membranes anywhere on the body.<sup>9</sup> Specific HPV types cause warts in specific areas of the body.<sup>4</sup> HPV-2, HPV-4, HPV-27, and HPV-57 are the most common cause of warts on the hands. HPV-1 is the most common cause of warts on the feet.<sup>7,12</sup>

### Clinical Presentation

The appearance, size, shape, and response to treatment of individual warts vary by HPV type and the specific location of the warts on the body.<sup>1,3,9</sup> [Table 42-1](#) describes the categories of warts.

Common warts are skin-colored or brown, hyperkeratotic, dome-shaped papules with a rough cauliflower-like appearance; they frequently occur on the hands.<sup>1,2</sup> Common warts are often painless.<sup>2</sup> Plantar warts are skin-colored callous-like lesions that occur on the feet.<sup>2</sup> Because of their deeply penetrating sloping sides and central depressions, plantar warts may be painful, especially if they occur in a weight-bearing location.<sup>1</sup> When tightly clustered, multiple plantar warts may appear as one large wart. In this presentation, the warts are called a mosaic wart.<sup>1,2</sup>

Plantar warts can be confused with corns or calluses.<sup>1</sup> If there is any question about whether the lesion is a wart, the patient should be referred to a medical provider for evaluation and treatment. To distinguish plantar warts from calluses, the provider may remove the outer keratinous layer of the lesion. When the surface layer is removed, the warts exhibit pinpoint bleeding, which resembles small black seeds. The bleeding is from thrombosed capillaries in the warts.<sup>1</sup>

Plantar warts can also be confused with malignant growths.<sup>6</sup> The latter are usually very painful and discolored, and they bleed and grow quickly.<sup>7</sup> Patients with lesions displaying these characteristics should be referred for medical evaluation and treatment.

### Treatment of Warts

No single regimen is universally effective in the treatment of warts.<sup>1,4,9</sup> Although several treatment options are available for relief of symptoms associated with warts and for their removal, none cure the HPV infection.<sup>1,4,9</sup> Limited high-quality evidence exists for the efficacy of most wart treatments, and a placebo effect cannot be ruled out.<sup>1,4,7</sup> Because many warts will resolve without treatment, one treatment option is a wait-and-see approach. However, many patients seek treatment because of the pain, cosmetic appearance, and social stigma associated with warts or because of concern about transmitting warts to others. The decision to treat a wart is based on the patient's desire for treatment; the presence of pain or bleeding, disabling/disfiguring lesions, or large or multiple lesions; the desire to prevent transmission of the warts; and the presence of an immunocompromising condition.<sup>4,8</sup> Warts often recur after treatment. Some warts, especially recurrent or recalcitrant warts, will require a combination of treatments.<sup>1</sup>

**TABLE 42-1 Types of Nongenital Warts**

<i>Type</i>	<i>Common Location</i>	<i>Commonly Occurs in</i>	<i>Characteristics</i>
Common (verruca vulgaris)	Hands	Children and adolescents	Skin colored or brown, dome-shaped, hyperkeratotic papules with a rough surface
Flat (verruca plana)	Face	Children	Smooth, flat topped, yellow-brown papules; common in children but rare in adults
Plantar (verruca vulgaris)	Feet	Adolescents and young adults	Skin-colored, flat, callous-like papules on the feet
Mosaic	Feet	Adolescents and young adults	Multiple, closely grouped plantar warts
Periungual	Nails	Persons who bite their nails	Thickened, fissured, cauliflower-like skin around the nail plate
Filiform	Face		Rapidly growing, thread-like projections

Source: References 1, 2, 5, and 9.

### Treatment Goals

The goals for the treatment of warts are to (1) eliminate signs and symptoms associated with the warts, (2) remove the wart without scarring, (3) prevent recurrence of the warts, and (4) prevent spread of HPV through autoinoculation of one's self or transmission to others.<sup>8</sup>

### General Treatment Approach

Determining the optimal treatment for a patient with warts depends on a number of factors, including the patient's age; the type, number, size, location, and duration of the lesions; the patient's immune status; the cost of therapy; access to therapies; side effects; and treatment preference.<sup>1,4</sup>

Although approximately 70% of warts will resolve after 2 years, even without treatment, only 46% of affected individuals will remain wart free.<sup>6</sup> Warts are less likely to resolve spontaneously in adults, immunocompromised patients, and patients with persistent warts.<sup>1</sup> A wait-and-see approach allows the continued spread of warts through autoinoculation and transmission to others.<sup>4,6,7</sup> Patient education regarding the cause of warts and ways to prevent their transmission to others is a key part of the treatment plan for any patient with warts.

**Figure 42-1** outlines the treatment of warts and lists exclusions for self-treatment. A medical provider should evaluate patients with multiple warts, warts in any area other than the hands and feet, large warts, and/or painful warts to determine whether the warts may be caused by a more serious condition. Patients with poor circulation or decreased sensitivity (e.g., patients with diabetes mellitus or peripheral vascular disease) should not self-treat warts because of the potential for injury.

### Nonpharmacologic Therapy

Nonpharmacologic therapies focus mainly on preventing the spread of the HPV virus. To prevent spreading warts through autoinoculation, patients should be instructed to avoid cutting, shaving or picking at warts; to wash hands before and after treating or touching warts; to keep feet clean and dry; to use a designated towel to dry warts; and to avoid using the designated towel to dry other body areas. To prevent transmission of the virus to others, patients

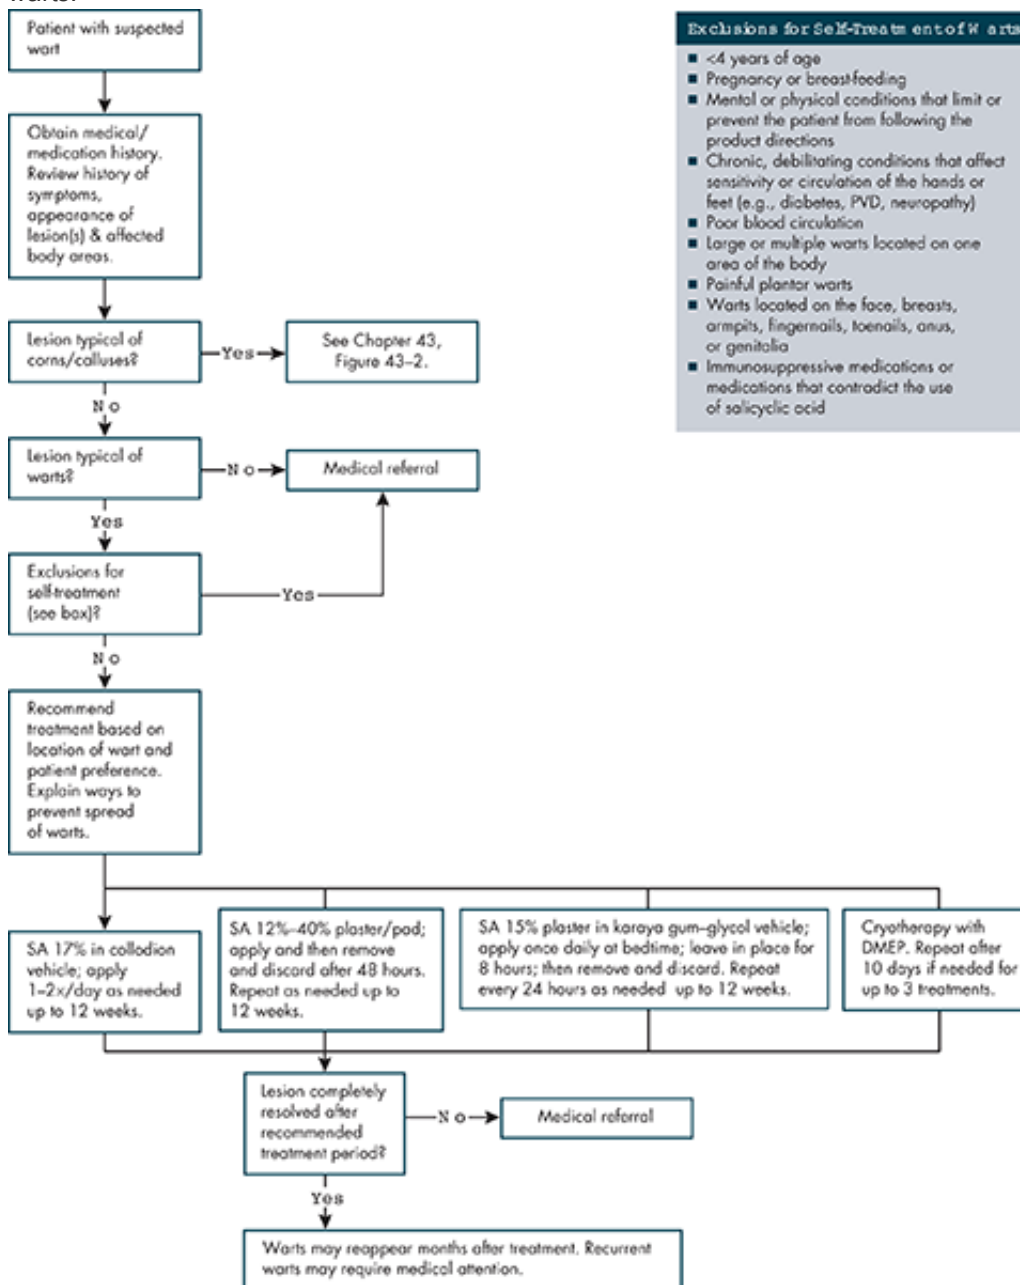

should be instructed to avoid sharing towels, razors, socks, shoes, and so; to keep the wart covered; and to not walk barefoot, especially in bathrooms or in public places.

## Pharmacologic Therapy

### Salicylic Acid

Salicylic acid is a keratolytic agent available in three different formulations for use in self-treatment of common and plantar warts: salicylic acid 12%–40% in a plaster vehicle, salicylic acid 17% in a collodion vehicle, and salicylic acid 15% in a karaya gum glycol plaster vehicle.<sup>2,13</sup> Table 42-2 lists selected products that contain salicylic acid products. Salicylic acid concentrations of 17% or less are generally used for common warts, and higher concentrations (i.e., 40%) are used for plantar warts.<sup>9</sup>

Salicylic acid slowly destroys the virus-infected cells. It may also induce an immune response secondary to mild irritation.<sup>1,3-5,9</sup> The Food and Drug Administration (FDA) recommends that use of salicylic acid for self-treatment of warts be restricted to common and plantar warts.<sup>13</sup> Self-treatment is not recommended for other types of warts because of the difficulty in accurately recognizing and treating warts without medical oversight. A medical provider should evaluate patients with painful plantar warts and lesions that are not easily recognizable as common or plantar warts.

Copyright © American Pharmacists Association  
All rights reserved. Any use is subject to the Terms of Use.

Self-care of warts. Key: DMEP = Dimethyl ether and propane; PVD = peripheral vascular disease; SA = salicylic acid.

The advantages of topical nonprescription products that contain salicylic acid include low cost, ease of access, few adverse effects if used as directed, and a reasonable effectiveness.<sup>1,3,5</sup> Compared with placebo, salicylic acid is more effective in treating warts at all locations but may be more effective for warts on the hands than those on the feet.<sup>5</sup> Disadvantages include the need for consistent, frequent application; the potential for damage to healthy skin surrounding the wart; and the duration of treatment needed to see a therapeutic response.<sup>1,3, 5,9</sup> Side effects include skin irritation and the potential for systemic toxicity.<sup>1,3,9</sup>

In most instances, warts will begin to improve within a couple of weeks of treatment with salicylic acid. Self-treatment of common and plantar warts should not continue past 12 weeks. A medical provider should evaluate patients who have warts that do not completely resolve after 12 weeks.

Table 42-3 provides guidelines for using salicylic acid products.<sup>14-16</sup>

**TABLE 42-2 Selected Self-Care Products for Warts**

<b>Salicylic Acid 40% Products</b>
Compound W One Step Pads
Compound W Pads for Feet
Compound W Pads for Kids
Compound W Waterproof Invisible Strips

Compound W Freeze Off Wart Removal System

**TABLE 42-3 Guidelines for Treating Warts with Selected Salicylic Acid Products**

**Salicylic Acid 40% Plasters/Pads/Strips<sup>14</sup>**

- Wash the affected area.
- May soak the affected area for 5 minutes in warm water.
- Dry the affected area thoroughly.
- Apply disc of appropriate size to wart and cover with pad. Or trim a plaster to fit the wart, apply plaster, and cover with an occlusive tape.
- Remove plasters/pads/strips after 48 hours.
- Repeat procedure every 48 hours as needed until the wart is removed. These products may be used for up to 12 weeks.

#### **Salicyclic Acid 17% Liquid in Collodion Vehicle<sup>15</sup>**

- Wash the affected area.
- May soak the affected area for 5 minutes in warm water.
- Dry the affected area thoroughly.
- Apply one drop at a time to cover the wart. Protect adjacent healthy skin from coming into contact with the drug.
- Let solution dry completely.
- Cover wart with self-adhesive cover-up discs or an occlusive tape.
- Repeat procedure 1-2 times a day until the wart is removed. This product may be used for up to 12 weeks.

#### **Salicyclic Acid 15% Patch in Karaya Gum Vehicle<sup>16</sup>**

- Wash the affected area.
- Dry the affected area thoroughly.
- Use a file to gently remove the keratinous surface.
- Trim patch to fit wart.
- Apply a drop of warm water to the wart.
- Apply patch at bedtime and allow patch to remain on wart for at least 8 hours.
- Cover patch with occlusive tape.
- Remove patch after at least 8 hours.
- Repeat daily until the wart is removed. This product may be used up to 12 weeks.

### Cryotherapy

Health care providers have used cryotherapy with liquid nitrogen and other agents for many years to treat warts in their offices.<sup>6</sup> Cryotherapy destroys the wart by freezing the wart tissue.<sup>6,9</sup> Liquid nitrogen can freeze tissue to temperatures around -196°C.<sup>3,7</sup> As temperatures fall to -5 to -15°C, extracellular ice crystals form.<sup>6</sup> At -40°C and below, intracellular ice crystals form.<sup>6</sup> As tissue freezes, microthrombi form, leading to ischemic necrosis and destruction of the HPV-infected keratinocytes.<sup>6</sup> The freezing also causes local inflammation that may clear the wart through a cell-mediated response.<sup>1,4</sup>

FDA has approved a mixture of dimethyl ether and propane for the self-treatment of common and plantar warts. Compared with liquid nitrogen used in physician's offices, nonprescription products containing dimethyl ether reach only temperatures around -70°C.<sup>1,3</sup>

Nonprescription cryotherapy products have similar, but product-specific, directions for preparing the applicator. [Table 42-4](#) provides guidelines for using cryotherapy products and illustrates the procedural differences between two selected nonprescription cryotherapy products.<sup>17-19</sup> The cryotherapy is applied directly to the wart. Patients must follow the directions carefully to avoid damaging the healthy skin surrounding the wart. A blister will form under the wart and, after about 10 days, the wart will fall off. Applicators must not be used more than once to avoid reinfecting

the tissue or spreading the virus to others.

**TABLE 42-4 Guidelines for Treating Warts with Selected Cryotherapy Products**

<b>General Guidelines</b>
• Wash hands before and after use.
• Soak the wart in warm water for 5 minutes; then use a file or pumice stone to remove the keratinous surface.
• Do not hold the canister close to your face, body, or clothing.
• Discard the foam applicator after a single use.
• Repeat after 14 days, if needed.
• Do not use product if:
- You cannot follow the instructions exactly as written.
- You are not sure if the condition is a wart.
- The wart is on children younger than 4 years.
- You are pregnant or breast-feeding.
- You have diabetes or poor circulation.
- The wart is on thin, sensitive, or irritated skin such as the face, breasts, genitals, or arm pits.
<b>Compound W Freeze Off<sup>17,18</sup></b>
• Keep the protective cap on the canister. Hold the Compound W Freeze Off applicator by the plastic stick. Attach the applicator to the canister by firmly inserting the applicator stick into the opening.
• Place the canister on a sturdy surface.
• Remove the protective cap from the canister. Keeping the can upright, press the dispensing valve all the way down for 3-5 seconds to saturate the applicator. Release your finger from the dispensing valve when droplets start to fall from the applicator tip.
• Turn the canister so that the applicator is pointing straight down and wait 15 seconds.
• Position the wart so that it faces upward.
• While keeping the applicator pointing straight down, lightly place the tip of the applicator on the center of the wart. Do not press the valve while the applicator is in contact with the skin. The applicator should be applied to the skin for no more than 40 seconds. Do not dab applicator onto the wart.
• Replace the protective cap after use.
• This product may be used for up to 3 treatments.
<b>Wartner Wart Removal System<sup>17,19</sup></b>
• Holding the end of the foam applicator between the thumb and index finger, squeeze until a small opening appears.
• Slide the opening of the foam applicator over the stick of the holder until the stick is no longer visible. You will find the holder in the bag containing the foam applicators.
• Insert the holder with the applicator in the opening on the top of the cap so that the foam applicator is no longer visible.

• Place the aerosol spray can on a sturdy surface.
• Holding the can firmly at the bottom, press down the valve for 2-3 seconds.
• Leave the foam applicator on the holder and wait 20 seconds.
• Lightly place the tip of the foam applicator to the wart.
- Apply 20 seconds for common warts.
- Apply 40 seconds for plantar warts.
• This product may be used for up to four treatments.

With regard to evaluating the effectiveness of cryotherapy in the treatment of both common and plantar warts, cryotherapy is no more effective than salicyclic acid or placebo.<sup>3,5,9</sup> One study found that cryotherapy may be more effective than salicyclic acid for warts on the hands but not on the feet.<sup>20</sup> The use of two freeze-thaw cycles during a treatment may improve the clearance of plantar warts, but this approach has not been shown to improve clearance of common warts on the hands.<sup>1,3,11</sup> Aggressive cryotherapy treatments are more effective (52%) than gentle treatments (31%) but have an increased incidence of adverse effects.<sup>1,3,5,9</sup> Treating the wart every 2-3 weeks with cryotherapy yields the best results.<sup>5,11</sup>

The advantages of nonprescription cryotherapy products include their easy access and lower cost, compared with the liquid nitrogen used in the physician's office, and one treatment may be sufficient to clear the wart. Disadvantages of cryotherapy include pain and the potential for damage to healthy skin surrounding the wart, and self-treatments may not be as effective as the liquid nitrogen used in the physician's office. Potential adverse effects include blistering, scarring, hypo- or hyperpigmentation, and tendon damage or nerve damage with aggressive therapy.<sup>1,3,9</sup> In most instances, warts will resolve after one treatment with cryotherapy. Self-treatment of common and plantar warts may be repeated every 2-3 weeks. Treatments should not continue beyond 3 months or a maximum of four treatments. If this regimen does not completely resolve the wart, the patient should be referred to a medical provider for evaluation and treatment.

#### Other Pharmacologic Therapies

Numerous prescription products, laser treatments, immunotherapies, and combinations of treatments are used to treat warts. Discussion of prescription products and procedures is outside the scope of this chapter. Limited or inconsistent data exist for the effectiveness of using products other than salicyclic acid and cryotherapy for self-treatment of common and plantar warts.

#### Complementary Therapies

##### Folklore

Some of the numerous folk remedies for warts include the following: "Rub dry toast on a wart then bury it at night by the full moon and by the next full moon it will be gone," and, as described in the Foxfire 40th Anniversary Book, "Take a knife, and on the wart make a cross over the top. It works with the sap of the trees."<sup>21</sup> Folk remedies such as these are often based on anecdotal successes and highlight the probability that many warts resolve spontaneously without treatment.<sup>1</sup>

##### Vitamin A

Retinoids such as vitamin A regulate epithelial cell differentiation and keratin expression. Vitamin A may interfere with HPV replication. One case report of a 30-year-old woman found vitamin A to be effective in clearing recalcitrant warts. The woman's warts had been present for a 9-year period despite various treatments. The treatment required 6 months to clear the largest wart. The report noted that untreated warts on the opposite hand cleared without application of vitamin A, which may illustrate either a placebo effect or an unknown mechanism of action.<sup>12</sup>

##### Dietary Zinc

Deficiencies of zinc lead to decreased immunity.<sup>1,10</sup> Dietary zinc is postulated to improve immune response and inhibit HPV replication.<sup>10</sup> One placebo-controlled trial evaluated 10 mg/kg/day of zinc to treat recalcitrant warts.

Complete clearance was reported in 87% of the treatment group versus no clearance in the placebo group.<sup>1,10</sup>

### Garlic (*Allium sativum*)

Garlic is thought to inhibit cellular proliferation of virus-infected cells.<sup>1,22</sup> One placebo-controlled trial reported that application of chloroform extracts of garlic resulted in complete resolution of warts for all 23 patients after 1-2 weeks, with no recurrence after 3-4 months.<sup>1,22</sup>

### Essential Oils

Essential oils contain a combination of oils with antiviral properties. One case report<sup>23</sup> of a woman with ovarian cancer found essential oils to be effective in clearing recalcitrant warts. Essential oils were applied directly on the wart; then a salicylic acid plaster (40%) followed by an adhesive bandage was used to cover the wart. The woman's warts cleared after 17 days of treatment with essential oils and salicylic acid and did not return. It is difficult to determine whether the essential oils contributed to the effectiveness of the salicylic acid.

### Occlusion with Duct Tape

Duct tape has become a popular, inexpensive treatment for warts.<sup>1</sup> The mechanism by which duct tape clears warts is still unclear, but local irritation may cause stimulation of the patient's immune response.<sup>5</sup>

One randomized controlled study<sup>24</sup> compared duct tape occlusion with cryotherapy for the treatment of common warts. In one treatment group, liquid nitrogen was applied to warts every 2-3 weeks, for a maximum of six treatments or until the warts resolved. In the other treatment group, duct tape was applied to the wart, left in place for 6 days, removed in the evening of the sixth day, and replaced with a new piece of duct tape the next morning; this procedure was repeated for up to 2 months or until the wart resolved. The treated warts were completely resolved in 84.6% of the patients in the duct tape group and 60% of the patients in the cryotherapy group.<sup>1,5</sup>

Another randomized controlled trial<sup>25</sup> yielded conflicting results. This trial compared occlusion of warts with either duct tape or moleskin. In each group the wart was shaved and the pad applied for 1 week. The wart was then debrided with an emery board, and the pad was reapplied for an additional week. This procedure was repeated for up to 2 months or until the wart resolved. Six months later, patients were asked if the wart had recurred. The treatment groups demonstrated no difference in resolution or recurrence of the warts.<sup>5,25</sup>

More evidence on the effectiveness of therapy with duct tape is needed. Duct tape may have a place in therapy for small children with warts or in combination with other treatments.<sup>1</sup>

### Assessment of Warts: A Case Based Approach

When a patient presents with a wart-like lesion, the provider should gather information from multiple sources to determine whether the lesion is suitable for self-treatment and whether available treatments are appropriate for that individual. Before a treatment plan is recommended, the provider should inspect the wart to accurately identify the lesion as a wart and to determine whether self-treatment is appropriate. The provider should question the patient about medication use and the existence of medical conditions that would preclude self-treatment. The patient should also be asked about previous attempts to treat the lesion and whether those attempts were successful. Patient preferences for type of treatment may be used to help guide product selection.

Table 42-5 compares characteristics of warts, corns, calluses, and malignant growths. Cases 42-1 and 42-2 illustrate the assessment of patients with warts.

**TABLE 42-5 Differentiation of Warts and Skin Disorders with Similar Presentation**

<b>Criterion</b>	<b>Warts</b>	<b>Corns</b>	<b>Calluses</b>	<b>Malignant Growth</b>
Location	Any area of skin susceptible to the virus	Over bony prominences in the feet	Weight-bearing areas of the feet	Any area of the skin
Signs	Rough cauliflower-like appearance; plantar warts disrupt normal skin ridges	Raised, sharply demarcated, hyperkeratotic lesions with a central core	Raised, yellowish thickening of the skin; broad based with diffuse borders; normal pattern of skin ridges	Bleeding; swelling; red, discolored, or multicolored and swollen
Symptoms	Usually not painful but pain	Pain	Pain	Pain

	may occur if the wart is located in areas undergoing repeated pressure (i.e., soles of the feet)			
Quantity/severity	Varies; may grow to approximately 1 inch in diameter	Varies; a few millimeters to 1 cm	Varies; a few millimeters to several centimeters	Varies; grows rapidly
Timing	Incubation period may be several months in length; may progressively enlarge	Variable onset; may progressively enlarge	Variable onset; may progressively enlarge	Variable onset; grows rapidly
Cause	HPV infection of the epidermal layer	Friction	Friction, walking barefoot, structural foot problems	Mutations related to damaged DNA cause skin cells to grow unchecked
Modifying factors	Prevention of spread; treatment with salicylic acid or cryotherapy	Alleviation of causative factors	Alleviation of causative factors	Surgical removal; prescription medications

**Case 42-1**

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	A female high school student, accompanied by her mother, tells you she has a rough spot on the bottom of her great right toe and asks if you can suggest anything to help her get rid of the lesion. When she first noticed the lesion 6 weeks ago, it was smaller than a pea but has gradually enlarged over the last several weeks. She says it is not painful, but she is concerned about how it looks and that it is getting larger. There is no inflammation, bleeding, significant discoloration, or discharge from the lesion.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	She plays high school basketball and has gym class 3 times a week. After gym and the games, she showers barefoot in the communal showers.
c. description of the patient's efforts to relieve the symptoms	She has not tried to treat the lesion.
d. patient's identity	Marri Nelson
e. age, sex, height, and	16 years old, female, 5 ft 4 in., 125 lb

weight	
f. patient's occupation	High school student
g. patient's dietary habits	She follows no particular diet. Her food choices are usually healthy. She sometimes skips breakfast.
h. patient's sleep habits	7-8 hours a night
i. concurrent medical condition, prescription and nonprescription medications, and dietary supplements	No medical conditions; medication(s): generic multivitamin daily, vitamin D 400 IU daily
j. allergies	None
k. history of other adverse reactions to medications	None
l. other (describe) _____	She lives at home and shares a bathroom with her two siblings. She is not pregnant or sexually active.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Marri most likely has a plantar wart.
3. Identify exclusions for self-treatment (Figure 42-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Recommend self-care with a nonprescription wart removal product and nondrug measures. (2) Recommend self-care until Marri can consult a medical provider for evaluation and treatment. (3) Refer Marri for medical evaluation and treatment (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Because Marri is concerned about the wart's cosmetic appearance and the possibility that it will continue to enlarge, and because there is significant possibility of transmitting the virus to others, pharmacologic treatment of the wart should be considered. Because the wart is a single, small, nonpainful lesion confined to one area, and the patient has no identifiable exclusions for self-treatment, she can be treated with a nonprescription wart removal product. She can prevent transmitting the wart to others by wearing shoes or covering the wart, especially when showering at

	the gym or when using her bathroom.
6. Describe the recommended therapeutic approach to the patient or caregiver.	See <a href="#">Figure 42-1</a> and the box Patient Education for Warts. “Salicylic acid in a pad or strip would be a good choice in this situation. Salicylic acid pads/strip products have to be applied every 48 hours. The pad should be covered with occlusive tape. Salicylic acid therapy might take up to 12 weeks for the wart to resolve.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“Salicylic acid in a strip/pad form is an appropriate recommendation for you because salicylic acid is effective for this type of wart, easy to use, and less painful than some other treatment options. Cryotherapy is another self-care option for the treatment of warts. However, cryotherapy is more painful than salicylic acid, and small warts may be adequately treated with salicylic acid.” “Your wart is not severe enough to warrant a referral to a health care provider at this time. Self-treatment is more cost-effective and should provide acceptable results in resolving your wart.”
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	“ <a href="#">Table 42-4</a> and the box Patient Education for Warts provide information on removing warts safely. Also, be sure to read and follow the directions that come with the product.” “The wart may be soaked in warm water for 5 minutes to soften the outer surface. The pad/strip should be applied directly over the wart. Remove the pad/strip every 48 hours and replace it with a new one. Treatment with salicylic acid may be continued for up to 12 weeks.” “If there is any irritation to the healthy tissue surrounding the wart, wash the area immediately with soap and water.”
Solicit follow-up questions from patient or caregiver.	(1) “Is there anything I can do to prevent the spread of the wart?” (2) “What should I do if the wart is not gone after 12 weeks?” (3) “Should I cover the wart?”
Answer patient or caregiver’s questions.	(1) “See the box patient Education for Warts for preventive measures.” (2) “If after 12 weeks of treatment, the wart is still present, you should consult a health care provider.” (3) “Yes. Covering the wart helps prevent spreading warts to others.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Follow up in 4-6 weeks to assess the patient’s progress in clearing the wart with the recommended therapy.

**Case 42-2**

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient’s symptoms and medical history, including:	
a. description of symptom(s) (i.e.,	A middle-aged male asks for something to get rid of a callus-like lesion on the

nature, onset, duration, severity, associated symptoms)	bottom of his foot. When he first noticed the lesion 3 months ago, it was about the size of a dime but has enlarged to the size of a quarter. The lesion is on the ball of the foot and appears to be multiple lesions fused together. He complains of discomfort when walking. There is no inflammation, bleeding, significant discoloration, or discharge from the growth.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	None
c. description of the patient's efforts to relieve the symptoms	He has soaked his feet and applied lotions regularly in an attempt to soften the lesion. He attempts to shave the lesion regularly.
d. patient's identity	Lee Williams
e. age, sex, height, and weight	45 years old, male, 5 ft 11 in., 200 lb
f. patient's occupation	High school gym teacher and football coach
g. patient's dietary habits	He attempts to follow a healthy diet but frequently indulges in concentrated sweets.
h. patient's sleep habits	6-7 hours a night
i. concurrent medical condition, prescription and nonprescription medications, and dietary supplements	Hypertension: lisinopril 10 mg daily; type 2 diabetes: metformin 1000 mg twice daily, Lantus 40 units at bedtime, and gabapentin 100 mg 3 times daily
j. allergies	None
k. history of other adverse reactions to medications	None
l. other (describe) _____	He walks 3-5 days a week.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Lee most likely has multiple plantar warts.
3. Identify exclusions for self-treatment (Figure 42-1).	Diabetes; neuropathy; multiple, large, painful warts
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is	Options include: (1) Recommend self-care with a nonprescription wart removal product and nondrug measures.  (2) Recommend self-care until Lee can consult a medical provider for

required, and share this information with the patient or caregiver.	evaluation and treatment. (3) Refer Lee for medical evaluation and treatment. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Lee should be referred to a health care provider for evaluation and treatment because the multiple warts seem to have coalesced into what appears to be one large wart, and because he has decreased sensation secondary to diabetic neuropathy.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should consult a health care provider to evaluate and treat the wart."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Self-treatment is not recommended because multiple warts have coalesced to form one large wart, and because you have decreased feeling in your feet, making it possible for you to injure your feet with the nonprescription wart removal products."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from patient or caregiver.	(1) "Is there anything I can do to keep from getting this again?" (2) "Will these spread to other people or other areas of my body?"
Answer patient or caregiver's questions.	(1) "It is common for warts to recur even after treatment. The box Patient Education for Warts lists things you can do to reduce the risk of reinfection." (2) "Warts are spread through person-to-person contact or by contact with contaminated surfaces such as towels or exercise equipment. The box Patient Education for Warts provides information on how to prevent spreading warts to other areas of your body or to other persons."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	The patient should follow-up with the health care provider as directed.

### Patient Counseling for Warts

Patients must understand that warts are caused by the HPV virus and are contagious. Providers should discuss with patients measures to prevent the spread of warts to other parts of the body or to other individuals. Providers should also point out the differences between available products, including their indications, contraindications, warnings, and precautions. The box Patient Education for Warts lists specific information for patients who are using either salicylic acid products or cryotherapy products. If warts persist despite self-treatment, patients should be referred to a medical provider for evaluation and treatment.

### Evaluation of Patient Outcomes for Warts

Salicylic acid may require up to 12 weeks of daily treatment to completely resolve the wart. Patients should see some improvement in 1-2 weeks. A follow-up should be scheduled at 4-6 weeks to evaluate the wart. If the wart does

not appear to be resolved, the patient should be encouraged to continue treatment. If the wart has not cleared after 12 weeks, prescription therapies may be warranted. The patient should be referred to a health care provider for further evaluation and treatment.

Cryotherapy may be repeated after 10 days for up to three treatments. If the wart is not cleared after three treatments, the patient should see a health care provider.

#### Patient Education for Warts

When treating warts, the goals are to (1) eliminate signs and symptoms associated with the warts, (2) remove the wart without causing scars, (3) prevent the wart from recurring, and (4) prevent spreading of warts to self or others. To ensure the best possible treatment outcomes, patients must follow product instructions carefully and must consistently use measures to prevent the spread of warts.

#### **Nondrug Measures**

- To decrease the chances of getting warts, avoid nail-biting; do not go barefoot; do not cut, shave, or pick at warts; wash hands before and after treating or touching warts; keep feet clean and dry; use one specific towel to dry warts; and do not use the same towel to dry other areas of the body.
- To avoid spreading warts to others, do not share towels, razors, socks, shoes, etc.; keep the wart covered; and do not walk barefoot, especially in bathrooms or in public places.

#### **Nonprescription Medications**

- Select only nonprescription salicylic acid products approved for self-treatment of warts. Follow the instructions on the label closely.
- Make sure to use these products only on common or plantar warts. Do not use on moles, birthmarks, warts with hairs growing from them, irritated or inflamed skin, or infected skin.
- If you are not 100% certain that the condition is a wart, consult a health care provider before using these products.
- Do not use these products to treat warts on the face, mucous membranes, armpits, breasts, genitals, or around fingernails.
- Do not use these products on children who are younger than 4 years, women who are pregnant or breast-feeding, or patients who have diabetes or poor circulation.
- Keep these products away from the eyes. If they come into contact with the eyes, seek medical help immediately.
- Do not apply these products to healthy skin. If they come into contact with healthy skin, wash the area with soap and water immediately.
- Some of these products are flammable or contain collodions that are poisonous if ingested. Keep away from heat and out of children's reach.
- Improvement should be seen within a week or two of beginning treatment. The wart should completely clear within 6-12 weeks. Self-treatment should not continue longer than 12 weeks.
- Warts may recur after treatment.

#### **Nonprescription Cryotherapy**

- Follow the instructions on the label closely.
- Use these products only on common or plantar warts. Do not use on moles, birthmarks, warts with hairs growing from them, irritated or inflamed skin, or infected skin.
- If you are not 100% certain that the condition is a wart, consult a health care provider before using these products.
- Do not use these products to treat warts on the face, mucous membranes, armpits, breasts, genitals, or around fingernails.
- Do not use these products on children who are younger than 4 years, women who are pregnant or breast-feeding, or patients who have diabetes or poor circulation.
- You will feel an aching, stinging sensation when the product is applied.
- A blister will form and the wart should fall off after about 10 days.
- If the wart does not completely clear after the first treatment, the procedure may be repeated in 10-14 days. The product should not be used more than 3 times.

#### **When to Seek Medical Attention**

- Stop using the products and consult a medical provider if severe irritation or pain occurs immediately after application.
- If the wart has not cleared after 12 weeks of treatment, consult a health care provider.

#### **Key Points for Warts**

- Because many warts will resolve without treatment, a wait-and-see approach may be an appropriate treatment option in some patients. However, this approach allows the continued transmission of the highly contagious HPV virus.
- Patients with diabetes, poor circulation, or immunodeficiencies should not self-treat with salicylic acid or cryotherapy without first consulting a health care provider.
- The nonprescription drug of choice for common and plantar warts is salicylic acid.
- Plantar warts should be treated with higher concentrations of salicylic acid ( $\leq 40\%$ ). Warts on the hands or areas with thinner epidermis should be treated with lower concentrations of salicylic acid ( $< 17\%$ )
- DMEP products are available for home cryotherapy treatments, but cryotherapy is no more effective than salicylic acid.
- The directions for use of nonprescription salicylic acid and cryotherapy products should be followed to prevent injury to healthy tissue surrounding the wart.
- Patients who experience adverse effects from nonprescription wart removal products or have warts that recur frequently should be evaluated by a health care provider.

**Handbook of Nonprescription Drugs > Chapter 43. Minor Foot Disorders****Minor Foot Disorders: Introduction**

Often neglected, overlooked, and unprotected, the feet contain nearly one quarter of all the bones in the body. The foot is intricately designed to absorb shock from pressure and assist in movement. On average, a person walks 115,000 miles in a lifetime, which is equivalent to circling the world nearly four times. Seventy-five percent of all Americans will develop foot-related disorders.<sup>1</sup> Individuals who exercise regularly are at risk for foot disorders. Without adequate precautions, particular problems and injuries, particularly those involving the feet, can arise.<sup>1</sup> Among the most common foot disorders are ingrown toenails, bunions, and corns and calluses. Therefore appropriate education and training for the prevention and treatment of minor foot disorders are important.<sup>1,2</sup> In some instances, self-care of foot disorders is inappropriate. Children with a congenital malformation, a deformity, or a specific disease that affects the foot (e.g., juvenile arthritis) need medical care by an orthopedic surgeon or a podiatrist. Adolescents may experience rapid growth, and growth plates in their feet may subsequently become stressed and irritated. Athletic activity at this age can also contribute to secondary conditions, especially if activity-associated injuries to the feet are not properly treated. Osteoarthritis, for example, can develop secondary to a foot injury. Patients may also encounter foot problems related to aging (e.g., arthritis) and disease (e.g., peripheral vascular disease). In particular, diabetes and arthritis can cause secondary foot problems. Therefore, patients should check their feet regularly for foot disorders. Common foot disorders could result in more serious injuries in patients with comorbid disorders (e.g., diabetes) and may be indicative of other serious underlying conditions.<sup>3</sup> In some instances, foot disorders or inappropriate foot care practices may be life threatening to patients with diabetes, severe arthritis, and impaired circulation (see the box **A Word about Chronic Diseases and Foot Disorders**).<sup>3-7</sup> For most patients, however, such problems cause nominal measures of discomfort and impaired mobility.

**A Word About Chronic Diseases and Foot Disorders**

Some chronic diseases predispose certain patients to foot complications. Patients who have diabetes often have poor circulation and diminished limb sensitivity, which make them especially vulnerable to infectious foot problems. Other susceptible patients include those with peripheral vascular disease or arthritis. The health care provider can identify these patients by asking about daily medication use or reviewing the patient's drug profile. Typical drug use patterns for high-risk patients include insulin; oral antidiabetic drugs (e.g., glipizide, glyburide, metformin, acarbose, and nateglinide); drugs for circulation disorders (e.g., clopidogrel, cycloandelate, isoxsuprine, papaverine, and pentoxifylline); drugs for neuropathic pain (e.g., gabapentin and duloxetine); and drugs for arthritic disorders (e.g., aspirin and other NSAIDs).

If not properly supervised in patients with impaired circulation, self-treatment with nonprescription products may induce more inflammation, ulceration, or even gangrene, particularly in cases of vascular insufficiency in the foot. Patients with diabetes and those with peripheral circulatory impairments are particularly susceptible to gangrene. In addition, simple lesions may mask more serious abscesses or ulcerations. If left medically unattended, these lesions may lead to conditions such as osteomyelitis, which may require hospitalization and aggressive intravenous antibiotic therapy.

**Diabetes Mellitus<sup>3-6</sup>**

Patients who have poorly controlled diabetes are at greater risk for lower extremity complications, which result in increased health care costs, decreased quality of life, and increased morbidity. Two major causes of foot ulcerations are peripheral neuropathy, which results in loss of injury perception and subsequently excessive plantar pressure, which contributes to decreased mobility and foot deformities. Patients with diabetes also contribute to foot complications by poor foot hygiene such as extreme hot water soaks, inappropriate footwear, and lack of daily foot self-examinations. Patients with diabetes need to be educated on proper foot care, such as trimming toenails appropriately, not applying creams/lotions between the toes, keeping socks clean and dry, performing foot examinations at home, and having foot examinations at the health care provider's office. (See **Chapter 45** for further discussion of diabetes management.)

**Peripheral Vascular Disease<sup>4,6</sup>**

Patients with peripheral vascular disease often have poor circulation of the feet and legs. Because of decreased blood flow and low oxygen perfusion, skin ulcerations and decreased wound healing may be problematic in these patients. They may complain of persistent and unusual feelings of cold, numbness, tingling, burning, or fatigue. Other symptoms may include discolored skin, dry skin, absence of hair on the feet or legs, or a cramping or tightness in the leg muscles. The provider should palpate for pedal pulses. The most discriminating questions that a provider can ask this type of patient are (1) Do you experience aching in your calves when you walk? (2) Do you have to hang your

feet over the edge of the bed during sleep to relieve the soreness in your calves? A yes response to either question warrants referral to a primary care provider or podiatrist.

Localized redness or unilateral coldness may indicate a possible blockage (a clot) of circulation to the foot.

Sometimes the involved foot or lower leg will appear physically larger than the other, may be red or waxy in appearance, may have no hair growth on the toes, and will exhibit thickened nails. If the medication history of the patient with suspected circulatory problems does not indicate the use of medications intended to relieve such symptoms, the patient should be referred immediately for further evaluation.

A daily footbath is a simple measure to assist patients with peripheral vascular disease. After the foot is patted dry, an emollient foot cream can be applied to aid the skin in retaining moisture and pliability. The footbath will also soften brittle toenails for clipping and filing. The feet should be kept warm and moderately exercised every day.

### **Arthritis<sup>6</sup>**

Osteoarthritis is a noninflammatory, degenerative joint disease that occurs primarily in older people. Degeneration of the articular cartilage and changes in the bone result in a loss of resilience and a decrease in the skeleton's shock-absorption capability. This condition, however, is also experienced by individuals in their late teens and early 20s as a secondary complication of a previous athletic injury. This condition might be evidenced by the development of hallux limitus or rigidus of the big toe (e.g., a painful flexion or extension of the big toe related to stiffness and spur formation in the metatarsophalangeal joint or a stiff toe, respectively). Subsequently, these patients have a lot of difficulty with their shoes not fitting properly. They may also develop an osteoarthritic condition in the ankle joint. Referral for further evaluation is appropriate. Most patients with rheumatoid arthritis eventually have foot involvement. The major forefoot deformities in these patients are painful metatarsal heads, hallux valgus, and clawfoot. Corrective surgical procedures are often indicated to reduce pain and improve function and mobility. Little evidence exists that conventional nonsurgical therapy (e.g., orthopedic shoes, metatarsal inserts, conventional arch supports, and metatarsal bars) is effective for these deformities.

Proper palliative foot care is especially important for arthritic patients. They should wear properly fitted shoes, pad their shoes with insoles to protect their feet from the shock of hard surfaces, and undergo regular podiatric or medical examinations. (See [Chapter 7](#) for use of topical or systemic nonprescription analgesics for osteoarthritis.)

### **Pathophysiology of the Foot**

At birth, an infant's foot has 33 joints, 19 muscles, 107 ligaments, and cartilage that will develop into 26 bones. The feet continue to develop and mature until ages 14-16 years for females and ages 15-21 years for males. Women and men will generally begin to notice changes in their feet in their 40s and 50s, respectively.<sup>8</sup> After years of bearing the body's weight, feet tend to broaden and flatten, thus stretching ligaments and causing bones to shift positions. These changes subject feet to stress, which is compounded by prolonged standing. An estimated 40% of the U.S. population spends about 75% of their workday on their feet, increasing the potential for painful foot conditions.<sup>1,2</sup>

### **Corns and Calluses**

Although corns and calluses are common foot disorders, they should not be ignored. They may indicate a biomechanical problem and lead to serious complications in predisposed patients.

### **Pathophysiology of Corns and Calluses**

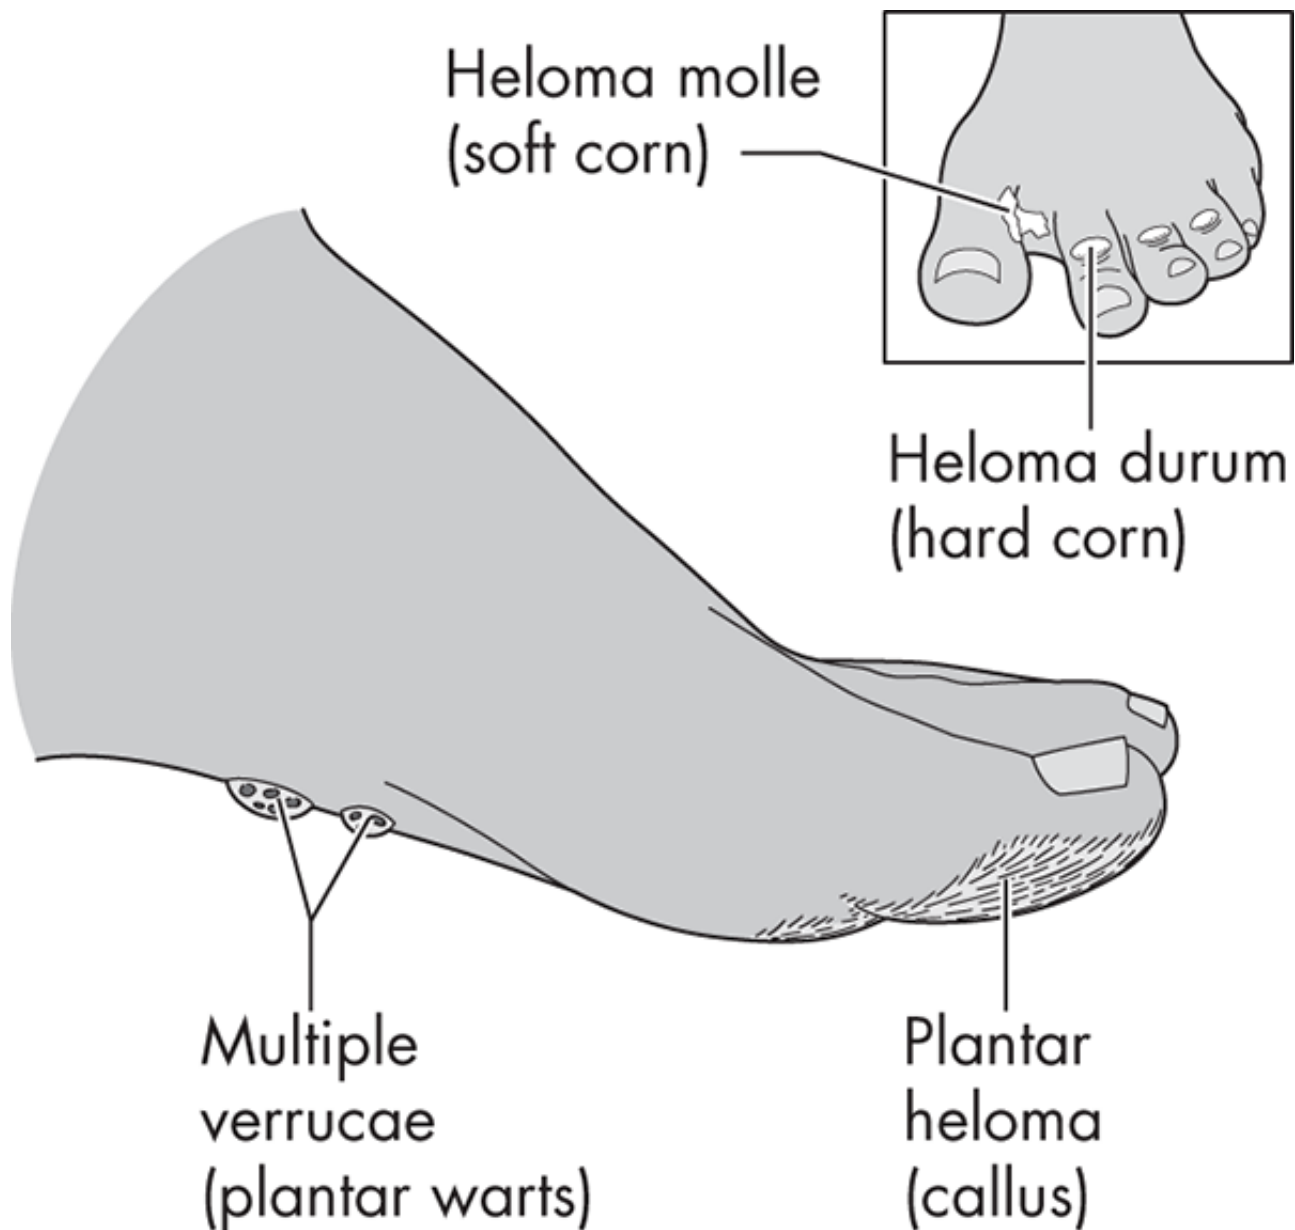

Under normal conditions, the cells in the skin's basal cell layer (stratum basale) undergo mitotic division at a rate equal to the continual surface cellular desquamation, leading to complete replacement of the epidermis in approximately 1 month. During corn or callus development, however, friction and pressure increase mitotic activity of the basal cell layer, leading to the migration of maturing cells through the prickle cell (stratum spinosum) and granular (stratum granulosum) skin layers (see [Chapter 32](#), Figure 32-1). As more cells reach the outer skin surface, they produce a thicker horny layer (stratum corneum). This process is a natural protective mechanism of the skin surface and may signal biomechanical problems resulting in abnormal weight distribution on the foot. When friction or pressure is relieved, mitotic activity returns to normal, causing remission and disappearance of the lesion.<sup>8-11</sup>

### **Clinical Presentation of Corns and Calluses**

Corns and calluses are similar in that both produce a marked hyperkeratosis of the stratum corneum, but they have marked differences.

#### **Corns**

A corn (clavus) is a small, raised, sharply demarcated, hyperkeratotic lesion with a central core; the lesion is caused by pressure from underlying bony prominences or joints ([Figure 43-1](#)). The central core of the corn differentiates it from a wart (see [Chapter 42](#), [Table 42-5](#)).

Copyright © American Pharmacists Association  
All rights reserved. Any use is subject to the Terms of Use.

Disorders affecting top and sole of foot (corns, callus, and plantar warts).

Misidentification of warts and corns is common. Differentiation can be made by shaving the central core. A corn has a hard center, whereas a wart will bleed because of the multiple capillary loops in its center.<sup>9</sup> Corns are yellowish gray and well circumscribed, with diameters of 1 cm or less. The base of the corn is on the skin surface; its apex points inward and presses on the nerve endings in the dermis, causing pain.<sup>7,12</sup>

Polished, shiny, dry hard corns (heloma durum) are the most prevalent and usually occur on the bulb of the great toe, the dorsum of the fourth or fifth toe, or tips of the middle toes. Soft corns (heloma molle) are whitish thickenings of the skin and may be extremely painful. Accumulated perspiration macerates the epidermis, giving this corn a soft appearance. Soft corns may occur between any adjacent toes but are most frequently found between the fourth and fifth toe.<sup>8,9</sup>

Pressure from inappropriate, tight-fitting shoes is the most frequent cause of pain from corns. As narrow-toed or high-heeled shoes crowd toes into a narrow toe box, the most lateral toe, the fifth, sustains the most pressure and friction and is the usual site of a corn. The resulting pain may be severe and sharp (when downward pressure is applied) or dull and discomforting. Consumer research approximates that 82% of women ages 35-54 years suffer moderate-severe pain from corns and that 35% are consequently limited or restricted in their activities.<sup>7,10,12</sup>

#### Calluses

A callus has a broad base, with relatively even thickening of skin, and is generally found on the bottom of the foot in areas such as the heel, ball of the foot, toes, and sides of the foot (Figure 43-1). A callus has indefinite borders and ranges from a few millimeters to several centimeters in diameter. The indefinite borders help health care providers

differentiate calluses from corns, which have well-circumscribed margins. A callus is usually raised and yellow, and it has a normal pattern of skin ridges on its surface. Calluses form on joints and weight-bearing areas of the hands and feet<sup>7,9,10,12</sup> (see Color Plates, photograph 31).

Friction (caused by loose-fitting shoes or tight-fitting hosiery), walking barefoot, and structural biomechanical problems contribute to the development of calluses. Structural problems include improper weight distribution, pressure, and development of bunions with age. Calluses can be symptomatic and protective.

Discrete-nucleated and diffuse-shearing calluses are most commonly found on the feet. The discrete-nucleated callus is smaller and has a localized translucent center; this type of callus is painful with applied pressure because of its central keratin plug. The diffuse-shearing callus covers a larger surface area and does not have a central core; therefore, this callus is not associated with pain.<sup>9,10,12</sup>

### **Treatment of Corns and Calluses**

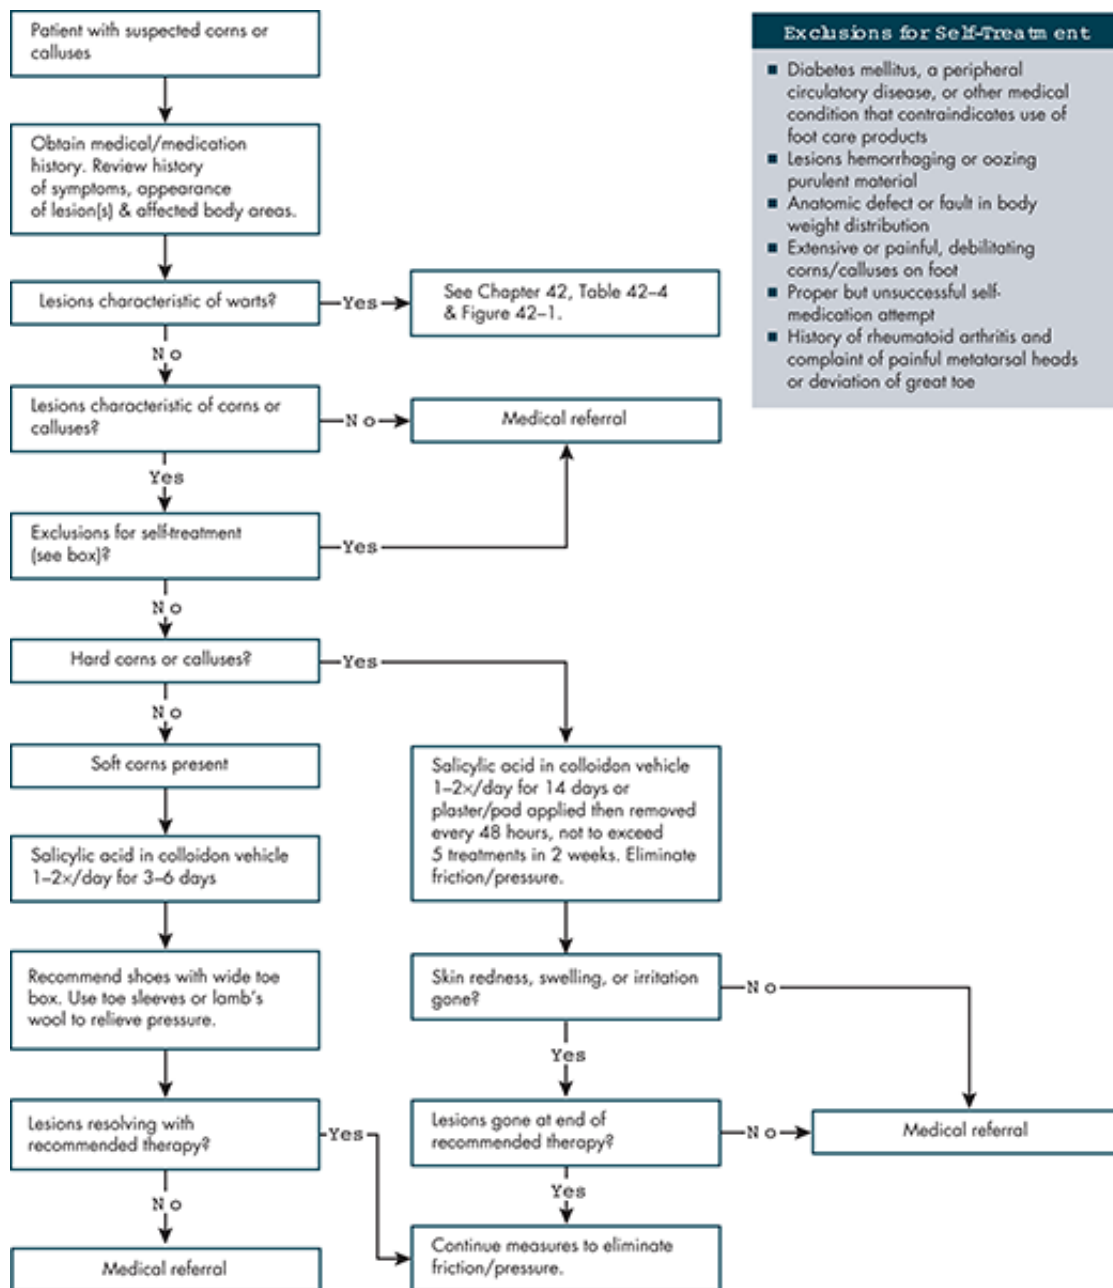

#### Treatment Goals

The goals of self-treatment are to (1) provide symptomatic relief, (2) remove corns and calluses, and (3) prevent their recurrence by correcting underlying causes.

#### General Treatment Approach

Although effective nonprescription products are available for removing corns and calluses, ultimate success depends on eliminating the causes. The algorithm in [Figure 43-2](#) outlines self-treatment of corns and calluses and lists exclusions for self-treatment.

#### Exclusions for Self-Treatment

- Diabetes mellitus, a peripheral circulatory disease, or other medical condition that contraindicates use of foot care products
- Lesions hemorrhaging or oozing purulent material
- Anatomic defect or fault in body weight distribution
- Extensive or painful, debilitating corns/calluses on foot
- Proper but unsuccessful self-medication attempt
- History of rheumatoid arthritis and complaint of painful metatarsal heads or deviation of great toe

Copyright © American Pharmacists Association  
All rights reserved. Any use is subject to the Terms of Use.

Self-care of corns and calluses.

#### Nonpharmacologic Therapy

Daily soaking of the affected skin area (for at least 5 minutes in warm, not hot, water) throughout the treatment period aids in softening dead tissue for removal. After normal washing of the foot, dead tissue should be removed gently, rather than forcibly, to avoid further damage. A callus file or pumice stone effectively accomplishes this purpose. Power-operated foot files may be too aggressive. Sharp knives or razor blades should not be used because these instruments may lacerate the skin, which could allow bacteria to enter the wound and result in localized infection.<sup>9,11</sup> Cushioning pads are another option. Circular foam cushioning pads may aid in relieving painful pressure from inflamed tissue. Some podiatrists recommend that patients change the pads every day. Many providers, however, are concerned that the pad adhesive may degrade the skin, leading to infection. Disadvantages associated with older pads have been overcome with polymer gel pads (e.g., Bunion Guard, available from the Mayo Clinic), which provide a protective cushion without leaving a sticky residue. Another advantage of gel pads is that the smooth outer surface does not cause snags and runs in socks and hosiery.<sup>9,13</sup> Silicone toe sleeves impregnated with mineral oil (i.e., Pedifix Visco-Gel Toe Protector) are another option for toes affected by corns. The mineral oil is slowly released to soften the skin. The sleeves also protect and cushion the corn area. A foam spacer or lamb's wool may be used to provide relief in areas with soft corns. Placement of a metatarsal pad may help relieve pain and pressure from a diffuse-shearing callus.<sup>8,14</sup>

Eliminating the pressure and friction that induce corns and calluses entails using well-fitting, nonbinding footwear

that evenly distributes body weight<sup>14</sup> (Table 43-1). For anatomic foot deformities, orthopedic corrections must be made. These measures relieve pressure and friction, which allow normal mitosis of the basal cell layer to resume. The stratum corneum will normalize after topical keratolytics are applied and total desquamation of the hyperkeratotic tissue occurs. Orthotics (i.e., arch supports) may be needed to help compensate for deformities by redistributing the mechanical forces. Ultimately, surgical correction of toe deformities and resection of the underlying bone may be necessary.

**TABLE 43-1 Selection of Properly Fitted Footwear**

- Buy shoes in the proper size (width and length). To obtain an accurate measurement, ask a trained salesperson to measure your feet. Recheck shoe size every 2 years.
- Base shoe length on the longest toe of your longest foot. The distance between the tip of the shoe and the longest toe is approximately one-half inch. In an athletic shoe, 1 inch is needed.
- For proper arch length, choose a shoe in which the first metatarsal head of the foot fits the metatarsal break of the shoe.
- For proper shoe width, choose a shoe that feels comfortable at the first metatarsal joint (i.e., toes do not feel cramped in the toe box).
- Once the shoe size is determined, choose a shoe shaped to match the shape of your foot.
- If you have abnormalities of the toes (e.g., hammer toes) or use orthotics or padding in your shoes, select a shoe with a toe box of adequate depth (vertical height) to prevent friction of the tops of the toes. A wide toe box will help relieve pressure between toes.
- Make sure the heel fits snugly and helps hold the foot straight.
- If you are physically active, make sure the shoe's midsole provides adequate cushioning and support.
- Try on both shoes at the time of purchase, preferably wearing a pair of socks or stockings of the type that will usually be worn with the new pair of shoes.
- If your feet tend to swell, select shoes at the end of the day.

Source: References 1, 8, 10, 14, and 23.

## Pharmacologic Therapy

### Salicylic Acid

Salicylic acid, the oldest of the keratolytic agents, is formulated in varying strengths (0.5%-40%). For the treatment of corns and calluses, the approved concentration ranges are 6%-17% in hydralic gel, 12%-40% in a plaster vehicle, and 12%-27.5% in a collodion-like vehicle.<sup>15-17</sup>

Salicylic acid is believed to act on hyperplastic keratin, without affecting viable epidermis. Product application will cause the area to swell, soften, macerate, and then desquamate the affected epithelium. The Food and Drug Administration (FDA) has stated that presoaking the affected area produced no significant positive effects before application of salicylic acid. In its final rule, FDA proposed allowing manufacturers of these products to use the following statement as an optional direction to the consumer: "May soak corn/callus (or wart) in warm water for 5 minutes to assist in removal."<sup>15-17</sup>

The FDA advisory review panel evaluated more than 20 agents for the treatment of corns and calluses. Of these agents, only salicylic acid in a plaster, pad, disk, gel, or collodion vehicle dosage form is approved as safe and effective for nonprescription marketing for the removal of corns and calluses (Table 43-2). FDA recognized that the term *plaster* includes disks and pads because these dosage forms are similar.<sup>16,17</sup>

**TABLE 43-2 Selected Corn and Callus Products**

<i>Trade Name</i>	<i>Primary Ingredients</i>
Curad Mediplast Corn, Callus & Wart Remover	Salicylic acid 40%
Dr. Scholl's Corn/Callus Remover Liquid	Salicylic acid 12.6%
Hydrisalic Gel	Salicylic acid 6%
Dr. Scholl's Cushlin Gel Corn/ Callus Remover Disk	Salicylic acid 40%
Freezone One Step Corn/Callus Remover Pads	Salicylic acid 40%

Source: Reference 15.

Salicylic acid is usually applied to a corn, callus, or common wart in a collodion or collodion-like vehicle. These vehicles contain pyroxylin and various combinations of volatile solvents (e.g., ether, acetone, or alcohol) or a plasticizer, which is usually castor oil. Pyroxylin is a nitrocellulose derivative that remains on the skin as a water-repellent film after the volatile solvents have evaporated.<sup>15-17</sup>

The advantages of collodions and liquid dosage forms are that they form an adherent flexible or rigid film and prevent moisture evaporation. These qualities aid penetration of the active ingredient into the affected tissue and result in sustained local action of the drug. The delivery systems are largely water insoluble, as are most of their active ingredients, such as salicylic acid. They are also less prone than other aqueous solutions to run onto surrounding skin.<sup>15-17</sup>

A disadvantage of collodions is that they are extremely flammable and volatile. Some patients may inhale and abuse these vehicles. Another disadvantage is the occlusion of normal water transport through the skin, which allows systemic absorption of some drugs (e.g., salicylic acid). Percutaneous absorption may be problematic with prolonged use on large surface areas of children and patients with renal or hepatic impairment because salicylic acid is largely metabolized in the liver and excreted in the urine. Although occlusive vehicles can enhance the percutaneous absorption of salicylic acid, it is highly unlikely that salicylate toxicity will result during corn, callus, or wart therapy at recommended dosages. However, if symptoms of possible salicylism (nausea, vomiting, dizziness, hearing loss, tinnitus, lethargy, hyperpnea, diarrhea, or psychiatric disturbances) occur, use of these products should be discontinued immediately.<sup>15-17</sup>

Salicylic acid may also be delivered to the skin through the use of a plaster, disk, or pad. This delivery system provides direct and prolonged contact of the drug with the affected area, resulting in quicker resolution of the condition. Salicylic acid plaster is a uniform solid or semisolid adhesive mixture of salicylic acid in a suitable base that is spread on appropriate backing material (e.g., felt, moleskin, cotton, or plastic). The usual concentration of salicylic acid in the base is 40%; these dosage forms may be applied directly to the corn or callus.<sup>9,15-17</sup> [Table 43-3](#) provides instructions for applying salicylic acid products.

**TABLE 43-3 Guidelines for Treating Corns and Calluses with Salicylic Acid Products**

<ul style="list-style-type: none"> <li>• Wash and dry the affected area thoroughly before applying any product.</li> <li>• May soak the affected foot in warm water for 5 minutes. Then remove the macerated, soft white skin of the corn or callus by scrubbing gently with a rough towel, pumice stone, or callus file. Do not debride the healthy skin.</li> </ul>
<p><b>Salicylic Acid 12%-17.6% in Collodion-Like Vehicle</b></p> <ul style="list-style-type: none"> <li>• Apply product no more than twice daily. Morning and evening are usually the most convenient times.</li> <li>• Do not let adjacent areas of normal healthy skin come in contact with the drug. If this happens, immediately wash off the solution with soap and water.</li> <li>- Petroleum jelly applied to the healthy skin will serve as protection if delivery of the medication to the intended treatment area might be unsuccessful.</li> <li>• Apply 1 drop at a time directly to the corn or callus until the affected area is well covered. Do not overuse the product.</li> <li>• Allow the drops to dry and harden so the solution does not run.</li> <li>• The solution is applied once or twice daily for up to 14 days.</li> <li>• After use, cap the container tightly to prevent evaporation and to prevent the active ingredients from assuming a greater concentration.</li> <li>• Store the product in an amber or light-resistant container away from direct sunlight or heat.</li> </ul>
<p><b>Salicylic Acid 12%-40% Plasters/Pads</b></p> <ul style="list-style-type: none"> <li>• If using plaster, trim the plaster to follow the contours of the corn or callus. Apply the plaster to the affected skin, and cover it with adhesive occlusive tape.</li> <li>• If using medicated disks with pads, apply the appropriately sized disk directly on the affected area, and then cover the disk with the pad.</li> <li>• Remove the plaster/pad and occlusive tape within 48 hours.</li> <li>• After removing the softened skin, reapply the plaster every 48 hours as needed to remove the corn/callus but not longer than 14 days.</li> <li>- Seek medical attention if redness or irritation of the skin occurs or if corn or callus is not removed after 14 days of treatment.</li> </ul>

Source: References 8 and 15-17.

Caution should be used while applying topical salicylic acid because misapplication may lead to inflammation or ulcer formation (see the box **A Word about Chronic Diseases and Foot Disorders**). These products may be hazardous

in pregnancy and should not be used in patients who are breast-feeding because of systemic absorption and the potential for Reye's syndrome. Salicylic acid may be used in pediatric patients older than 2 years at concentrations of 1.8%-6%. FDA requires the following warning on salicylic acid product labels:

Do not use this product on irritated skin, any area that is infected or reddened, moles, birthmarks, warts with hair growing from them, genital warts, warts on the face, or warts on the mucous membranes, such as inside the mouth, nose, anus, genitals, or lips. Do not use if you are diabetic, or if you have poor blood circulation. <sup>15-17</sup>

### Assessment of Corns and Calluses: A Case-Based Approach

A private area where patients can be comfortable removing their shoe(s) allows direct inspection of the feet and enables accurate assessment of the nature and extent of the problem and its underlying cause. The patient should be asked about any self-care attempts and their outcome. The patient's health status and current medication regimen should also be assessed. Lifestyle factors (e.g., occupation, daily exercise, and footwear); underlying pathology (e.g., circulatory or neurologic disorders); the possibility of an aggravating event; and the walking/working surface must also be evaluated. This information should be recorded and regularly updated in the patient's medication profile. Case 43-1 illustrates the assessment of a patient with corns.

#### Case 43-1

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient describes thick, yellowish patches of rough skin on her heels and on her fourth and fifth toes.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The patient says she does not have any pain, but she is irritated because her feet snag her hosiery and socks. She feels her feet look horrible when she is barefoot or wearing sandals.
c. description of the patient's efforts to relieve the symptoms	The patient has not tried anything other than applying lotion to her feet after showering.
d. patient's identity	Erin Mathers
e. age, sex, height, and weight	37 years old, female, 5 ft 7 in, 148 lb
f. patient's occupation	Florist
g. patient's dietary habits	Fruit, toast, or yogurt for breakfast; too busy for lunch; eats on the run a lot for dinner because of her child's ball schedule.
h. patient's sleep habits	4-7 hours nightly
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Allergies: cetirizine 10 mg nightly and mometasone nasal 2 sprays each nostril daily

j. allergies	Seasonal allergies
k. history of other adverse reactions to medications	None
l. other (describe) _____	None
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Erin has developed diffuse shearing calluses ( <a href="#">Figure 43-1</a> ).
3. Identify exclusions for self-treatment ( <a href="#">Figure 43-2</a> ).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Erin to an appropriate health care provider. (2) Recommend self-care with a nonprescription callus remover and nondrug measures. (3) Recommend self-care until Erin can see an appropriate provider. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Erin should use a nonprescription callus remover, callus cushioning pads, and nondrug measures to treat her condition.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Daily foot soaks, pumice stone or foot file may be used to reduce roughness of your calluses. Completely dry the feet before applying the callus remover. Applying cushioning pads will help to reduce pressure point areas on your feet, allowing the calluses to improve. You should also consider selection of appropriate shoes as outlined in <a href="#">Table 43-1</a> ."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Calluses can be removed by nonprescription products and the use of foot files. However, it is important to assess the cause of the callus formation and correct the cause with appropriate footwear."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	See <a href="#">Table 43-3</a> for instructions for applying salicylic acid products. Also see the box Patient Education for Corn and Calluses. Erin should see a response to treatment recommendations within 14 days.
Solicit follow-up questions from the patient or caregiver.	(1) "Would it be better to go without shoes as often as possible, rather than wearing my dress shoes?" (2) "Can I speed up the process by cutting the callus down with a razor blade before applying the nonprescription medication?"

Answer the patient's or caregiver's questions.	(1) "Selecting a shoe that fits appropriately will prevent rubbing of the foot or a too snug fit, which will eliminate the cause of a callus and protect against callus formation." (2) "It is best to soak the feet and use foot files to pare down the callus. Do not cut on your feet because of the risk of injury and infection."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Ask Erin to call in 14 days to update you on the response to your treatment recommendations. Or you could call her into the pharmacy to evaluate the response.

### Patient Counseling for Corns and Calluses

Remission of corns and calluses can take several days to several months. Patients suffering from corns and calluses should understand that effective treatment and maintenance depend on eliminating predisposing factors that contributed to the foot problem. It is important to discuss the need for wearing footwear of adequate width and length. Pads and cushions also help to reduce the pressure and shearing associated with corn and callus development. The patient or caregiver should be counseled on how to use nonprescription medications that remove corns and calluses. Because many products contain corrosive materials, they must be applied to only the corn or callus. Patients should be alerted that products containing collodions are poisonous when ingested and that these products, as well as all other medications, should be stored out of children's reach. The box Patient Education for Corns and Calluses lists specific information to provide patients.

#### Patient Education for Corns and Calluses

The objectives of self-treatment are to (1) provide symptomatic relief, (2) remove corns or calluses, and (3) prevent their recurrence by correcting underlying causes. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Nondrug Measures

- To avoid spreading the infection to another body site, clean the instruments used to remove dead skin after each use.
- Do not use sharp knives or razor blades to remove dead skin from corns and calluses. These instruments may cause bacterial infections.
- If you have trouble applying the product only to the affected area, apply petroleum jelly to healthy skin surrounding the treatment area before applying the corn and callus remover.
- For temporary relief of painful pressure in the area under a corn or callus, cover the affected area with a pad.
- Consult a health care provider if the symptoms described come back.

#### Preventive Measures

- To eliminate the pressure and friction that cause corns and calluses, wear well-fitting shoes that evenly distribute body weight ([Table 43-1](#)).
- Consult a podiatrist about foot deformity corrections.

#### Nonprescription Medications

- To remove corns and calluses, use a salicylic acid product labeled for use on these types of lesions ([Table 43-2](#)).
- Do not use this product on irritated, infected, or reddened skin.
- Do not use this product if you are diabetic or have poor blood circulation.
- Salicylic acid is poisonous. Do not allow it to come in contact with the mouth, and keep it out of children's reach.
- Note that the medication sloughs off skin and may leave an unsightly pinkish tinge to the skin.

#### When to Seek Medical Attention

- Stop treatment and consult a health care provider if swelling, reddening, or irritation of the skin occurs, or if pain occurs immediately with product application.

#### Evaluation of Patient Outcomes for Corns and Calluses

The progress of patients with hard corns or calluses should be checked after 14 days of treatment. The affected area should be visually inspected to determine whether the corns or calluses have decreased in size or resolved. The

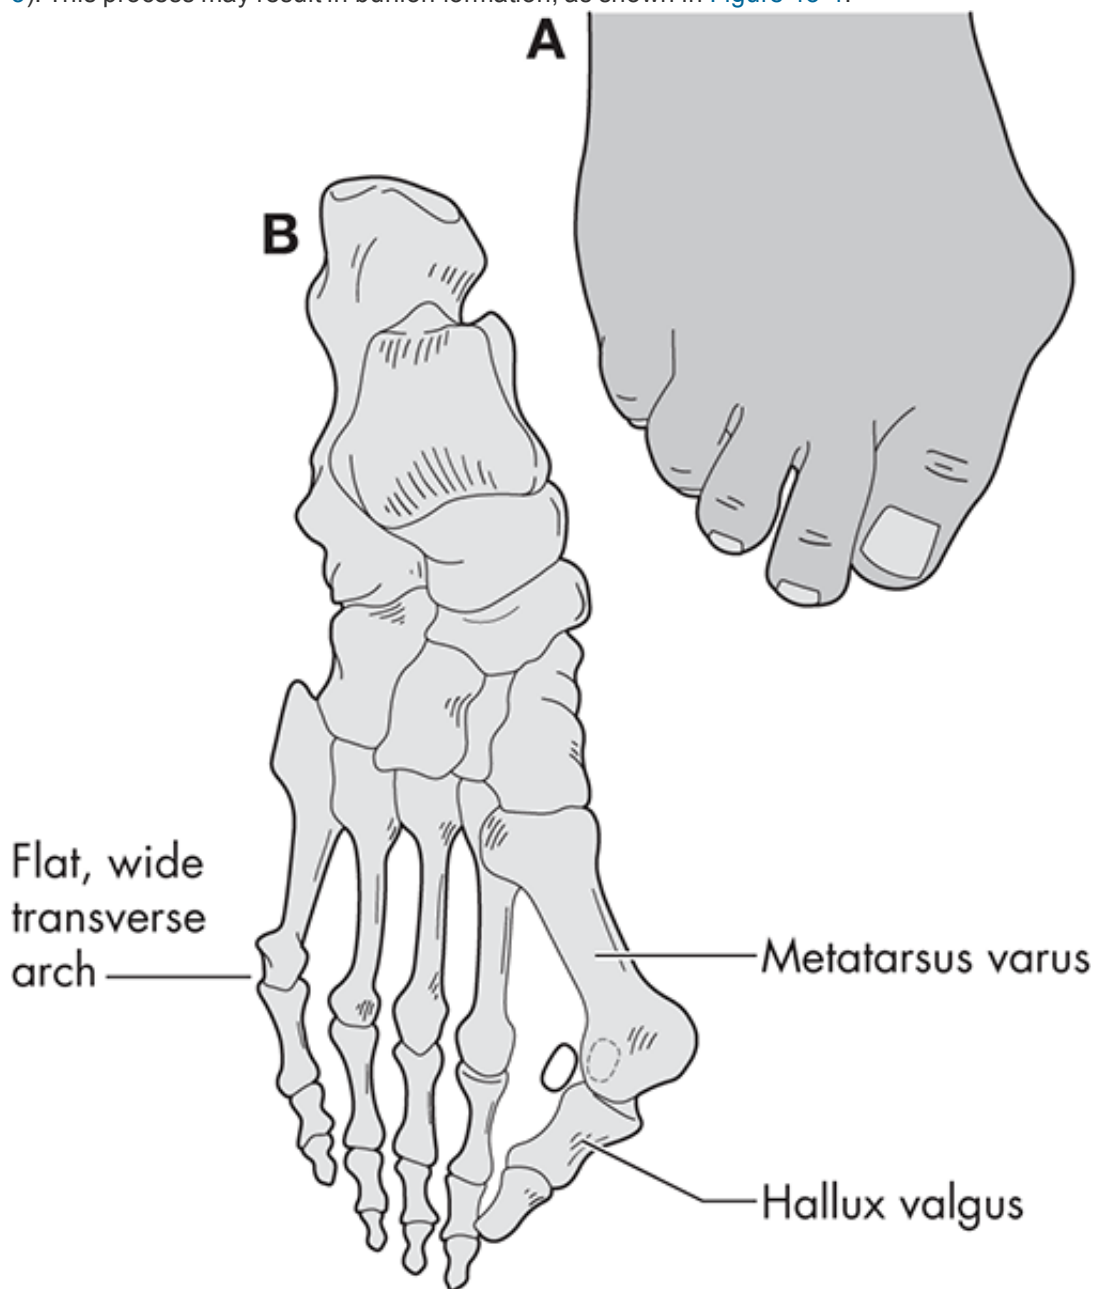

methods used to eliminate the corns or calluses should also be evaluated. If these conditions are still present, the patient should seek further medical evaluation.

## Bunions

Nearly half of Americans have bunions. Women are 10 times more likely than men to develop bunions because of improperly fitting shoes with narrow toe boxes or too-high heels. Often, several family members suffer from this disorder. Obesity can also lead to a higher prevalence of bunion formation. However, despite a positive family history, aggravating circumstances (e.g., wearing tight shoes) must also be present for a bunion to actually develop.<sup>14,18,19</sup>

### Pathophysiology of Bunions

The hallux, or great toe, and the inner side of the foot provide the elasticity and mobility needed to walk or run. Prolonged pressure over the prominent, angulated metatarsophalangeal joint of the great toe from external shoe irritation may result in painful inflammation, swelling, and exostosis over the involved bony joint structure (Figure 43-3). This process may result in bunion formation, as shown in Figure 43-4.

Bunion and ingrown toenail.

Bunions can be caused by various conditions. Pressure on the metatarsal head of the great toe may result from the manner in which a person sits, walks, or stands. In women, pressure from high-heeled shoes and too-narrow or too-shallow toe boxes forces the side of the toe inward and can aggravate the condition. Friction on the toes from bone malformations (wide heads or lateral bending) is also a major factor in bunion production, as are biomechanical defects. Vigorous exercise such as running or jumping can cause or exacerbate existing bunions. Bunions can increase the severity of a hallux valgus deformity, a deviation of the great toe, toward the lateral side of the foot.<sup>14,16,18</sup>

### Clinical Presentation of Bunions

Bunions are usually asymptomatic but may become quite painful, swollen, red, and tender. The bunion itself is usually covered by an extensive keratinous overgrowth. The bunion may have a fluid-filled sack called bursitis. Patients may experience increased pain or decreased movement of the great toe.<sup>18-20</sup>

### Treatment of Bunions

Corrective steps to alleviate bunions often depend on the degree of discomfort. In some cases, corrective surgery is necessary.

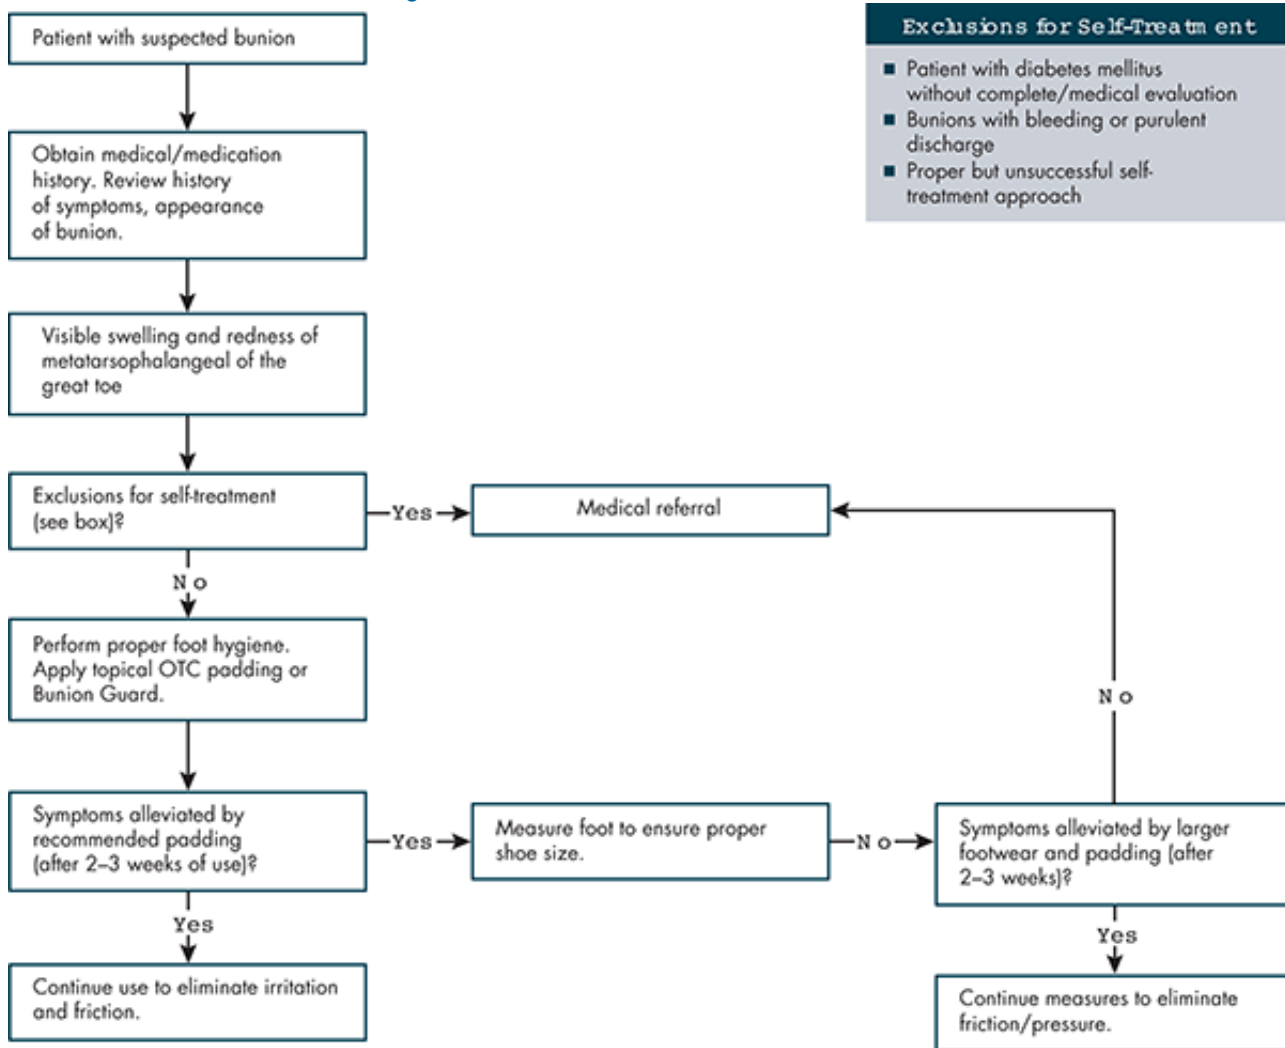

#### Treatment Goals

The self-treatment goals are to (1) decrease irritation of the affected area and (2) prevent worsening of the condition by correcting the cause.

#### General Treatment Approach

Bunions are not amenable to topical drug therapy, and the chronic use of oral nonprescription analgesics is not suggested. Management of the bunion should address the cause (e.g., tight-fitting or high-heeled shoes, excessive pronation of the foot, or a previous injury). Therefore, self-treatment includes avoiding high-heeled shoes; using

protective padding (e.g., bunion pads or toe separators); and taking oral anti-inflammatory drugs on a short-term basis, if needed. Self-treatment relieves only the swelling caused by shoe friction; therefore, well-fitted shoes with a wide toe box should be worn at all times to prevent subsequent flares of inflammation. If shoe adjustments fail to alleviate pain, medical referral is indicated. Physical therapy may be beneficial to provide relief from pain and inflammation. Orthotics may help control irregularities of the foot movement.<sup>18</sup> Self-treatment of bunions and exclusion criteria are outlined in Figure 43-5.

Self-care of bunions. Key: OTC = Over-the-counter.

## Nonpharmacologic Therapy

### Selection of Footwear

Table 43-1 provides guidelines for selecting properly fitted footwear.

### Bunion Pads/Cushions

Topical nonprescription padding (e.g., moleskin) can be helpful and may be all that is necessary to decrease the irritation and inflammation from footwear. Before the protective pad is applied, the foot should be bathed and thoroughly dried. The pad is then cut into a shape that conforms to the bunion. If the intention is to relieve the pressure from the center of the bunion area, the pad should be cut to surround the bunion. Precut pads are available for immediate patient use. To minimize the risk of skin maceration and ulceration, the patient should avoid constant skin contact with adhesive-backed pads, unless their use is recommended by a podiatrist or health care provider.<sup>13,21-22</sup>

For patients who are allergic to adhesives, a nonmedicated, nonadhesive gel bunion cushion (i.e., Bunion Guard) can be used for up to 3 months. Toe separators (i.e., Bunion Relievers) may also be used in conjunction with pads to align crooked toes and relieve irritation between toes.<sup>13</sup>

Larger footwear may be necessary to compensate for the space taken up by the pad; in fact, failure to increase shoe

size appropriately may cause pressure in other areas. In addition, protective pads should not be used on bunions when the skin is broken or blistered. Abraded skin should receive palliative treatment before pads are applied. If symptoms persist, these patients should consult a podiatrist or orthopedist.

### Assessment of Bunions: A Case-Based Approach

Measures discussed in Assessment of Corns and Calluses: A Case-Based Approach also apply to bunions. Specific information to obtain from patients includes the bunion's location, duration, and possible association with specific footwear, as well as the degree of discomfort it causes. Asking about methods used to relieve symptoms (e.g., shoes, cushioning pads, or NSAIDs) is also important.

### Patient Counseling for Bunions

It should be stressed to patients that effective, long-term treatment of bunions is to remove the source of irritation. Patients who do not achieve permanent relief by changing footwear should consult a podiatrist or orthopedist to determine whether anatomic defects are causing bunions. The proper short-term use of bunion pads and cushions should be explained to patients who want to use them. In addition, nondrug measures such as applying ice to relieve pain and inflammation can be recommended.<sup>13,21,22</sup> The box Patient Education for Bunions lists specific information to provide patients.

#### Patient Education for Bunions

The objective of self-treatment is to decrease irritation of the bunion until the cause is corrected. For patients whose bunions are not related to anatomic defects of the foot, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

- To help prevent footwear from rubbing the feet, make sure the footwear fits properly (Table 43-1).
- To decrease inflammation around existing bunions, apply adhesive-backed moleskin padding or a polymer gel cushion (e.g., Bunion Guard) to the bunion.
- If the skin of the bunion is broken or blistered, treat the skin and wait until it heals before applying bunion pads.
- Before applying the protective pad, bathe and thoroughly dry the foot.
- Cut the pad into a shape that conforms to the bunion. Cut the pad large enough to surround the bunion.
- Note that constant exposure to the adhesive of moleskin pads may cut and irritate the skin. If irritation occurs, stop wearing the pads.
- When using a polymer gel cushion, remove the cushion before showering and reapply afterward. The cushion can be worn for up to 3 months.
- Note that larger footwear may be needed to compensate for the space taken up by the pad or cushion.
- Applying ice several times daily may reduce inflammation and pain.

### When to Seek Medical Attention

- If the irritation persists after 2-3 weeks of implementing self-treatment measures, consult a health care provider.

### Evaluation of Patient Outcomes for Bunions

Bunions that are not caused by biomechanical defects of the foot may take a few weeks to resolve, depending on the severity of the irritation. Follow-up should occur after 2-3 weeks to determine whether wearing new shoes and using bunion cushions or pads have eliminated the discomfort. If the patient is still experiencing discomfort, medical referral is appropriate.<sup>21,22</sup>

### Tired, Aching Feet and Other Painful Disorders

With every step taken (8000-10,000 steps each day), gravity-induced pressure of up to twice the body's weight bears down on each foot, releasing powerful shocks of energy that the foot's natural padding must struggle to absorb.<sup>1,20,23</sup> In an unpaddinged shoe, the shock as the foot strikes the ground is absorbed throughout the foot, ankle, leg, and back. This shock can fatigue muscles, resulting in tired, aching feet and/or back pain.<sup>20,23,24</sup> An estimated two-thirds of Americans suffer from tired, aching feet (the most common foot problem). In addition, 2 million adults are estimated to suffer from heel pain. People simply do not realize the daily abuse their feet must endure.<sup>25</sup>

### Pathophysiology of Tired, Aching Feet and Other Painful Foot Disorders

Aching feet can be caused by increased frequency of standing and/or walking (especially on hard surfaces), age-

related erosion of the fat padding on the bottom of the foot, circulatory or neurologic disorders, and poor-fitting/inappropriate footwear.<sup>20,23,25</sup>

Because the cause of heel pain is difficult to determine, treatment can often be prolonged and expensive. The three common types of heel pain are heel spurs (i.e., bony growths on the underside of the heel bone),<sup>20,24</sup> plantar fasciitis (strain on the connective tissue that attaches the arch to the front of the heel),<sup>26</sup> and Sever's disease (calcaneal apophysitis).<sup>12,27</sup>

Heel spurs are the result of strained foot muscles and the wearing away of the fat tissue surrounding the heel bone. Incorrect walking or running technique, excessive running, poor-fitting shoes, obesity, and aging are common contributors to this condition.<sup>9,18</sup>

Plantar fasciitis is caused by high arches, flat feet, repetitive stress during athletic activity, pronated feet, or prolonged standing. This disorder can be determined by the patient's description of the pain and its occurrence.<sup>16,18,19,24,26</sup>

Sever's disease is heel pain seen in children that is precipitated by running, jumping, and excessive walking. It predominately occurs in males between ages 8 and 15 years and usually resolves once the bone has completed growth or activity is lessened.<sup>27</sup>

### Clinical Presentation of Tired, Aching Feet, and Other Painful Foot Disorders

Individuals who suffer from tired, aching feet most often describe either general foot pain or heel pain. Calcium deposits may form on the calcaneous bone (heel spurs) from constant foot stress. Heel spurs are detected via X-ray; they cause pain of increasing intensity after prolonged periods of rest. Plantar fasciitis usually presents with pain from the first moment the person gets out of bed in the morning or stands up after sitting; the pain results from tissue contraction. The sensation on the bottom of the heel is quite painful, and the patient may complain of a burning sensation.<sup>12,14,16,18,26</sup> Sever's disease presents with no swelling, skin changes, erythema, or visible abnormalities. The squeeze test aids in the diagnosis of Sever's disease: pressure is applied at the point of attachment of the calcaneal apophysis to the main body of the os calcis to determine if the patient experiences pain.<sup>27</sup>

### Treatment of Tired, Aching Feet and Other Painful Foot Disorders

#### Treatment Goals

The primary goal in self-treating tired, aching feet, and other painful foot disorders is to provide additional support and shock absorbance for the feet in order to reduce foot pain and fatigue. Stretching muscles to prevent limitations on daily activities is also desired.

#### General Treatment Approach

The first measure to avoid tired, aching feet is to use well-fitted footwear that has sufficient padding and cushioning ([Table 43-1](#)). Wearing sport-specific shoes with good arch support (e.g., running shoes) is an excellent measure for preventing heel pain. Individuals should purchase shoes carefully to ensure a proper fit.<sup>14,18</sup>

Individuals who are physically active or stand for prolonged periods during the day may need to take additional measures, such as replacing worn shoes or heel pads, using a night splint, strapping or taping the arch, decreasing the amount of weight-bearing activity, and, if necessary, entering a weight-reduction program.<sup>24</sup> Oral nonprescription anti-inflammatory agents and topical anti-inflammatory treatments such as ice applications ([Table 43-4](#)) are also appropriate. Magnesium sulfate baths (Epsom salts) have historically been used for soothing tired aching muscles, sprains, and bruising, but no scientific evidence supports these claims. When self-treatment fails, patients should be referred to an appropriate health care provider for evaluation of possible bony malalignments and possible orthotic therapy. [Figure 43-6](#) outlines self-treatment of tired, aching feet and other painful foot disorders.

#### TABLE 43-4 Guidelines for Applying Cold Compresses

Ice Bag Method
<ul style="list-style-type: none"> <li>• Fill the ice bag with crushed or shaved ice to one-half to two-thirds of its capacity, if possible. These forms of ice will ensure greater contact with the injured body part.</li> <li>• If needed, break ice into walnut-sized pieces with no jagged edges. An overfilled bag will be difficult to apply because it will not rest on the contour of the body area.</li> <li>• After filling the bag, squeeze out trapped air. Then dry the outside of the bag and check for leaks.</li> <li>• Bind the injured body part with a wet elastic wrap, and then apply the ice bag. The wet wrap aids transfer of cold to the injured area.</li> <li>• If the ankle is being treated, keep it in a dorsiflexed position (foot toward the nose) when it is wrapped in the elastic bandage.</li> </ul>

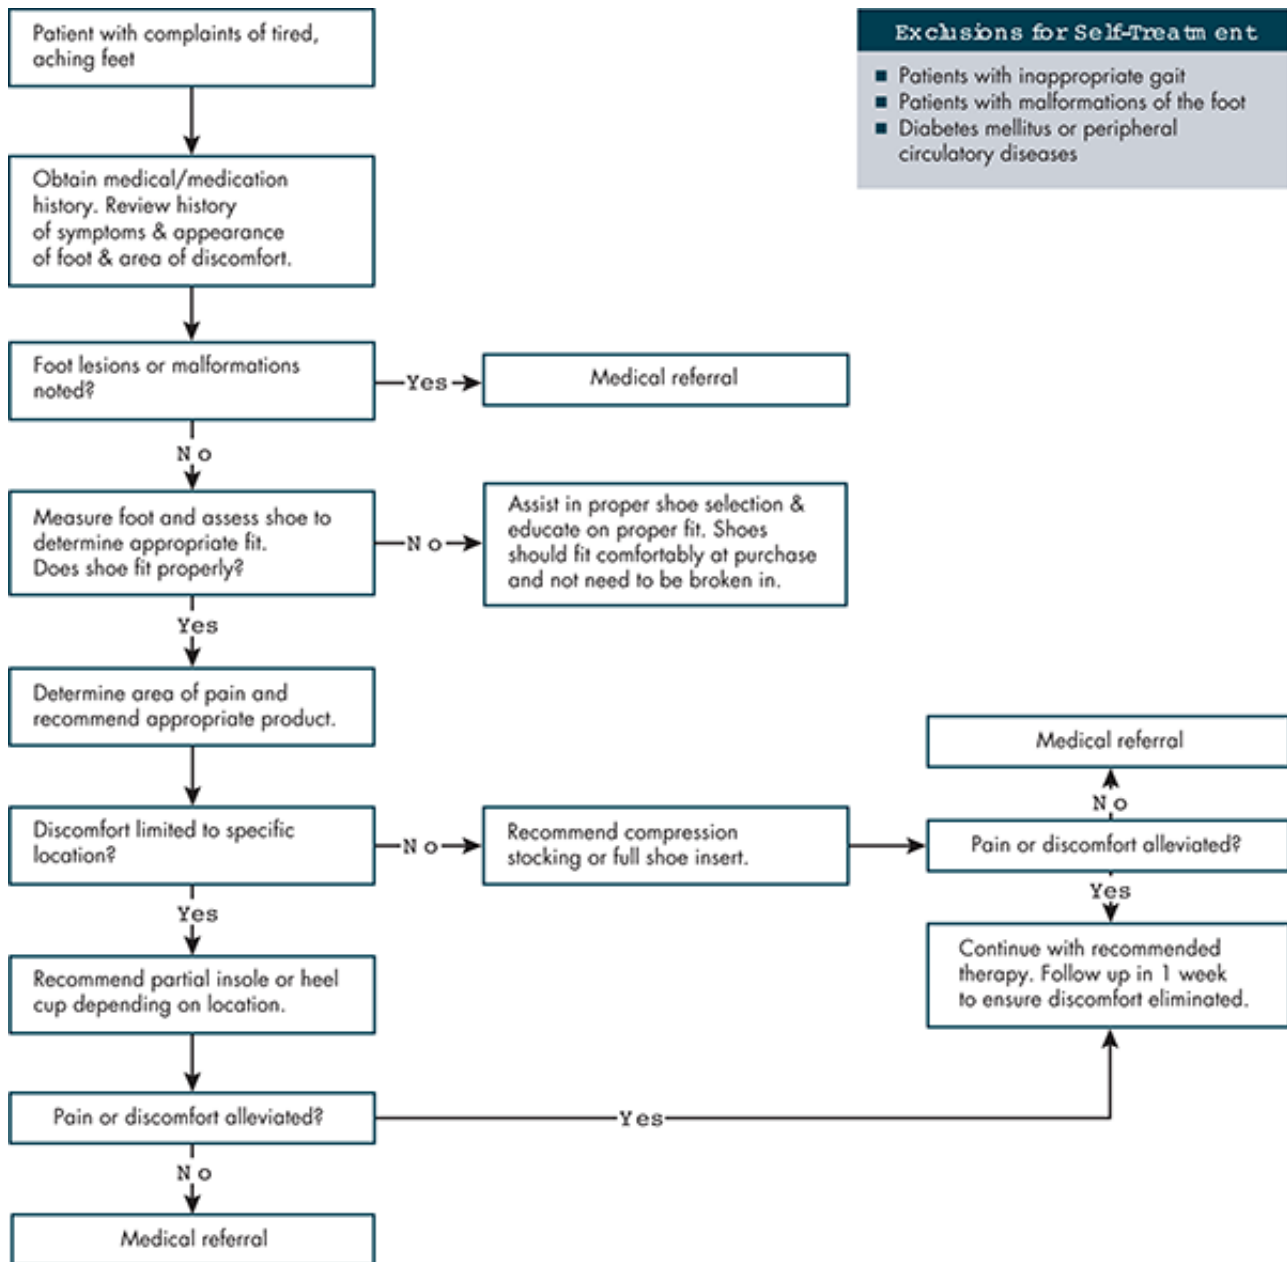

- Apply the ice bag to the specific body part.
- To avoid tissue damage, apply the ice bag for 10 minutes and then remove it for 10 minutes. If the bag is not cloth covered, wrap the injured area or the ice bag in a thin towel to prevent tissue damage.
- Follow this procedure 3-4 times a day.
- For most injuries, continue the cryotherapy until swelling decreases or for a maximum of 12-24 hours. Application of ice may be necessary for up to 48-72 hours, depending on the severity of the injury. (For example, the maximum swelling of ankle injuries may occur up to 48 hours after the injury.)
- Before storing the ice bag, drain it and allow it to air dry. If possible, turn it inside out for more efficient drying. Cap the bag and store it in a cool, dry place.

### **Cold Wraps**

- To activate a single-use cold pack, squeeze the middle of the pack to burst the bubble. This action initiates an endothermic reaction of ammonium nitrate, water, and special additives.
- For a reusable cold wrap (cold pack or gel pack), store it in the freezer for 2 hours. Do not put the cloth cover in the freezer.
- Remove the cold wrap from the freezer, insert it in the cloth cover, and apply it to the injured body part.
- If the cold wrap is uncomfortable, remove it for 1-2 minutes and then reapply it.
- Alternate application of the cold wrap (10 minutes on; 10 minutes off) 3-4 times a day for 24-48 hours.
- After use, store the cold wrap in the freezer.
- Although some gel packs are nontoxic, keep all cold wraps out of children's reach.

Self-care of tired, aching feet.

## Nonpharmacologic Therapy

### Shoe Inserts, Partial Insoles, and Heel Cups/Cushions

Full-shoe inserts, which can provide cushioning and absorb shock, are available in various sizes and thicknesses to accommodate most individuals. These inserts help decrease the incidence of lower back pain associated with the impact from walking. The patient must select an insert that conforms to the type of shoe worn.<sup>8,9</sup>

Partial insoles are preferred when a patient needs cushioning or support in a certain portion of the shoe. For example, metatarsal arch supports, which fit into the ball-of-foot region of a woman's shoe, help lift the arch behind the toes to alleviate pain associated with the spreading of the foot, a condition that occurs with increasing age. There are inserts specifically designed to fit in high heels (e.g., Dr. Scholl's for Her High Heel Insoles). Finally, the arch support insert is intended to cushion and support painful longitudinal arches.<sup>9,14</sup>

A heel cup or heel cushion may be indicated, depending on the location and extent of the pain. For example, a heel cushion might be appropriate when the pain is confined to the bottom of the heel. A heel cushion supports the entire heel as it elevates the sensitive area to prevent further irritation. Alternatively, when the pain is widespread and diffuse, a heel cup might be more appropriate. Heel cups help relieve the pain caused by the breakdown of the heel's natural padding or by intense athletic activity.

Caution should be used when selecting shoe inserts. If an insole affects the patient's gait, the patient should be referred to a podiatrist or pedorthist; the latter specializes in the designing, manufacturing, modifying, and fitting of

footwear and orthotics. Insoles should be used only to cushion the foot, not to correct malformation, which requires a specialist's attention.

### Compression Stockings

Compression stockings are also an option to enhance support for individuals who spend many hours on their feet. Compression stockings may be purchased without a prescription in compressions ranging from 15 to 40 mm Hg. These stockings will decrease inflammation by improving circulation, thereby reducing fatigue of the feet, legs, and back.<sup>28,29</sup>

### Assessment of Tired, Aching Feet and Other Painful Disorders

Treatment of tired, aching feet requires evaluation of lifestyle factors (e.g., occupation, daily exercise, and footwear); the possibility of underlying pathology (e.g., circulatory or neurologic disorders); the possibility of an aggravating event; and the walking/working surface. If underlying pathology is suspected, the patient should be referred to a primary care provider or podiatrist for initial evaluation.

### Patient Counseling for Tired, Aching Feet and Other Painful Foot Disorders

The provider can play an integral role in counseling patients on preventing and treating foot disorders caused by friction and excessive impact. The cornerstone of preventing these disorders is selecting the appropriate footwear. If the disorder persists after a change in footwear, the provider can help patients select in-shoe supports and advise them of other measures to reduce the impact of weight-bearing activities. The box Patient Education for Tired, Aching Feet and Other Painful Foot Disorders lists specific information to provide patients.

#### Patient Education for Tired, Aching Feet and Other Painful Foot Disorders

The objectives of self-treatment are to (1) reduce impact on the feet by providing additional support and shock absorbance and (2) relieve foot discomfort. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

- To reduce friction of the feet and impact on weight-bearing parts of the feet, wear well-fitted footwear that has sufficient padding and cushioning (Table 43-1).
- Consider other measures to further decrease impact on the feet, such as decreasing the length of time you stand or exercise, switching to exercises that have less effect on the feet, and, if necessary, losing weight.
- To relieve swelling or discomfort, apply an ice bag or cold wrap to the affected area (Table 43-4).
- For acute pain relief, nonsteroidal anti-inflammatory medications such as ibuprofen or naproxen may be used.
- To improve circulation, select a compression stocking with mild-moderate compression (<15 mm Hg).
- Choose a full-shoe insert when the entire foot aches. Make sure the insert conforms to the shoe. For example, choose a thin insole for a woman's pump and a thicker insole for a sneaker.
- Use partial insoles to cushion or support a certain portion of the foot, such as the ball of the foot, the arch, or the toes.
- Use a heel cushion for pain confined to the bottom of the heel.
- Use a heel cup when the pain is widespread and diffuse.

### When to Seek Medical Attention

- If discomfort or swelling continues after 1 week of implementing appropriate self-care measures, consult a health care provider.

### Evaluation of Patient Outcomes for Tired, Aching Feet and Other Painful Foot Disorders

Resolution of pain in the soles or heels of the feet depends on whether the patient has exclusions for self-treatment and how long the foot problem has persisted. Follow-up should occur after 1 week to determine whether the use of new shoes and/or in-shoe supports has eliminated the discomfort. If the symptoms persist, the patient should consult a podiatrist for evaluation.

### Exercise-Induced Foot Injuries

Providers should be aware of possible exercise-induced foot injuries, particularly those caused by running, jogging, or other high-impact physical activities (Figure 43-7). Often, individuals fail to take certain precautions and dive head first into a strenuous exercise program. To minimize potential injuries and dangers, individuals who are typically sedentary, are older than 35 years, have hypertension, or have a history of heart disease or diabetes should seek medical evaluation before beginning a strenuous exercise program. Patients with potential orthopedic problems may benefit from walking instead of performing strenuous forms of exercise.<sup>30</sup>

Copyright © American Pharmacists Association  
All rights reserved. Any use is subject to the Terms of Use.

Selected foot and leg injuries associated with excessive impact shock.

### Treatment of Exercise-Induced Foot Injuries

#### Treatment Goals

The goals in self-treating exercise-induced foot problems are to (1) relieve any pain, (2) prevent secondary bacterial infection if the skin is broken, and (3) institute measures to prevent further injury.

#### General Treatment Approach

Measures to prevent exercise-induced injuries entail using suitable footwear that fits properly ([Table 43-1](#)); running on the proper surface; using correct posture (i.e., running erect); and stretching muscles before exercising. Most running injuries can be successfully treated with measures such as shoe modifications, shoe inserts, and in-shoe supports, as discussed in the section Treatment of Tired, Aching Feet and Other Painful Foot Disorders.

If an injury to the leg or foot occurs, activity must usually be interrupted to allow the injured leg or foot to rest. Relative rest (i.e., avoiding activities that produce the symptoms) is often indicated. Alternative exercise such as swimming, rowing, and/or bicycling (stationary or outdoor) should be encouraged.

If the injury warrants it, the patient can be instructed on selecting and using nonprescription accessories (e.g., cryotherapy, a compression ice wrap, ice bags, compression bandages, arch supports, and heel cushions) that will alleviate injuries or problems. Systemic analgesics can also relieve the pain and inflammation of minor foot injuries

(see [Chapter 5](#)).

## Nonpharmacologic Therapy

[Table 43-5](#) provides specific recommendations for self-treatment of the discussed exercise-induced foot injuries.<sup>28-39</sup>**TABLE 43-5 Differentiation and Management of Exercise-Induced Foot Injuries**

<i>Type of Injury</i>	<i>Common Causes</i>	<i>Pathophysiology</i>	<i>Signs/Symptoms</i>	<i>Recommendations</i>
Shin splints	Overzealous workout; inappropriate stretching; running/walking on sloped or hard surfaces; wearing ill-fitting footwear; overstriding	Excessive pronation weakens/strains posterior tibialis; anterior tibial muscle stretches away from periosteum that lines shinbone	Pain in medial lower third of shin, or below knee and above ankle; pain worsens with exercise; cramping, burning, and tightness on anterior lateral section of shin	PRICE or RICE therapy; acetaminophen or ibuprofen; shoe orthotic; medical referral
Stress fracture	Running on hard, rigid surfaces; rapid increase in physical activity; jumping; estrogen deficiency; nutritional deficiencies; obesity; ill-fitting footwear	Outer cortex of long bones of leg or foot cracks from alternation in tensile forces sent by ligaments, tendons, and muscles	Deep pain in lower leg; tender to the touch; swelling; pain worsens with exercise	Medical referral; complete rest; NSAID therapy
Achilles tendonitis	Running on hills or in sand; ill-fitting footwear; excessive pronation; arthritis	Inflammation of Achilles tendon; rupture of tendon	Posterior heel pain; tenderness; swelling	Medical referral
Blisters	Repetitive movement; ill-fitting footwear; tight hosiery	Continual friction on small surface of foot separates stratum corneum and stratum lucidum skin layers, causing space between layers to fill with fluid	Accumulation of fluid beneath stratum corneum; may be painful	Do not remove blister; protect with topical bandage; medical referral for drainage, if needed
Ankle sprains	Ankle rotating outside acceptable range	Lateral ligament damage	Pain; bruising; tenderness; difficulty walking	PRICE or RICE therapy; compression bandage
Intermetatarsal neuritis	Small toe box space	Inflammation of nerves from compression or entanglement between metatarsal heads and digital bases	Pain and numbness between toes	Proper footwear
Toenail loss	Long, thick toenails in small toe box space; friction and pressure from running in "stop and go" sports, such as tennis	Fluid beneath nail plate pushes toenail from nail bed	Dark discoloration from blood underneath nail plate; pain at toe; nail loss	Referral to podiatrist or PCP

Key: NSAID = Nonsteroidal anti-inflammatory drug; PCP = primary care provider; PRICE = protection, rest, ice, compression, elevation; RICE = rest, ice, compression, elevation.

Source: References 28-39.

## Athletic Footwear

Appropriate footwear can be a powerful tool for manipulating human movement and can greatly influence the healing of injured tissues, both positively and negatively. The importance of appropriate footwear has been reported by Cheung and Ng.<sup>37</sup> Their study demonstrated that the type of footwear chosen by recreational runners is important to prevent injury. Consequently, inappropriate or worn-out shoes can result in foot injuries and pain. Athletic shoes should be replaced after 200-400 miles of use, as detailed by Meadows.<sup>38</sup>

## Compression Bandages

Typically, a compression bandage (e.g., Ace Bandages) is used for an ankle or knee sprain. If a compression bandage is to be used, the width of the bandage depends on the injury site. For example, a foot or an ankle requires a 2- to 3-inch bandage.<sup>39</sup> Table 43-6 describes the proper method of applying this type of bandage.

### TABLE 43-6 Application Guidelines for Compression Bandages

- Choose the appropriate size of bandage for the injured body part. If you are unsure of the size, purchase a product designed for the appropriate body part.
- Recommended elastic bandage widths according to coverage area:
  - 2 inches: foot, wrist, ankle
  - 3 inches: elbow, knee, ankle
  - 4 inches: knee, lower leg, shoulder
  - 6 inches: shoulder, upper leg, chest
- Unwind about 12-18 inches of bandage at a time, and allow the bandage to relax.
- If ice is also being applied to the injured area, soak the bandage in water to aid the transfer of cold (Table 43-4).
- Wrap the injured area by overlapping the previous layer of bandage by about one-third to one-half of its width.
- Tightly wrap the point most distal from the injury. For example, if the ankle is injured, begin wrapping just above the toes.
- Decrease the tightness of the bandage as you continue to wrap. (Follow package directions on how far to extend the bandage past the injury.) If the bandage feels tight or uncomfortable or if circulation is impaired, remove the compression bandage and rewrap it. Cold or swollen toes and fingers indicate that the bandage is too tight.
- After using the bandage, wash it in lukewarm, soapy water; do not scrub it. Rinse the bandage thoroughly, and allow it to air-dry on a flat surface. Roll up the bandage to prevent wrinkles, and store it in a cool, dry place. Do not iron the bandage to remove wrinkles.

Source: Reference 39.

## Cryotherapy

Applying cold compresses to an injury such as a muscle sprain anesthetizes the area and decreases the pain and inflammation. Ice bags or cold wraps are useful for cold application in 10-minute increments. Table 43-4 describes the proper method of cold application to injuries.

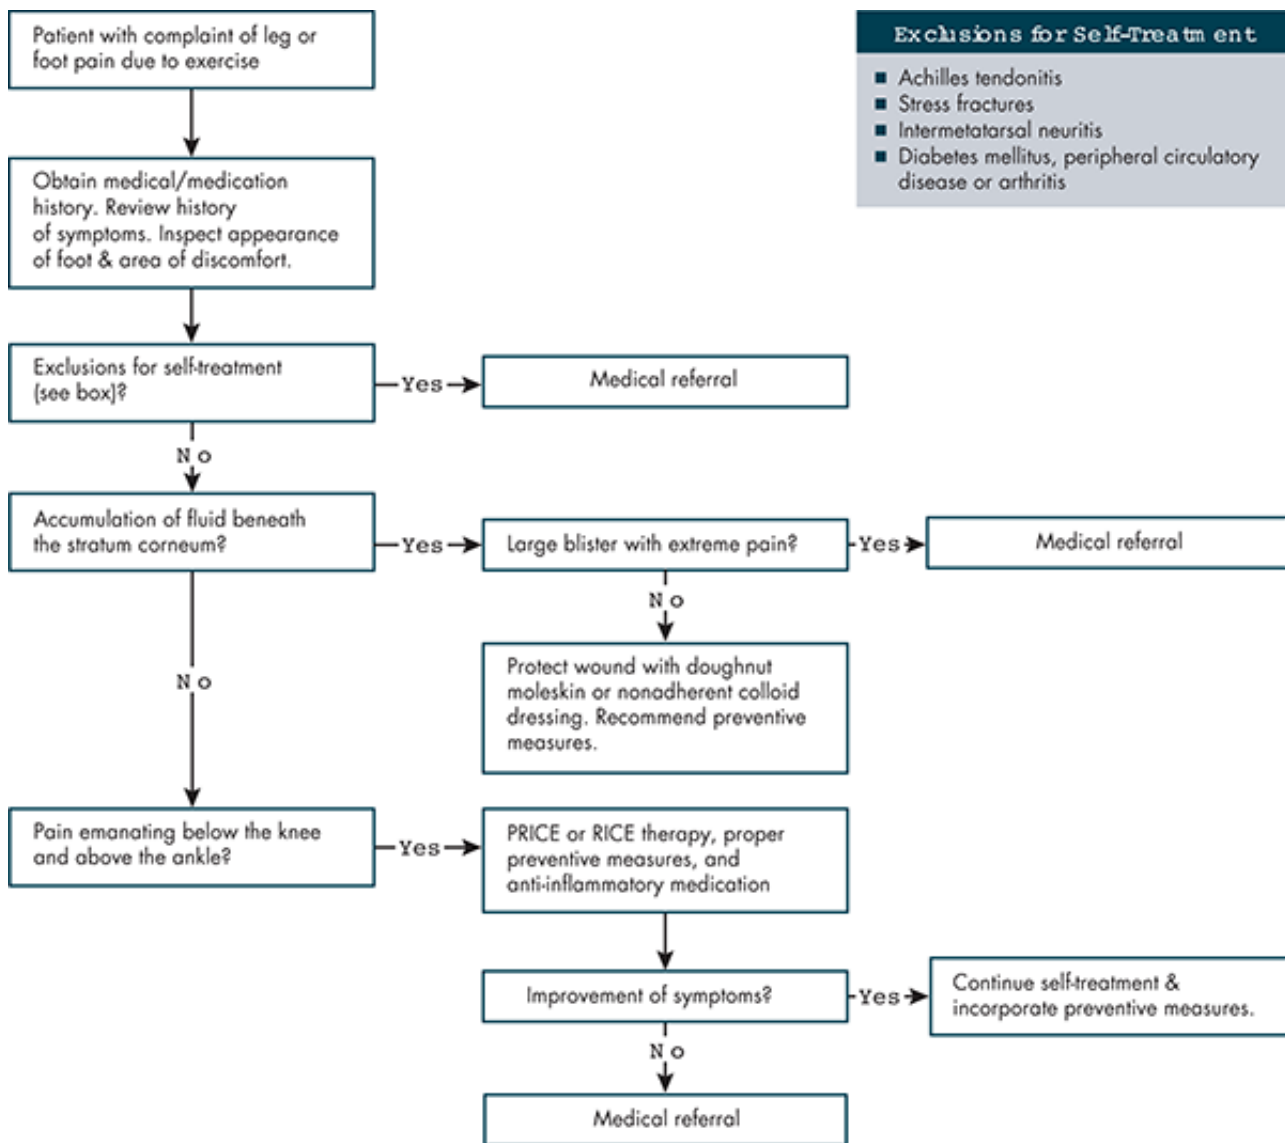

## Contrast Bath Soaks

For acute injury, cold application is beneficial during the first 48 hours to decrease ensuing inflammation. After the acute injury, some podiatrists advocate the use of alternating applications of cold therapy and warm therapy for chronic, nagging pain. Specifically, the cold therapy is intended to decrease inflammation. The warm therapy attempts to bring increased blood flow to the affected area and effect smooth muscle relaxation.

## Assessment of Exercise-Induced Foot Injuries

The provider may be called on to play a triage role in treating an exercise-induced injury to the foot (Figure 43-8). Identifying the location of the pain will help determine the type and extent of the injury. Asking about the nature and duration of the pain will help in determining whether the injury is self-treatable.

Copyright © American Pharmacists Association  
All rights reserved. Any use is subject to the Terms of Use.

Self-care of exercise-induced injuries. Key: PRICE = Protection, rest, ice, compression, and elevation; RICE = rest, ice, compression, and elevation.

### Patient Counseling for Exercise-Induced Foot Injuries

Rest and appropriate preventive measures for the patient's particular injury should be explained. When rest alone does not relieve foot discomfort, the proper use of oral nonprescription analgesics, compression bandages, and cryotherapy should be recommended. The correct procedure for wrapping a bandage, which is also described on the package, should be reviewed with the patient. If inappropriate use of a compression bandage is a concern, simply elevating the body part and applying an ice pack should be recommended. If warranted by the severity of the injury, medical referral should be recommended. The box Patient Education for Exercise-Induced Injuries lists specific information to provide patients.

#### Patient Education for Exercise-Induced Injuries

The objectives of self-treatment are to (1) rest the injured foot or limb to allow healing, (2) relieve discomfort, and (3) take measures to prevent further injury. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### General Measures

- When a leg or foot injury occurs, rest the injured limb. If desired, perform other types of exercise that do not put a great deal of force on the feet, such as swimming or bicycling (stationary or outdoor).
- Take the following actions to prevent exercise-induced injuries:
  - Stretch muscles before exercising.
  - Choose sport-specific shoes with good arch support for athletic activities.
  - Run or walk on a relatively smooth, level, and resilient surface.
  - Keep the back straight when running.

## Shin Splints

- Rest the feet and apply an ice bag or a cold wrap to the painful area (Table 43-4).
- If desired, take aspirin or NSAIDs to relieve pain and reduce tissue inflammation.
- Do not use analgesics to suppress pain or to increase your endurance during a workout.

### When to Seek Medical Attention

- Seek medical attention if the discomfort becomes a cramping, burning tightness that repeatedly occurs at the same distance or time during a run.

## Blisters

- To prevent blisters during running, wear moisture-wicking socks (i.e., wool or acrylic). If desired, wear two pairs of socks with ordinary talcum powder sprinkled between them. Using an acrylic sock next to the foot will assist in drawing moisture from the foot.
- Apply compound tincture of benzoin or a flexible collodion product (e.g., New Skin) to the blister before exercise to decrease pain and accelerate healing by promoting reepithelialization.
- Apply an antiperspirant that contains aluminum chloride 20% to decrease incidence of blisters.
- If blisters break, apply a first-aid antibiotic to the broken skin to prevent secondary bacterial infection.
- Cover blistered area with moleskin to protect the surface.

## Ankle Sprains

- Although maximum swelling will not occur for 48 hours, begin treatment as soon as possible.
- Stay off the injured foot, wrap a compression bandage around the ankle, apply ice, and elevate the ankle. (Tables 43-4 and 43-6 provide guidelines on applying ice and compression bandages.)

### When to Seek Medical Attention

- Seek medical attention if swelling persists more than 72 hours.

## Toenail Blisters/Loss

- To prevent blisters under the toenail, keep toenails trimmed and run in properly fitted shoes.
- Should a blister develop, do not disturb or puncture the blister roof.

### When to Seek Medical Attention

- If the toenail separates from the skin or is lost, consult a primary care provider or podiatrist for proper treatment.

## Evaluation of Patient Outcomes for Exercise-Induced Injuries

Follow-up of patients who have shin splints or ankle sprains should occur 7 days after the use of compression bandages, cryotherapy, or other anti-inflammatory therapy to determine symptom resolution. If symptoms of swelling and/or pain persist, medical referral is appropriate. Patients with blisters on the feet or under the toenail should also be reevaluated after 7 days of the recommended therapy. If signs of infection are present or the toenail has separated from the nail bed, medical referral is appropriate.

## Ingrown Toenails

The most frequent cause of ingrown toenails, or onychocryptosis, is incorrect trimming of the nails. The correct method is to cut the nail straight across, without tapering the corners. Wearing pointed-toe or tight shoes or too-tight hosiery has also been implicated. Other causes are hyperhidrosis, trauma, obesity, and excessive pressure on the toes. Direct pressure on a toe can force the lateral or medial edge of the nail into the soft tissue. The embedded nail may then continue to grow, resulting in swelling and inflammation of the nail fold.<sup>8,10,38,40</sup>

Bedridden patients may develop ingrown toenails if tight bedcovers press the soft skin tissue against the nails. Nail curling, which can be hereditary or secondary to incorrect nail trimming, onychomycosis, or a systemic, metabolic disease, can also result in ingrown toenails.

## Pathophysiology of Ingrown Toenails

An ingrown toenail occurs when the nail curves and embeds into the flesh at the corner(s) of a toe, causing pain (Figure 43-4). Puncturing of the skin that is accompanied by soft tissue hypertrophy and subsequent invasion by

opportunistic resident foot bacteria can cause a superficial infection. Swelling, inflammation, and ulceration are secondary complications that can arise from an ingrown toenail.<sup>38</sup>

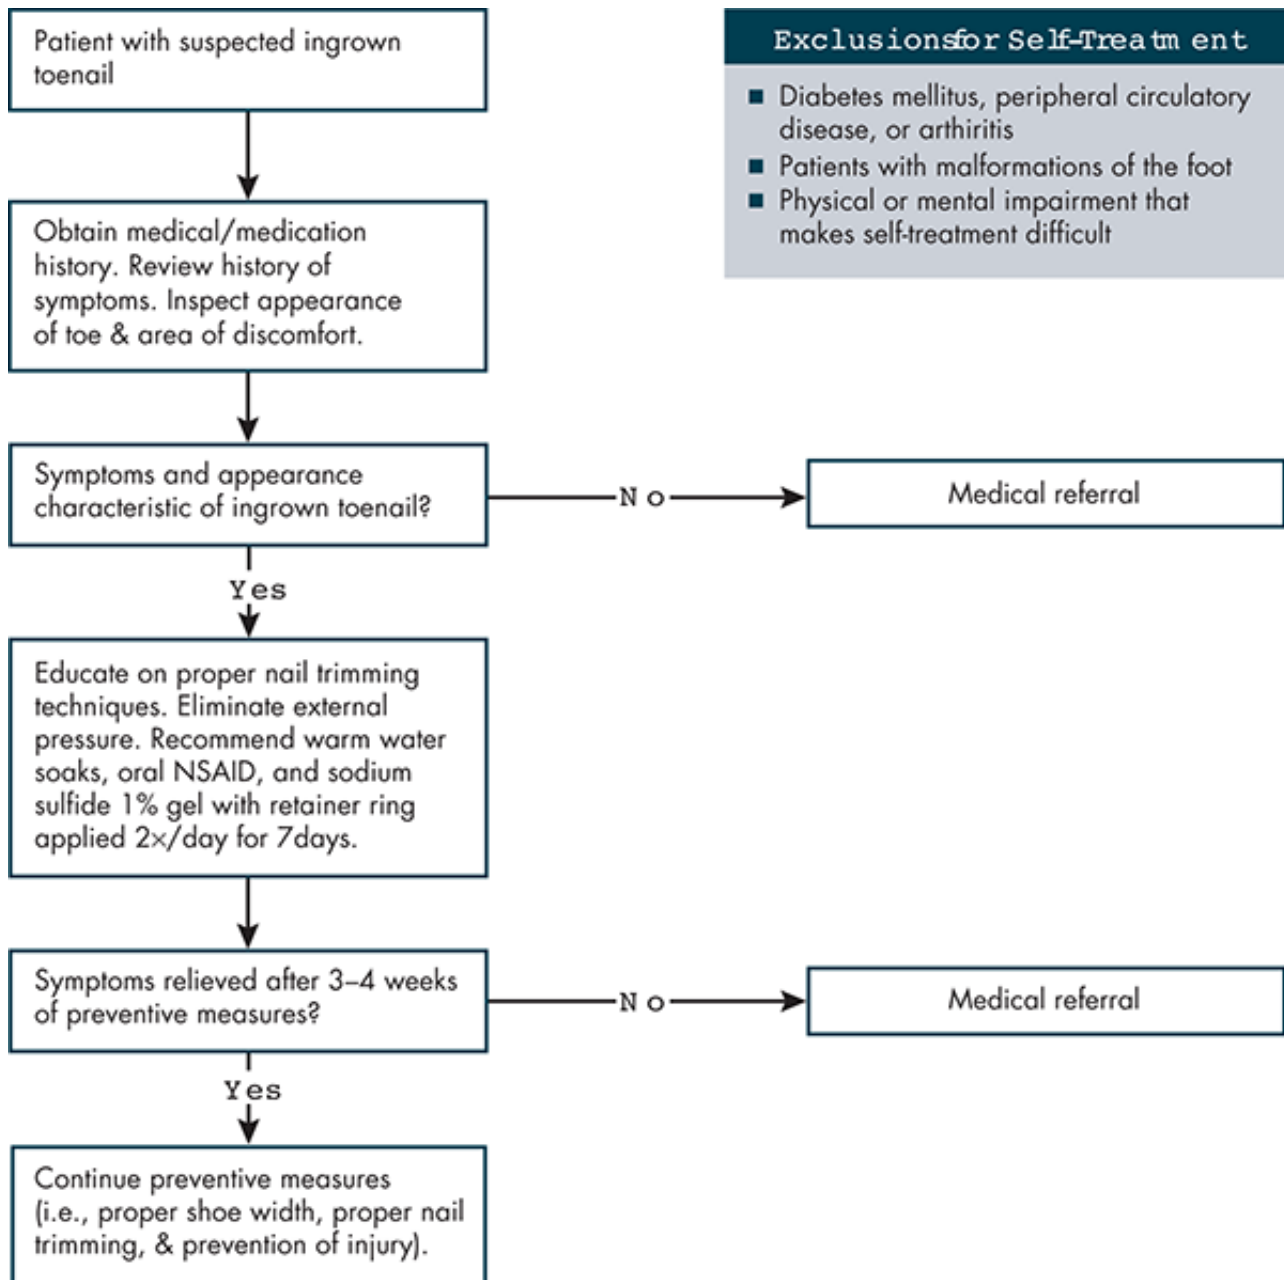

### Treatment of Ingrown Toenails

#### Treatment Goals

The goals of self-treating ingrown toenails are to (1) relieve pressure on the toenails, (2) relieve pain, and (3) prevent recurrence of the disorder.

#### General Treatment Approach

Patient education is the best means of preventing the development of ingrown toenails. In the early stages of development, therapy is directed at providing adequate room for the nail to resume its normal position adjacent to soft tissue. This therapy is accomplished by relieving the external source of pressure. Warm water soaks for 10-20 minutes several times a day until resolution will help soften the area. Topical antiseptics prescribed by a primary care provider can be applied to prevent possible opportunistic infections. Insertion of small cotton wisps or dental floss under the impinged nail edge has a 79% rate of symptomatic improvement. No evidence is linked to secondary infection from the cotton wisps or dental floss.<sup>40</sup> Medical referral is necessary if the condition is recurrent or gives rise to an oozing discharge, pain, or severe inflammation. Sometimes surgery is warranted; with subsequent systemic antibiotic therapy, the toe may take up to 3-4 weeks to heal. The most common surgical procedure is removal of the lateral edge of the nail followed by chemical matricectomy using phenolization. This process destroys the exposed nail-forming matrix.<sup>38,40</sup> Figure 43-9 outlines self-treatment options for ingrown toenails.<sup>37</sup>

### Exclusions for Self-Treatment

- Diabetes mellitus, peripheral circulatory disease, or arthritis
- Patients with malformations of the foot
- Physical or mental impairment that makes self-treatment difficult

Copyright © American Pharmacists Association  
All rights reserved. Any use is subject to the Terms of Use.

Self-care of ingrown toenails. Key: NSAID = Nonsteroidal anti-inflammatory drug.

### Pharmacologic Therapy

#### Sodium Sulfide Gel

Dr. Scholl's Ingrown Toenail Pain Reliever contains sodium sulfide 1%. The gel is applied topically, and a retainer ring is then placed around the affected area to help maintain the product at the site of action. The mechanism of action of sodium sulfide 1% is relief of pain by softening the nail or by hardening the nail bed. It may be applied twice daily for up to 7 days for relief of the discomfort of ingrown toenails.<sup>41-43</sup> Providers must be aware of misleading trade-name products marketed for ingrown toenails. Products such as Outgro Pain-Relieving Formula contain benzocaine 20% to relieve pain associated with ingrown toenails, but this agent does not treat the underlying problem.<sup>43-45</sup>

Patients with ingrown toenails often fail to realize that oral medications to alleviate pain and inflammation may help their condition. Provided no contraindications exist for their use by a particular patient, oral aspirin, ibuprofen, or naproxen may be recommended; all are proven analgesics with anti-inflammatory activity (see [Chapter 5](#)).

### Assessment of Ingrown Toenail

The provider can play a vital role in recommending measures for relieving acute pain from ingrown toenails and in preventing their recurrence. For relief of ingrown toenail, initial recommendations include warm bath soaks to soften

the skin and oral anti-inflammatory therapy for temporary pain relief. If the toenail or nail bed is infected, immediate referral is warranted.

### Patient Counseling for Ingrown Toenails

The box Patient Education for Ingrown Toenails lists specific information to provide patients.

#### Patient Education for Ingrown Toenails

The ultimate goals for self-treatment of ingrown toenails are to relieve the pain and pressure associated with the condition and to prevent recurrence.

- Ensure that shoes fit properly to eliminate pressure on the toenails (Table 43-1).
- Prevent recurrence of ingrown toenails by cutting toenails straight across, rather than at an angle.
- Decrease pain and swelling of the ingrown toenail by taking a nonsteroidal anti-inflammatory medication such as ibuprofen or naproxen.
- Relieve impingement of the nail by soaking your feet in warm water to soften the nail and the skin around it.
- Place cotton wisps or dental floss under the edge of the ingrown nail for almost immediate pain relief.

### Evaluation of Patient Outcomes for Ingrown Toenails

Patient evaluations should be made after 3-4 weeks to determine whether pressure relief and preventive measures have been successful. Medical referral is appropriate if the condition shows no improvement or worsens or if there is a discharge from the site of irritation.

### Hyperhidrosis

Hyperhidrosis, or excessive sweating, comprises two types: primary focal hyperhidrosis and secondary hyperhidrosis. The incidence of hyperhidrosis is 2.8% of the U.S. population; it occurs equally in men and women.<sup>46,47</sup> It is most prevalent in people ages 25-64 years.<sup>46</sup> Hyperhidrosis is a complicated process that involves sympathetic and parasympathetic pathways.<sup>46</sup>

*Primary focal hyperhidrosis* is defined as visible, excessive sweating that has lasted 6 months without cause and that has two or more of the following characteristics: bilateral and symmetrical presentation, one or more episodes a week, hindrance of social activities, family history of the disorder, and absence of sweating during sleep.<sup>44</sup> This disorder seems to begin during childhood. Symptoms of hyperhidrosis usually improve with age. Family history is positive in 30%-50% of patients.<sup>47</sup> Hyperhidrosis can be embarrassing to affected individuals and may affect their daily activities, lifestyle, and social interactions. Although psychological morbidity is prevalent in most patients experiencing hyperhidrosis, few people seek medical attention for the disorder.

*Secondary hyperhidrosis* can have a focal or generalized presentation that affects the entire body. Secondary hyperhidrosis is usually caused by a variety of medical conditions. Examples include endocrine disorders (e.g., hyperthyroidism or diabetes mellitus); pregnancy; neurologic disorders; malignant disorders; cardiovascular disorders; respiratory failure; licit and illicit drug use; and alcohol abuse.<sup>47</sup> This discussion will focus on primary focal hyperhidrosis because nonprescription medications are available to treat it.

### Pathophysiology of Hyperhidrosis

Primary focal hyperhidrosis occurs mainly in the palms, plantar surfaces, and axillae. The more than 4 million sweat glands in the body are classified as either eccrine or apocrine, with eccrine glands making up 75% of the total. Eccrine glands primarily produce colorless, odorless sweat and are located all over the body. They are more concentrated in the soles of the feet, forehead, and palms. The apocrine glands are scented sweat glands located in the axillae and genital areas. The pathophysiology of hyperhidrosis is not fully understood, but it may be caused by dysfunction of the autonomic nervous system. It seems that once sweating begins, a vicious cycle predominates, and evaporative cooling of the skin increases a reflex sympathetic outflow, which actually increases sweating.<sup>47</sup>

### Clinical Presentation of Hyperhidrosis

The most common sign of hyperhidrosis is profuse sweating.<sup>47</sup> Excessive sweating is considered to be any amount of sweat that interferes with daily life and activities. Laboratory diagnosis is not necessary. The starch-iodine test has been used to identify the primary area of sweating. Starch is applied to the area previously covered by an iodine solution. The starch/iodine solution turns a dark blue color wherever excessive sweating is present. This test helps direct treatment to the affected areas and allows providers to note improvement in treated areas as a subsequent decrease in the focal area.<sup>46,48</sup>

No physical complications are associated with focal hyperhidrosis. Some patients may experience odor problems from sweaty feet or underarms. Psychological complications may result from the embarrassment of hyperhidrosis.

More than 35% of patients report they have altered their lifestyle by decreasing leisure activity time because of hyperhidrosis. Simple social interactions such as shaking hands, holding hands, and hugging may be difficult.

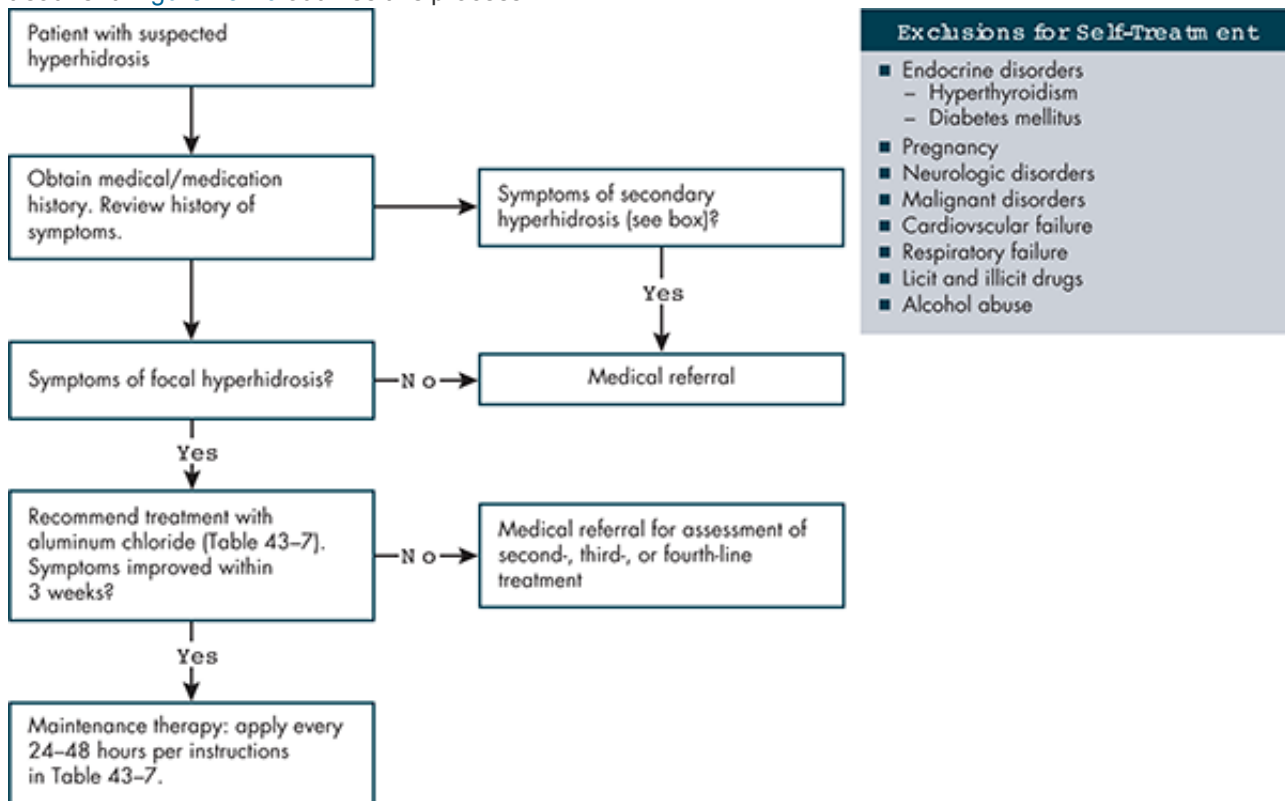

## Treatment of Hyperhidrosis

### Treatment Goals

The main goal of treatment is to eliminate profuse sweating in a cost-effective, minimally invasive method. Several types of treatments are available.

### General Treatment Approach

Patients should consider convenience, ease of administration, side effects, and cost in choosing the best self-treatment. Figure 43-10 outlines this process.

Copyright © American Pharmacists Association  
All rights reserved. Any use is subject to the Terms of Use.

Self-care of hyperhidrosis.

### Nonpharmacologic Therapy

One of the primary concerns of this disorder is its psychosocial implications. Psychotherapy has been beneficial in a small number of cases.<sup>49</sup> Few noninvasive methods to treat hyperhidrosis are available because the disease involves mainly the autonomic nervous system. Several surgical and nonsurgical treatments are available.

Iontophoresis is used as a second-line therapy for hyperhidrosis.<sup>46-48</sup> This treatment, which involves the passage of a direct electrical current onto the skin, is safe and effective for plantar hyperhidrosis. Its mechanism of action may be related to induction of hyperkeratosis of the sweat pores, which obstructs sweat flow and secretion.<sup>46-50</sup>

### Pharmacologic Therapy

Several pharmacologic treatments are available for hyperhidrosis. Aluminum chloride is recommended as first-line treatment in hyperhidrosis because it is inexpensive and relatively easy to administer.<sup>46,47,50</sup> The same treatments used in axillary hyperhidrosis are used for treatment of plantar hyperhidrosis. The most common nonprescription treatments are topical aluminum salts. Aluminum salts indicated for treatment of excessive perspiration are commonly found in nonprescription antiperspirants. Their mechanism of action is related to mechanical obstruction of the eccrine gland duct or atrophy of eccrine secretory ducts.<sup>46</sup> Aluminum chloride solutions are available in concentrations of 20%-25%. The nonprescription antiperspirant Certain Dri contains 12% aluminum chloride and is available as a roll-on antiperspirant. Drysol is a common prescription drug used to treat hyperhidrosis; it contains

aluminum chloride hexahydrate 20% topical solution in absolute anhydrous ethyl alcohol.

Frequent applications, every 24–48 hours, of products that contain aluminum chloride are needed; improvement may be seen as early as 3 weeks. Patients should apply the product sparingly at bedtime and wash it off after 6–8 hours. To prevent stinging and burning, patients should not apply the product after bathing or shaving, or to broken, irritated skin.<sup>46–48</sup> The short duration of action and frequency of repeated applications make these products inconvenient for patients. The side effects associated with use of aluminum chloride solution include localized burning, stinging, and irritation. Hydrocortisone can be applied if irritation occurs. These agents may be used on the hands, axillae, or feet. Products containing aluminum chloride should not be used on children and patients with reduced renal function. Also, patients who are pregnant or lactating should not use these products because their safety for use in these patients has not been studied.

Botulinum toxin A (Botox), a neurotoxin produced by clostridium botulinum, is a third-line treatment that is available by prescription and administered by a health care provider. It inhibits the release of acetylcholine, which causes excessive perspiring, from sympathetic nerves.<sup>46</sup> Botulinum toxin A is indicated for axillary hyperhidrosis and has shown great promise in treating the disorder.

Some patients with hyperhidrosis who do not want to consider surgery or prescription medications have found that insoles such as Summer Soles and other foot inserts help keep the feet comfortable. They prevent the slipping and sliding in shoes that sometimes occur when the feet are wet. These products, which are made of a wool and rayon blend that absorbs sweat, are available online and in some shoe stores. Some patients may add talcum powder to their shoes or apply it to their feet. However, this measure does not stop or slow the physiologic sweating that occurs with hyperhidrosis. The water and powder combination can also result in a glue-like substance.

### Assessment of Hyperhidrosis: A Case-Based Approach

For proper assessment of hyperhidrosis, the patient's medical history and medication history related to this disorder are needed. Most often, patients with hyperhidrosis have had symptoms since childhood. A comfortable screening area may allow observation of the bilateral excessive sweating. The health care provider should also discuss treatment options and determine the patient's comfort level with the treatment standards and the expense and invasiveness of the therapies.

Case 43-2 illustrates the assessment of a patient with hyperhidrosis.

#### Case 43-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b><i>Information Gathering</i></b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient presents with profuse sweating of her feet that makes wearing shoes uncomfortable.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Warm weather or situations that make her nervous make her symptoms worse.
c. description of the patient's efforts to relieve the symptoms	The patient has tried rubbing aluminum chloride hexahydrate solution (Drysol) on her feet every other night. She also uses Summer Soles in her shoes during the summer so that she can wear sandals without her feet slipping.
d. patient's identity	Connie Smith
e. age, sex, height, and weight	35 years old, female, 5 ft 6 in, 145 lb

f. patient's occupation	Nurse
g. patient's dietary habits	Vegetarian; eats three meals and two snacks a day.
h. patient's sleep habits	Averages 5-6 hours per night.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Known diagnosis of plantar and palmer hyperhidrosis. Takes 1 One A Day vitamin daily with her breakfast.
j. allergies	NKDA
k. history of other adverse reactions to medications	None
l. other (describe) _____	Connie says that she is tired of this situation and would like advice on what she should do about her sweaty feet.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	The patient is experiencing plantar hyperhidrosis.
3. Identify exclusions for self-treatment (Figure 43-10).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Recommend OTC products for focal hyperhidrosis. (2) Refer patient for plantar hyperhidrosis. (3) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Patient should consult a health care provider because the response to treatment of her hyperhidrosis with topical preparations and nonpharmacologic measures has been inadequate. Options such as Botox therapy or surgical treatment may be warranted.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should consult a health care provider about your hyperhidrosis."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"This option is best because you have tried nonprescription products without success. Second-line therapy is iontophoresis. You will need to consult your health care provider for details about iontophoresis or other possible options."
<b>Patient Education</b>	
8. When recommending self-care with	Criterion does not apply in this case.

nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
Solicit follow-up questions from the patient or caregiver.	“Is this a common problem in women?”
Answer the patient’s or caregiver’s questions.	“Hyperhidrosis occurs in 2.8% of the population; it occurs equally in men and women.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact Connie in a day or two to ensure that she made an appointment and sought medical care.

Key: NDKA = No known allergies; OTC = over-the-counter education for counter.

### Patient Counseling for Hyperhidrosis

The box Patient Education for Hyperhidrosis provides specific information for patients.

#### Patient Education for Hyperhidrosis

The main goal of self-treatment of hyperhidrosis is to eliminate profuse sweating in a cost-effective manner.

- The easiest and most cost-effective therapy would be treatment with aluminum chloride.
- Use an application modality (e.g., roll-on, aerosol, or cream) that ensures the most beneficial application.
- Use caution with topical treatments; they may result in an allergic reaction or burning, stinging, or irritation at the application site.
- Remember to reapply topical product every 24-48 hours to ensure reduction of hyperhidrosis symptoms.
- Shoe liners (i.e., Summer Soles) may be used in sandals and shoes to absorb wetness and prevent foot slippage.

### When to Seek Medical Attention

- If satisfactory results are not seen with topical products, consider therapies such as Botox or surgical procedures.
- For those who have tried other treatment modalities, surgical treatments may be an option. Compensatory sweating, neuralgia, and sexual dysfunction may result and should be considered before taking this step.

### Evaluation of Patient Outcomes for Hyperhidrosis

Patients and health care providers should discuss the expectations of the treatment modalities used for hyperhidrosis. In addition, patients may need to incorporate a routine to allow continued compliance with treatments that require consistent reapplications. The patients’ quality of life should be discussed to determine whether the treatments are effective in improving daily activities.

### Key Points for Minor Foot Disorders

- The nonprescription drug of choice to treat corns and calluses is salicylic acid in a collodion-like vehicle or plaster form.
- Predisposing factors responsible for corns and calluses must be corrected.
- Patients should also be cautioned that frequent recurrence of any of these foot disorders is an indication to consult a podiatrist or health care provider.
- Patients with diabetes, circulatory problems, and/or arthritis should be counseled to avoid self-medicating with any topical or oral nonprescription drug without first checking with their health care provider.
- Nonprescription products are powerful drugs and may exacerbate certain conditions; the provider must monitor patient progress carefully and be attuned to patient comments that might indicate the occurrence of drug-related problems.
- Providers should be prepared to educate and assist patients who develop exercise-induced injuries.
- Most exercise-induced injuries can be treated with shoe modifications, in-shoe supports, modified training methods, ice applications, and stretching exercises.

- Maintaining good foot hygiene is an important component of overall health care.
- Talking with patients about proper foot hygiene is an important aspect of caring for the patient as a whole.<sup>50</sup>
- Aluminum salts are commonly used in nonprescription products used to treat focal hyperhidrosis, which occurs in the palms, plantar surfaces, and axillae.

## Handbook of Nonprescription Drugs &gt; Chapter 44. Hair Loss

**Hair Loss: Introduction**

Significant numbers of men and women experience hair loss, with up to 50% of men and women affected at some point in their life.<sup>1</sup> Hair loss has many potential contributing factors (Table 44-1).<sup>1-9</sup> Regardless of the cause, hair loss can have a significant psychological and social impact. Individuals affected by hair loss often experience low self-esteem; personal, social, and work-related challenges; and psychiatric disorders, such as depression and anxiety.<sup>10</sup> The economic impact is also substantial, with patients spending approximately \$3.5 billion each year on products and procedures to treat hair loss.<sup>11</sup>

**TABLE 44-1 Causes of Hair Loss**

<b>General Causes</b>	<b>Specific Examples</b>
Hormonal changes	Menopause Pregnancy Post-partum Hyperandrogenic conditions (e.g., polycystic ovary syndrome)
Physiologic stress	Surgery Trauma Fever, infections Hemorrhage
Chronic illnesses	Eating disorders (e.g., anorexia, bulimia) Endocrine disorders (e.g., hypo/ hyperthyroidism, hypopituitarism, diabetes mellitus, growth hormone deficiency, hyperprolactinemia) Autoimmune diseases (e.g., rheumatoid arthritis, lupus) Hepatic or renal failure Infections (e.g., HIV, syphilis)
Medications	Beta-blockers (e.g., propranolol, metoprolol) ACE-inhibitors (e.g., enalapril, captopril) Allopurinol Anticonvulsants (e.g., phenytoin, carbamazepine, valproate) Anticoagulants (e.g., warfarin, heparin) Antidepressants (e.g., SSRIs, tricyclic antidepressants) Androgenic action (e.g., oral contraceptives, danazol, testosterone, anabolic steroids) Cholesterol-lowering drugs (e.g., clofibrate, gemfibrozil) Chemotherapeutic agents
Dietary changes or deficiencies	Rapid weight loss Strict vegetarian diet Protein restriction/deficiency Zinc, biotin, or iron deficiencies
Local trauma	Tinea capitis Hair care practices Compulsive hair pulling (trichotillomania)
Genetics	HLA genes, such as HLA-DRB1*0401 and DQB1*0301, in alopecia areata <sup>7</sup> Polymorphisms in the androgen-receptor gene in AGA <sup>8,9</sup> Chromosome 3q26 and 20p11 in AGA <sup>9</sup>

Key: ACE = Angiotensin-converting enzyme; AGA = androgenetic alopecia; HIV = human immunodeficiency virus; SSRI = selective serotonin reuptake inhibitor.

Source: References 1-9.

Hair loss is broadly categorized as nonscarring or scarring alopecia. Forms of nonscarring alopecia include androgenetic alopecia (AGA, or pattern hereditary hair loss); alopecia areata (rapid onset, patchy hair loss); anagen effluvium (rapid shedding of growing hairs); telogen effluvium (rapid shedding of resting hairs); cosmetic hair damage; and trichotillomania (a compulsive pulling out of one's hair). Types of hair loss secondary to medication use, acute or chronic illness, or dietary changes typically are also nonscarring. Table 44-2 provides information on common types of nonscarring alopecia.<sup>1,3,7,12-14</sup> Scarring alopecia may be related to conditions such as discoid lupus erythematosus, syphilis, sarcoidosis, tinea capitis, or lichen planus.

**TABLE 44-2 Characteristics of Common Types of Nonscarring Alopecia**

<b>Type of Hair Loss</b>	<b>Etiology</b>	<b>Epidemiology</b>	<b>Clinical Presentation</b>
Androgenetic alopecia/pattern hereditary hair loss	Hormonal, hereditary	Female: 40%-50% by age 70 years <sup>1,3</sup> Male: 80% by age 70 years <sup>12</sup> Affects white men more often than men of other ethnicities <sup>12</sup>	Gradual onset with progression of patterned hair loss Female: Central portion of scalp, sparing frontal hairline; wide midline part on the crown with progression to diffuse thinning over crown Male: Top rear of the head (vertex), frontal hairline, and occipital regions
Alopecia areata	Autoimmune	2% of U.S. population; affects men and women of all races equally; most cases (70%) occur in children and young adults <sup>7</sup>	Abrupt onset (may wax and wane with relapses); usually patchy but can be generalized; can occur in any hair-bearing area: axillary, pubic, and other body hair often not affected, but eyebrows and eyelashes can be lost and sometimes are only sites affected <sup>14</sup>
Anagen effluvium	Chemotherapy, radiation, heavy metal poisoning	Data not available	Abrupt loss of 80%-90% of body hair
Telogen effluvium	Metabolic or hormonal disturbances, stress; severe illness or injury; medications <sup>1</sup>	Exact prevalence unknown; can occur in either gender at any age, but not common in childhood <sup>3,13</sup>	Generalized, abrupt onset (often with trigger factor); rapid hair thinning without bare patches
Cosmetic hair damage	Hair care practices (e.g., braiding, permanents, bleaching)	Any age; associated with specific social, cultural, and cosmetic practices <sup>1</sup>	Gradual or abrupt loss on any area of the scalp depending on cause; broken hairs with blunt rather than tapered tips
Trichotillomania	Psychiatric compulsive disorder	More common in children but may persist into adulthood <sup>1</sup>	Twisted and broken-off hairs are visible in patchy areas across the scalp <sup>1</sup>
Tinea capitis <sup>a</sup>	<i>Trichophyton tonsurans</i>	Any age; common in childhood <sup>1</sup>	Any area of the scalp; usually round patch(es) of hair loss

<sup>a</sup> May also be considered scarring alopecia.

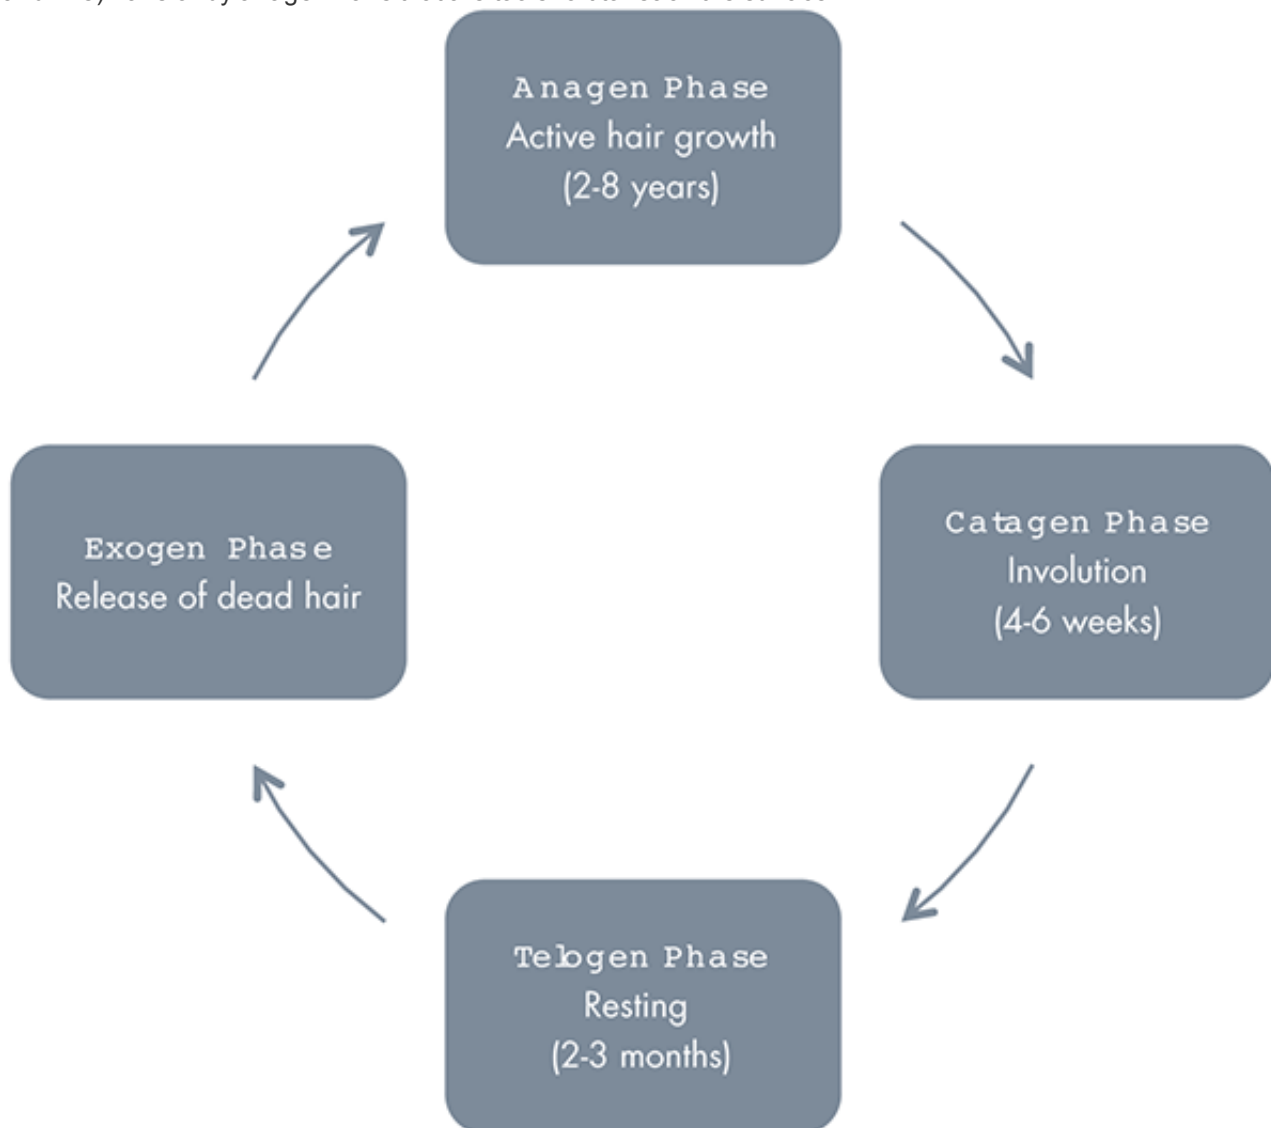

AGA is the most common form of hair loss and the only type of alopecia to be approved by the Food and Drug Administration (FDA) for nonprescription therapy. AGA is characterized by progressive, patterned hair loss from the scalp. Caucasian men are more likely than men of other ethnicities to experience baldness and more extensive hair

loss.<sup>12</sup> By age 30, about 30% of white men have AGA, with the incidence increasing to 50% by age 50 and 80% by age 70.<sup>12</sup> Although the prevalence of hair loss in women is lower, it is still significant, with approximately 40%-50% of women developing female pattern hair loss (FPHL) by age 70.<sup>1,3</sup>

### Pathophysiology of Hair Loss

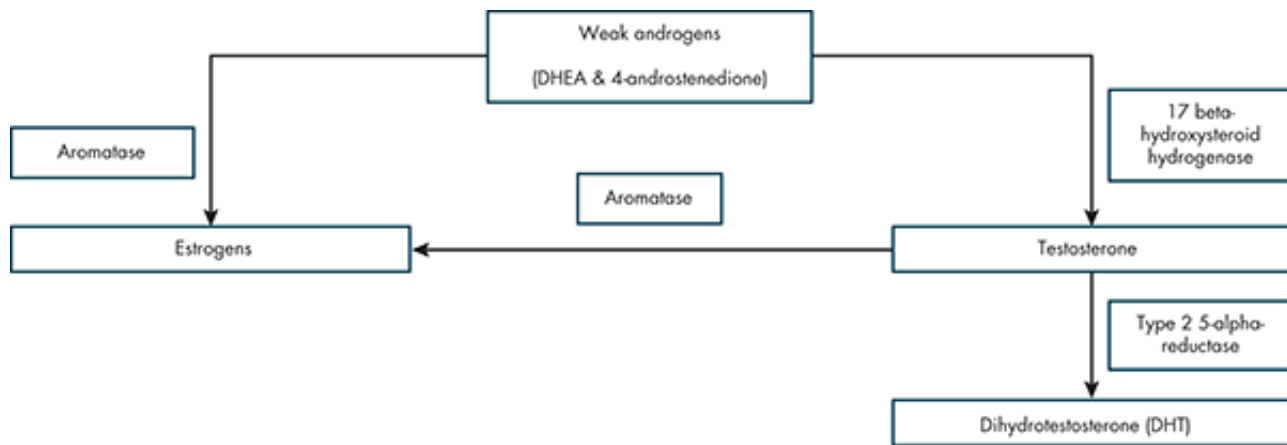

Hair follicle activity is cyclic (Figure 44-1). A variety of triggers can alter the hair follicle cycle, resulting in hair loss. In AGA, the hair follicle undergoes a stepwise miniaturization and change in growth dynamics. With each successive cycle, the anagen phase becomes shorter and the telogen phase becomes longer. Consequently over time, the anagen-to-telogen ratio decreases from 12:1 to 5:1. Because telogen hairs are more loosely anchored to follicles, their presence in increased numbers eventually manifests as increased shedding. In addition, the catagen phase lengthens, reducing the number of hairs. As telogen hairs are shed, they are gradually replaced by vellus-like (short and fine) hairs or by anagen hairs that are too short to reach the surface.

Hair follicle cycle.

Hair follicles and their sebaceous glands produce enzymes that convert weak androgens to estrogens, testosterone, and dihydrotestosterone (DHT) (Figure 44-2). These enzymes are believed to maintain androgen balance in the follicle, thereby regulating the hair cycle. Testosterone and DHT stimulate production of growth factors and proteases, affect vascularization of the follicle and the composition of basement membrane proteins, and alter the amounts of cofactors required for follicle metabolism.

All rights reserved. Any use is subject to the Terms of Use.

Androgen metabolism within the hair follicle. Key: DHEA = Dehydroepiandrosterone.

DHT is believed to be a primary repressor of hair growth. It binds five times more readily than testosterone to androgen receptors. Increased 5-alpha-reductase-mediated conversion of testosterone to DHT in the balding areas of women with AGA also supports the contention that DHT is important in this process. Women with this disease rarely lose all their hair, not only because they have less 5-alpha-reductase but also because they have more aromatase that converts testosterone into estradiol.<sup>15</sup> In addition, women are more likely to have follicles with fewer localized androgen receptors and, therefore, are more likely to retain actively growing hair.<sup>16</sup>

Chemotherapeutic agents (e.g., antimetabolic drugs) are identified as a potential cause of anagen effluvium. They cause narrowing of the hair shaft, which may fracture the hair or stop hair growth. Current nonprescription drug therapies are not FDA approved for the treatment of alopecia caused by anagen effluvium.

Hair care products and hair-grooming methods associated with scarring or burns on the scalp may result in scarring alopecia. Traction alopecia is seen primarily in individuals who braid their hair tightly every day. Braiding traumatizes the hair follicles, causing hairs to loosen and break. Patients who use oily moisturizers to make hair more manageable and to stop the scalp from flaking may develop folliculitis and hair loss. Hot combs used to straighten hair may cause scalp inflammation and result in scarring alopecia.<sup>14</sup>

Scaly dermatoses, such as psoriasis and seborrheic dermatitis, may also lead to scarring alopecia. Nonprescription agents marketed for the treatment of psoriasis and seborrheic dermatitis are not effective in treating alopecia.

[Chapter 33](#) provides additional information on the self-care of scaly dermatoses.

Untreated or improperly treated tinea capitis may lead to hair loss. This disease must be treated with systemic antifungals; hair regrowth occurs after eradication of the dermatophyte.

Psychological stress may potentiate several types of hair loss, although the literature on this subject is conflicting. Trichotillomania, a compulsive psychiatric disorder most common in children, involves an individual repetitively pulling or plucking hairs, leading to patchy hair loss.

### Clinical Presentation of Hair Loss

The scalp of a patient with AGA shows no signs of inflammation or scarring. Hair loss is gradual; in contrast to other alopecias, the number of hairs that come out during brushing or shampooing does not suddenly increase. Typically, male pattern hair loss (MPHL) is insidious in onset and usually does not start until after puberty. Progression fluctuates considerably, with 3-6 months of accelerated loss followed by 6-18 months of no loss. Most men take 15-25 years to lose their hair. The loss begins with a recession of the frontal hairline and continues with thinning at the vertex until only a fringe of hair at the occipital and temporal margins remains. The pattern and extent of MPHL are often characterized with the Norwood Scale; images are viewable at the referenced Web site.<sup>17</sup>

In women with alopecia, hair loss is typically more diffuse. FPHL manifests as gradual hair thinning over the crown and mid-frontal portion of the scalp. Several scales (e.g., Ludwig, Sinclair, and Savin) have been used to classify the extent of FPHL.<sup>4,18</sup> The Ludwig and Savin scales use similar images for degrees of hair loss; these images can be viewed at the referenced Web site.<sup>18</sup> In contrast, the Sinclair Scale uses 5 ratings for severity of hair loss.<sup>4</sup> These scales are helpful in visualizing the typical progression of hair loss in male and FPHL, but they may have limited clinical utility when making assessments and recommendations within a community setting.

FPHL is often classified as AGA; genetic components along with hormonal factors contribute to the hair loss.<sup>3,8,19</sup> Women with AGA may present with symptoms of hyperandrogenism (an excess of androgen), such as significant acne, hirsutism (hairiness in other parts of the body), menstrual irregularities, and infertility. It is conceivable that a patient with FPHL may be using a hair regrowth treatment agent on the scalp while using an antihirsute agent (e.g.,

topical eflornithine or oral spironolactone [off label]) to remove excess hair on the face. Androgen excess may indicate serious metabolic disturbances, such as cardiovascular disease, diabetes mellitus, polycystic ovarian syndrome, and endometrial cancer.<sup>19</sup> Women with multiple symptoms should be referred for medical evaluation and treatment.<sup>1,8,19</sup>

Alopecia areata has three stages: sudden loss of hair in patches, enlargement of the patches, and regrowth. The cycle may take months, sometimes years, and can occur in any hair-bearing area. Up to 5% of patients lose all their scalp hair (alopecia totalis), and 1% of patients lose all their body and scalp hair (alopecia universalis). Hair loss may accompany or be preceded by nail pitting or other nail abnormalities, itching, tingling, burning, or other painful sensations in the patch of hair loss.

Telogen effluvium (also known as diffuse alopecia) can be acute (lasting <6 months) or chronic (lasting >6 months). The precipitating factor usually precedes shedding by 1-6 months, but identifying a specific causal event is often difficult, if not impossible. This point is especially important to note with medication use because hair loss will often occur one to several months after the patient has begun a particular drug therapy. Health care providers should assess the start date of all medications as a part of the clinical workup of patients with telogen effluvium. This type of hair loss is usually reversible.<sup>1</sup>

Hair loss may be assessed by using a variety of tests (e.g., biopsy of the scalp, daily hair loss count, and hair-pull test).<sup>2,20</sup> A hair-pull test is done by holding 40-60 hairs between the thumb and forefinger and firmly (but not forcefully) pulling the hairs away from the scalp. A positive test, noted when more than 10% of the hairs come out, suggests specific types of alopecia (e.g., effluvium or alopecia areata).<sup>2,13</sup> All patients presenting with hair loss that is not considered androgenetic should be referred to a primary care provider for complete medical evaluation.

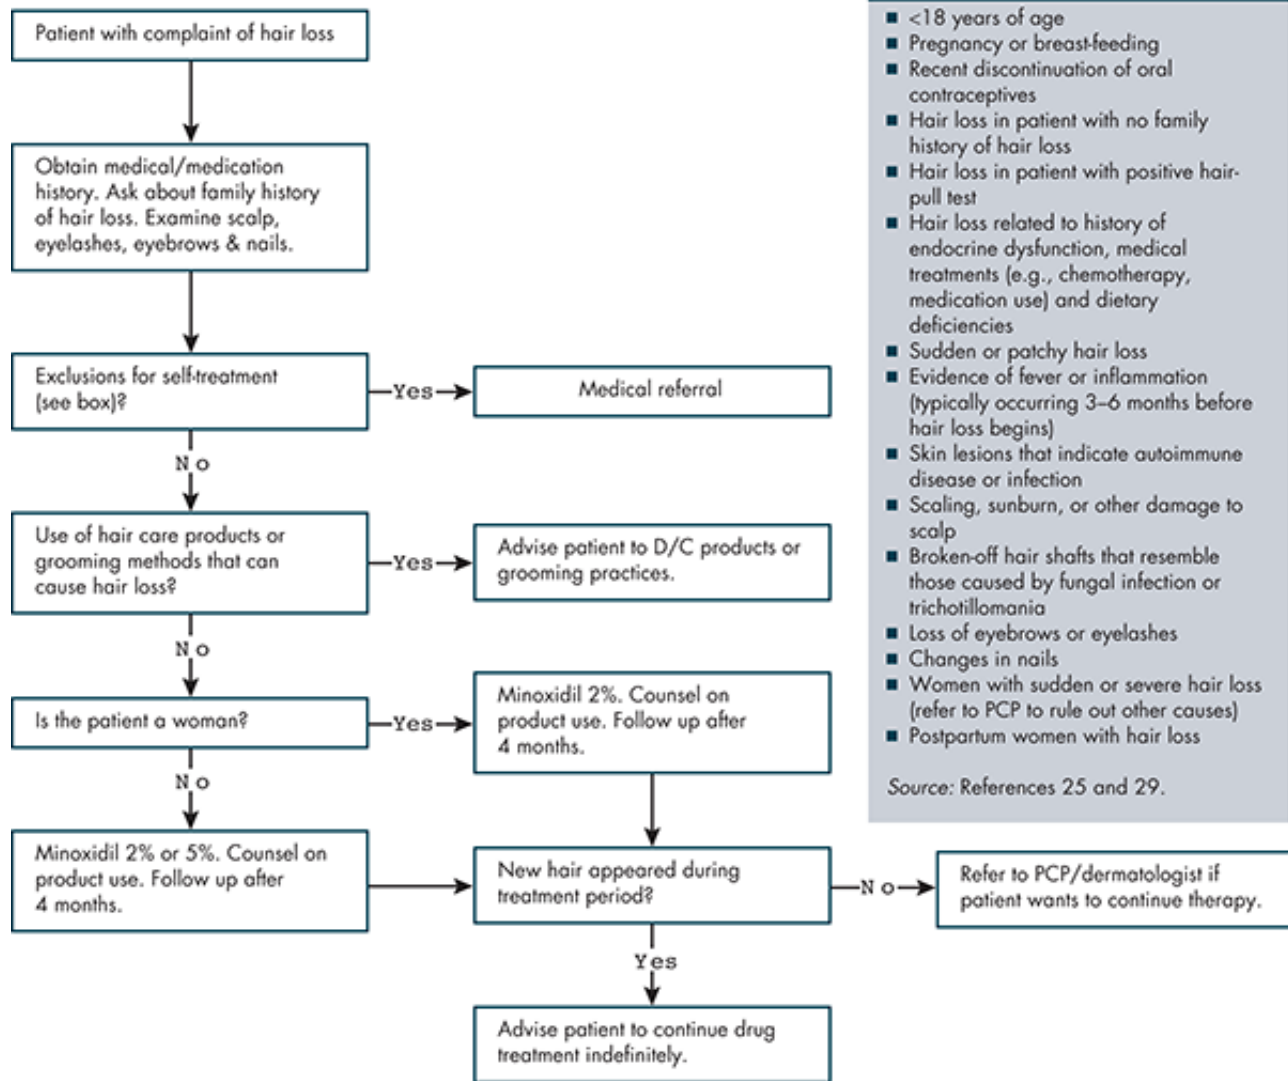

## Treatment of Hair Loss

### Treatment Goals

The goal in self-treating hair loss is to achieve an appearance the patient considers acceptable.

### General Treatment Approach

Treatment goals for hair loss can be accomplished through the following nonprescription measures: (1) nonpharmacologic therapy such as cosmetic camouflage and/or (2) the use of topical minoxidil to stimulate hair growth, if applicable. With the exception of AGA, all other types of hair loss should be referred to a health care provider to determine the cause and proper treatment. The algorithm in [Figure 44-3](#) outlines the self-treatment of hair loss and lists specific exclusions for self-treatment.

### Exclusions for Self-Treatment

- <18 years of age
- Pregnancy or breast-feeding
- Recent discontinuation of oral contraceptives
- Hair loss in patient with no family history of hair loss
- Hair loss in patient with positive hair-pull test
- Hair loss related to history of endocrine dysfunction, medical treatments (e.g., chemotherapy, medication use) and dietary deficiencies
- Sudden or patchy hair loss
- Evidence of fever or inflammation (typically occurring 3–6 months before hair loss begins)
- Skin lesions that indicate autoimmune disease or infection
- Scaling, sunburn, or other damage to scalp
- Broken-off hair shafts that resemble those caused by fungal infection or trichotillomania
- Loss of eyebrows or eyelashes
- Changes in nails
- Women with sudden or severe hair loss (refer to PCP to rule out other causes)
- Postpartum women with hair loss

Self-care of hair loss. Key: D/C = Discontinue; PCP = primary care provider.

### Nonpharmacologic Therapy

Hair loss that is dramatic and extensive can be emotionally distressing. Camouflaging thinning hair with wigs and hair weaves may help relieve the distress of hair loss. Technological advances have made production of custom wigs that match the wearer's original hair a standard practice. These advances have tremendously improved the psychological impact of hair loss. Approaches to treating less severe hair loss include hair sprays, gels, colorants, permanents, and scalp camouflaging products (e.g., topical hair fibers, powder cakes, scalp lotions, scalp sprays, and hair crayons); these products can create an illusion of fullness without decreasing hair loss.<sup>21</sup> Scalp massage, frequent shampooing, and electrical stimulation have been proposed as treatments for hair loss; however, these remedies are considered ineffective.<sup>22</sup> Although its efficacy remains unknown, low-level light therapy is a safe therapy marketed for hair growth.<sup>23</sup>

Both acute and chronic telogen effluvium should be referred to a health care provider for further evaluation. Acute telogen effluvium usually resolves spontaneously, and treatment is limited to comforting and reassuring the patient. Chronic telogen effluvium is slower to resolve, but the patient will still need comfort and reassurance. If a patient's hair loss is caused by poor diet or iron deficiency, the patient may benefit from consulting a dietitian. In deficiency states, increasing protein intake or taking iron supplements may be simple solutions to reversing hair loss. Surgical transplantation of terminal hair follicles from another anatomic site is an alternative nonpharmacologic approach to hair loss. This method may be useful in frontal and vertex hair loss.

### Pharmacologic Therapy

#### Minoxidil

Minoxidil, the only FDA-approved self-treatment option for AGA, is available as a 2% and 5% hydroalcoholic solution and a 5% solvent-free foam. Minoxidil can be applied by various methods (Table 44-3), depending on the applicator (spray, dropper, and rub-on assembly).<sup>24</sup> Treatment is indicated for baldness at the crown of the head in men and for hair thinning at the frontoparietal area in women.<sup>25</sup> The 2% and 5% products are approved for use in both men and women. When used orally to control hypertension, minoxidil is a potassium channel opener and vasodilator. When used topically for hair loss, the drug appears to act by increasing cutaneous blood flow directly to hair follicles, which increase in size after treatment.<sup>26</sup> Minoxidil also promotes and maintains vascularization of hair follicles in alopecia.<sup>26,27</sup> Minoxidil, which has been shown to directly stimulate follicular hypertrophy and prolong the anagen phase,<sup>26</sup> may transform resting (telogen phase) hair follicles into active (anagen phase) hair follicles.<sup>24</sup> After up to 12 months of therapy, a subset of these same patients also revealed a reduction in the percentage of telogen hairs.

**TABLE 44-3 Administration Guidelines for Nonprescription Minoxidil**

Minoxidil Solution
<ul style="list-style-type: none"> <li>• Apply minoxidil to clean, dry scalp and hair.</li> <li>• Rub about 1 mL of the product into the affected area of the scalp twice daily (morning and night). Some products have a measuring cap with a 1 mL fill line. Do not apply more often than twice daily.</li> <li>• Wash and dry hands after applying the medication. If it gets into the eyes, mouth, or nose, rinse these areas thoroughly.</li> <li>• Do not double the dose if you miss an application.</li> <li>• Allow 2-4 hours for the drug to penetrate the scalp. Do not participate in any activity that might wash away or dilute the drug (e.g., bathing or swimming without a cap) for 2-4 hours after application.</li> <li>• At night, apply the drug 2-4 hours before bedtime; if minoxidil is not fully dry, it can stain clothing and bed linen.</li> <li>• Do not dry the scalp with a hair dryer after applying the drug. This action will reduce the drug's effectiveness.</li> <li>• If applicable, apply hair grooming and styling products (e.g., sprays, mousses, or gels) or coloring agents, permanents, or relaxing agents after the minoxidil has dried. These products usually do not affect the efficacy of topical minoxidil.</li> </ul>
Minoxidil Foam
<ul style="list-style-type: none"> <li>• The foam may melt on contact with warm skin. Therefore, wash hands in cold water before applying. Dry hands thoroughly before applying foam.</li> <li>• Within the thinning hair area, part the hair into one or more rows to maximize contact of the foam with the scalp. The hair should be completely dry before application.</li> <li>• Holding the can upside down, apply one-half of a capful of the foam to the fingertips. The 5% product for men should be applied twice daily, in the morning and at night. The 5% product for women should be applied once daily.</li> <li>• Using the fingertips, spread the foam over the thinning scalp area, and then massage gently into the scalp. Wash hands thoroughly after application.</li> <li>• Allow the product to dry completely before lying down or applying grooming, styling, or coloring products.</li> </ul>

Source: References 25 and 29.

For men undergoing hair transplantation whose hair follicles may be viable but not functioning optimally in the area to be transplanted, topical minoxidil can increase hair density, speed regrowth in transplanted follicles, and complement the surgical outcome by minimizing the likelihood of progression of hair loss.<sup>28</sup>

After initiation of minoxidil treatment, an increase in hair loss may occur within the first few weeks of product usage.<sup>29</sup> Several months may elapse before hair growth is apparent. If increased hair density fails to appear after 4 months of using minoxidil, the patient should consider ending treatment and discussing other options with a health care provider. For many patients, increased hair density is minimal and treatment response is difficult to assess. Once the drug is discontinued, hair density returns to pretreatment levels in a matter of months; therefore, the patient must continue to use the product indefinitely to maintain new growth.<sup>25</sup>

Several studies have evaluated the effectiveness and safety of minoxidil 2% and 5% preparations. In a 48-week study, men using 5% minoxidil had an earlier response and greater hair regrowth (45% more hair regrowth) than did men using 2% minoxidil.<sup>30</sup> Increased frequency in itching and local irritation was also noted in the 5% minoxidil treatment group compared with the 2% minoxidil group.<sup>30</sup> A randomized, double-blind, placebo-controlled trial compared the efficacy and safety of 5% topical minoxidil with 2% topical minoxidil and placebo in the treatment of FPHL.<sup>31</sup> Both 5% and 2% minoxidil were superior to placebo, and the 5% topical minoxidil group showed statistically significant benefits over the 2% topical minoxidil group.<sup>31</sup> The incidence of itching, local irritation, and hypertrichosis

in the group receiving 5% minoxidil was greater than that of the 2% minoxidil and placebo groups; however, both concentrations were considered well tolerated with no evidence of systemic side effects.<sup>31</sup> In a randomized, single-blind trial studying 113 women with androgenetic alopecia, once-daily 5% minoxidil foam was found to be as effective as twice-daily 2% minoxidil solution; the 5% concentration was also associated with several aesthetic and practical advantages.<sup>32</sup>

Primary care providers may consider treating male patients who have failed nonprescription minoxidil with finasteride 1 mg tablets daily. Finasteride is the only currently FDA-approved prescription product for treatment of alopecia in male patients. Finasteride has been studied in female patients; however, the results have shown the drug to be no better than placebo in women.<sup>23</sup> Topical minoxidil solution 2% has also been investigated in combination with oral finasteride 1 mg in male patients. The outcomes of this study indicate a higher percentage of responders with the combination treatment than with either agent alone. It is inferred that efficacy may be enhanced by the two-drug regimen, which acts on multiple AGA etiologies.<sup>33</sup>

The most common side effect associated with minoxidil—local itching, irritation, and dryness or scaling at the site of application—may be related to the hydroalcoholic/propylene glycol vehicle. A 5% minoxidil topical formulation in a propylene glycol-free foam vehicle is available to reduce the risk of local side effects.

The most common side effect of long-term use is transient hypertrichosis (excessive hair growth), usually on the forehead and cheeks. Occasionally, patients may notice hypertrichosis on the chest, back, forearms, and ear rims, which could indicate that the product has been applied excessively.<sup>34</sup> Rare side effects include acne at the site of application, increased hair loss, inflammation (soreness) of the hair roots, reddened skin, swelling of the face, and allergic dermatitis.<sup>25,29</sup> No differences in side effects or other problems were demonstrated in a limited number of older patients (≤65 years of age).

Minoxidil is absorbed through the skin in relatively low concentrations; documented systemic side effects are rare. In the unlikely event of an accidental ingestion, the patient should seek emergency medical attention. Symptoms may include the following<sup>29</sup>:

- Low blood pressure (dizziness, confusion, fainting, and lightheadedness)
- Blurred vision or other changes in vision
- Headache or chest pain
- Irregular heart rate
- Swollen hands or feet
- Flushing of the skin
- Numbness or tingling of the face, hands, or feet

Although minoxidil-induced hemodynamic changes have not been detected in most controlled clinical studies, patients with cardiovascular disorders may have an increased risk of cardiotoxicity.<sup>35</sup>

The use of topical minoxidil is not associated with any known drug interactions. However, the concurrent use of guanethidine could potentiate orthostatic hypotension, and the concurrent use of oral minoxidil could increase its systemic levels and enhance its effects. Topical application of corticosteroids, petrolatum, or retinoids (e.g., Retin-A) to the scalp in combination with minoxidil may increase absorption of minoxidil and the risk of side effects. In addition, minoxidil should not be used for 24 hours before or after application of a permanent, hair color, or hair relaxant.<sup>25,29</sup>

Patients who are allergic to minoxidil or to any component of the preparation should avoid this medication, as should patients with scalp damage from psoriasis, severe sunburn, or abrasions, which may increase minoxidil absorption. Topical minoxidil has a Pregnancy Category C rating; its effect on nursing babies is not known. Therefore, pregnant and lactating women should be advised to consult a primary care provider before using minoxidil.

The solution formulation is alcohol based and will burn or irritate eyes, mucous membranes, and abraded skin. When spraying either formulation of the product, the patient should avoid inhalation. If the product gets into the eyes, mouth, or nose, the patient should thoroughly rinse these areas. Patients should wash and dry their hands after using the product. These precautions are also intended to prevent the systemic entry of minoxidil by alternative routes.

Products containing minoxidil should not be used on any other part of the body.<sup>29</sup>

Researchers have found little evidence of a potential effect of minoxidil on systemic endocrine functions.<sup>36</sup>

Measurement of plasma testosterone and excretion of urinary hydroxysteroids and ketosteroids in hypertensive patients who had been treated with oral minoxidil did not reveal any effects. Moreover, although serum cortisol, testosterone, and thyroid indexes are apparently unchanged by topical minoxidil, modification of follicular testosterone metabolism does occur.<sup>37</sup>

Safety and efficacy of the product in children younger than 18 years have not been established, so the use of minoxidil in this population is contraindicated.

### Product Selection Guidelines

Either the 2% or 5% formulations can be recommended for use by women; however, men are usually advised to use

the 5% concentration. One study demonstrated a lower incidence of contact dermatitis with foam products, which do not contain propylene glycol, than with topical solutions.<sup>3,23</sup> Accordingly, the foam formulation *may* be more desirable in patients with a history of sensitive skin or dermatitis. Patient preference for method of application is a critical factor in product selection. Patients with impaired vision or physical dexterity may find the rub-on method of application preferable to using sprays or droppers. Table 44-4 lists examples of commercially available products.

**TABLE 44-4 Selected Nonprescription Hair Regrowth Products**

<i>Trade Name</i>	<i>Primary Ingredient</i>
Minoxidil Topical Solution (various manufacturers)	Minoxidil 2%
Minoxidil Topical Solution 5% for Men (various manufacturers)	Minoxidil 5%
Rogaine Extra Strength Topical Solution for Men (Johnson & Johnson Healthcare)	Minoxidil 5%
Rogaine Men's Topical Solution (Johnson & Johnson Healthcare)	Minoxidil 2%
Rogaine Men's Topical Foam (Johnson & Johnson Healthcare)	Minoxidil 5%
Rogaine Women's Topical Solution (Johnson & Johnson Healthcare)	Minoxidil 2%

Source: Reference 25.

### Complementary Therapies

In the past, FDA advisory panels have proposed removing from the market a number of ingredients that were known to be safe for external use but lacked scientific data to support their purported efficacy in preventing hair loss or promoting hair growth.<sup>38</sup> The false claims generally are no longer made, but many of these ingredients are still available today in nonprescription lotions and shampoos. In addition, oral and topical dietary supplements marketed to improve the structure and function of hair growth have become more popular. Ingredients included in shampoos, topical solutions, and dietary supplements for hair loss include amino acids, aminobenzoic acid, B vitamins, jojoba oil, lanolin, maidenhair fern (*Adiantum capillis-verneris*), polysorbates 20 and 660, royal jelly (white secretion of *Apis melliferis* worker bees), tetracaine hydrochloride, urea, and wheat germ oil.<sup>14,22,37,39</sup> Saw palmetto demonstrated increased hair growth in 6 of 10 men with AGA in one randomized, double-blind, placebo-controlled study.<sup>23</sup>

### Assessment of Hair Loss: A Case-Based Approach

Before treatment for hair loss, the provider should first identify any possible underlying medical cause. To assess alopecia areata or telogen effluvium, the provider can direct the patient to perform a gentle hair-pull test. The patient should be referred to a dermatologist if a pull-test is positive. However, the test may be falsely negative if the patient's hair has been recently combed, brushed, or shampooed.<sup>6</sup> If pathology-induced and active hair loss is ruled out, the provider should determine whether the balding fits the criteria for AGA.

Cases 44-1 and 44-2 illustrate the assessment of patients with hair loss.

#### Case 44-1

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b><i>Information Gathering</i></b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient has had gradual hair loss at the temples and a recently a little thinning at the vertex; no signs of inflammation or scarring on scalp.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	None

c. description of the patient's efforts to relieve the symptoms	Has changed shampoos several times with no noticeable change/improvement in hair loss
d. patient's identity	Michael Jones
e. age, sex, height, and weight	42 years old, male, 5 ft 10 in., 170 lb
f. patient's occupation	Accountant
g. patient's dietary habits	Skips breakfast, eats out for lunch during the week; eats with family in the evening.
h. patient's sleep habits	Sleeps ~6 hours nightly.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Patient in good health; takes no prescribed medications; has taken 2 fish oil capsules daily for several years to "improve cholesterol."
j. allergies	Penicillin (skin rash)
k. history of other adverse reactions to medications	None
l. other (describe) _____	Father and maternal uncles suffer from male pattern baldness. Michael prefers to use a topical treatment because he is concerned about the side effects of systemic therapy.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	The patient has androgenetic alopecia, as evidenced by gradual hair loss at temple and vertex. He has no signs of inflammation or scarring on scalp. Eyebrows and eyelashes are normal.
3. Identify exclusions for self-treatment (Figure 44-3).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Recommend self-care using OTC minoxidil topical treatment and/or camouflage measures. (2) Refer Michael to a PCP for treatment. (3) Recommend self-care until a PCP can be consulted. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Topical minoxidil 2% or 5% solution or foam
6. Describe the recommended therapeutic approach to	"Apply approximately 1 milliliter of minoxidil 5% topical

the patient or caregiver.	foam twice daily to a clean, dry scalp.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“The most effective nonsystemic therapy is topical minoxidil 5%. A solution or foam is available. The foam formulation may cause less irritation.”
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	See <a href="#">Table 44-3</a> .
b. maximum number of days the therapy should be employed	See the box Patient Education for Hair Loss.
c. product administration procedures	See <a href="#">Table 44-3</a> .
d. expected time to onset of relief	See the box Patient Education for Hair Loss.
e. degree of relief that can be reasonably expected	“Progressive hair loss will be slowed.”
f. most common side effects	See the box Patient Education for Hair Loss.
g. side effects that warrant medical intervention should they occur	See the box Patient Education for Hair Loss.
h. patient options in the event that condition worsens or persists	See the box Patient Education for Hair Loss.
i. product storage requirements	See the box Patient Education for Hair Loss.
j. specific nondrug measures	“Minimize exposure to agents that may trigger hair loss.”
Solicit follow-up questions from the patient or caregiver.	“How can I tell if I am responding to the treatment?”
Answer the patient’s or caregiver’s questions.	“Hair density will increase if the treated area involves early thinning. Look for fine, short hairs as a first response.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	You can ask the patient to call you right away with significant concerns of side effects (skin irritation, redness) and to monitor and report any hair regrowth in 1-4 months.

Key: OTC = Over-the-counter; PCP = primary care provider.

**Case 44-2**

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient has noticed a sudden increase in hair loss in the shower and in her hair brush, resulting in noticeable thinning over the past few weeks. No signs of inflammation or scarring on scalp are present. No bare patches are noted but hair pull-test is positive.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	None
c. description of the patient's efforts to relieve the symptoms	Patient has not tried anything for the hair loss.
d. patient's identity	Katherine James
e. age, sex, height, and weight	41 years old, female, 5 ft 4 in., 165 lb
f. patient's occupation	High school science teacher
g. patient's dietary habits	Started Weight Watchers to improve health and lose weight.
h. patient's sleep habits	Sleeps ~7-8 hours a night.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	DVT 3 months ago after a significant car accident: warfarin 8 mg daily x> 3 months
j. allergies	None
k. history of other adverse reactions to medications	None
l. other (describe) _____	"It seems like everything has been falling apart since my car accident 3 months ago. There is no history of hair loss among family members."
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	The patient likely has telogen effluvium, as evidenced by the positive hair-pull test and rather sudden onset of hair loss. She has no signs of inflammation or scarring on the scalp. Eyebrows and eyelashes are normal, with no bare patches noted. Several possible causes include medications and possible stress/injury associated with the car accident.

3. Identify exclusions for self-treatment (Figure 44-3).	Hair loss with positive hair-pull test, hair loss related to medications
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Katherine to a PCP for evaluation and treatment. (2) Recommend self-care until a PCP can be consulted. (3) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Refer Katherine to PCP for evaluation and treatment.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Minimize or eliminate exposure to triggers for hair loss. For example, reduce stress and discontinue warfarin when the recommended duration of treatment is fulfilled."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	If possible causes of hair loss can be identified and eliminated or minimized, hair loss will stop or lessen and hair will regrow.
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	See the box Patient Education for Hair Loss for specific nondrug measures.
Solicit follow-up questions from the patient or caregiver.	"Will my hair grow back if my medications are adjusted?"
Answer the patient's or caregiver's questions.	"You will also need to minimize new triggers for hair loss. Hair density will gradually increase as the causes of your hair loss are removed. Look for fine, short hairs as a first response."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Ask the patient to report to you the outcome of the PCP evaluation and recommendations.

Key: DVT = Deep venous thrombosis; PCP = primary care provider.

### Patient Counseling for Hair Loss

Patients should be advised that most treatment regimens for hair loss do not alter its progression, especially if the hair loss has gone on for a prolonged period of time. Patients who want to use nonprescription minoxidil should be informed that the longer the hair thinning or loss has continued, the less likely it is that treatment will elicit a regrowth response. If the patient still wants to use minoxidil, the provider should review product instructions with the patient,

making sure that the patient understands the possible adverse effects and the signs and symptoms that indicate the need for medical attention. In addition, the patient should be counseled that if hair regrowth is achieved, long-term continuation of minoxidil will be necessary to maintain the regrowth. If the patient is concerned about long-term continuation of treatment regimens to maintain the effect or is not achieving desired endpoints with minoxidil, cosmetic products, camouflaging options, and hair transplants/surgical interventions may be acceptable alternatives. The box Patient Education for Hair Loss lists specific information to provide patients.

#### Patient Education for Hair Loss

The goal in self-treating hair loss is to achieve an appearance the patient considers acceptable. This objective can be accomplished through nonprescription means by recommending (1) cosmetic camouflage and/or (2) the use of topical minoxidil to stimulate hair growth, when appropriate. To ensure optimal therapeutic outcomes, it is essential that patients carefully follow product packaging information and consider the following measures.

#### **Nondrug Measures**

- If desired, use wigs to cover severe hair loss until hair is regrown.
- For less severe hair loss, use hair sprays, gels, colorants, permanents, or hair-building products in moderation to create the illusion of full hair. These cosmetics will not affect the rate of hair loss.
- Avoid the use of oily hair products that can cause folliculitis.
- Avoid hairstyles that pull on the hair, such as tight braids.
- Avoid heat from hair dryers and curling/flat irons because their use can make the hair more brittle.

#### **Nonprescription Medications**

- Note that use of minoxidil must be continuous and indefinite to maintain regrowth. It may take up to 4 months to see any results. If treatment is interrupted, regrowth will typically be lost within 4 months or less, and progression of hair loss will begin again.
- Minoxidil is not recommended in patients who are pregnant, breast-feeding, or planning to become pregnant while using this product. Consult a primary care provider before you use this product.
- See [Table 44-3](#) for instructions on how to use this product.
- Do not apply the product more often than directed. More frequent applications will not achieve better regrowth or a faster response but may increase side effects.
- Do not apply the product to damaged or inflamed areas of the scalp, including areas with active scalp psoriasis or eczema lesions and open scalp wounds of any kind.
- Note that local itching or irritation at the site of application may occur. More rarely, allergic contact dermatitis or transient hypertrichosis (unwanted facial hair growth) may occur.
- Keep product container in a cool, dry place, but do not put it in the refrigerator.
- Keep the product out of children's reach. Ingestion of minoxidil is potentially hazardous, and a poison control center should be contacted immediately.
- The solution is flammable. Keep away from fire or flame.
- Do not use on infants or children ages 18 years or younger.
- Do not use if you have heart disease except under the supervision of a primary care provider.
- If hair fails to appear within the time specified on the product (generally 4-6 months) despite consistent use of the product, consider stopping the treatment and seeing your primary care provider for further evaluation.

#### **Evaluation of Patient Outcomes for Hair Loss**

Patients should use minoxidil for the minimum recommended period. If new hair growth does not occur after using minoxidil 2% or 5% for 4 months, the patient should consider ending treatment. If new hair does appear within the recommended period, the patient should be advised to continue the drug treatment indefinitely.

#### **Key Points for Hair Loss**

- Minoxidil is not effective for everyone.
- Positive treatment results may take several weeks to be noticed. Hair loss will recur if therapy is stopped.
- Adherence is critically important for pharmacologic treatment.
- Offering cosmetic solutions may also be helpful.
- Patients, particularly women, are seeking treatment not only for hair loss but also for lost self-esteem resulting from the association of hair loss with illness and advanced age.
- Providers should dispense medication with a dose of emotional support and should describe the limitations of the existing treatment.

**Handbook of Nonprescription Drugs > Chapter 45. Self-Care Components of Selected Chronic Disorders****Self-Care Components of Selected Chronic Disorders: Introduction**

Chronic diseases affect approximately one in two adult Americans (133 million) and account for 7 of 10 deaths in the United States each year.<sup>1</sup> These diseases put a significant burden on the U.S. health care system, including both direct and indirect costs. Chronic diseases most often have a gradual onset, have no cure, change over time, and require significant interventions, including pharmacologic and nonpharmacologic management.

Self-care management of chronic disease requires an educated and involved patient.<sup>2</sup> Although active engagement is vital, it can be difficult, considering the physical, emotional, and psychological toll chronic diseases may impart. Other comorbid conditions, persistent symptoms, daily medication use, poor communication among patients and health care providers, subpar family support, financial stressors, and the need to interpret and treat symptoms may contribute to less than ideal patient involvement in self-care activities. Therefore, cooperative identification and management of these barriers by providers and patients are essential to achieve the common goal of optimal condition management.

Modifiable risk factors such as tobacco use, lack of exercise, poor nutrition, and excessive alcohol use may contribute to worsening or causing chronic diseases. Therefore, behavioral changes such as tobacco cessation, moderation of alcohol use, improvement in nutrition, and participation in more physical activity may prevent and lessen the suffering associated with chronic diseases. Determining the patient's readiness to change a behavior, providing proper education on the benefits to making lifestyle changes, and setting realistic goals may help improve the success of a plan to eliminate some or all of the modifiable risk factors.

The day-to-day monitoring and adjustments by the patient are central to achieve optimal outcomes. This model of self-care engagement requires the patient to think outside the traditional role of depending only on the provider to achieve optimal care. For this shift to happen, providers must empower patients to actively engage in self-care. Patients who voice their goals of therapy and regularly participate in their care may better adhere to their regimen, thereby increasing the likelihood of achieving set goals. Providers can assist patients by cultivating a relationship that will allow them to assess the patient's capability for self-care, identify gaps in the patient's knowledge, teach patients proper self-care strategies, and monitor self-care measures.

This chapter explores commonly encountered chronic medical conditions that involve extensive self-care, including diabetes mellitus, asthma, osteoporosis, heart failure, hypertension, and dyslipidemia.

**Diabetes Mellitus**

As defined by the American Diabetes Association (ADA), diabetes mellitus is a group of metabolic diseases characterized by hyperglycemia resulting from defects in insulin secretion, insulin action, or both.<sup>3</sup> Although several types of diabetes are recognized, types 1 (5%-10% of patients) and 2 (90%-95% of patients) account for the majority of cases.

More than 25.8 million people in the United States, or 8.3% of the population, have diabetes.<sup>4</sup> Of these, 7 million individuals are undiagnosed cases. Another 79 million Americans older than 20 years are estimated to have prediabetes. In 2007, the total annual combined direct and indirect costs attributed to diabetes were estimated to be \$174 billion.<sup>4</sup> Because most health care expenditures are related to treatment of long-term diabetes complications, focus should be on prevention, early diagnosis, and aggressive metabolic control.

**Pathophysiology of Diabetes Mellitus**

Working in conjunction with counterregulatory hormones (e.g., glucagon, epinephrine, norepinephrine, growth hormone, and cortisol), endogenous insulin maintains normal blood glucose (BG) concentrations between 60 and 100 mg/dL. A defect in insulin action or secretion, or a combination of the two, results in hyperglycemia categorized as type 1, type 2, or prediabetes. Type 1 diabetes is often caused by autoimmune-mediated pancreatic beta-cell destruction that leads to absolute insulin deficiency. Type 2 diabetes is caused by insulin resistance, impaired insulin secretion, and increased hepatic glucose production. Prediabetes precedes type 2 diabetes and is diagnosed by an impaired fasting glucose level, oral glucose tolerance test, or A1C (glycosylated hemoglobin) test that is elevated but not to the extent of that of a patient with type 2 diabetes.

**Clinical Presentation of Diabetes Mellitus**

Type 1 diabetes is typically characterized by individuals who present with a younger age of onset (usually <30 years), are thin in physique, and may or may not have a family history of diabetes. In contrast, type 2 diabetes is characterized by individuals who present with an older age of onset (usually >40 years), are overweight, obese, or both, and have a family history of diabetes.

For individuals with new-onset diabetes mellitus, as plasma glucose concentrations rise to exceed the normal renal threshold of 180 mg/dL, glycosuria produces an osmotic diuresis and potential dehydration resulting in polyuria (frequent urination), especially at night (nocturia). Dehydration can progress to significant hypovolemia (decrease in volume of circulating blood), electrolyte loss, and cellular dehydration, causing dry mouth and polydipsia (increased thirst). A lack of insulin production or presence of insulin resistance prevents cells from using circulating plasma glucose, and the nervous system signals polyphagia (hunger accompanied by increased appetite). The onset of clinical symptoms is usually more rapid and pronounced for patients with type 1 diabetes and often follows a stressful event. For patients with type 2 diabetes, symptoms of long-term diabetes complications may appear before elevated plasma glucose is detected. Chronic hyperglycemia is associated with the development and progression of complications affecting major organs and physiologic systems. Complications of diabetes are categorized as microvascular and macrovascular. Achieving reductions in A1C, a marker for longer-term glycemic control, lowers the overall risk of developing microvascular complications.

Microvascular complications affect the eyes (retinopathy), nervous system (neuropathy), and kidneys (nephropathy). Among adults ages 20-74 years in the United States, diabetes is the leading cause of new-onset blindness.<sup>4</sup> More than 60% of patients with diabetes have mild-moderate damage to their nervous system. Severe peripheral neuropathy is a main contributor to lower-extremity amputations.

Although peripheral neuropathy is one example, patients can experience other disorders (e.g., gastroparesis and erectile dysfunction) as a result of nerve damage. Finally, diabetes is the leading cause of kidney failure in the United States.<sup>4</sup>

Macrovascular complications include atherosclerosis, contributing to peripheral vascular disease (PVD), cardiovascular disease (CVD), and stroke. Heart disease is the leading cause of diabetes-related deaths,<sup>4</sup> and compared with people without diabetes, those with diabetes have two to four times the risk of heart attack and stroke.

In addition to micro- and macrovascular complications, patients with diabetes may have abnormalities in immune function that increase their rates of morbidity and mortality from infection.

Poorly controlled diabetes is a risk factor for the development of oral and dental complications, including gingivitis, periodontitis, dental caries, oral mucosal diseases, oral infections, salivary dysfunction, and taste disturbances. Maintaining glucose control and good dental hygiene, having regular checkups with a dentist, and smoking cessation can decrease the risk of developing oral and dental complications.

### Treatment of Diabetes Mellitus

Patients can reduce their risk of developing or decrease the progression of diabetes complications by instituting self-care and other preventive measures. Providers should educate patients about the role of self-care and other preventive measures and encourage their use (Table 45-1). The provider should review life style modifications with the patient and stress their importance in controlling the disorder. However, medical referral for further evaluation is needed if the assessment process reveals any of the following:

- No formal diagnosis of diabetes
- Uncontrolled diabetes (signified by symptoms or blood glucose readings that identify hypo- or hyperglycemia)
- Concurrent condition (e.g., acute illness) or medication (e.g., steroids) that may be affecting the patient's blood glucose and that has not been evaluated by the provider
- No visit (or missed visit) to a primary care provider in the last year
- History of hypo- or hyperglycemia severe enough to warrant medical attention
- Nonadherence to any provider-recommended prescription medications, nonprescription medications, or self-care measures
- Pregnancy
- Perception that prescription medications are ineffective
- Unknown status of other comorbid conditions (e.g., dyslipidemia)
- Use of dietary supplements without provider's knowledge or without achieving set goals

In addition to self-care measures, patients with diabetes should receive medical care from an interprofessional team with expertise in diabetes.<sup>3</sup> Effective diabetes management is patient centered, taking into account factors such as the patient's health beliefs, attitudes, preferences, practices, health literacy, daily routines, and socioeconomic situation that may affect his or her self-care abilities.

Collaborative diabetes management therefore includes patients, their families, and caregivers as central members of the team.

Because heart disease is the leading cause of diabetes-related deaths, proper management and prevention of disease-related risk factors such as hypertension and dyslipidemia are essential. Patients with hypertension and/or dyslipidemia in conjunction with diabetes are treated to more stringent goals than those without diabetes.

### Treatment Goals

Glycemic control is the cornerstone of diabetes management. It includes preventing hypoglycemic and hyperglycemic occurrences. Treatment goals should be individualized, taking into account patient-specific factors, such as age (e.g., children, adolescents, and the elderly), pregnancy status, and comorbid conditions. Table 45-2 summarizes the ADA recommendations for nonpregnant adults with diabetes. The diabetes guidelines issued by the American Association of Clinical Endocrinologists have stricter goals than the ADA guidelines.

### General Treatment Approach

A diabetes care plan should include the following eight steps:

1. Assessment of the patient's knowledge (e.g., of disease state and goals of therapy), current care regimen, comorbid conditions, and any factors (e.g., cultural, health literacy, and socioeconomic) that may affect the patient's care.
2. Meal planning and healthy eating instructions.
3. Physical activity recommendations.
4. Self-monitoring of BG and, when appropriate, ketone concentrations.
5. Safe and effective use of medication therapy.
6. Patient self-management education.
7. Assessment of adherence to self-monitoring of blood glucose (SMBG), medical nutrition therapy (MNT), and other nonpharmacologic and pharmacologic therapy.
8. Follow-up care to alter or adjust the plan as needed to achieve metabolic goals, which could be accomplished by sending written or verbal documentation directly to the provider or instructing the patient to talk with the provider and review the diabetes care plan during follow-up visits. Depending on the patient comfort level and relationship with the provider, the latter option may allow the patient to be empowered and active in his or her treatment regimen.

**TABLE 45-1 Self-Care and Other Preventive Measures for Diabetes Complications**

<i>Self-Monitoring of Blood Glucose</i>
• Determine patient's frequency of BG testing (e.g., fasting, preprandial, postprandial, or bedtime) and target BG goals.
• Discuss signs and symptoms of low BG episodes, and have patient test when symptoms arise and record the date, time, and BG value for evaluation.

- Educate patient on proper management of hypoglycemic episodes.

### Medical Nutrition Therapy

- Tailor nutrition and physical activity to individual patient characteristics, such as timing of meals, glycemic control, and comorbid conditions.
- Educate patient on ways to maintain a healthy weight.
- Refer patient to a dietitian if necessary.

### Tobacco Use

- Assess the patient's willingness to quit.
- Recommend tobacco cessation (see [Chapter 47](#)).

### Eye Care

- Recommend an annual eye examination after an initial dilated and comprehensive eye exam. Less frequent examinations (e.g., every 2-3 years) may be an option after having one or more normal examinations.
- Review any topical eye preparations for potential contraindication.
- Recommend medical attention if vision changes or eye irritation occurs.

### Dental Care

- Recommend professional teeth cleaning and oral health evaluation by a dentist twice each year.
- Recommend that teeth be brushed and flossed twice daily.
- Recommend a dental consult at the first sign of any gum abnormalities (e.g., bleeding).
- Have patient review dental care products with a dentist before use.

### Skin Care

- Recommend daily bathing with mild soap and drying skin thoroughly.
- Recommend that skin be inspected daily—head to toe—for signs of potential infection.
- Instruct patient to cleanse minor cuts and scratches promptly with soap and water.
- Instruct patient to avoid topical drying agents (e.g., alcohol, except for use when sterilizing for insulin injection) or salicylic acid-containing products.

### Foot Care

- Perform annual foot examination.
- Have patient remove shoes at each visit with the primary care provider for visual inspection.
- Evaluate for any changes in foot appearance or tactile sensation.
- Advise patients identified at high risk of ulcers (e.g., neuropathy) to see a podiatrist regularly.
- Teach patient to clean and inspect feet daily for any changes (e.g., corn, callus, open wound, or fungal infection).
- Instruct patient that nails should be trimmed carefully, preferably straight across, and filed with an emery board to the contour of the toe.
- Instruct patient to avoid walking barefoot.
- Recommend use of soft cotton, synthetic blend, or wool socks to absorb moisture.
- Recommend that patient wear properly fitting, comfortable shoes and use caution when “breaking in” new shoes.
- Recommend that patient inspect shoes for foreign objects before inserting feet.
- Recommend that patient (1) use moisturizing lotion sparingly for the tops and bottoms of dry feet, (2) allow feet to completely dry before wearing shoes to prevent excess moisture, and (3) avoid use of moisturizers between the toes.

### Medication Adherence: Information for Patients

- Discuss each medication's indication.
- Advise patient to take medications as prescribed. Patient should not discontinue medications without consulting provider.
- If indicated, advise patient to take low-dose aspirin daily to prevent heart attack and stroke.

- Advise patient to avoid taking any nonprescription medications, herbal products, or supplements without first discussing them with a provider.
- Advise patient to consult with a health care provider about strategies to help keep track of medications and daily doses.
- Confirm that all immunizations are up to date.

### Sick Day Management

- Establish a sick day plan for insulin use during an acute illness.
- Recommend testing of BG and urine ketones (especially with type 1 diabetes) frequently during acute illness. During a period of illness, blood glucose levels may be elevated and patients may have an altered caloric intake.
- Advise patient to maintain ample hydration with noncaloric liquids.

Key: BG = Blood glucose.

**TABLE 45-2 ADA Treatment Goals for Nonpregnant Adults with Diabetes**

<i>Glycemic Control</i>	
Hemoglobin A1C	<7.0% <sup>a,b</sup>
Fasting plasma glucose	70-130 mg/dL (3.9-7.2 mmol/L)
Peak postprandial plasma glucose <sup>c</sup>	<180 mg/dL (<10.0 mmol/L)
Body mass index	<25.0 kg/m <sup>2</sup>
Blood pressure	<140/80 mm Hg
Immunizations	Influenza vaccination annually Pneumococcal vaccination All others should be up to date (e.g., tetanus, hepatitis A and B, and zoster)

Key: ADA = American Diabetes Association; A1C = glycosylated hemoglobin.

<sup>a</sup>Reference to a normal range for patients without diabetes of 4.0%-6.0% using a Diabetes Control and Complications Trial-Based Assay.

<sup>b</sup>Lower (e.g., <6.5%) or higher (e.g., <8%) A1C goals may be considered in individual patients.

<sup>c</sup>Postprandial plasma glucose measured 1-2 hours from the start of the meal.

### Nonpharmacologic Therapy

#### Medical Nutrition Therapy

Coupled with regular physical activity, MNT is an essential nonpharmacologic component of diabetes care. Rather than focusing on the need to “diet” or “lose weight,” the term “nutrition” is used to emphasize the importance of eating for a healthy lifestyle and achieving and maintaining metabolic goals.

The concepts of MNT are similar for patients with types 1 and 2 diabetes, but treatment goals differ. For patients with type 1 diabetes, the goals are to integrate insulin regimens with usual habits of eating and physical activity, and to ensure normal growth and development during childhood and adolescence. Because obesity and a sedentary lifestyle are key issues in type 2 diabetes, the main objectives are healthy eating habits (including caloric and fat restriction), moderate weight loss, and increased physical activity to achieve optimal metabolic goals.

Current guidelines for meal planning entail an individualized approach and should involve the patient in the decision-making process, taking into account personal and cultural preferences.<sup>5</sup> If necessary, a referral should be made to a dietitian or certified diabetes educator. Clinical studies have reported significant benefits of MNT, including 0.25%-2.9% reductions in A1C at 3-6 months, 15-25 mg/dL reductions in low-density lipoprotein cholesterol, and improved blood pressure.<sup>3</sup>

#### Macronutrients

In general, the optimal mix of macronutrients (i.e., carbohydrate, protein, and fat) is individualized. A meal plan high in fresh fruits and vegetables and moderate in starches is recommended. High-fiber starches (e.g., legumes, whole-grain breads, and fiber-rich cereals with a goal of 14 grams fiber per 1000 kcal per day, or 25-38 grams fiber per day) are preferred over low-fiber starches (e.g., mashed potatoes, pasta, and rice).

Not all carbohydrates affect plasma glucose concentrations equally. Elevated glucose concentrations are determined by both the quality (e.g., glycemic index) and the total quantity of carbohydrates (e.g., glycemic load [GL]) consumed. Glycemic index is a system that ranks carbohydrates on a scale of 0%-100% based on their potential to raise plasma glucose concentrations immediately after they are consumed. Diets with low-glycemic-index foods (e.g., some fresh fruits and vegetables, beans, oatmeal, and whole-grain pasta) may improve glucose and lipid concentrations in people with diabetes. Not all fruits and vegetables have a low glycemic index and therefore should be considered on an individual basis. GL is the total glycemic response to a food or meal and is based on the grams of carbohydrates consumed. GL is calculated by multiplying the glycemic index percentage by the total grams of carbohydrates per serving. ADA states that the use of glycemic index or GL may be beneficial for glycemic control.<sup>3</sup>

With regard to fat, the main goal for people with diabetes is to reduce CVD risk factors. Less than 10% of the total daily caloric intake should come from saturated fats, with monounsaturated oils (e.g., olive oil) favored; consumption of trans fats should be minimized. A daily cholesterol intake of less than 300 mg/day and two or more servings of fish per week are recommended.

Lifestyle changes, moderate daily physical activity, and portion-size control for carbohydrates, protein, and fats are the critical factors in controlling obesity in patients with diabetes. Sodium intake should be limited (<2300 mg/day), especially when hypertension is present.<sup>5</sup> All health professionals should encourage patients to keep a meal plan and physical activity log to track the effects of food, physical activity, and medication on BG. In addition, patients should learn how to interpret these data and to identify patterns to make a cause-and-effect relation for glycemic control.

#### Use of Sweeteners and Sugar-Free Products

Both nutritive (caloric) and nonnutritive (noncaloric) sweetening agents are available and are good alternatives to using table sugar. Consuming large amounts of sugar alcohols (e.g., sorbitol, mannitol, xylitol, maltitol, lactitol, erythritol, isomalt, and hydrogenated starch hydrolysates) may cause diarrhea, resulting from the laxative effects of polyols.

Currently the Food and Drug Administration (FDA) has approved six nonnutritive sweeteners, including saccharin (Sweet'N Low), sucralose (Splenda), acesulfame potassium (Sweet One, Sunett), aspartame (Equal, NutraSweet), neotame, and stevia (Truvia).

Aspartame contains phenylalanine in a high enough concentration that it should be avoided in patients with phenylketonuria.

Sugar-free products such as cough and cold medications are preferred for patients with diabetes to avoid unnecessary elevations in BG.

While using sugar-containing products, patients should monitor their BG closely. Occasional use of a sugar-containing product at the recommended dose is unlikely to cause significant BG elevations. However, several doses of a medication in an uncontrolled type 1 diabetic patient who is ill may exacerbate or precipitate diabetic ketoacidosis (DKA). (See the section Ketones.)

#### Use of Alcohol

Patients with diabetes should be educated that alcohol (1) is considered a fat (7 cal/g) in the meal plan and (2) increases insulin response. Acute alcohol consumption can cause and prolong hypoglycemia, especially if consumed on an empty stomach.

Adult patients choosing to drink alcohol should be advised as follows:<sup>5</sup>

- Limit daily intake to no more than two alcoholic beverages for men and one for women.
- One drink is considered 12 ounces of beer, 5 ounces of wine, or 1.5 ounces of distilled spirits (hard alcohol). Each contains 15 grams of alcohol.
- Calories from alcoholic beverages and sugar-containing mixes must be included as an addition to the regular meal plan.
- To reduce hypoglycemia risk, consume alcohol with food.
- Refrain from drinking if you are pregnant, overweight, or have other medical problems such as pancreatitis, advanced neuropathy, hypertriglyceridemia, or alcohol abuse.

#### Physical Activity

Patients with diabetes benefit from an active lifestyle. Regular physical activity can improve glycemic control (increases insulin sensitivity), facilitate weight loss (reduces body fat and increases muscle mass), reduce cardiovascular risk factors (reduces low-density lipoprotein cholesterol and triglycerides; increases high-density lipoprotein cholesterol with weight loss; improves blood pressure), and improve self-esteem.<sup>6</sup> Regular physical activity can even prevent the onset of type 2 diabetes.<sup>7</sup>

Before increasing physical activity, patients should undergo medical evaluation to screen for any underlying diabetes-related complications that may limit certain activities. The patient's lifestyle, preferences, metabolic goals, complications, and limitations should be considered to create an individualized fitness program. The current ADA recommendation for adults with diabetes is a minimum of 150 minutes per week of moderate-intensity aerobic physical activity. Moderate intensity is defined as reaching 50%-70% of the maximum heart rate or working hard enough to increase heart rate and break a sweat while being able to maintain a conversation. The 150 minutes per week should be divided over at least 3 days of the week with a gap of no more than 2 days in a row without exercise. An additional 2 days per week of resistance training should be recommended for patients with type 2 diabetes. Patients of advanced age should start slowly (5-10 minutes a day) and increase the amount of time gradually as tolerated. Patients are encouraged to use the large muscle groups and participate in aerobic activities (e.g., walking, swimming, and biking). Some modifications of physical activity are needed for patients with certain diabetes-related complications. For example, patients with moderate or worsening retinopathy should avoid activities that elevate blood pressure or are strenuous (e.g., heavy competitive sports and power weightlifting). Patients who have neuropathy with loss of protective sensation should avoid repetitive sports such as prolonged walking or jogging, although low-impact alternatives may be recommended by their provider with close follow-up.<sup>3</sup>

Effects of physical activity on BG vary in type 1 diabetes. In general, patients who use insulin may need to consume extra carbohydrates or adjust insulin to account for the potential hypoglycemic effects of physical activity. Patients with type 1 diabetes may be at risk of hypoglycemia up to 8-15 hours after prolonged physical activity. [Table 45-3](#) provides guidelines for patients who perform physical activity. Patients should be reminded to include their physical activity in their daily log.

#### Use of Tobacco Products

Tobacco use is associated with an increased risk of mortality, macrovascular complications, and early microvascular complications.

Therefore, providers should encourage cessation of all tobacco products (see [Chapter 47](#)).

#### TABLE 45-3 Education for Patients with Diabetes Who Conscientiously Perform Physical Activity

• Wear properly fitted shoes and a diabetes identification bracelet.
• Perform SMBG before and after physical activity. SMBG testing during physical activity may be necessary for prolonged physical activity.
• Perform a 5- to 10-minute, low-intensity, aerobic (e.g., walking or bicycling) warm-up (to prepare the muscles and heart) and cooldown (to bring heart rate down).
• Adjust insulin or carbohydrate intake if needed because physical activity may cause hypoglycemia if medication doses and/or carbohydrate intake is not adjusted accordingly. Before physical activity, if glucose concentration is normal or low (e.g., <100 mg/dL),

consume a 10- to 15-gram carbohydrate snack (e.g., one small apple, 6-ounce cup of yogurt, or four to six whole-grain crackers), and add an additional snack if needed after the activity.

- To avoid increased absorption of regular or rapid-acting insulin (and possible hypoglycemia) from physical activity, inject insulin into the abdomen or do physical activities 30 minutes to 1 hour after insulin administration.

- Avoid physical activity if glucose concentration is greater than 250 mg/dL in the presence of ketosis (particularly in patients with type 1 diabetes). Use caution if BG concentrations are greater than 300 mg/dL without ketosis.

- Late-onset hypoglycemia can occur 8-15 hours after the physical activity, especially in patients with type 1 diabetes. If a patient performs physical activities during the day, recommend an increase in carbohydrate intake and performing SMBG during the night to detect nocturnal hypoglycemia.

Key: BG = Blood glucose; SMBG = self-monitoring of blood glucose.

Source: References 3 and 6.

## Monitoring of Glycemic Control

With knowledge of their glycemic status, patients may be better able to self-manage their diabetes. Glycemic testing methods can be divided into two main categories: day-to-day glycemic measures (e.g., BG, blood ketones, and urine ketones) and chronic glycemic control measures (e.g., A1C and glycosylated serum proteins). Home testing products for urine protein are also available.

## Self-Monitoring of Blood Glucose

Over the past decade, SMBG has become the standard for day-to-day assessment of glycemic control. SMBG provides patients with immediate feedback. Patients can recognize glucose patterns to track whether daily goals are being met, to prevent or detect hypoglycemia, and to evaluate glycemic response to foods, physical activity, or medication changes. Providers use SMBG data to help patients make changes to their diabetes care plan.

For most patients who have type 1 diabetes or who are using multiple insulin injections a day or pump therapy, self-monitoring should occur at a minimum for the following: prior to meals and snacks, periodic postprandially, at bedtime, prior to exercise, when low BG is expected, after treating low BG until returning to normoglycemic, and before critical tasks such as driving or operating machinery. This may be 6-8 times per day or more. For patients who are not on insulin therapy or are on a single insulin injection, self-monitoring may be useful as a guide to the success of therapy, and whether to monitor or not should be decided collaboratively by the patient and provider. The decision to test and the frequency of testing should be patient specific and should include factors such as the impact on quality of life and cost.

More frequent monitoring may be necessary for patients prone to hypoglycemia and during illness, or for dose changes in insulin or other diabetes medication, physical activity, diet changes, or travel. The patient must be trained in SMBG technique, instructed on appropriate timing for testing, and given specific guidelines for therapy alterations.<sup>3</sup>

Several factors play a role in SMBG product selection, including costs of necessary supplies and special considerations for individual patients (e.g., manual dexterity and visual acuity). Although SMBG offers many benefits, some drawbacks include out-of-pocket expense and time required for testing, possible invasive finger or skin punctures, motivation, and health literacy (e.g., cognition) required to perform SMBG and to learn to interpret test results.

### Bg Monitoring with Glucose Monitors

A glucose monitor used in conjunction with reagent strips measures the specific BG concentration. All monitors are calibrated and will generally analyze the BG concentration according to programmed data. All monitors provide a digital display of the BG concentration, although the display size may vary. Most have memories for later recall of recent BG concentrations. If meters have a capacity to download information, it may be saved, printed, and copied into the electronic medical record. Patients who are blind or visually impaired may benefit from monitors with audio features.

Many factors are used to select a monitor for an individual patient, first of which is generally the cost of the meter and test strips, which may be driven by the patient's insurance coverage where applicable. Additional factors may include the monitor size, size of display, blood sample size, capabilities for alternate site testing, timing devices, calibration, accuracy, ease of use, effect of temperature on accuracy, memory or data management and download features, battery types, need for cleaning, accessories required, audio capabilities, and price. A comprehensive list and description of blood glucose monitors is published annually in the ADA *Diabetes Forecast*. The 2013 guide can be found free online at [www.diabetesforecast.org/2013/jan/blood-glucose-meters-2013.html](http://www.diabetesforecast.org/2013/jan/blood-glucose-meters-2013.html).

Even when BG monitors are used properly, calibrated frequently, and interpreted correctly, accuracy can vary by up to 20%. Most glucose monitors report plasma glucose concentrations (similar to laboratory-reported results), but a few report capillary (whole blood) glucose concentrations. Because BG concentrations in plasma are approximately 11% higher than those in whole blood, patients should know which results their monitors yield to determine their glycemic goals.<sup>8</sup> Therefore, education about the type of meter being used (capillary versus plasma) is essential if patients will be making treatment decisions (e.g., adjusting an insulin dose) based on the reading obtained. Plasma monitors should be recommended when possible to avoid any confusion in differences between laboratory- and meter-reported values.

Many BG monitors allow blood sampling at alternate sites from the fleshy part of the palm, forearm, upper arm, thigh, and calf. Blood flow to the finger is faster than that to the forearm. Therefore, when glucose concentrations are rapidly fluctuating (e.g., after meals, during hypoglycemia, or with increased physical activity), alternate site testing should be avoided because a finger stick will reflect the change in BG before the alternate sites will.<sup>9</sup>

Tips for improving accuracy of SMBG via finger stick can be found in [Table 45-4](#). For patients who intend to use alternate sites, providers should spend sufficient time reviewing the technique and assessing the patient's understanding of alternate site testing.

Proper education in the methods for self-monitoring, the differences between individual monitors, the importance of timing and frequency, and the interpretation and application of test results will encourage patients to perform SMBG consistently.<sup>9</sup> Return demonstration by the patient is necessary to ensure the patient's understanding of the procedure and to correct any errors as they are observed. Patients should

be encouraged to maintain accurate records of SMBG and to return with their logbook, which should also contain records of medication use (e.g., name, dose, and time taken), diet changes, activities, and body weight. In addition, computerized data management systems that come with some monitors can be used at home or in the health care provider's workplace. The programs include software for downloading monitor information, modules for personal digital assistants, electronic logbooks, and Web-based programs to help patients track SMBG trends.

### Lancets and Blood Sampling Equipment

Most BG testing requires the use of lancets and lancet devices. Several lancing devices are available and are provided with BG monitors. These devices allow a finger stick with less associated pain, because most have an auto-retractable needle and the amount of skin penetration can be adjusted in some products. Lancing devices should not be shared because they can harbor blood-borne pathogens and promote infection. Obtaining an adequate blood sample is essential for test accuracy. Providers should instruct patients on proper techniques for improving accuracy (Table 45-4).

**TABLE 45-4 Tips for Improving Accuracy of Finger Stick Technique**

<i>Using Test Strips</i>
• Properly store test strips at room temperature in the original vial or container.
• Avoid exposing test strips to changes in temperature, humidity, and light.
• Check expiration date on test strips.
• Code monitor for the batch of test strips (if applicable).
• Use control solutions to verify test strips are working properly.
<b>Using Glucose Monitor</b>
• Follow manufacturer's directions for calibrating monitor and using control solutions.
<b>Obtaining an Adequate Blood Sample</b>
• Gather all necessary supplies (e.g., monitor, test strips, lancet, lancet device, and tissue).
• Vigorously clean hands with warm soapy water to increase blood circulation.
• Allow hands to dry completely to avoid diluting the blood sample.
• If alcohol must be used to clean hands, wait 1 minute to ensure alcohol has completely evaporated.
• Dry hands thoroughly.
• Hang hand below heart for 30-60 seconds to increase blood flow to fingers.
• Using the other hand, apply pressure on the finger from the base to the finger pad.
• If possible, rotate the fingertip for each self-monitored BG test.
<b>Lancing the Finger</b>
• Use a lancet device with an adjustable puncture depth, and adjust as needed to ensure adequate blood drop.
• Point fingers to the ground and lance the side of the fingertip.
• Avoid lancing finger pads because the presence of more nerves in these areas may cause pain.
• If lancing the index finger or thumb causes pain, avoid these areas as well.
<b>Applying the Drop of Blood</b>
• Ensure adequate size of blood drop is applied to test strip.
• If necessary, apply light pressure on the finger from the base to the finger pad to increase size of blood drop.
• Quickly place drop of blood on test strip. Method varies with monitor type. Refer to monitor instructions for proper technique.

### Continuous Glucose Monitoring

An alternative method of monitoring glucose control is using a continuous glucose monitoring (CGM) system. A CGM device contains a sensor that is inserted into the subcutaneous tissue and then records glucose concentrations at a regular interval (e.g., every 1 or 5 minutes). The sensor stays in place for several days up to a week, depending on the device, before being replaced. Although not intended for day-to-day glucose monitoring, CGM offers the advantage of detecting glucose fluctuations, excursions, and trends throughout the day (e.g., unrecognized nocturnal or daytime hypoglycemia, or 3- to 4-hour postprandial hyperglycemia) that go unnoticed if only A1C and SMBG values are used as guides for treatment. Results from CGM allow better pattern management, particularly for insulin users. Challenges with CGM include insurance coverage and the need for a motivated patient who will wear the device and then obtain and record SMBG readings.

Testing for Ketones, Microalbumin, and Protein

### Ketones

The development of self-monitoring of blood ketone levels has revolutionized the process of detecting or predicting ketoacidosis. When the body does not have sufficient insulin, BG concentrations rise and the body's cells become energy deprived. During these times of low

carbohydrate availability, the liver breaks down fat to produce ketone bodies (acetoacetate, 3-beta-hydroxybutyrate, and acetone). A sufficient blood concentration of ketones can result in diabetic ketoacidosis, a potentially fatal condition. Because ketones in the blood overflow into the urine, urinary ketone concentrations can be tested. The basis for the urinary ketone testing is that sodium nitroprusside alkali turns lavender in the presence of acetoacetate. These tests require comparing the color change to a reference chart. Several urine ketone testing products are available (e.g., Ketostix Reagent Strips, KetoCare Ketone Test Strips, and DiaScreen 1K).

In addition to testing BG, certain monitors (e.g., Precision Xtra) are capable of using test strips designed to detect 3-beta-hydroxybutyrate concentrations in the blood. This type of meter may eliminate the need for two different testing devices. Unlike urine ketone tests, blood ketone tests provide a real-time picture. Because ketone bodies will be detected in the blood first, blood tests allow earlier detection and treatment of ketoacidosis. Another advantage of blood ketone testing over urine ketone and tablet testing is the lack of false positives in the presence of vitamin C or during exposure to ambient air.

It is important to note that DKA, which occurs most often in type 1 diabetic patients, differs from hyperglycemic hyperosmolar nonketotic syndrome (HHNS), which is more common in elderly patients with type 2 diabetes. The primary cause of DKA is insulin deficiency, whereas the primary cause of HHNS is prolonged hyperglycemia paired with dehydration. DKA can present with a lower BG (e.g., >240 mg/dL) compared with HHNS (e.g., >600 mg/dL). In addition, DKA is classified by the presence of ketones at elevated BG levels, whereas in HHNS usually few or no ketones are produced. Ketone urine or blood monitoring should be recommended any time a condition exists that may lead to poor glycemic control (e.g., illness) for patients who are prone to elevated ketones. Patients should be counseled on the proper methods of testing for ketones in the urine and blood.

#### Microalbumin and Protein

Detection of microalbuminuria (trace protein in the urine) is an early sign of kidney damage. ADA recommends annual screening to measure urine albumin in patients with type 1 diabetes start 5 years after diagnosis and for all patients with type 2 diabetes.<sup>3</sup>

A nonprescription test for microalbumin is available (Kidney Screen At Home), but the urine specimen is mailed to a laboratory for analysis and reporting. Large protein particles in the urine can be determined by using an array of products (e.g., Albustix and Chemstrip). When testing at home, patients should note that, in addition to kidney damage secondary to diabetes, other factors may cause microalbuminuria, such as uncontrolled blood pressure, intense exercise, heart failure, or a recent urinary tract infection. The presence of microalbumin and protein in the urine should be reported to the primary care provider.

#### Self-Monitoring of Glycosylated Hemoglobin

Compared with SMBG, A1C and glycated protein testing provide useful information about a patient's glycemic control over a longer period. Traditionally, these tests were performed in a laboratory setting from venipuncture samples. New technology allows home or clinic testing with smaller blood samples.

Plasma glucose binds to red blood cells. A1C is formed at a rate directly proportional to the BG concentration over the previous 120 days (lifespan of the average erythrocyte). Because A1C concentrations correlate with the weighted mean plasma glucose values over the preceding 2-3 months, A1C may be used to assess overall glycemic control in patients with diabetes. Patients may find it easier to understand their glycemic control if they use an estimated average glucose (eAG). The eAG is calculated by using the formula  $eAG = 28.7 \times (A1C - 46.7)$ . For example, A1C values of 7% and 10% are equivalent to eAG values of 154 mg/dL and 240 mg/dL, respectively.

Providers can refer patients to a useful online eAG calculator ([professional.diabetes.org/glucosecalculator.aspx](http://professional.diabetes.org/glucosecalculator.aspx)).

In general, ADA recommends testing A1C twice yearly in patients who are stable and meeting their glycemic goals, and every 3 months for patients who are not at goal or whose therapy has changed.<sup>3</sup> The exact testing frequency should be based on clinical judgment. The normal nondiabetic A1C range is 4%-6%. According to ADA guidelines, the goal for most people with diabetes is less than 7%. Several nonprescription A1C kits are available (e.g., A1CNow, AccuBase A1c Test Kit, A1c At Home, and BIOSAFE Hemoglobin A1c Test Kit). (See [Chapter 48](#) for further discussion of home A1C tests.)

#### Identification Tags

Persons with diabetes should consider wearing a visible identification bracelet, necklace, or tag that indicates the person has diabetes and takes medication. Specifically, patients requiring insulin therapy should be strongly encouraged to wear an identification tag in the case of an emergency secondary to hypoglycemia. Patients should also be encouraged to carry an identification card (e.g., in a wallet) that includes their name, address, and telephone number; the amount and type of medication used; and the name and telephone number of the patient's primary care provider. This information may be lifesaving in the event of hypoglycemia or ketoacidosis that requires emergency services or hospitalization.

#### Travel Supplies and Preparations

Patients with diabetes who are planning to travel should pack enough diabetes supplies for the entire trip, plus at least 1 additional week's supply (or double what they anticipate needing). Patients should be advised to carry their supplies with them, not in checked luggage. The following is a travel checklist:

- A written note from patient's provider indicating the need for diabetes supplies (especially syringes and needles)
- Extra vials of insulin, as applicable
- Extra supply of syringes and needles because access may be limited (patients should refrain from prefilling syringes for a trip because of potential for leakage and the potential for compromised stability)
- Extra insulin pump supplies
- Extra supply of all oral medications in their original prescription bottles
- Extra SMBG supplies (e.g., glucose monitor, test strips, control solutions, lancets and devices, and batteries if needed)
- Written prescriptions for medications, including insulin and diabetes supplies (e.g., syringes and test strips), in case of an emergency
- A summary of the patient's current medication regimen and emergency contact information
- Identification cards and a diabetes identification bracelet or tag
- Snacks and glucose tablets (and glucagon kit for insulin users) as preparation for schedule changes or prevention of hypoglycemia (see the section Hypoglycemia)
- If traveling abroad, the names of English-speaking primary care providers in each city and some cards with several key phrases in

the language of the country being visited (e.g., “I have diabetes” and “Please get me a doctor”) to access care

Travelers should monitor their caloric intake carefully and allow time for physical activity. Because most airlines currently provide limited or no meal options onboard, patients should plan accordingly to bring their food. Patients should wear comfortable well-fitting shoes if they intend to walk more than usual during the trip. They should also anticipate changes in activity level because of extra walking and potentially erratic meals. Insulin users should be educated that time zone changes of 2 or more hours usually require insulin dose adjustments. They can work with their providers on specific adjustments to their basal and/or mealtime insulin doses. More frequent SMBG may be necessary.

### Pharmacologic Therapy

Pharmacologic treatment options for patients with type 1 diabetes include insulin therapy delivered by injection or insulin pump. Because they are unable to produce insulin, patients with type 1 diabetes must inject themselves with insulin each day. Insulin therapy should be tailored to balance the effects of diet and physical activity.

Patients with prediabetes may be able to normalize their BG concentrations with diet, physical activity, and weight loss alone. However, some may benefit from the addition of pharmacotherapy. Patients with type 2 diabetes require MNT and physical activity combined with pharmacologic intervention.

### Insulin

Insulin is the primary medication used to treat type 1 diabetes. Insulin is also commonly used in the treatment of type 2 diabetes. Although primary care providers prescribe insulin therapy, other health care providers, especially pharmacists, are often consulted by both primary care providers and patients about insulin and issues related to its use (e.g., initiation, adjustments, monitoring, injection technique, etc.). Thus, health care providers should be knowledgeable about insulin products and their use.

Insulin stimulates uptake and storage of glucose as glycogen (in muscles and the liver) and synthesis of fatty acids and triglycerides. In addition, insulin decreases hepatic glucose output, lipolysis, and ketone production. Finally, insulin enhances amino acid incorporation into proteins.

Human insulin is available without a prescription, whereas insulin analogues and oral agents require a prescription. In the United States, insulin is commercially available in concentrations of 100 units/mL (designated as U-100) and 500 units/mL (designated as U-500). The goal of insulin therapy in patients with type 1 diabetes is to mimic physiologic pancreatic insulin secretion to maintain normal plasma glucose concentrations. Physiologic insulin therapy provides basal and bolus (mealtime) needs. Doses are adjusted according to BG response, glycemic goals, and other patient-specific variables (e.g., BG concentrations, growth, diet, activity, and ketosis). Dosing regimens are also tailored to patients' lifestyle and routine (e.g., number of daily meals and snacks, sleep, and work schedules). Insulin doses are adjusted based on patient response to therapy as evidenced by trends in A1C and fasting, preprandial and postprandial plasma glucose concentrations, and incidence of hypoglycemia and hyperglycemia. Patients can learn to manage and adjust their daily insulin requirements on the basis of BG concentrations, diet, and activity levels.

Insulin therapy in patients with type 2 diabetes is mainly determined by the amount of glycemic control and duration of disease. Patients with type 2 diabetes whose BG is not controlled with noninsulin BG-lowering agents may require insulin therapy to achieve glycemic goals. In some cases, patients with newly diagnosed type 2 diabetes with severe hyperglycemia may require insulin therapy alone or in combination with other medications to reduce A1C values and BG concentrations.

The most common side effect of insulin therapy is hypoglycemia. Many other factors (e.g., a decrease or inconsistency in mealtime carbohydrate content, physical activity, alcohol intake, and medications) can contribute to hypoglycemic episodes. For this reason, when adjusting insulin therapy, providers should carefully assess the relationship of insulin dose and timing with patient BG trends, including hypoglycemic or hyperglycemic episodes. Patients with comorbid conditions, such as gastroparesis or reduced renal function, may be at increased risk of hypoglycemia. Insulin doses should be adjusted accordingly.

Weight gain is another common side effect. It is usually caused by increased efficiency of glucose and fat storage resulting from insulin therapy. Hypoglycemic episodes, which stimulate appetite, also contribute to weight gain because patients consume additional calories to correct the low BG.

Some patients experience local reactions on insulin injection, such as pain, redness, bruising, burning, stinging, or irritation. Using a new syringe or pen needle with each injection may help minimize or alleviate pain associated with injections. Reminding patients to inject insulin at room temperature minimizes pain associated with cold insulin injections. Proper insulin injection technique minimizes redness, swelling, and bruising. Good hygiene along with proper use and storage of syringes and other delivery devices minimizes the risk of infection.

### Hyperglycemia

Hyperglycemia can occur if an insulin dose is missed or if the dose is insufficient to meet metabolic needs or carbohydrates that are consumed. Hyperglycemic symptoms—frequent urination, dehydration, thirst, increased appetite—usually occur at BG concentrations greater than 180 mg/dL. If ketosis develops, the patient's breath may have a fruity odor. Untreated hyperglycemia requires immediate medical attention because it could progress to DKA or HHNS, followed by coma and death.

Morning hyperglycemia may result from an asymptomatic nocturnal hypoglycemia (Somogyi effect) in patients who are otherwise well controlled on intensive insulin regimens. In response to hypoglycemia, the body secretes epinephrine, which induces hepatic glucose production and results in morning hyperglycemia. Another reaction that can present with a similar morning hyperglycemia is termed the “dawn phenomenon.”<sup>10</sup> As part of the circadian rhythm, hormones such as growth hormone, cortisol, and epinephrine are released during the night. In response, the plasma glucose concentration rises in the early morning hours, and insulin is released from the functioning pancreas. In people with diabetes, the insulin release may not occur, resulting in morning hyperglycemia. Thus, a Somogyi effect is caused by too much insulin, whereas the dawn phenomenon is caused by too little insulin. Patients with morning hyperglycemia should monitor their plasma glucose concentration between 2 am and 3 am to determine whether it is low (Somogyi effect), normal, or high (dawn phenomenon). They should record the results along with any changes in their diet and physical activities, and seek assistance in interpreting the results and adjusting therapy accordingly.

### Hypoglycemia

Several factors can contribute to hypoglycemia, including insufficient caloric intake (e.g., skipping or delaying meals, and/or vomiting), inaccurate insulin dose (e.g., too high, frequent adjustments, inadequate preparation, and/or irregular timing), concomitant use of hypoglycemic drugs, drug interactions, very tight glycemic control, and physical activity. Although a BG concentration of less than 70

mg/dL indicates hypoglycemia, some patients experience symptoms at higher glucose concentrations. Early warning symptoms may be both autonomic (e.g., trembling, shaking, sweating, palpitations, and/or tachycardia) and neuroglycopenic (e.g., slow thinking, difficulty concentrating, slurred speech, lack of coordination, and/or dizziness). Some patients may be hypoglycemic without experiencing any symptoms, a serious condition called hypoglycemia unawareness.

**TABLE 45-5 Selected Fast-Acting Carbohydrates for Treating Hypoglycemia (15 grams)**

<i>Source</i>	<i>Quantity</i>
Milk (low-fat or nonfat)	8 ounces (1 cup)
Fruit juice (e.g., apple, orange)	4 ounces (1/2 cup)
Soft drink (nondiet)	4 ounces (1/2 cup)
Sugar	1 tablespoon or 3 cubes
Raisins	2 tablespoons
Hard candies (e.g., peppermint, butterscotch, Skittles, Life Savers, jelly beans)	3 pieces of hard candy, such as peppermint or butterscotch, or 5-6 pieces of Skittles, Life Savers, or jelly beans
<b>Glucose Tablets</b>	
Various products on the market with different amounts of glucose per tablet and flavors available	
<b>Glucose Gels</b>	
Various products on the market with different amounts of glucose per tablet and flavors available	

Mild-moderate hypoglycemic symptoms usually are rapidly relieved by ingestion of glucose. As a preventive measure, people with diabetes should always carry a source of fast-acting carbohydrate (Table 45-5). At the onset of hypoglycemic symptoms, patients should check their plasma glucose value if a BG monitor is available. If a patient is experiencing hypoglycemia symptoms, it is safer to initiate treatment with carbohydrates even if the plasma glucose value is not known. If a patient is able to test and determine that the blood sugar is low, he or she should follow the “rule of 15.” According to the “rule of 15,” the patient should consume 15-20 grams of carbohydrates once hypoglycemia is determined. If symptoms persist or BG concentrations are still below 70 mg/dL after 15 minutes, an additional 15 grams of carbohydrates should be consumed.<sup>3</sup> Patients who take alpha-glucosidase inhibitors (acarbose or miglitol) should use oral glucose during an episode of hypoglycemia since the medication will inhibit the breakdown of more complex sugars (e.g., sucrose from table sugar or fructose from juices).

Once hypoglycemia is treated, if mealtime is not within 1 hour, a small snack containing a carbohydrate plus protein (e.g., crackers and peanut butter, piece of fruit and cheese, or a small protein-containing sandwich) should be consumed to prevent further hypoglycemia. BG should be monitored frequently to prevent recurrent hypoglycemia.

Severe hypoglycemia, which may result in unconsciousness, coma, seizures, and inability to swallow, should be treated with glucagon.<sup>3</sup> All patients using insulin should have a glucagon emergency kit, particularly those with type 1 diabetes. Available by prescription, these kits contain a 1 mg ampule of glucagon, a syringe of diluent, and administration directions. Glucagon is indicated when an individual becomes unconscious because of hypoglycemia. For this reason, family members, other patient caregivers, and co-workers should be taught to mix and administer glucagon by subcutaneous or intramuscular injection. The usual dose is 1 mg for adults and children weighing 20 kg or more, and 0.5 mg for children weighing 20 kg or less. Glucagon may cause vomiting, lasting up to 24 hours. Unconscious individuals should therefore be turned on their side before glucagon is administered, to prevent choking. Glucagon usually works within 5-10 minutes, but the effects are short lived. If no response is seen after 5-10 minutes, a second injection may be given. If this is ineffective, the caregiver should call 911 immediately. Once an individual is conscious and can swallow, the caregiver should give a carbohydrate liquid (e.g., juice, milk, or nondiet soft drink) followed by a carbohydrate snack (small sandwich or crackers with peanut butter). For the next 24 hours, regular SMBG and adequate food intake are necessary to replenish hepatic glycogen stores. The primary care provider should be informed of the episode.

#### **Insulin Administration, Contamination, and Storage**

Unless age (e.g., the very young) or physical or mental impairments preclude self-injection, a patient should be trained on (1) how to prepare his or her dose for subcutaneous injection, (2) the location of acceptable self-injection sites, and (3) proper subcutaneous injection technique. Table 45-6 describes the steps for preparing an insulin dose using a syringe and insulin vial or a prefilled insulin-delivery device.

**Injection Sites, Routes, and Absorption Rates.** Insulin injection site may influence insulin absorption. Acceptable subcutaneous injection sites include the abdomen, upper arms (deltoid region), thighs (anterior and lateral aspects), and buttocks (Figure 45-1). If a patient chooses the upper arms or buttocks, self-injection may be difficult and assistance may be required.

Different anatomic sites differ in their rates of absorption. The abdomen is considered the preferred site for subcutaneous injection of insulin by most experts because insulin absorption is more predictable. Patients should avoid the area within 2 inches around the navel. Rotation of injection sites within an anatomic area helps prevent lipohypertrophy or lipoatrophy. Proper subcutaneous injection technique for use of nonprescription insulin syringes is depicted in Figure 45-2 and described step by step in Table 45-7. Injection technique may need to be altered for certain patients (e.g., 45-degree injection angle for infants and extremely thin individuals with minimal subcutaneous fat). Nonprescription insulin syringes differ in size (e.g., 6 mm, 8 mm, and 12.7 mm) compared to the prescription pen needles that are shorter in length (e.g., 4 mm, 5 mm, 8 mm, and 12.7 mm). Where possible, the shortest length should be used to ensure the injection is provided in the subcutaneous area and not in the muscle. Pinching the skin provides a firm injection surface and lifts the fat off the muscle to avoid intramuscular or intravenous injection. Properly injected insulin should leave only a needle puncture dot; bruising generally should not occur. Patients should be instructed to inject and leave the needle in place for 5-10 seconds to prevent the leakage of insulin.

**TABLE 45-6 Guidelines for Preparing a Dose of Insulin Using a Vial and Syringe**

- Wash hands with soap and warm water.

- |  |
|--|
| • Check the insulin label on the vial to verify the type of insulin to be injected.  |
| • Visually inspect the insulin vial for signs of contamination or degradation (e.g., white clumps or color changes).         |
| • Remove the cap and wipe the top of the vial with an alcohol swab or cotton ball dipped in alcohol.                         |
| • Remove the protective coverings over the plunger and needle of the syringe.  |
| • Taking care not to touch the needle, draw up air equal to the insulin dose to be administered into the syringe.            |
| • Inject the air into the insulin vial.  |
| • With the syringe still inserted, invert the vial and withdraw the insulin dose.  |
| • Be sure to keep the hub of the needle below the surface of the insulin to prevent creating air bubbles within the syringe. |
| • If bubbles are present, inject the insulin back into the vial and pull the dose back into the syringe.                     |
| • Remove the syringe from the vial and self-inject dose, using proper injection technique ( <a href="#">Table 45-7</a> ).    |

Injection pain can be reduced by injecting insulin at room temperature, ensuring air bubbles are not present in the syringe, and penetrating the skin quickly in one motion. Patients who routinely experience soreness, pain, bruising, welts, or redness should have their injection technique evaluated by a health care provider. In patients complaining of pain, bruising, or redness, the provider should ensure that the patient is not reusing needles.

Subcutaneous absorption rates can be highly variable within and across patients. Patients should be educated about the influence of factors such as physical activity, massage, temperature, and smoking on insulin absorption. Performing physical activity or massaging the injection area can increase absorption rates. Heat from hot weather, a hot bath or shower, or a sauna can increase peripheral blood flow, which can increase absorption rates. Cold has the opposite effect. A smoker may require a higher amount of insulin than a nonsmoker because of a decrease in insulin absorption and an increase in insulin resistance secondary to smoking. Therefore, upon cessation of smoking, patients should monitor their BG more closely to determine if a reduction of the insulin dose is warranted.

**Storage of Insulin.** Insulin preparations must be stored carefully to maintain stability and maximum potency. Patients should inspect their insulin for visible changes in appearance before each injection. Because patients should inspect for visible changes in their insulin, including the presence of particulates, it is important to note that regular insulin is a clear suspension, whereas NPH insulin is a cloudy suspension. Color changes may be associated with protein denaturation and should be interpreted as evidence of potency loss.

Body map of subcutaneous insulin injection sites.

Unopened insulin vials and cartridges may be stored in the refrigerator (36°F-46°F [2°C-8°C]) until the expiration date listed on the product. Insulin should never be frozen. The refrigerator door is usually a good storage location to ensure that insulin does not become frozen. The stability of unopened and in-use insulin vials or cartridges stored at room temperature varies depending on the product. Providers should contact individual manufacturers with specific questions about the stability of individual insulin products and devices under different storage or exposure conditions.

Correct method of subcutaneous insulin injection.

Patients who transport insulin regularly (e.g., to and from school or work, or while running errands) should be reminded to insulate insulin from heat, direct sunlight, and excess agitation. Patients should never store insulin in the car. Insulin should be carried in an insulated pack (e.g., cold pack) by patients when traveling by bus, train, or air to ensure proper storage conditions.

**TABLE 45-7 Subcutaneous Self-Injection Technique of OTC Insulin Syringes**

<ul style="list-style-type: none"> <li>• Determine the appropriate size of the needle (e.g., 6 mm, 8 mm, 12.7 mm). A shorter length needle is preferred where possible to allow for a subcutaneous injection with minimal risk of entering the muscle.</li> </ul>
<ul style="list-style-type: none"> <li>• Prepare insulin dose for administration (Table 45-6).</li> </ul>
<ul style="list-style-type: none"> <li>• Pinch the area to be injected. This is especially important when using longer OTC needles compared to the shorter prescription pen needles (e.g., 4 mm).</li> </ul>
<ul style="list-style-type: none"> <li>• Insert the needle at a 90-degree angle to the skin in the center of the pinched area (a 45-degree angle for insertion may be used in small children and very thin adults).</li> </ul>
<ul style="list-style-type: none"> <li>• Release the pinch.</li> </ul>
<ul style="list-style-type: none"> <li>• Press down on the syringe or device plunger to inject insulin.</li> </ul>
<ul style="list-style-type: none"> <li>• Hold the syringe or device in the area for 5-10 seconds to ensure full delivery of insulin. This step is particularly important for insulin pen devices.</li> </ul>
<ul style="list-style-type: none"> <li>• Remove the syringe or device.</li> </ul>

Key: OTC = Over-the-counter.

### Product Selection Guidelines

**Insulin Delivery Devices and Injection Aids.** Providers should ensure that patients purchase the right type of supplies to facilitate insulin administration. Insulin available in vials must be administered with syringes. Durable (reusable) and disposable insulin pens and other delivery devices provide added convenience and ease of use, especially in patients with impaired vision or dexterity. A resource guide with information on selected insulin syringes, other delivery aids, and related products currently available in the United States is published annually in an issue of ADA's *Diabetes Forecast* (available free online at [www.diabetesforecast.org/landing-pages/lp-consumer-guide.html](http://www.diabetesforecast.org/landing-pages/lp-consumer-guide.html)). Insulin pumps are an alternative delivery device available for use in selected patients.

Insulin syringes are plastic, disposable syringes that come with very fine, well-lubricated needles. Insulin syringes are designed for U-100 insulin and are marked in insulin units. Marker increments may differ among syringes; this should be pointed out to patients. Depending on the manufacturer, insulin syringes are available in 0.3, 0.5, and 1 mL capacities, which hold 30, 50, and 100 units, respectively. Patients should be reminded to purchase syringes closely matched to their individual insulin dose(s). For example, a patient taking 38 units of regular insulin should use a 0.5 mL syringe to draw up insulin to the 38-unit mark. Because U-500 insulin syringes are not available, patients initiated on U-500 insulin should have the dose expressed as a volume, and a tuberculin syringe marked in volume should be supplied to a patient. If tuberculin syringes are not readily available or covered by insurance, the patient will need to know how much U-500 insulin to pull up in the U-100 syringe. If the prescriber did not provide the conversion value, the pharmacist dispensing the insulin should do so and ensure that the patient understands proper use of the U-500 insulin to avoid a potential error.

Today's needles have virtually no "dead space" or air space at the needle's hub to reduce a potential source of dosing error. Several needle lengths, including 1/2, 3/8, and 5/16 inch, are available. Needles also come in a variety of gauges (e.g., 28-31). The higher the gauge, the finer is the needle, which lessens injection site pain. Silicone coating eases insertion, also reducing pain.

For patients who would rather not use a sharps container, a device such as the BD Safe-Clip Device

([www.bd.com/us/diabetes/page.aspx?cat=7002&id=7416](http://www.bd.com/us/diabetes/page.aspx?cat=7002&id=7416)) lets users clip off the needle into a device that stores hundreds of needles until disposal is necessary. A selected list of related products and services is published in the *Diabetes Forecast* Consumer Guide ([www.diabetesforecast.org/landing-pages/lp-consumer-guide.html](http://www.diabetesforecast.org/landing-pages/lp-consumer-guide.html)). Patients should consult with their local jurisdiction about sharps disposal or call the Coalition for Safe Community Needle Disposal at 800-643-1643 for instructions for proper needle disposal. Several types of insulin injection aids and devices are available for patients who have an aversion to or difficulty with self-injection. Such products include syringe magnifiers, needle guides and vial stabilizers, syringe insertion aids, insulin pens, and jet injectors. Syringe magnifiers enlarge the marks on a syringe barrel, making them easier to see for visually impaired patients. Patients should be reminded that, depending on the manufacturer, magnifiers work only with specific syringe brands. Needle guides and vial stabilizers are available to help patients with limited dexterity safely insert syringes into vials and draw up accurate insulin doses. Insertion aids and jet injectors may be useful for patients with needle or self-injection phobias.

**Special Populations.** Children and adolescents with diabetes differ from their adult counterparts in many ways. These differences include insulin sensitivity related to growth and puberty, neurologic vulnerability to hypoglycemia, and the ability to provide self-care.<sup>3</sup> Diabetes care and education for children and adolescents should therefore be delivered by health care providers experienced in the unique physiologic, developmental, emotional, and psychosocial aspects and challenges faced by this population and their families. Women with diabetes who are trying to conceive should receive special preconception care to ensure the health and safety of themselves and the developing fetus. Diabetes can increase the risk of complications during pregnancy, including fetal malformations. Women with diabetes need to be educated about the importance of family planning and good glycemic control before conception and throughout pregnancy. Insulin is used for glycemic control during pregnancy, and dosing may need to be adjusted to ensure good glycemic control throughout pregnancy.<sup>3</sup>

Older individuals with diabetes have higher rates of co-existing comorbid conditions, disability, and early death than do older individuals without diabetes.<sup>3</sup> Individuals who are physically, functionally, and cognitively intact with a normal life expectancy should have the same goals of therapy and self-care as their younger counterparts. However, special considerations for self-care measures and medication therapy, including insulin, may be relevant for certain individuals. In older patients whose physical, functional, or cognitive abilities are impaired or diminished, or those who have significantly reduced life expectancies, less aggressive metabolic goals should be considered. Their abilities for self-care management should also be assessed. Depending on their individual situations, these patients may be less likely to benefit from reducing the risk of microvascular and macrovascular complications and more likely to have serious adverse events from hypoglycemic episodes. For example, patients who are at a significant risk for falls may be treated less aggressively to avoid impaired consciousness caused by hypoglycemia. Glycemic goals, however, must be tempered to avoid potential consequences of uncontrolled hyperglycemia, such as dehydration, poor wound healing, and hyperglycemic hyperosmolar coma.

Chronic conditions can also affect glycemic control in patients with diabetes. Patients with significantly decreased renal function may have decreased insulin clearance and should be closely monitored for hypoglycemic episodes. Patients undergoing hemodialysis may have fluctuating BG concentrations and should be closely monitored. Certain medications, such as beta-adrenergic blockers, corticosteroids, diuretics, niacin, hormonal contraceptives, protease inhibitors, and atypical antipsychotics, can alter BG concentrations. Beta-blockers can mask symptoms associated with hypoglycemia, such as tachycardia and tremor, so patients should be counseled about how to recognize hypoglycemia. Patients taking hypoglycemic agents or insulin in combination with medications known to raise or lower BG or medications that can alter their physiologic response to hypoglycemia should be instructed to perform SMBG regularly and to carefully monitor for other symptoms of hypoglycemia.

#### Aspirin Therapy

Rheologic changes contribute to diabetes-related PVD and CVD, and platelets in patients with diabetes are hypersensitive to platelet aggregates. People with type 2 diabetes and CVD overproduce thromboxane, a potent vasoconstrictor and platelet aggregate. Low-dose aspirin therapy (75-162 mg/day) should be recommended for secondary prevention in patients with diabetes and a history of CVD, and for primary prevention for patients with type 1 or type 2 diabetes not at an increased risk for bleeding with a 10-year cardiovascular risk score greater than 10%. This includes most men older than 50 years and women older than 60 years who have one or more additional risk factors for CVD (e.g., family history, hypertension, smoking, etc.). Recommending low-dose aspirin therapy for patients with diabetes who have a 10-year risk score of 5%-10% depends on the provider's clinical judgment. Finally, low-dose aspirin therapy for patients with diabetes who have a 10-year risk score of less than 5% is not recommended. This would include most men younger than 50 years and women younger than 60 years who do not have additional risk factors for CVD.<sup>3</sup>

#### Immunizations

Individuals with diabetes who are 6 months of age and older should receive an annual influenza vaccine. The pneumococcal vaccine should also be given to all patients with diabetes who are 2 years of age and older. A one-time pneumococcal revaccination is recommended for patients older than 64 years who were previously immunized more than 5 years earlier when they were younger than 65 years. The hepatitis B vaccine should be administered to unvaccinated adults (ages 19-59 years) with diabetes, and consideration should be given for administration to those who are unvaccinated over the age of 60.<sup>3</sup> Patients should also be able to show current immunization status for other vaccinations, such as tetanus-diphtheria, hepatitis A, and hepatitis B.

#### Complementary Therapies

People with diabetes are 1.6 times more likely to use some form of complementary and alternative medicine, including herbal products or dietary supplements, than are people without diabetes.<sup>11</sup> (For an in-depth discussion of natural products as they may relate to patients with diabetes, see [Chapter 51](#).)

#### Electronic Management Resources for Patients with Diabetes

Advances in technology make diabetes disease management and monitoring much easier. From BG monitors customized for iPhones, mobile applications, and Web sites that allow tracking progress, a vast array of tools is available to make patients' lives easier. Directing patients to free online tools is a great way to keep them actively involved in managing their diabetes. Many online management Web sites allow patients to track daily blood sugar values and other labs, insulin usage, medication, food consumption, and activity. Data are stored on a secure Web site in a quick, easy-to-read format. Three of the more comprehensive online

management tools, discussed below, are ADA's 24/7, My Diabetes Home, and [SugarStats.com](http://SugarStats.com).

Diabetes 24/7 ([247.diabetes.org](http://247.diabetes.org)) allows patients to quickly and easily input and share all valuable health care information with their health care team. ADA has integrated its online management system with Microsoft's HealthVault. The benefit of being linked with HealthVault is that the patient can securely import data from physicians' offices, the hospital laboratory, or the local pharmacy and share that information with anyone he or she chooses. Diabetes 24/7 allows users to monitor their disease by tracking the following: BG, A1C, blood pressure, cholesterol, daily activity levels, weight, and medications. Users can print reports for their caregivers with the most up-to-date information and bring this to their visits. Target goals and times can also be programmed, allowing patients to set and meet individualized goals. Using this system allows patients to quickly and accurately assess response to treatment, and depending on the degree to which they are empowered to make changes, adjust their regimen for better results. Overall, Diabetes 24/7 is extremely functional and easy to use.

The My Diabetes Home ([mydiabeteshome.com](http://mydiabeteshome.com)) Web site provides a "fun, motivational and personalized dashboard" with quick access to tools and resources. This system allows its users to record, track, and monitor medications and certain laboratory information such as BG, blood pressure, weight, cholesterol, and A1C values. Once data are input, comprehensive myVisits reports can be generated, printed, and shared with the patient's health care providers. For more visually oriented patients, custom graphs are available, which provide a great illustration of patient health over time. This site also provides access to a team of health care professionals, including an endocrinologist, registered dietitians, pharmacists, and certified diabetes educators who can provide additional information and suggestions. The site also provides links to money-saving opportunities such as coupons, patient assistance programs, and other cost-saving opportunities that can be used at local pharmacies. Last, My Diabetes Home offers a unique feature called myArticles. Experts have researched the best articles available, and all the information is tailored to fit each patient's specific needs on topics such as fitness tips, blood sugar management ideas, recipe options, and nutrition plans.

A third online management resource is [SugarStats.com](http://SugarStats.com). This site also has links for inputting data (via multiple devices including smartphones) such as medications, blood sugar and A1C readings, foods, and exercise. Information can be shared with providers electronically, or charts, reports, and graphs can be printed.

### Assessment of Diabetes Mellitus: A Case-Based Approach

If a patient describes classic symptoms of diabetes, the health care provider should ask whether a primary care provider has made this diagnosis. If not, screening for diabetes is appropriate. For asymptomatic individuals, ADA recommends that a laboratory-based glucose test be considered to detect type 2 diabetes or prediabetes in individuals who are overweight or obese and have one or more risk factors (e.g., family history, physical in-activity, hypertension, etc.). If normal, patients should be retested every 3 years.<sup>3</sup> Patients with risk factors for diabetes should be considered for testing more frequently and at an earlier age (see Pathophysiology of Diabetes Mellitus). Screening can start with the diabetes risk calculator developed by ADA ([www.diabetes.org/diabetes-basics/prevention/diabetes-risk-test/](http://www.diabetes.org/diabetes-basics/prevention/diabetes-risk-test/)). Individuals with a high risk of prediabetes or diabetes can then be tested for capillary BG (finger stick). High-risk patients identified during screening should be referred to a primary care provider for follow-up.

When working with a patient with newly diagnosed diabetes, the provider should determine all medications and supplements the patient takes, any known drug allergies, any concurrent diseases or infections, and relevant social history (e.g., tobacco use, alcohol use, and insurance coverage). Providers should sensitively assess the patient's beliefs, attitudes, and knowledge about the disease and the effect of diabetes care on the patient's lifestyle. These assessments allow development of a culturally sensitive diabetes education and care plan centered on the patient's expectations and needs. Providers should be prepared to negotiate treatment and adherence strategies, provide information, and answer the patient's questions about diabetes and related conditions. Case 45-1 illustrates assessment of patients with type 2 diabetes mellitus.

For overweight patients with type 2 diabetes, providers should also discuss weight loss (see [Chapter 26](#)). Education should focus on the link between overweight or obesity and type 2 diabetes, as well as the importance of weight loss in helping control the disease. The overall health benefits of weight reduction should also be discussed. Learning that weight loss and consistent physical activity may obviate the need for medications may motivate an individual to lose weight.

#### Case 45-1

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<i>Information Gathering</i>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient presents to the pharmacy with a refill for metformin 500 mg (twice daily) for diabetes. She complains of feeling shaky, lightheaded, and dizzy. These symptoms have worsened over the last 2 hours.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	When asked about recent blood glucose readings, the patient notes she has a meter at home but does not typically check on a regular basis. Last time she checked was 1 week ago in the morning before breakfast and it was 98. She notices that she feels more of these symptoms since also starting glipizide XL 10 mg once daily a few days ago. When you check today in the pharmacy, the reading is 52 mg/dL.
c. description of the patient's efforts to relieve the symptoms	Sitting down helps some but not very much.

d. patient's identity	Sandra Dippel
e. age, sex, height, and weight	77 years old, female, 5 ft 2 in., 105 lb
f. patient's occupation	Retired (former elementary school teacher)
g. patient's dietary habits	Consumes approximately 1600 calories per day and classifies her diet as "pretty normal" where she rarely eats out and tries to cook for herself at home.
h. patient's sleep habits	6 hours (12 am to approximately 6 am)
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Diabetes (type 2): metformin 500 mg twice daily, glipizide XL 10 mg every morning; dyslipidemia: simvastatin 20 mg at bedtime
j. allergies	NKA
k. history of other adverse reactions to medications	NA
l. other (describe) _____	None
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	The patient has type 2 diabetes and is presenting with symptoms of hypoglycemia since recently starting a new medication (glipizide XL 10 mg). According to the patient's age, weight, and blood glucose level that was at goal when self-checking approximately 1 week ago before starting the glipizide, the dose is likely too high and needs to be adjusted. She has other comorbidities (dyslipidemia) that highlight the need for appropriate blood glucose control. Her age, weight, and gender may put her at risk for a fracture from a fall secondary to her symptoms of low blood sugar.
3. Identify exclusions for self-treatment.	Sandra has hypoglycemia signified by her reading at the pharmacy today and symptoms since initiating a new medication. Also, the status of her comorbidity of dyslipidemia is unknown.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Sandra to receive immediate medical treatment. (2) Treat the low blood glucose in the pharmacy, and then recommend follow-up as soon as possible with her PCP. (3) Provide Sandra with instructions to self-treat her low blood sugar on her own, and then encourage a follow-up appointment as soon as possible with her PCP.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Recommend treating the low blood glucose in the pharmacy and then referring for appropriate follow-up with the PCP as soon as possible. <b>Acute plan:</b> Take 15 grams of carbohydrates (e.g. glucose tablets, small glass of a soft drink or juice). Have the patient wait in the pharmacy in an observable place for approximately 15 minutes. At that point, recheck the blood glucose level, and if it is still below 70 mg/dL, have her take an additional 15 grams of carbohydrates. Continue this process until the blood glucose is >70 mg/dL. At that time, if a meal is not planned within the hour, the patient should consume a small snack containing a carbohydrate plus a protein (e.g., crackers and peanut butter). If her blood glucose level is not improving (and/or continues to drop) despite treatment, the pharmacist should call 911. <b>Once resolved:</b> In addition, refer the patient to her PCP for a follow-up. Because Sandra is at risk for hypoglycemia, suggest initiation of self-monitoring of blood glucose. According to ADA guidelines, the evidence for self-testing for patients not on multiple-dose insulin therapy is mixed. However, in this case, self-testing for a period of time until seeing the PCP may be warranted because of the episode of hypoglycemia. Therefore, until Sandra can see her PCP, recommend that she monitor and record her blood glucose level once daily, alternating testing between fasting and 2 hours after the biggest meal of the day. These values can be shared with the PCP. Counsel her on proper use of the blood glucose meter, as well as management and identification of the signs and symptoms of hypoglycemia. At the conclusion of the session, Sandra should demonstrate her understanding of how to test her blood glucose. Stress to Sandra that it is not

	ideal to use another patient's blood glucose meter and supplies.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You are currently experiencing low blood sugar that needs to be treated. I would like you to consume these carbohydrates and sit here in the waiting area so I can observe you over the next 15 minutes. After 15 minutes, I will recheck your blood sugar to see if it is above 70 mg/dL and to determine how you are feeling. If your blood sugar is not above 70 in 15 minutes, I will have you take another dose of carbohydrates. We will repeat that process until your sugar is above 70 mg/dL."
"Now that your blood sugar is at the recommended level, you should follow up with your primary care provider. In the meantime, I recommend that you test your blood sugar once daily (alternating between first thing in the morning before you eat breakfast and 2 hours after your biggest meal of the day). Please record your blood sugar values to share with your PCP during the follow-up visit."	
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"You need to see a primary care provider because of the symptoms you are having and the other conditions you have that may increase your risk for further problems. It is important for your provider to know of these symptoms so that proper adjustments can be made to your medication therapy to achieve the desired goals. In the meantime, it is important that you check your blood sugar regularly. This will help you identify trends in your daily values, and your provider will have more information about your blood sugar levels at your visit."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"Is there anything I can do to prevent this from happening again?"
Answer the patient's or caregiver's questions.	"Yes, it is important that you follow up with your primary care provider as soon as possible to determine the best medications for you that will help control your blood sugar but will not cause it to go too low. In the meantime, I am going to call your PCP to let him or her know what happened and to determine the appropriate immediate steps that need to be taken, such as potentially stopping the glipizide XL medication and checking your blood sugar."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact the patient in a day to ensure she made a follow-up appointment with her PCP, to determine how she is feeling, and to assess her understanding of using a blood glucose monitor.

Key: ADA = American Diabetes Association; NA = not applicable; NKA = no known allergy; PCP = primary care provider.

### Patient Counseling for Diabetes Mellitus

Adhering to healthy eating, regular physical activity, and medication regimens is often a challenge for individuals with diabetes. Providers can assist patients to overcome barriers to adhering to their diabetes therapies while also providing encouragement and counseling on meal planning and physical activity. Each patient encounter is an opportunity for the provider to evaluate and educate patients. A good way to start a conversation and help identify patient knowledge and commitment to self-care is asking simple questions such as the following: "What are your blood glucose readings running these days?" "What was your last A1C value?" If insulin was prescribed, the provider should explain the various diabetes care products, teach the patient how to use the selected products, and review the symptoms and treatment of hyper- and hypoglycemia. Patients should be encouraged to return for reevaluation of injection technique, self-monitoring of their BG, and adherence to a prescribed self-care routine. Moreover, providers should be familiar with new medications and devices, as well as keep abreast of current practice guidelines for the care of people with diabetes. The box Patient Education for Diabetes Mellitus lists specific information to provide patients.

### Patient Education for Diabetes Mellitus

The primary objective of diabetes self-care is to achieve and maintain metabolic control. Secondary benefits of meeting metabolic goals are to (1) prevent or reverse diabetes complications, (2) maintain normal daily activities with maximum lifestyle flexibility, (3) avoid weight gain by following a proper nutrition and physical activity plan, (4) avoid infection, and (5) achieve a sense of well-being. For most patients, carefully following product instructions (including instructions on the proper use of insulin) and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Nondrug Measures

- Recognize that having diabetes requires lifestyle and behavioral changes.
- Consult with your primary care provider, dietitian, nurse, or pharmacist to develop a nutrition plan and physical activity program that suits your lifestyle.
- Learn how to read food labels.
- Involve your entire family in your healthy lifestyle changes.
- Knowledge is power. Know your glucose and other diabetes-related goals (Table 45-2). Learn about your disease and the ways you can take control of your diabetes.
- Where indicated check your BG (blood glucose) regularly and know what makes your glucose concentrations go up and down (e.g., foods, activity, medications, and/or stress).
- Use a logbook to document BG results, diet, physical activity, insulin, or other medication administration changes, and bring it with you to every health care visit.
- To avoid being overwhelmed, set realistic, achievable goals. Make one or two specific changes at a time and recognize your accomplishments.
- If you have a diabetes complication, consult a diabetes specialist. Practice the preventive measures listed in Table 45-1.
- When performing physical activities conscientiously, follow the guidelines in Table 45-3.
- Where indicated monitor your BG several times each day (e.g., before meals, 2 hours after meals, or at bedtime). If a BG reading is greater than 240 mg/dL, check urine ketones. If your values indicate a problem, see your primary care provider for adjustments to your therapy.
- If you use tobacco products, it is strongly advised you quit. A tobacco cessation program, which includes counseling and smoking cessation medications, is highly recommended (see Chapter 47).
- See your primary care provider if you have cuts or bruises that are not healing.

#### Nonprescription and Prescription Medications

- Follow your prescribed medication regimen, including insulin, carefully.
- Inject your insulin at the proper sites, and rotate your injection sites (Figure 45-1).
- Follow the guidelines in Tables 45-6 and 45-7 for preparing and injecting insulin doses.
- Know the signs and symptoms related to low or high BG concentrations as well as appropriate monitoring and management strategies.
- Discuss with your primary care provider taking a low dose of aspirin daily to prevent heart attack and stroke.
- Take your medications as directed by your provider. Do not stop taking any of your medications unless you first discuss it with your provider.
- Do not start taking any nonprescription medications or complementary therapies without first discussing them with your pharmacist or primary care provider. Consult your pharmacist for safe nonprescription medication options to treat self-limiting conditions such as allergies, cough, or upset stomach.
- Read the labels of nonprescription medications to identify sugar and alcohol content. Avoid medications that contain sugar or alcohol.
- Certain cold medications, such as pseudoephedrine, may raise BG concentrations and blood pressure levels. Talk to your provider or pharmacist before selecting any allergy, cough, or cold preparations.
- Talk to your pharmacist about strategies to help you remember to take your medications.

#### When to Seek Medical Attention

- If you use insulin and experience symptoms of hypoglycemia (e.g., sweating, hunger, rapid heartbeat, and/or confusion), hyperglycemia (e.g., frequent urination, dehydration, thirst, and/or increased appetite), or ketoacidosis (e.g., BG greater than 240 mg/dL plus urine ketones and flu-like symptoms, confusion, and/or stupor), contact your primary care provider.

#### Evaluation of Patient Outcomes for Diabetes Mellitus

ADA recommends specific therapeutic goals for people with diabetes (Table 45-2). If the patient is not achieving these outcomes, adherence to the care plan should be assessed. Nonadherent patients should be reevaluated and, if necessary, reeducated about the need for and benefits of the care plan. If nonadherence is not the problem, medical referral is appropriate. In addition, weight management should be closely monitored in patients with type 2 diabetes.

#### Key Points for Diabetes Mellitus

- Early detection; extensive patient education; and early, aggressive glycemic control through MNT, physical activity, and pharmacologic therapy can prevent the development and progression of the long-term complications, morbidity, and mortality associated with diabetes.
- Familiarity with the most current standards for diabetes screening and management is imperative to reducing and eliminating health disparities associated with diabetes risk, outcomes, morbidity, and mortality, and to improving care for all patients with diabetes.
- Patients should be educated about diabetes, the role of BG control in the prevention of long-term complications, self-care strategies (including SMBG and MNT), and pharmacologic therapy.
- Providers should be familiar with and assist patients in selecting BG monitors and related supplies.

- Patients using insulin therapy should be educated about insulin and related supplies, proper injection site and technique, insulin storage, and potential adverse events and their management.
- Providers and patients should negotiate adherence strategies tailored to patient-specific factors such as, but not limited to, food and activity preferences; sleep, mealtime, and work schedules; insurance status; and income.
- Patients with diabetes should be educated about the safety and efficacy of nonprescription medications for self-care of limited acute conditions and about complementary and alternative medicines.

## Asthma

Asthma remains one of the most common chronic health conditions in the United States. The most recent statistics describing asthma prevalence suggest that almost 26 million people in the United States had this condition in 2010. This includes approximately 7 million children younger than 18 years and almost 19 million adults. Of patients diagnosed with asthma, just over half have had at least one asthmatic attack on an annual basis (55.8% in 2001, 51.9% in 2009). Hospital outpatient department visits per 100 persons with asthma have ranged from a low of 4.8 (2006, 2009) to a high of 7.6 (2003), with a slight downward trend from 2008 to 2009. Emergency department visits per 100 persons with asthma ranged from 7 (2006) to 9.5 (2002) with the rate holding steady for the last 2 years of the survey (2008 and 2009; 8.2 and 8.4, respectively). For all the preceding parameters, those in the age group of 4 years and younger had the highest incidence. The overall death rate has decreased from 2.1 per 10,000 persons with asthma in 2003 to 1.4 in 2009. Asthma more negatively affects some subsets of the population. Data for 2009 for hospital outpatient department visits for blacks were twice the rate for whites, while the rate for the Hispanic or Latino population was similar to whites. The rate of physician office visits for blacks and Hispanics/Latinos was 50% more than for whites and blacks, and Hispanic/Latinos had at least twice the rate of emergency department visits compared with whites. Blacks with asthma were twice as likely to die compared with whites or Hispanics and Latinos.<sup>12</sup> In addition to the factors mentioned above, the following groups tend to have a higher incidence of asthma: children (boys in particular), adult women, Puerto Ricans, residents in the northeast corridor of the United States, those living in poverty, and people exposed to certain chemicals in the workplace.<sup>13</sup>

## Pathophysiology of Asthma

The exact etiology of asthma is unknown.<sup>14</sup> Potential causes or risks for developing asthma include positive family history, concurrent atopy (increased production of immunoglobulin E, or IgE, after allergen exposure), smoking or exposure to secondhand smoke, higher body mass index, and severe viral respiratory infections during the first 3 years of life. Once asthma develops, various stimuli (often called "triggers"; Table 45-8) can precipitate asthma symptoms. Not all patients with asthma have the same triggers, and the response of an individual to a particular trigger can change over time.

Although bronchoconstriction may be responsible for some acute asthma symptoms, inflammation is largely responsible for severe and persistent asthma symptoms.<sup>15</sup> Once exposed to a trigger, an immediate or early asthmatic response occurs within minutes. The mechanism of this response includes degranulation of mast cells to release histamine and leukotrienes, which causes bronchoconstriction. As the airways narrow, the peak expiratory flow (PEF) decreases and may result in wheezing, chest tightness, cough, and shortness of breath.

A significant number of patients with asthma also have reflux, yet the specific relationship between gastroesophageal reflux disease (GERD) and asthma or worsening asthma is still not completely clear.<sup>16</sup> Initial studies demonstrated that proton pump inhibitor therapy may improve symptoms and pulmonary function in some patients with GERD and asthma,<sup>17</sup> but some newer data show proton pump inhibitors offer little to no benefit.<sup>18</sup>

Although some asthma patients insist that certain foods make them wheeze or experience shortness of breath, confirmed asthmatic reactions to food are uncommon.<sup>19</sup> Even when the trigger is known, prospective identification and avoidance of foods containing these compounds can be challenging. Questionnaires to help identify these triggers are available (see Nonpharmacologic Therapy and Table 45-9).

**TABLE 45-8 Examples of Asthma Triggers**

<i>Environmental</i>	<i>Drugs or Chemicals</i>	<i>Conditions or Events</i>
Animals (e.g., cats, dogs, rodents)	Aspirin	Allergic rhinitis
Cockroaches	Beta-adrenergic blockers	Emotional stress, excitement
Cold air	Food or drug preservatives (e.g., metabisulfite)	Exercise
House dust mites	Household cleaning agents	GERD
Indoor irritants (e.g., wood-burning stoves)	NSAIDs	Menstruation, pregnancy
Outdoor air pollution (e.g., vehicle emissions, sulfur dioxide, ozone, nitrogen oxides)	Occupational exposure to dust, chemicals, irritants	Panic attacks
Indoor or outdoor molds and fungi	Perfumes	Viral respiratory infections
Pollen (e.g., grass, weeds, trees)		
Tobacco smoke		
Food allergies (such as seafood, shellfish)		

Key: GERD = Gastroesophageal reflux disease; NSAID = nonsteroidal anti-inflammatory drug.

### Clinical Presentation of Asthma

Key features of asthma are recurrent bouts of wheezing, shortness of breath, chest tightness, and cough, especially at night and in the early morning hours. Asthma symptoms vary in duration, severity, and frequency. Exacerbation severity is assessed based on symptom severity. Patients with asthma need to monitor for worsening control and try to identify the onset of acute asthma exacerbations. A drop in PEF can be the first sign of an impending exacerbation and may precede the onset of significant symptoms.

Other conditions may present with asthma-like symptoms (Table 45-10). In assessing someone who presents with shortness of breath, inquiring about a prior diagnosis of asthma, tobacco use, and onset and duration of symptoms is important. If the individual does not have a prior diagnosis of asthma or if the symptoms are different or more severe than usual, a medical referral is necessary for further evaluation (Table 45-11). Symptoms usually respond to medications; however, severe asthma exacerbations may require emergent care and systemic corticosteroids. Even patients with mild asthma can develop life-threatening exacerbations.

**TABLE 45-9 Example of a Trigger Screen Tool<sup>a</sup>**

<i>Thinking about how you have felt in the past month, please answer the following questions:</i>
• Do you ever have problems with wheezing or catching your breath when exposed to cold air?
• Do you wheeze when dusting, vacuuming, or using cleaning solvents in the home?
• Do you wheeze, cough, or sneeze, or become short of breath when around household pets such as cats or dogs?
• Do you have problems breathing when exposed to high levels of stress or excitement?
• Have you ever noticed wheezing or worsening shortness of breath before or during your menstrual period?
• Have you ever had a reaction such as shortness of breath, or swollen throat, lips, or tongue after you took medications such as aspirin or ibuprofen?
• Do you have breathing problems after eating shellfish, peanuts, or any other foods?
• Do you have breathing problems when exposed to latex (e.g., rubber gloves or balloons)?
• Does it take you a long time to get over a viral cold?
• Do you have chronic heartburn?
• Do you have problems breathing at work yet are fine during holidays or weekends spent at home?
• Does anyone else at work appear to have similar symptoms?
• Do you typically have a runny nose and watery eyes and experience repetitive sneezing during outdoor activities?
• Are these symptoms worse during: Early spring? Late spring? Late summer to fall? Summer and fall?
• Do you experience shortness of breath during or after exercise?
<i>If you answered yes to any of the above questions, please show this questionnaire to your primary care provider.</i>

<sup>a</sup> See Chapter 11 for more information on allergies and their triggers.

**TABLE 45-10 Comparison of Selected Conditions That May Present with Respiratory Symptoms**

	<i>Asthma</i>	<i>COPD</i>	<i>Respiratory Infection</i>	<i>Heart Failure</i>
Signs	Decreased PEF Increased heart rate Increased respiratory rate	Progressive decline in PEF and FEV <sub>1</sub> Polycythemia Signs of right heart failure Pulmonary hypertension Decreased oxygen saturation Pursed lip breathing Increased heart rate Increased respiratory rate	Increased heart rate Increased respiratory rate Fever Increased white blood cell count	Ejection fraction <40% Lower-extremity edema, S <sub>3</sub> heart sound Positive hepatojugular reflex Jugular venous distension
Symptoms	Wheezing Cough Chest tightness	Progressive dyspnea on exertion Productive cough Wheezing	Productive cough Nasal congestion Rhinitis	Dyspnea on exertion Orthopnea

Onset	Often occurs in childhood, but can develop in adults	Usually the fourth or fifth decade of life Progressive; symptoms develop over years	Any age Symptoms acute, sudden	Older adults
Etiology	Often atopy	Most commonly tobacco smoking	Viruses Bacteria	Hypertension Coronary artery disease
Exacerbating factors	Trigger exposure	Continued smoking		Heavy salt intake Myocardial infarction Nonadherence with medications

Key: COPD = Chronic obstructive pulmonary disease; FEV<sub>1</sub> = forced expiratory volume at 1 second; PEF = peak expiratory flow.

**TABLE 45-11 Comparison of Indications for Self-Treatment with Nonprescription Medications versus Medical Care for Asthma**

<p><b>Self-treatment <i>may</i> be appropriate when:</b></p> <ul style="list-style-type: none"> <li>• The current symptoms are mild, intermittent (less than twice weekly), and of short duration (e.g., &lt;24 hours) OR</li> <li>• A prior diagnosis of intermittent asthma has been made by a primary care provider AND</li> <li>• The individual knows the warning symptoms indicating the need for urgent medical care AND</li> <li>• The individual does not have any other serious concurrent diseases that might impair oxygenation or breathing (e.g., COPD, coronary artery disease) AND</li> <li>• The individual is 5 years of age or older and not pregnant AND</li> <li>• The current asthma symptoms are consistent with previous symptoms AND</li> <li>• The nonprescription medications are for short-term (&lt;24 hours) treatment of mild symptoms until the individual can be seen by a primary care provider</li> </ul>	<p><b>Referral for medical care <i>should</i> be made when:</b></p> <ul style="list-style-type: none"> <li>• The symptoms are of moderate severity (e.g., affect activities or sleep) or are more frequent than twice weekly OR</li> <li>• The symptoms have lasted more than 24 hours OR</li> <li>• The symptoms do not respond to nonprescription asthma medications within 24 hours OR</li> <li>• The symptoms differ in quality or severity from those in previous episodes OR</li> <li>• Signs or symptoms of a respiratory or sinus infection are also present (e.g., fever or purulent nasal discharge) OR</li> <li>• The individual does not have a previous diagnosis of asthma OR</li> <li>• The individual has a concurrent condition with symptoms (e.g., cough, wheeze, or shortness of breath) that may be similar to asthma (e.g., heart failure, chronic obstructive pulmonary disease, or vocal cord dysfunction) OR</li> <li>• The individual has a history of asthma episodes severe enough to require systemic corticosteroids or urgent medical care OR</li> <li>• The individual is taking (or nonadherent to) other prescription long-term controller medications for asthma OR</li> <li>• The individual does not have an asthma care provider or has not seen the asthma care provider in the last year OR</li> <li>• The individual is pregnant or a child younger than 5 years of age OR</li> <li>• The individual perceives that the prescription medications are not effective</li> </ul>
--	--

Key: COPD = Chronic obstructive pulmonary disease.

### Treatment of Asthma

Ideally, most treatment for asthma should be in the ambulatory setting and should focus on preventing symptoms rather than treating asthma exacerbations. Patients with asthma need to know how to take their medications, monitor for worsening symptoms, manage environmental triggers, and recognize when to seek medical care. Developing an optimal, comprehensive, and individualized asthma care plan requires a partnership between individuals with asthma and their primary care providers. Therefore, self-care is a critical part of management. However, isolated self-treatment of asthma-like symptoms is potentially dangerous because other serious conditions, such as heart failure, can cause similar symptoms. In addition, mild asthma symptoms may escalate into serious exacerbations if inadequately treated.

#### Treatment Goals

Optimal asthma management and therapy imply that *all* goals are met, which include the following:

- Achieving and maintaining control of symptoms; one tool to assess symptom control is the Asthma Control Test, a series of five questions patients with asthma should answer prior to each visit to a health care provider and take to each visit to help with therapy assessment and response.<sup>20</sup>
- Having normal activity levels
- Infrequently using an inhaled short-acting beta<sub>2</sub>-agonist (less than twice per week)
- Maintaining pulmonary function as close to normal as possible (PEF ≥ 80% of personal best)
- Preventing recurrent exacerbations and the need for urgent care visits
- Providing optimal pharmacologic therapy with minimal or no adverse effects
- Meeting the patient's and his or her family's expectations of asthma care<sup>21</sup>

Even relatively mild-moderate asthma symptoms can significantly impair quality of life. Because most symptoms are readily responsive to medications, the patient needs to understand that frequent symptoms (even mild ones) can and should be prevented. Patients with asthma also need to be confident that they can successfully prevent escalation of symptoms into significant asthma exacerbations. Most patients realize that severe symptoms requiring the need for urgent medical care represent uncontrolled asthma. All these issues should be addressed in a self-management asthma action plan.

#### General Treatment Approach

Asthma medications are categorized into two groups. Quick-relief medications are used as needed to treat symptoms. Long-term control medications are used daily to prevent symptoms. Inhaled medications have fewer adverse reactions compared with systemic medications. However, the effectiveness of inhaled medications is severely limited when poor device technique decreases drug delivery to the lungs. A detailed discussion of the therapeutic options and rationale for the treatment of asthma in adults and children can be found in the guidelines from the National Asthma Education Prevention Program<sup>21</sup> and the Global Initiative for Asthma.<sup>14</sup>

A comprehensive, individualized *asthma self-care plan* includes when to use long-term control medications and quick-relief medications, how to use asthma devices to optimally deliver medications, how to avoid and minimize effects of asthma triggers, how to prevent the escalation of asthma symptoms into exacerbations, and how to recognize warning signs that require emergent medical treatment. Specific recommendations are provided for when to use quick-relief medications (e.g., prior to exposure to known triggers) and how much to use (e.g., “x” number of puffs every “y” hours). [Figure 45-3](#) is an example of a symptom-based asthma self-care plan. Some self-care plans include recommendations based on the patient’s personal best PEF.

Another issue to consider related to asthma treatment is the cost of care. For some individuals, physician office and prescription co-payments are much less than the cost for self-care options. However, for others with little or no insurance, the only options would be nonprescription products and emergency care, with little or no emphasis on preventive care. Determining the significance of health care costs early in the patient assessment process is recommended.

#### Nonpharmacologic Therapy

Because exposure to triggers can lead to worsening asthma symptoms and because each patient’s asthma triggers are different, a comprehensive, individualized trigger management plan should be developed. Once triggers are identified, suggestions are incorporated into the self-care plan to minimize exposure to triggers at home, work, or school. Specific triggers that occur frequently and require further attention include allergy symptoms, exposure to medications that may exacerbate asthma symptoms, and exposure to tobacco smoke. Proper management of allergy symptoms may improve upper-airway hyperreactivity and asthma symptoms. Labels on first-generation antihistamines (e.g., diphenhydramine) caution persons with asthma against using these agents because of concern that the anticholinergic properties may thicken mucus and decrease mucociliary clearance. These effects are generally minor and are outweighed by the benefits of treating allergic rhinitis in asthma patients. The second-generation antihistamines (e.g., loratadine, cetirizine, and fexofenadine) have little to no anticholinergic properties and do not carry this labeling precaution.

Because certain medications can worsen symptoms, patients with asthma should be cautious about the use of aspirin and nonprescription nonsteroidal anti-inflammatory drugs (NSAIDs) used to treat fever, pain, or inflammation. These medications pose an increased risk of aspirin sensitivity (see [Chapters 5](#) and [6](#)). Symptoms of aspirin sensitivity can be severe and life-threatening and may include itchy or watery eyes, itchy rashes, rashes around the mouth, nasal congestion, hives, worsening asthma, cough or wheezing, and anaphylaxis.<sup>22</sup> Significant potential for cross-sensitivity exists with NSAIDs such as ibuprofen and naproxen. Someone with aspirin sensitivity can usually tolerate acetaminophen. Patients sensitive to aspirin should be cautioned to check the labels of analgesic and antipyretic medications before use to see if they contain NSAIDs. Aspirin-sensitive patients should also be cautioned to avoid other agents that contain salicylates such as oil of wintergreen and bismuth subsalicylate.

Finally, patients with asthma and their family members should be urged not to smoke because tobacco smoke may trigger an asthma exacerbation. Mothers who smoke during pregnancy increase their children’s risk of acquiring asthma.<sup>23</sup> Children exposed to secondhand tobacco smoke are more likely to develop asthma and have poorer asthma control. Providers should educate all patients who use tobacco products about options for cessation (see [Chapter 47](#)). The commercially available forms of nicotine replacement therapy may be effective as part of a comprehensive tobacco cessation plan. However, the prescription nicotine nasal spray and inhaler are not recommended for people with asthma because nicotine could irritate the airways and trigger an exacerbation.

### ASTHMA ACTION PLAN

St. Louis Regional **Asthma Consortium**  
Sponsored by the American Lung Association of Eastern Missouri

Name: \_\_\_\_\_  
 Provider: \_\_\_\_\_  
 Date: \_\_\_\_\_  
 Phone for doctor or clinic: \_\_\_\_\_  
 After office hours call: \_\_\_\_\_

#### GREEN ZONE

**YOU'RE OK! TAKE ALL OF THESE MEDICATIONS EVERY DAY!**

Medicine	How much to take	When to take it
_____	_____	_____
_____	_____	_____
_____	_____	_____

20 minutes before physical activity, use this medicine: \_\_\_\_\_

- Breathing is good
- No cough or wheeze
- Can work and play

#### YELLOW ZONE

**CAUTION! TAKE 2 PUFFS (OR 1 NEBULIZER TREATMENT) OF YOUR QUICK RELIEVER MEDICINE NOW: \_\_\_\_\_ YOU MAY REPEAT THIS EVERY 20 MINUTES FOR 2 MORE TIMES. IF YOU ARE NO BETTER CALL YOUR DOCTOR IMMEDIATELY AT \_\_\_\_\_ !**

- You are feeling sick or it's harder to breathe

Medicine	How much to take	When to take it
 Cough	 Wheeze	 Tight chest
_____	_____	_____
_____	_____	_____

Wake up at night 

#### RED ZONE

**DANGER! TAKE 4 MORE PUFFS (OR 1 NEBULIZER TREATMENT) OF YOUR QUICK RELIEVER MEDICINE NOW. CALL 9-1-1 OR GO DIRECTLY TO THE NEAREST HOSPITAL!**

- Medicine is not helping
- Breathing is hard and fast
- Nose opens wide
- Can't walk or talk well
- Ribs show

**TABLE 45-12 Medications Included in Nonprescription Products for the Treatment of Asthma**

Drug	Mechanism	Dosage and Administration			Safety Considerations	
Racipinephrine (e.g., Asthmanefrin) nebulizer solution	Bronchodilator	Adults and children 4 years and older 2.25% racipinephrine HCl. For use in an atomizer (EZ Breathe Atomizer). Add contents of one vial (0.5 mL) of solution to atomizer. Adults and children ≥ 4 years of age: 1-3 inhalations. Do not use more than every 3 hours and not more than 12 inhalations in 24 hours.			Relative contraindications include pregnancy, hyperthyroidism, hypertension, heart disease, use of other medications (prescription, nonprescription, or herbal therapy). Do not use this product if it is brown in color or cloudy.	
Ephedrine/guaifenesin combination products	Bronchodilator + expectorant	Bronkaid Dual Action Formula	Ephedrine 25 mg	Guaifenesin 400 mg	1 tablet every 4 hours as needed; do not exceed 6 tablets per day. Do not use in children < 12 years old.	Ephedrine side effects include palpitations, tachycardia, arrhythmias, seizures, hypokalemia, angina, hyperglycemia, hypotension, and hypertension.
		Primatene Tablets	Ephedrine 12.5 mg	Guaifenesin 200 mg	1-2 tablets every 4 hours as needed; do not exceed 12 tablets per	Guaifenesin: Case reports have linked nephrolithiasis to

					day. Do not use in children < 12 years old.	guaifenesin alone and in combination with ephedrine.
		Dynafed Asthma Relief Tablets	Ephedrine 25 mg	Guaifenesin 200 mg	1/2-1 tablet every 4 hours as needed; do not exceed 6 tablets per day.	
		Mini Two Way Action Asthma Relief Tablets	Ephedrine 25 mg	Guaifenesin 200 mg	1/2-1 tablet every 4 hours as needed; do not exceed 6 tablets per day.	

Source: References 24-27.

#### Closed Mouth Technique

- Step 1
  - Remove dust cap from inhaler.
  - Attach inhaler to spacer/holding chamber if you have one.
  - Shake the inhaler well, as shown in drawing A.

A

- Step 2
  - Blow out all the air in your lungs (see drawing B).

B

- Step 3
  - Seal lips tightly around the mouthpiece.
  - Press down on the inhaler to release medicine as you breathe in slowly until your lungs are full.
  - If using a spacer/holding chamber press down on the inhaler and then wait 5 seconds before breathing in (see drawing C).

C

- Step 4
  - Hold your breath for 10 seconds to allow medicine to reach deeply into your lungs (see drawing D).

D

- Step 5
  - Blow out the air in your lungs (see drawing E).

E

#### Open Mouth Technique

- Step 1
  - Take off the cap.
  - Shake the inhaler (see drawing F).

F

- Step 2
  - Stand up and tilt head back a little (see drawing G).

G

- Step 3
  - Place your hand between your mouth and the inhaler. This will help measure how far away the inhaler should be from your mouth (see drawing H).

H

- Step 4
  - Take a cleansing breath, in and out.

I

- Step 5
  - Open your mouth wide.
  - Start to breathe in slowly.
  - Push down on the medicine and continue to breathe in (see drawing I).

- Step 6
  - Hold your breath.
  - Count to 10 and then breathe out.

- Step 7
  - If asthma care plan instructs you to use 2 puffs, wait 15–30 seconds and repeat steps 1–6.

Guidelines for using a metered-dose inhaler.

#### Pharmacologic Therapy

Few nonprescription medications are available to manage asthma (Table 45-12).<sup>24-27</sup> Patients who are started on a metered-dose inhaler (MDI) should receive counseling for proper technique (Figure 45-4). Nonprescription medications are generally indicated only for mild infrequent symptoms. Patients who have more frequent or serious symptoms should be referred to a primary care provider so a long-term controller medication can be prescribed. Figure 45-5 lists additional exclusions for self-care. All patients with asthma should be followed closely by a primary care provider.

The pharmacist should review with the patient the lifestyle modifications listed in the Nonpharmacologic Therapy section. The importance of these measures in controlling asthma-related symptoms and complications should be discussed.

Self-care of asthma. Key: ADR = Adverse drug reaction; AR = allergic rhinitis; CAM = complementary and alternative medicine; COPD = chronic obstructive pulmonary disease; GERD = gastroesophageal reflux disease; OTC = over-the-counter; Rx = prescription; S/S = signs and symptoms.

### Bronchodilators

Two nonselective beta-agonists, epinephrine and ephedrine, are available without a prescription (Table 45-12). Sales of ephedrine fall under the Combat Methamphetamine Epidemic Act of 2005 and therefore have purchase restrictions, such as quantity limits, placement where customers do not have direct access, and required proof of identification. Because nonselective beta-agonists also act on alpha-receptors, they can constrict blood vessels and increase blood pressure, potentially causing arrhythmias, nervousness, and palpitations. Generally, nonprescription beta-agonists have a shorter duration of action requiring more frequent administration, and they have a greater potential for side effects and abuse compared with prescription beta-agonist medications. Asthmanefrin, introduced fall 2012, is a racemic epinephrine solution for inhalation available over the counter. Primatene Mist was removed from the market in 2011 because of concerns about chlorofluorocarbons and the environment. According to the package labeling, Asthmanefrin is indicated "for temporary relief of shortness of breath, tightness of chest, and wheezing due to bronchial asthma." Dosing recommendations are provided for individuals 4 years of age and older, with 1-3 inhalations every 3 hours up to a maximum of 12 inhalations in 24 hours. The medication is available as a 2.25% solution in 0.5 mL, 5 vials in foil pouches. The manufacturer, Nephron Pharmaceuticals Corporation, offers two packages: a starter kit that includes the EZ Breathe Atomizer and 10 vials of medication, and the refill package that includes 30 vials of medication.<sup>27</sup> In September 2013, FDA warned Nephron Pharmaceuticals Corporation that aerosolized Asthmanefrin is an unapproved new drug and that the claim as an alternative to Primatene Mist CFC Inhaler is false or misleading.<sup>28</sup> On September 30, 2013, FDA warned patients and health care professionals about safety concerns with Asthmanefrin.<sup>29</sup> Adverse events reported to FDA in the past year include chest pain, nausea and vomiting, increased blood pressure, increased heart rate, and hemoptysis.

### Combination Bronchodilator Products

Compared with inhaled medications, nonprescription oral products (Table 45-12) have a greater potential for side effects because of their systemic absorption. An expectorant, guaifenesin, is often included in combination products, but its efficacy in asthma has not been shown (see Chapter 12). Guaifenesin has no bronchodilatory effects but is marketed to assist with loosening phlegm and thinning bronchial secretions (to increase cough productivity), although efficacy has not been established.

### Influenza Vaccine

All patients with asthma who are 6 months of age and older should receive an influenza vaccination yearly.<sup>21</sup> In addition to the traditional influenza vaccine, FDA approved two new versions of influenza vaccines at the end of 2012/early 2013. One product, Flublok, indicated for patients ages 18-49, is manufactured using an insect virus expression system in combination with recombinant DNA technology. The second product, Flucelvax, indicated for patients ages 18 years and older, is manufactured using the familiar cell culture technology; however, animal cells are used rather than the traditional fertilized chicken egg model. Both manufacturing processes allow quick production cycles in case of a pandemic.<sup>30,31</sup>

The live intranasal influenza vaccine, FluMist, is not recommended for patients with a history of asthma or reactive airways disease and should not be administered to children younger than 5 years with recurrent wheezing because of the risk of wheezing after vaccination.<sup>32</sup>

Pneumococcal Polysaccharide Vaccine, Polyvalent (Ppsv23)

The Advisory Committee on Immunization Practices recommends pneumonia vaccination for all patients with asthma between ages 19 to 64 years. A second pneumococcal dose is recommended for those 65 years and older, and for those who received their first dose when they were younger than 65 and 5 or more years have expired since the first dose.<sup>33</sup>

Product Selection Guidelines

### Special Population Considerations

**Persons of Advanced Age.** Older patients with asthma should be strongly cautioned against self-treating with nonprescription asthma medications because of the risk of cardiovascular adverse effects with these products. Elderly persons with a new-onset breathing problem should be referred to their primary care provider to rule out other causes of shortness of breath that mimic asthma, such as congestive heart failure, pneumonia, and chronic obstructive pulmonary disease (COPD) (Table 45-10). Dexterity issues (e.g., secondary to arthritis) may make using asthma devices correctly difficult for elderly people.

**Pregnant Patients.** Pregnant women with asthma should be urged not to use nonprescription asthma medications without the knowledge of their primary care provider. Poorly controlled asthma can worsen outcomes of the pregnancy. Ephedrine and epinephrine are both Pregnancy Category C drugs that stimulate alpha- and beta-adrenergic receptors.<sup>34</sup> Inhaled prescription bronchodilators (e.g., albuterol)<sup>35</sup> are preferred, because localized delivery and selective beta2-adrenergic activity limit fetal drug exposure.

**Pediatric Patients.** Children with wheezing or a chronic cough but without a diagnosis of asthma should be referred to rule out other causes. Providers caring for school-age children should know local laws that may allow children to carry and administer asthma medications at school. Children should be encouraged to carry their quick-relief medications so they can promptly respond to asthma symptoms and minimize asthma exacerbations when away from home. Written permission from the parents and provider may be required. The school nurse should also have a copy of the child's asthma self-care plan, enabling the nurse to respond appropriately to acute asthma exacerbations that develop at school. Student athletes should check with school administrators before self-administering nonprescription asthma medications. The National Collegiate Athletic Association does not permit the use of ephedrine,<sup>36</sup> and Olympic athletes are not permitted to use stimulants.

### Patient Preferences

Inhaled delivery systems are generally preferred to minimize systemic absorption and side effects such as increased heart rate, anxiety, and tremor. Administering medication by MDI is usually less expensive than using a nebulizer and does not require special equipment.

Complementary Therapies

Although not well studied, complementary and alternative medicine (CAM) therapy use among asthma patients is relatively common. The 2006-08 Asthma Call-back Survey solicited information from parents of 5435 children with asthma to determine CAM use. Almost 27% used some form of CAM, including herbal products, vitamins, and breathing techniques (the most popular). Children with financial issues to more traditional therapies and those with poorly controlled asthma were most likely to use CAM.<sup>37</sup> Data from an Asthma Call-back Survey, part of the 2006 Behavioral Risk Factor Surveillance System, analyzed CAM use in adults. Findings suggested approximately 40% of adults stated they used some form of CAM, including vitamins, herbs, homeopathy, aromatherapy, and nonsystemic interventions such as breathing techniques, acupuncture, acupressure, yoga, and reflexology. Those more likely to use CAM were female, were nonwhite, had lower annual incomes, had an emergency room visit for asthma care, and had more disability days related to their asthma.<sup>38</sup>

For an in-depth discussion of natural products as it may relate to patients with asthma, see Chapter 51.

### Assessment of Asthma: A Case-Based Approach

To correctly assess whether a patient's breathing problems meet criteria for self-treatment (Table 45-11), the provider needs to gather information from the patient regarding signs, symptoms, and duration of the problem. Other disease states with signs and symptoms similar to asthma should be ruled out (Table 45-10). The provider should also inquire about the patient's current use of prescription and nonprescription medications, CAM therapies, and dietary habits before recommending a nonprescription agent for asthma.

### Patient Counseling for Asthma

Educating patients with asthma is extremely important. Even people with mild asthma can have exacerbations; therefore, all patients with asthma must know how to self-monitor and recognize asthma symptoms, and what action to take if they have symptoms that do not respond to quick-relief medications. Health care providers should assess each patient's readiness to learn about asthma, assist the patient in identifying individualized goals, and identify and correct any misconceptions about asthma or medications. Concerns or fears about asthma or asthma medications should be elicited and addressed.

Peak Flow Meters

The airflow and the relative diameter of the larger airways can be assessed by the forced expiratory volume at 1 second (FEV<sub>1</sub>) and the PEF. FEV<sub>1</sub> measures the amount of air expired in the first second as the subject forcefully exhales from a maximum inspiration. The PEF is

the maximum flow at the outset of forced expiration. PEF meters are handheld devices, available by prescription or over the counter.<sup>39</sup> These meters are relatively inexpensive and portable, which makes PEF monitoring suitable for home assessment of asthma. Guidelines for use are included in Figure 45-6. Home monitoring of PEF is recommended for patients who have moderate-severe persistent asthma, a history of a severe exacerbation, an unexplained response to environmental or occupational exposures, and for those who may not correctly perceive airflow obstruction and worsening symptoms.<sup>21</sup>

■ Step 1

- Get your peak flow meter, a pencil, and your asthma care plan ready.

■ Step 2

- Some peak flow meters have a mouthpiece.
- Put the mouthpiece on the meter, as shown in drawing A.

A

■ Step 3

- Move the indicator to the bottom of the numbered scale to set the meter to zero. See drawing B.

B

■ Step 4

- Stand up.
- Keep the meter upright so the numbers run up and down.
- Do not cover the hole in the back of the meter or the numbers in the front with your fingers. (See finger positions in drawing C.)
- Take a deep breath, filling your lungs completely.

C

■ Step 5

- Place the mouthpiece in your mouth and close your lips tightly around it, as shown in drawing D.
- Do not put your tongue inside the hole or your teeth on the mouthpiece.
- Blow out as hard and as fast as you can in a single blow.

D

■ Step 6

- Find your number on the scale.
- The button will go up and stay at the number you blew (see drawing E).

E

■ Step 7

- Repeat steps 1–6 two more times.
- Record the best of the three blows in your asthma diary.
- Check your asthma care plan for further instructions regarding the number you blew (the red, yellow, and green zones).

Guidelines for using peak expiratory flow meters.

Predicted values for PEF and FEV<sub>1</sub> are determined in part by the individual's age, gender, and height. A value greater than 80% of the predicted value is considered within normal limits. However, significant individual variation exists based on body type and ethnic background. Therefore, "personal best" PEF is recommended for use in asthma self-care plans.<sup>21</sup> The personal best PEF is the highest value achieved by the patient over a 2-week period of monitoring when the patient is well. To determine the PEF, patients check their PEF twice daily, once in the morning and again in the late afternoon or early evening hours, 15-20 minutes after using the quick-relief inhaler.<sup>21</sup> For routine home monitoring, patients check their PEF daily in the morning when they first wake up and before taking their asthma medication.

Many patients with moderate-severe persistent asthma should monitor PEF daily as part of their asthma self-care plan. The green, yellow, and red zone method discussed in the section Asthma Self-Care Plans is often used. The green zone is a PEF reading of at least 80% of the predicted or personal best value, the yellow zone is 50%-79%, and the red zone is less than 50%. Readings are recorded in a diary that is brought to each primary care visit. A decrease in the PEF may precede symptoms of a significant asthma exacerbation; this is why having a self-care plan is critical.

### Valved Holding Chambers and Spacers

One of the challenges of using inhaled medications is ensuring optimal delivery of the active drug to the desired site of action, in this case the lungs. Technique with traditional press-and-breathe MDIs is often less than ideal, resulting in medication being sprayed in the mouth, back of the throat, and even the nose. To better ensure drug delivery to the lungs, patients are encouraged to use a valved holding chamber (VHC) with their inhaler. This chamber attaches to the inhaler and allows the user to actuate the inhaler, placing a dose of medicine in the chamber that is then inhaled into the lungs. The VHC has a valve that keeps the medication in the chamber until the patient inhales it through the mouthpiece (which is different from a spacer that only creates additional space between the inhaler and the patient's mouth). Holding chambers also come with different sized masks that fit over a patient's mouth and nose; these are very useful for younger patients. Anyone using an MDI should use a VHC to help ensure optimal medication delivery to the lungs.

### Asthma Self-Care Plans

Patients who have moderate-severe persistent asthma or a history of a severe exacerbation should have an asthma self-care plan (Figure 45-3), which provides guidance for symptom treatment and when to seek immediate medical attention. Self-care plans are developed with a health care provider and encourage communication and partnership between individuals and their providers. The self-care plan should be concise and easily understandable and empower patients to take charge of their asthma.

Self-care plans allow patients to make decisions regarding when to seek medical care. Typically, self-care plans are divided into several sections based on the PEF zones. Green-zone plans focus on what to do when the patient feels well and has normal lung function. Green-zone directions encourage adherence with long-term controller medications. Yellow-zone directions provide guidance when PEF readings are in the 50%-80% range of one's personal best, or when symptoms begin or persist. The red-zone section details management of an episode that is severe (e.g., when PEF is <50% of one's personal best) or does not improve with initial treatment. Copies of self-care plans should be given to school nurses, teachers, and day care personnel to ensure prompt treatment of asthma episodes that occur when

children are away from the home.

### Nonadherence to Prescription Asthma Medications

Adherence rates with asthma medications are inconsistent and dependent on the type of medication and method of determination.<sup>40</sup> Inhalers are the mainstay of therapy, but some people may feel they are somewhat bulky to carry. Nonadherence to long-term control medications is a significant problem, often because the benefits are not immediate. Adherence can usually be improved if the person (1) accepts the diagnosis of asthma, (2) believes that asthma may be dangerous or is a problem, (3) believes that he or she is at risk for more serious breathing or health problems, (4) believes that the treatment is safe, (5) feels in control, and (6) feels that communication with the primary care provider is good. Therefore, education regarding asthma and asthma medications can improve adherence with medications and self-care plans.

The box Patient Education for Asthma offers specific information to provide patients.

### Evaluation of Patient Outcomes for Asthma

Acute asthma symptoms should respond to inhaled bronchodilators quickly (within 1 hour). Medical attention should be sought if symptoms worsen or keep returning for longer than 24–48 hours, or if PEF readings remain in the yellow zone for 2 or more days. If any symptoms of severe asthma exacerbations or imminent respiratory arrest develop, immediate medical attention should be sought. Patients with persistent asthma should be scheduled for follow-up appointments at least every 6 months with their health care provider to assess the adequacy of their self-care plan and achievement of their goals (Table 45-13). Patients with asthma-like symptoms who are not candidates for self-care should be referred to their health care providers (Table 45-11).

### Key Points for Asthma

- Candidates for self-care of asthma are few. Medical referral is appropriate for those with persistent asthma or those with concurrent diseases but no prior diagnosis of asthma (Table 45-11).
- Nonprescription medications should be used for mild, infrequent symptoms or exacerbations lasting less than 2 days.
- All patients with asthma need to know warning signs and symptoms of severe asthma exacerbations and need to recognize when to seek urgent care.
- Education regarding asthma, appropriate medication use, and self-monitoring is a crucial part of asthma self-care.
- Self-care plans should be developed in a partnership between patients, family members where appropriate, and their health care providers. All patients with moderate-to-severe persistent asthma should have a written self-care plan.
- Environmental and trigger control can help reduce symptoms of asthma.
- Certain concomitant conditions (e.g., GERD, allergic rhinitis, and tobacco use) can worsen asthma symptoms and should be treated individually.

### Patient Education for Asthma

The objectives of self-treatment are to (1) identify candidates for self-care (Table 45-11), (2) prevent acute asthma exacerbations with quick-relief medications, and (3) have tools available to manage acute exacerbations (Figure 45-3). Asthma is an inflammatory disorder characterized by periods of stable lung function coupled with acute exacerbations. Symptoms of an acute exacerbation include wheezing, chest tightness, shortness of breath, and cough. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

### Nondrug Measures

- Identify and control environmental triggers (Table 45-8).
- Stop smoking cigarettes.
- Control concomitant disease states (e.g., GERD, allergic rhinitis, and tobacco use).

### Nonprescription Medications

- See Table 45-12 for examples of available medications.
- Two types of nonprescription asthma medications are available: inhaled and oral.
  - Inhaled medications contain epinephrine or racemic epinephrine.
  - Possible adverse drug effects of inhaled medications include nervousness and rapid heartbeat.
  - Oral medications include ephedrine and guaifenesin.
  - Possible adverse drug effects of oral medications include nervousness, tremor, sleeplessness, nausea, and loss of appetite.
- Precautions and contraindications for inhaled and oral asthma medications include the following:
  - Do not use unless a diagnosis of asthma has been made.
  - Do not take with monoamine oxidase inhibitors.
  - Use only under the supervision of a health care professional if you have heart disease, high blood pressure, thyroid disease, diabetes, or difficulty with urination because of enlargement of the prostate gland.
  - Do not use if you have been hospitalized for asthma or if you are taking a prescription medication for asthma.
- Monitoring parameters include relief of symptoms and occurrence of adverse effects:
  - If acute symptoms do not improve or become worse within 20 minutes of use of nonprescription bronchodilator medications, seek immediate medical attention.
  - Monitor continuously for adverse effects such as palpitations, angina, anxiety, nervousness, tremor, agitation, dizziness, insomnia, and restlessness. Discontinue use and notify provider if experiencing unwanted adverse effects.
- See Figure 45-3 for safe administration of medication.
- See Table 45-12 for recommended daily dose.
- Store epinephrine inhalers at room temperature (68°F–77°F). Do not store near open flame or heat above 120°F.
- Store combination oral products in a cool, dry place. Do not take products after expiration date on packaging.

### When to Seek Medical Attention

- Seek a medical referral if symptoms occur or nonprescription bronchodilator is used more than twice a week.

**TABLE 45-13 Asthma Therapeutic Goals and Monitoring Parameters**

<i>Therapeutic Goal</i>	<i>Monitoring Parameter</i>
Control of symptoms	Symptom frequency: 1-2 times per week; symptoms resolve within several minutes after bronchodilator
Normal pulmonary function	Peak expiratory flow rate: >80% of personal best PEF <i>consistently</i> every day
Normal activity levels	Few missed school or work days; able to perform desired activities (e.g., play, activities of daily living, etc.)
Prevention of recurrent episodes of asthma (minimize the need for urgent care visits)	No hospitalizations or emergency department visits: goal is none; have regular follow-ups for asthma
Prevention of adverse effects	No increased heart rate, insomnia, palpitations, nervousness, anxiety
Meeting expectations of asthma care	Achievement of patient's goals (e.g., able to perform desired activities); participates in care, is comfortable asking questions, is confident in dealing with symptoms and triggers

Key: PEF = Peak expiratory flow.

### Osteoporosis and Osteopenia

Osteoporosis is a silent disease affecting more than 9 million Americans, with 48 million affected by low bone mass. An estimated 54 million adults older than 50 years have osteoporosis or osteopenia; that number is expected to grow to 64 million by 2020.<sup>41</sup> The majority (80%) of osteoporosis cases affect women. Costs to the U.S. health care system for osteoporosis-related fractures were approximately \$19 billion dollars in 2005; costs in 2025 are expected to rise to \$25 billion.<sup>42</sup> Fractures may result in physical symptoms such as pain or disability, as well as psychological symptoms such as depression and decreased feeling of self-worth because of limited mobility. The importance of appropriate screening, prevention, and treatment is apparent, considering the impact of fractures on morbidity and mortality in the elderly.

*Osteopenia* is defined by the World Health Organization as a bone density between 1.0 and 2.5 standard deviations below the mean for young normal adults (T-score between -1.0 and -2.5). In contrast, *osteoporosis* is defined as a bone density 2.5 or more standard deviations below the young normal mean (T-score at or below -2.5). In addition, patients who have had a previous fracture are classified to have "severe" or "established" osteoporosis.<sup>42</sup>

### Pathophysiology of Osteoporosis and Osteopenia

Osteoporosis and osteopenia are a result of progressive bone loss after peak mass is achieved between 18 and 25 years of age. Bone is made of collagen and minerals. The balance of these substances for flexibility and strength is essential to maintain bone function and decrease risk of a fracture. An imbalance of bone remodeling (removing older bone while building new bone) can result in bone loss and subsequent risk for fractures. This imbalance most often occurs with increasing age and the onset of menopause.<sup>42</sup>

### Clinical Presentation of Osteoporosis and Osteopenia

Patients with osteopenia or osteoporosis typically are asymptomatic unless they present secondary to a complication from the disease (e.g., fracture). In addition, patients with degrading bone loss may attribute their pain to other sources (e.g., arthritis) of pain and not associate it with osteopenia or osteoporosis. Other signs and symptoms or complications that patients may or may not be aware of are decreased immobility, shortened stature, and pain.

### Treatment of Osteoporosis and Osteopenia

#### Treatment Goals

The primary goals are to prevent osteopenia and osteoporosis from developing or progressing and to prevent morbidity and mortality associated with complications secondary to osteopenia and osteoporosis (e.g., fractures). Other goals of therapy include prevention of hospital visits, improved quality of life through improved mobility, prevention or management of pain, and participation in activities of daily living.<sup>42</sup>

#### General Treatment Approach

The provider should review lifestyle modifications with the patient and stress their importance in controlling the disorder. However, medical referral for further evaluation is needed if the assessment process reveals any of the following:

- No formal diagnosis (or identified risk factors) of osteoporosis or osteopenia
- Concurrent use of a medication (e.g., steroids) that may affect bone density or strength and that has not been evaluated by the primary care provider
- No visit (or missed visit) to a provider in the last year
- Nonadherence to provider-recommended prescription medications, nonprescription medications, or self-care measures
- Inability to assess the dietary intake of calcium and vitamin D
- Perception that prescription medications are ineffective
- Signs of bone loss (pain, immobility, shortened stature) that have not been evaluated by the provider

- Use of dietary supplements without the provider's knowledge or without achieving set goals

**TABLE 45-14 Selected Risk Factors Associated with Osteoporosis**

<i>Dietary</i>	<i>Medications</i>	<i>Other Factors</i>
Decreased calcium intake	Aluminum (antacids)	Age
Increased caffeine intake	Anticonvulsants	Gender
Increased sodium intake	Aromatase inhibitors	Decreased physical activity or limited mobility
Increased vitamin A intake	Barbiturates	Increased alcohol intake (>3 drinks per day)
Vitamin D insufficiency	Glucocorticoids	Smoking
		Low body mass index
		Previous fracture
		Onset of menopause

*Note:* This list does not include all factors that may contribute to osteoporosis and/or related factors (e.g., genetics, endocrine disorders, etc.). For an inclusive list, see reference 42.

Besides increasing age and onset of menopause, other factors put an individual at risk for bone loss (Table 45-14). Current recommendations are that all postmenopausal women and men 50 years of age and older should be assessed for osteoporosis risk factors to determine the need for bone mineral density (BMD) testing. According to the National Osteoporosis Foundation, women older than 65 years and men older than 70 years should receive BMD testing (hip or spine acceptable locations).<sup>42</sup> Providers must play a role in encouraging appropriate screening and prevention measures given the tendency of individuals at risk to avoid screenings for a silent disease such as osteoporosis. Although screening tools are available for providers to use in the community setting, a thorough evaluation of the accuracy of the tool should be completed.

Besides factors that contribute to weakening of bone structure, providers should also focus on factors that may lead to falls, such as lack of assistive devices, loose floor items that may lead to tripping, poor lighting, dehydration, medications that cause drowsiness or sedation, and poor balance. An assessment of the patient's home and close collaboration with a caregiver may prevent a fall and the resulting fracture.<sup>42</sup>

Recommendations for individuals to reduce the risk of osteopenia and osteoporosis and ultimately a fracture are listed in Table 45-15.

#### Nonpharmacologic Therapy

Self-care measures for the prevention and management of osteoporosis include adherence to medications (prescription and nonprescription), completion of weight-bearing (e.g., walking, jogging, or dancing) and muscle-strengthening exercises (e.g., weight and resistance training) where appropriate, following a diet that allows adequate intake of vitamins and minerals while maintaining a healthy body weight, and avoiding detrimental behaviors such as smoking and excessive consumption of alcohol.<sup>42</sup>

**TABLE 45-15 General Recommendations to Prevent Osteoporosis and Osteopenia**

<i>Prevention/Treatment Parameter</i>	<i>Recommendation</i>
Calcium intake	See Table 22-4 for specific recommended calcium intakes based on age and gender
Vitamin D intake	See Table 22-3 for specific recommended vitamin D intakes based on age and gender
Exercise	Regular weight-bearing and muscle-strengthening exercises (after evaluation by a primary care provider)
Tobacco use	Cessation <sup>a</sup>
Alcohol intake	No more than moderate use of alcohol ( $\geq 3$ drinks per day may be harmful to bone health)
Bone mineral density testing	Assessment of need for BMD (based on risk factors) for postmenopausal women and men ages 50-69 years BMD recommended for women 65 years and older, and men 70 years and older

<sup>a</sup> All patients with osteoporosis who are using tobacco products should be advised to quit. Please refer to Chapter 47 for a more in-depth description of smoking cessation.

Key: BMD= Bone mineral density.

Source: Adapted from reference 42.

#### Pharmacologic Therapy

Assessment of dietary intake of calcium and vitamin D should be completed prior to making a recommendation for additional supplemental use. A thorough discussion of the evidence regarding the use of calcium and vitamin D, the recommended intake, types,

and formulations of calcium and vitamin D can be found in [Chapter 22](#).

### Assessment of Osteoporosis and Osteopenia: A Case-Based Approach

Case 45-2 provides an example of how to assess a patient with risk factors for osteoporosis or osteopenia.

#### Patient Counseling for Osteoporosis and Osteopenia

Patient counseling for self-care of osteopenia and osteoporosis should be complementary to assessment, treatment, or monitoring by the patient's primary care provider. Counseling should focus on engaging the patient in appropriate self-care measures outlined in [Table 45-15](#). The patient should be educated on the impact of untreated osteoporosis and osteopenia as well as the importance and efficacy of pharmacologic and nonpharmacologic measures. The box Patient Education for Osteoporosis lists specific information to provide patients.

#### Evaluation of Patient Outcomes for Osteoporosis and Osteopenia

Evaluation of outcomes associated with osteopenia and osteoporosis should be completed by the patient's provider. Self-care measures should complement rather than replace the provider recommendation(s).

##### Patient Education for Osteoporosis and Osteopenia

The primary objective of self-treatment is to prevent osteoporosis and osteopenia. For patients who already have osteopenia or osteoporosis, the primary goals of treatment are to (1) prevent complications, (2) reduce risk factors, and (3) prevent morbidity and mortality. For most patients, carefully following their primary care provider's treatment plan and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Nondrug Measures

- See [Table 45-15](#).

#### Nonprescription Medications

- Calcium is a major component of bone and teeth. Vitamin D helps the body absorb calcium. See [Tables 22-3](#) and [22-4](#), respectively, for recommended intakes of calcium and vitamin D based on age and gender. If dietary consumption of calcium is inadequate, initiate calcium and vitamin D supplementation.
- The National Osteoporosis Foundation recommends that women older than 65 years and men older than 70 years undergo bone mineral density testing.

#### When to Seek Medical Attention

- If you experience decreased mobility, shortened stature, or pain, consult your primary care provider.

#### Case 45-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient presents to the pharmacy with questions about using a calcium supplement.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	She asks if she should be taking calcium every day for her "bones." She is concerned because she doesn't feel she has any problems with her bones.
c. description of the patient's efforts to relieve the symptoms	NA
d. patient's identity	Mildred Phillips
e. patient's age, sex, height, and weight	71 years old, female, 5 ft 5 in., 111 lb

f. patient's occupation	Retired from 45 years as an elementary school teacher; still likes to work around the house with her husband
g. patient's dietary habits	Relatively normal diet with limited meat and vegetable consumption, but she does attempt to have at least 3 helpings of fruit/day.
h. patient's sleep habits	8-9 hours per night
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Hypertension: metoprolol succinate 50 mg by mouth every morning; osteoarthritis of the knee: acetaminophen 325 mg every 4-6 hours
j. allergies	NKA
k. history of other adverse reactions to medications	None
l. other (describe) _____	Has smoked one pack per day for the last 40 years. Occasional alcohol use (less than 1 glass of wine/week).
<b>Assessment and Triage</b>	
2. Differentiate the patient's signs/symptoms and correctly identify the patient's primary problem(s).	The patient has several risk factors (age, smoking history, likely postmenopausal, gender, low body mass index) that would indicate she is at risk for osteoporosis or osteopenia. An assessment of the patient's dietary consumption of calcium and vitamin D should be completed.
3. Identify exclusions for self-treatment.	See exclusions for self-treatment in the Osteoporosis and Osteopenia section, subsection General Treatment Approach. Mildred has no formal diagnosis of osteoporosis or osteopenia but does have several risk factors that warrant initiation of calcium/vitamin D therapy.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Mildred to her PCP. (2) Recommend OTC calcium and vitamin D supplementation after assessing her dietary consumption. (3) Recommend that OTC calcium and vitamin D supplementation be initiated until Mildred can see her PCP. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The patient prefers starting OTC calcium and vitamin D supplementation until she can be evaluated by her PCP.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Because you are not consuming enough calcium and vitamin D in your diet, you should increase your dietary intake of calcium and start taking calcium and vitamin D supplementation. In addition, you should stop smoking, perform weight-bearing exercises, and see your primary care provider to obtain a referral for a bone mineral density scan."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the	"Calcium and vitamin D are essential to help build bone growth and to prevent complications associated with bone loss, such as fractures. In addition, a referral to your primary care provider is necessary to assess whether a bone scan should be completed. A bone scan will measure the density (or thickness) of your bones to determine how much bone loss has taken place. The results of the scan will allow the provider to determine whether to continue the plan as is or whether to add a prescription medication. Finally, with the

considered therapeutic alternatives.	more recent data suggesting possible increased risk of cardiovascular complications in patients using calcium supplements, versus receiving calcium in the diet, you should discuss this issue with your provider.”
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	See <a href="#">Chapter 22</a> for a discussion of the types, dosages, and formulations of calcium and vitamin D. The dose should be divided to twice daily to allow adequate absorption.
b. maximum number of days the therapy should be employed	“You should take the supplement(s) until the provider visit, which should be scheduled as soon as possible.”
c. product administration procedures	“Take the supplement by mouth. The absorption of some medications may be affected by calcium, so please talk to a primary care provider before starting any new medications.”
d. expected time to onset of relief	NA
e. degree of relief that can be reasonably expected	NA
f. most common side effects	“Upset stomach and headache may occur.”
g. side effects that warrant medical intervention should they occur	“If you have continued constipation while taking these supplements, see your primary care provider.”
h. patient options in the event that condition worsens or persists	“If you experience signs of bone loss, specifically pain, shortened stature, or fractures, see your primary care provider immediately.” [Because the patient does not have any symptoms, it is unlikely that the patient will know if the condition is worsening unless she experiences the signs just described.]
i. product storage requirements	NA
j. specific nondrug measures	“Getting a referral for a bone mineral density scan is important. The scan will let you know how much, if any, bone loss has occurred. In the meantime, you can minimize bone loss if you stop smoking and start performing weight-bearing exercises.”
Solicit follow-up questions from the patient or caregiver.	(1) “Will the calcium and vitamin D affect any of my other medications?” (2) “What are common dietary sources of calcium?”
Answer the patient’s or caregiver’s questions.	(1) “In general, the absorption of some medications may be affected by calcium, so please talk to a primary care provider before starting any new medications. With regard to your current regimen (metoprolol), take the calcium and vitamin D 1-3 hours after your metoprolol.” (2) “Common dietary sources of calcium include dairy foods (milk, yogurt, cheese), green leafy vegetables (spinach, broccoli, kale), beans/peas, and fish (salmon, sardines).”
<b>Evaluation of Patient Outcome</b>	

9. Assess patient outcome.	Contact the patient in a week or two to ensure that she made a follow-up appointment with her PCP, to determine how she is tolerating the supplement, and to assess her status with regard to tobacco cessation.
----------------------------	--

Key: NA = Not applicable; NKA = no known allergies; OTC = over-the-counter; PCP= primary care provider.

## Heart Failure

Heart failure (also known as congestive heart failure or chronic heart failure) is a condition characterized by the heart's inability to pump enough blood (and subsequently oxygen) to fulfill the body's requirements. Affecting approximately 5.1 million people in the United States over the age of 20, heart failure will cost the U.S. health care system approximately \$32 billion in 2013.<sup>43</sup> More prevalent in the aging populations, heart failure leads to poor quality of life and early mortality. Heart failure is classified by the American College of Cardiology Foundation and the American Heart Association (AHA) as Stages A-D and by the New York Heart Association as Classes I-IV. An increase in stage or class indicates an increase in disease severity.<sup>44,45</sup>

### Pathophysiology of Heart Failure

Defined as the ineffectiveness of the heart to pump enough blood to meet the metabolic needs of the body, heart failure is often the result of an acute event that damages the myocardium (i.e., myocardial infarction) or long-term damage that is secondary to a cardiovascular condition (e.g., hypertension).<sup>45</sup> Although these are common causes, heart failure can result from any condition that compromises the ability of the myocardium to contract (systolic dysfunction) or relax (diastolic dysfunction). To compensate for the inability to pump sufficient blood, the body relies on secondary mechanisms such as increased contractility through sympathetic nervous system stimulation and initiation of the renin-angiotensin-aldosterone system. These compensatory mechanisms ultimately lead to vasoconstriction, hypertrophy and remodeling of the ventricles, and sodium and water retention. Although these mechanisms are designed to be short term, they often persist and lead to exacerbation of heart failure.

### Clinical Presentation of Heart Failure

Patients with heart failure most often present with dyspnea and fatigue. These, in addition to the compensatory mechanisms, can lead to the retention of fluids and subsequently pulmonary congestion and/or peripheral edema. Because patients present at different stages of the disease and may have various comorbidities, the symptoms can vary significantly. Other common signs and symptoms or complications include exercise intolerance, orthopnea, cough, fatigue, and cool extremities.

### Treatment of Heart Failure

#### Treatment Goals

General treatment goals for heart failure include (1) improving quality of life, (2) reducing or relieving symptoms, (3) prolonging survival, and (4) reducing exacerbations that would lead to hospitalizations and/or discomfort to the patient. Because heart failure is not reversible, it is also prudent to treat the underlying cause if applicable (e.g., diabetes, hypertension, etc.) to prevent or slow the progression of the disease.

#### General Treatment Approach

The approach for treatment of heart failure should focus on accurate staging of the disease, identifying and treating any risk factors (e.g., smoking) or comorbid conditions (e.g., hypertension), and using pharmacologic and nonpharmacologic treatment options. In 2009, the American College of Cardiology and AHA issued an update for the diagnosis and management of chronic heart failure in adults.<sup>44</sup> The pharmacist should review lifestyle modifications with the patient and stress their importance in controlling the disorder. However, medical referral for further evaluation is needed if the assessment process reveals any of the following:

- No formal diagnosis of heart failure
- Another comorbid condition (e.g., asthma or COPD) that may make it difficult to distinguish heart failure-related symptoms (e.g., difficulty breathing)
- No visit to a primary care provider in the last year
- Nonadherence to provider-recommended prescription medications, nonprescription medications, or self-care measures
- Perception that prescription medications are ineffective
- Use of dietary supplements without provider's knowledge or without achieving set goals

#### Nonpharmacologic Therapy

Patients should always be assessed, monitored, and treated by a primary care provider; treatment should not be solely self-managed. Self-care for patients with heart failure may be especially challenging in light of other comorbid conditions (e.g., hypertension, diabetes, etc.) that result in complex medical regimens, dietary restrictions, required monitoring, the burden of decision-making, and/or feeling ill.<sup>46</sup> For example, a patient with heart failure and diabetes may be burdened with monitoring both conditions, adhering to dietary modifications for sodium and carbohydrate intake, and having to make several decisions based on findings throughout the day.

Stepwise process for self-management of peripheral edema.

Although the data are inconsistent and limited in terms of effectiveness of self-management interventions on clinical markers (e.g., mortality and readmissions),<sup>47,48</sup> self-care measures for patients with heart failure are recommended by AHA.<sup>46</sup> Patients should be educated and ultimately should be responsible for recognizing and evaluating symptoms, determining the need for treatment, implementing treatment (if approved by provider), and evaluating that change. Figure 45-7 highlights an example of how a patient with heart failure can participate in appropriate self-care.<sup>46</sup>

Consideration should be given to screening patients with heart failure to assess for any medications that may be exacerbating symptom control. NSAIDs should be avoided where possible because of sodium retention, peripheral vasoconstriction, and potential to decrease the effectiveness of diuretics and angiotensin-converting enzyme inhibitors.<sup>44</sup> In addition, products such as stimulant laxatives and nonprescription products containing diuretics may lead to dehydration and electrolyte imbalances. Patients may be self-treating symptoms with nonprescription diuretics (e.g., caffeine, pamabrom, and pyrilamine), and should consult their prescriber to avoid potential harm. These diuretics may alter electrolyte levels and are typically contained in products marketed to women with premenstrual symptoms. In addition, sympathomimetics such as pseudoephedrine may lead to an increase in blood pressure, heart rate, and systemic vascular resistance and should be avoided. Caution should also be given to products that are high in sodium or potassium, or other medications that may alter electrolyte levels, such as nonprescription supplements (e.g., potassium).

Table 45-16 provides a summary of nonpharmacologic recommendations for patients with heart failure. Although the data are limited and inconsistent regarding sodium intake in patients with heart failure, the AHA consensus statement recommends a maximum daily dose of 2.3 grams. Patients should be educated on foods that are typically higher in sodium, such as processed meats, canned products, frozen dinners, and cheeses. Fluid restriction is important for several apparent reasons in patients with heart failure and should be an education point to patients, considering the generally held concept that more water is better.<sup>46</sup>

In terms of body weight, the conventional thought is less is better. However, patients with heart failure may be the exception. Although the data are not conclusive, patients with a higher weight show lower mortality and hospitalization rates than those with a normal body mass index (BMI). Because cachexia in chronic diseases such as heart failure often predicts a worse prognosis, the current recommendation is to endorse weight loss for patients with a BMI of 40 or higher to achieve a BMI less than 40. However, patients who have a BMI of 30 or higher are not currently recommended to lose weight, but rather to focus on signs of weight loss, muscle wasting, and a loss of appetite. Finally, in an effort to decrease inflammation and improve the delivery of oxygen, routine exercise should be recommended and tailored on the basis of the severity of the patient's symptoms.<sup>46</sup>

**TABLE 45-16 Nonpharmacologic Recommendations for Patients with Heart Failure**

<i>Nonpharmacologic Category</i>	<i>Recommendation</i>
Sodium consumption	Maximum of 2.3 g/day
Fluid intake	<2 L/day <sup>a</sup>
Tobacco use	Cessation or prevention of use <sup>b</sup>
Weight loss	Encouraged only if BMI ≥ 40
Exercise	Recommended (tailored by the provider on the basis of symptom control)
Immunizations	Influenza yearly (inactivated); pneumococcal (maximum of 2 doses in a lifetime) <sup>c</sup>

<sup>a</sup> Patients with mild-moderate heart failure symptoms may not benefit from fluid restriction.

<sup>b</sup> All patients with heart failure who are using tobacco products should be advised to quit. See Chapter 47 for a more in-depth description of smoking cessation.

<sup>c</sup> Specific immunizations listed in the Centers for Disease Control and Prevention Adult Immunization Schedule. Consideration should also be given to routine tetanus vaccinations and other vaccines where appropriate (i.e., high-risk situations).

Source: Adapted from reference 46.

#### Pharmacologic Therapy

Currently, no nonprescription pharmacologic agents are recommended for the treatment of heart failure. However, providers and patients

should share responsibility in ensuring that vaccine records are up to date. Where applicable, adults with heart failure should be up to date on tetanus; diphtheria and pertussis; varicella; zoster; and measles, mumps, and rubella. In addition, patients with heart failure should receive an annual influenza vaccine and the pneumococcal vaccine (maximum of 2 doses in a lifetime).

### Complementary Therapies

The use of nonprescription medications<sup>49</sup> and CAM<sup>49,50</sup> by patients with heart failure is significant, leading to potential harm if not evaluated appropriately. Patients with heart failure are specifically at risk for adverse effects because symptom control is often achieved with specific adjustments of prescription medications and monitoring of nonpharmacologic factors such as salt and fluid intake. Although very few herbal supplements are used for heart failure specifically, providers should assess all herbal medications being used for other comorbid conditions. (See [Chapter 51](#) for a more in-depth discussion of herbal supplements related to cardiovascular health.)

### Patient Counseling for Heart Failure

Patient counseling for self-care of heart failure should be complementary to the assessment, treatment, and monitoring being delivered by a provider. Counseling should focus on engaging the patient in appropriate nonpharmacologic measures ([Table 45-16](#)) and stressing the importance of these measures.

Effective complementary therapies for heart failure control are limited. However, patients may be using these therapies for other comorbid conditions (e.g., diabetes, hypertension, etc.). Patients should be asked about use of these products and, if applicable, warned of possible effects on control of heart failure symptoms.

The patient should be educated on common signs and symptoms of heart failure and the impact that comorbid disease states can have on symptom control and progression. The box Patient Education for Heart Failure lists specific information to provide patients.

### Evaluation of Patient Outcomes for Heart Failure

Evaluation of outcomes associated with heart failure should be completed by the patient's provider. Self-care measures should complement rather than replace the provider's recommendations.

#### Patient Education for Heart Failure

The objectives of self-treatment measures for heart failure are to (1) prevent exacerbation of symptoms, (2) prevent progression of the disease, and (3) improve overall quality of life. For most patients, carefully following their primary care provider's treatment plan and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Nondrug Measures

- Patients can play a role in managing heart failure by:
  - Monitoring fluid, salt, and alcohol intake. Foods that typically have high sodium content include processed meats, canned products, frozen dinners, and cheeses.
  - Stopping the use of tobacco (if applicable).
  - Maintaining an appropriate weight.
  - Participating in a planned and monitored exercise regimen.
- See [Table 45-16](#) for specific recommendations.

#### Nonprescription Medications

- Currently, no nonprescription medications are recommended for the treatment of heart failure. Follow carefully your primary care provider's instructions for prescription medications.
- The following nonprescription medications can worsen heart failure and should be avoided:
  - Ibuprofen and naproxen can cause sodium retention and peripheral vasoconstriction and possibly can decrease the effectiveness of prescribed diuretics and angiotensin-converting enzyme inhibitors.
  - Stimulant laxatives may lead to dehydration and electrolyte imbalances.
  - Nonprescription products containing diuretics (e.g., caffeine, pamabrom, and pyrilamine) may also lead to dehydration and electrolyte imbalances. These diuretics are typically contained in products marketed to treat premenstrual symptoms.
  - Do not use nonprescription diuretics to self-treat symptoms of heart failure unless the use is approved by your primary care provider.
  - Products that are high in sodium or potassium, or other medications that may alter electrolyte levels, such as nonprescription potassium supplements, can also cause electrolyte imbalances.
  - Pseudoephedrine, which is used to treat nasal congestion, may lead to an increase in blood pressure and/or heart rate.
- Keep up to date on vaccinations for tetanus, varicella, zoster (if >50 years), and measles, mumps, and rubella.
- Make sure you receive an influenza vaccine every year.
- Recommendations for the pneumonia vaccine are to take the first dose between the ages of 19-64 years. A second dose is recommended for those 65 years and older. Make sure the two doses are administered 5 years apart.

#### When to Seek Medical Attention

- If you experience excessive fluid retention, weight gain (from fluid retention), shortness of breath, fatigue or weakness, rapid or irregular heartbeat and/or persistent cough or wheezing, please consult with your primary care provider or seek immediate care.

#### Hypertension

High blood pressure (hypertension) contributes to heart disease and stroke, the first and fourth leading causes of death in the United States, respectively. Affecting approximately one in three adult Americans,<sup>51</sup> hypertension cost the U.S. health care system approximately \$51 billion in direct and indirect costs in 2009.<sup>43</sup> Lifetime prevalence of hypertension is high, with 90% of people who are normotensive at age 55 and older becoming hypertensive.<sup>52</sup> Persistent hypertension may lead to the development of coronary artery disease, stroke, and renal failure. In light of the effects that hypertension can have on cardiovascular and kidney health and its effect in patients with other

comorbid conditions (e.g., diabetes), appropriate management and self-care of hypertension are essential.

### Pathophysiology of Hypertension

Blood pressure is a result of the resistance of the blood vessels from the force of blood contracted from the heart. Arterial blood pressure is recorded as millimeters of mercury (mm Hg) and reported as systolic blood pressure (during cardiac contraction) and diastolic blood pressure (after contraction when the heart chambers are filling). In the majority of individuals, hypertension has an unknown etiology (essential or primary hypertension). Although the condition cannot be cured, it can be treated with various pharmacologic and nonpharmacologic measures. In patients with a known cause of hypertension (secondary hypertension), the cause may be removed if possible (e.g., excessive sodium use), or the hypertension may be treated if the cause cannot be removed (e.g., necessary therapy for chronic asthma with a steroid). The most common causes of secondary hypertension are renal dysfunction and medications that increase blood pressure.<sup>53</sup>

The exact mechanism leading to essential hypertension is unknown, but several theories include factors that affect the renin-angiotensin-aldosterone system, a defect in neuronal regulation, a defect in sodium excretion, a deficiency of vasodilation substances (e.g., prostacyclin and bradykinin), or an excess of vasoconstriction substances (e.g., angiotensin II). It is hypothesized that a combination of these factors, rather than a single factor alone, is likely.<sup>53</sup>

### Clinical Presentation of Hypertension

Patients with hypertension traditionally present asymptomatic and appear otherwise healthy unless they have subsequent cardiovascular risk factors such as diabetes, obesity, and tobacco use. In addition, the patient may or may not have previous signs of complications such as target organ damage secondary to hypertension. Examples of complications secondary to hypertension include stroke, retinopathy, myocardial infarction, chronic kidney disease, or peripheral artery disease. Therefore, proper screening of blood pressure values is essential for early recognition of a condition that can have silent symptoms with detrimental long-term effects.

### Treatment of Hypertension

#### Treatment Goals

The primary goal of treatment of hypertension is to reduce morbidity and mortality. Numerous pharmacologic options are available and usually are necessary for patients to achieve desired blood pressure goals. The pharmacist should review lifestyle modifications with the patient and stress their importance in controlling the disorder. However, medical referral is needed if the assessment process reveals any of the following:

- No formal diagnosis of hypertension
- No visit to a primary care provider in the last year
- Concurrent medication (e.g., stimulants) that may affect the patient's blood pressure and has not been evaluated by the prescriber
- Nonadherence to provider-recommended prescription medications, nonprescription medications, or self-care measures
- Perception that prescription medications are ineffective
- Use of dietary supplements without the provider's knowledge or without achieving set goals

#### General Treatment Approach

Hypertension is classified as normal, prehypertension, stage 1 hypertension, or stage 2 hypertension. The classification of hypertension determines pharmacologic and nonpharmacologic measures necessary to achieve the desired goals. In light of the correlation between risk factors and the additional risk from hypertension, the focus should be on managing and addressing these factors early and often. (See [Table 45-17](#) for risk factors for hypertension.)

#### Nonpharmacologic Therapy

Appropriate self-care measures include self-monitoring of blood pressure, reducing body weight, adopting the dietary approach to stopping hypertension (DASH diet), increasing physical activity, abstaining from smoking, and moderating the amount of alcohol use.<sup>52</sup>

Key components of the DASH diet<sup>54</sup> are provided in [Table 45-18](#). Additional information about smoking cessation can be found in [Chapter 47](#). The correlation between several of these risk factors and a corresponding reduction in systolic blood pressure is outlined in [Table 45-19](#).

**TABLE 45-17 Selected Risk Factors for Developing or Worsening Hypertension**

<i>Medications</i>	<i>Other Factors</i>
Amphetamines	Increased caffeine intake
Decongestants	Increased sodium intake
Erythropoietin	Increased alcohol intake
Estrogen derivatives	Advanced age
Nicotine	Females who are postmenopausal
Nonsteroidal anti-inflammatory drugs	Decreased physical activity
Steroids	Tobacco smoke
Venlafaxine (Effexor, Effexor XR)	

Home blood pressure monitoring may have a small effect in improving blood pressure and adherence in patients with hypertension.<sup>55,56</sup> Steps to obtaining an accurate blood pressure reading are listed in Table 45-20.<sup>57</sup> Specific patients who may benefit from home monitoring include patients with white coat hypertension (elevated blood pressure in a clinical setting but not in other settings); patients with periodic hypotensive episodes; and patients using pharmacologic or nonpharmacologic measures who are monitoring the progress in disease control. Home blood pressure monitoring should complement rather than replace provider monitoring. Therefore, patients who are self-monitoring should be encouraged to keep a record or logbook of their home readings and bring them to provider visits to help identify patterns or trends in blood pressure over time. Limitations of home monitoring should be considered, such as using devices that are not validated or that have not been calibrated according to manufacturer-recommended frequency, dexterity needed for measuring, cost of devices, and potential for patients to make changes in therapy based on readings without consulting the prescriber. (See Chapter 48 for additional information on home blood pressure monitors.).

**TABLE 45-18 Key Components of the Dietary Approach to Stopping Hypertension (DASH) Diet**

<i>Food Group</i>	<i>Recommendation</i>
Fat-free or low-fat milk products	2-3 servings per day
Fruits	4-5 servings per day
Grains	6-8 servings per day
Lean meats, poultry, fish	6 or fewer servings per day
Nuts, seeds, and legumes	4-5 servings per week
Vegetables	4-5 servings per day
Sodium	Start with 2300 mg/day and then decrease to 1500 mg/day.
Potassium	A potassium-rich diet (from fruits and vegetables rather than supplements) may help reduce blood pressure.

Source: Adapted from references 52 and 54.

Note: Based on a 2000 calorie per day diet.

**TABLE 45-19 Effect of Managing Risk Factors on Systolic Blood Pressure**

<i>Lifestyle Modification</i>	<i>Recommendation</i>	<i>Approximate Reduction in Systolic Blood Pressure</i>
Adopt DASH eating plan.	Follow a diet rich in fruits, vegetables, and low-fat dairy products. Reduce intake of saturated and total fat.	8-14 mm Hg
Reduce weight.	Achieve a body mass index of 18.5-24.9	5-20 mm Hg
Increase physical activity.	Participate in regular aerobic exercise (≥30 minutes/day) for most days of the week.	4-9 mm Hg
Reduce intake of dietary sodium.	Reduce sodium intake to ≤2.4 grams of sodium or 6 grams of sodium chloride.	2-8 mm Hg
Consume alcohol in moderation.	≤2 drinks for men per day ≤1 drink for women per day	2-4 mm Hg

Key: DASH = Dietary approach to stopping hypertension.

Source: Adapted from reference 52.

**TABLE 45-20 Steps to Obtaining an Accurate Blood Pressure Measurement**

1. The patient should be seated quietly for a minimum of 5 minutes with feet flat on the floor and the arm supported at heart level.
2. Caffeine and nicotine consumption should be avoided for 30 minutes prior to a reading.
3. An appropriate size cuff should be used for the measurement.
4. The palpatory method should be used to estimate the systolic blood pressure. While palpating the radial pulse, inflate the cuff at a steady rate until the pulse can no longer be felt. Then, further inflate the cuff by about 20 mm Hg. Slowly release the valve on the inflating bulb and allow the pressure to drop by about 5 mm Hg per second. The point at which the palpation of the radial pulse reappears is the systolic blood pressure.
5. Place the bell of the stethoscope over the brachial artery.

6. Inflate the cuff to approximately 30 mm Hg above the estimated systolic blood pressure (completed in step 4).

7. Deflate the cuff slowly at a rate of 2-3 mm Hg per second. The first audible Korotkoff sound is the systolic blood pressure. The last audible sound is the diastolic blood pressure.

8. Deflate the cuff completely.

9. Record the measurement to the nearest 2 mm Hg.

10. Two measurements should be taken and the average should be recorded. Wait 1-2 minutes between measurements.

Source: Adapted from reference 57.

Patients should be advised that some nonprescription preparations, including decongestants with sympathomimetic activity (e.g., phenylephrine and pseudoephedrine), may increase blood pressure. At higher doses (210-240 mg), pseudoephedrine has been shown to increase blood pressure and heart rate, which are undesirable in a patient with hypertension. In addition, central nervous system stimulation and risk of stroke (in patients with hypertension) may occur with pseudoephedrine use.<sup>58</sup> Although the doses that caused ill effects are relatively high compared with normal dosing, pseudoephedrine should be avoided if possible in patients with hypertension. A further review of decongestants can be found in [Chapter 11](#).

#### Complementary Therapies

An in-depth discussion of natural products that are widely used for hypertension and/or overall cardiovascular health can be found in [Chapter 51](#).

#### Patient Counseling for Hypertension

Patient counseling for self-care of hypertension should be complementary to the assessment, treatment, and monitoring being delivered by a provider. Counseling should focus on engaging the patient in the appropriate nonpharmacologic measures outlined in [Tables 45-18](#) and [45-19](#). Natural products for the management of hypertension are available. A further discussion of those agents can be found in [Chapter 51](#). The patient should be educated on the impact of uncontrolled hypertension and the importance and efficacy of nondrug measures. The box Patient Education for Hypertension lists specific information to provide patients.

#### Evaluation of Patient Outcomes for Hypertension

Evaluation of outcomes associated with hypertension should be completed by the patient's primary care provider. Self-care measures should complement but not replace the provider's recommendation(s).

#### Patient Education for Hypertension

The objectives of self-treatment are to prevent progression of the disease and prevent morbidity and mortality. For most patients, carefully following their primary care provider's treatment plan and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### Nondrug Measures

- Manage risk factors for elevated systolic blood pressure by:
  - Adopting the DASH diet ([Table 45-18](#)):
    - Reducing excessive body weight
    - Participating in physical activity
    - Minimizing dietary sodium intake
  - Moderating alcohol consumption
  - Stopping use of tobacco (if applicable)
  - Self-monitoring blood pressure

#### Nonprescription Medications

- Currently, no nonprescription medications are recommended for the treatment of hypertension. Follow carefully your health care provider's instructions for prescription medications.

#### When to Seek Medical Attention

- If you measure an abnormal elevated blood pressure reading or experience a headache, visual abnormalities or loss of vision, chest pain, or confusion, consult your primary care provider or seek immediate medical care.

#### Dyslipidemia

Coronary heart disease (CHD) is the leading cause of death in the United States, contributing to over 600,000 deaths in 2008. Hypercholesterolemia, elevated low-density lipoproteins (LDLs), and decreased high-density lipoproteins (HDLs) are directly linked to CHD and cerebrovascular accidents. Approximately 43% of individuals older than 20 years in the United States have total cholesterol (TC) levels of 200 mg/dL or higher, 31% have LDL levels of 130 mg/dL or higher, and 22% have HDL levels less than 40 mg/dL.<sup>43</sup> Genetic and environmental factors leading to high TC, high LDL, and low HDL make appropriate pharmacologic and nonpharmacologic treatment

essential.

### Pathophysiology of Dyslipidemia

Lipids in the body (cholesterol, triglycerides, and phospholipids) are transported by proteins, known as lipoproteins. The major classes of lipoproteins include LDLs, HDLs, and very low-density lipoproteins (VLDLs). VLDLs are carried in blood circulation as triglycerides (TGs). Although lipids are essential for cell membrane formation, hormone synthesis, and a source of free fatty acids, elevated levels of lipoproteins may result in coronary, cerebrovascular, or peripheral vascular disease. Dyslipidemia is defined by some combination of elevated TC, LDL, and TG levels and/or low HDL levels. Atherosclerosis of the blood vessels leading to the myocardium is the most significant consequence of dyslipidemia. The risk factor of dyslipidemia is additive to other factors for CHD, such as smoking, hypertension, and diabetes. Prevention is key, considering that a previous myocardial infarction or a diagnosis of CHD increases the risk of a myocardial infarction significantly.

### Clinical Presentation of Dyslipidemia

Similar to hypertension, patients with dyslipidemia traditionally present asymptomatic and appear otherwise healthy unless they have subsequent cardiovascular risk factors or complications consistent with metabolic syndrome, or they present acutely with chest pain, palpitations, sweating, anxiety, or similar symptoms that may signify angina or myocardial infarction. Diagnosis of dyslipidemia is most often completed by laboratory tests of some combination of TC, LDL, TGs, and HDL. (See [Chapter 48](#) for more information on nonprescription cholesterol tests.)

### Treatment of Dyslipidemia

#### Treatment Goals

The primary goal of therapy is to prevent first-time (primary prevention) or recurrent (secondary prevention) cardiovascular events associated with atherosclerosis, such as myocardial infarctions, angina, heart failure, stroke, and/or peripheral artery disease. After baseline cholesterol levels are obtained, pharmacologic and/or nonpharmacologic agents may or may not be warranted. Patient-specific risk factors (e.g., age, family history, smoking, hypertension, and HDL level) are used to determine the risk category and ultimately the goal LDL. The 10-year risks (of myocardial infarction or death) are calculated based on the Framingham risk scores, which are calculated using age, gender, HDL, TC, blood pressure, and smoking status.<sup>59</sup>

The pharmacist should review lifestyle modifications with the patient and stress their importance in controlling the disorder. However, medical referral for further evaluation is needed if the assessment process reveals any of the following:

- No formal diagnosis of dyslipidemia
- No visit (or missed visit) to a primary care provider in the last year
- Nonadherence to any provider-recommended prescription medications, nonprescription medications, or self-care measures
- Unknown status of other comorbid conditions (e.g., hypertension)
- Perception that prescription medications are ineffective
- Use of dietary supplements without provider's knowledge or without achieving set goals

#### General Treatment Approach

Patients with an elevated fasting lipid panel may be initiated on nonpharmacologic and pharmacologic treatment regimens depending on the goals of therapy. Individuals 20 years of age and older should have a fasting evaluation of TC, LDL, HDL, and TGs at least every 5 years. If an atypical result is obtained, the patient should be classified accordingly, and further evaluation (family history, secondary causes, risk factors [[Table 45-21](#)]), and/or treatment should be initiated. Comorbidity of diabetes, which is defined as a CHD risk equivalent, means that a patient with diabetes and no known CHD has the same level of risk as someone with known CHD but without diabetes. Patients with diabetes are therefore treated to a more-aggressive LDL goal. In terms of treating LDL, certain risk factors may modify the treatment goal.<sup>59</sup> These include the following:

- Age (men  $\geq$  45 years; women  $\geq$  55 years or premature menopause without estrogen replacement therapy)
- Family history of premature CHD
- Cigarette smoking
- Hypertension ( $\geq$ 140/90 mm Hg or on medications for hypertension)
- Low HDL cholesterol (defined as  $<$ 40 mg/dL)

**TABLE 45-21 Selected Factors Contributing to Dyslipidemia**

<i>Conditions</i>	<i>Medications</i>
Obesity	Beta-blockers
Diabetes mellitus	Estrogens/progestins
Hypothyroidism	Glucocorticoids
Obstructive liver disease	Isotretinoin
Systemic lupus erythematosus	Protease inhibitors Thiazide diuretics

*Note:* This list does not include every condition/medication that may cause dyslipidemia.

A family history of premature CHD is defined as a myocardial infarction or sudden death before 55 years of age for male relatives and 65

years for female relatives. The term *relatives* as used here refers to a father, mother, or other first-degree male or female relative.<sup>59</sup>

### Nonpharmacologic Therapy

Nonpharmacologic treatment options, including therapeutic lifestyle changes (TLC), should be the forefront of the management of dyslipidemia. Dietary counseling or referral to a dietitian for education on intake of fat, saturated fats, and TC may be beneficial for preventing the progression of atherosclerosis. TLC focuses on reducing the intake of saturated fats and cholesterol, increasing the intake of plant stanols/sterols and fiber, reducing weight, and increasing the amount of physical activity (Table 45-22). This regimen may prevent or delay the need for drug therapy if implemented early and aggressively. Unless patients are at very high risk of developing CHD (e.g., have severe hypercholesterolemia, a CHD risk equivalent, strong family history), a minimum of a 3-month trial of TLC should be used before initiation of drug therapy.<sup>59,60</sup>

**TABLE 45-22 Key Components of the TLC Diet**

<b>Category</b>	<b>Recommendation</b>
Saturated fat	<7% of total daily calories
Fat	25%-35% of total daily calories
Dietary cholesterol	<200 mg/day
Sodium	≤2400 mg/day

Key: TLC = Therapeutic lifestyle changes.

Source: Adapted from reference 59.

The following dietary considerations should be given for patients with dyslipidemia to reduce cardiovascular risk<sup>59,60</sup>:

- Consuming 20-30 grams of dietary fiber per day, of which 5-10 grams minimum should be soluble fiber
- Substituting nonhydrogenated unsaturated fats for saturated and trans fats
- Increasing the amount of omega-3 fatty acids consumed from marine and plant sources
- Increasing the amount of fruits and vegetables with a low glycemic index (measure of the effect of carbohydrates on BG, reported as a percentage)
- Substituting whole grains for simple carbohydrates

### Patient Education for Dyslipidemia

The objective of self-treatment is to prevent progression of the disease and prevent morbidity and mortality. For most patients, carefully following their health care provider's treatment plan and the self-care measures listed here will help ensure optimal therapeutic outcomes.

#### **Nondrug Measures**

- Self-management of dyslipidemia includes implementing the therapeutic lifestyle changes diet as outlined in Table 45-22.

#### **Nonprescription Medications**

- Currently, no nonprescription medications are recommended for the treatment of dyslipidemia. Follow carefully your primary care provider's instructions for any prescription medications.

#### **When to Seek Medical Attention**

- If you experience any signs or symptoms such as chest pain, shortness of breath, cold sweats, nausea/vomiting, and/or upper body aches/pains, seek immediate medical care. These may be signs or symptoms of a heart attack that is secondary to high cholesterol, among other factors.

Fiber intake, although recommended, is often lower than desired. The two types of fiber include insoluble and soluble, defined by their ability to dissolve in water or gastrointestinal fluids. Soluble fiber is preferred in aiding the lowering of cholesterol and can be found in dietary sources such as oat bran, barley, nuts, seeds, beans, lentils, peas, and some fruits and vegetables. A more in-depth discussion of fiber can be found in Chapter 23.

Although the majority of Americans do not participate in regular moderate physical activity, the benefits have been well documented in terms of weight control, blood pressure control, improved insulin resistance, dyslipidemia management, and a decrease in cardiovascular events among patients with cardiovascular disease.<sup>60</sup> In terms of dyslipidemia, regular moderate physical activity can have improvements on all components, including LDL, HDL, and TGs. The amount and level of change depend on the level at baseline as well as the duration and intensity of exercise. The current AHA recommendation for most healthy individuals is 30 minutes of moderate aerobic exercise at least 5 days per week or 25 minutes of vigorous aerobic exercise 3 days a week. Moderate intensity is defined as working hard enough to increase heart rate and break a sweat while being able to maintain a conversation. This time may be accumulated in smaller sessions (e.g., 10-15 minutes). Higher intensity and durations may be needed for patients who are trying to achieve more weight loss versus weight maintenance.<sup>61</sup> In addition to aerobic exercise, individuals should participate in moderate to high intensity muscle-strengthening exercises for a minimum of 2 days per week. Patients who are at higher risk for cardiovascular events or who are concerned about how to start an exercise regimen should contact their primary care provider.

### Complementary Therapies

For an in-depth discussion of natural products as it may relate to patients with dyslipidemia, see Chapter 51. Further discussion on niacin can be found in Chapter 22.

## Patient Counseling for Dyslipidemia

Patient counseling for self-care of dyslipidemia should be complementary to the assessment, treatment, and monitoring being delivered by a provider. Counseling should focus on engaging the patient in the appropriate nonpharmacologic measures outlined in [Table 45-22](#). Natural products for the management of hyperlipidemia are available and widely used. A further discussion of these agents can be found in [Chapter 51](#). The patient should be educated on the impact of uncontrolled hyperlipidemia. The box Patient Education for Dyslipidemia lists specific information to provide patients.

## Evaluation of Patient Outcomes for Dyslipidemia

Evaluation of outcomes associated with hyperlipidemia should be completed by the patient's provider. Self-care measures should complement but not replace the provider's treatment plan.

**Handbook of Nonprescription Drugs** > Chapter 46. Insomnia, Drowsiness, and Fatigue**Insomnia**

Insomnia is one of the most common patient complaints, ranking third behind headache and the common cold.

Insomnia is a symptom with diverse etiologies, and it can progress to a disorder.<sup>1</sup> Insomnia occurs when a person has trouble falling or staying asleep, wakes up too early and cannot return to sleep, or does not feel refreshed after sleeping. Patients with other sleep disorders, such as sleep apnea, narcolepsy, and restless legs syndrome, also seek nonprescription sleep aids. Because of potentially significant adverse clinical effects, patients with these disorders preferably should see a sleep specialist.

Although the average adult requires 8 or more hours of sleep nightly, the typical American gets 6.7 hours.<sup>2</sup> An estimated 64% of the U.S. population experiences sleep problems at least a few nights a week with 7% of adults reporting the use of alcohol, 7% a nonprescription sleep aid, and 8% a prescription hypnotic to manage their insomnia.<sup>2</sup> Patients with insomnia are significantly more likely to report being unable to work efficiently, exercise, eat healthfully, and engage in leisure activities because they are too sleepy.<sup>2</sup>

Total annual cost estimates for insomnia in the United States range from \$30 billion to \$107.5 billion, depending on the prevalence rates assumed.<sup>3</sup> Compared with patients without insomnia, this disorder is associated with a significant economic burden for younger (ages 18-64) and older (ages ≥ 65) patients in terms of the average and indirect costs.<sup>4</sup> More than half of adults older than 65 report at least one sleep complaint, with 3%-21% of men and 7%-29% of women reporting the use of hypnotics.<sup>5</sup> Five percent of older adults reported using nonprescription medications every night or a few nights a week.<sup>6</sup> This group also has an increased incidence of sleep apnea and restless legs syndrome. Significant morbidity is associated with obstructive sleep apnea, including increased mortality from cardiovascular death.<sup>7</sup> As a result, complaints of insomnia in older patients should be carefully evaluated.

Despite these data, only a small percentage of patients with a sleep disorder actually tell their medical provider.<sup>1</sup> The combination of frequent misuse of hypnotics and availability of nonprescription agents makes insomnia a disorder of significant concern.

**Pathophysiology of Insomnia**

Physiologically, sleep can be categorized into different stages by using the sleeping electroencephalogram (EEG) in conjunction with electro-oculography and electromyography. Stage 1 sleep is a transitional stage, occurring as the patient falls asleep; the EEG resembles the waking state more than sleep. Stage 2 sleep constitutes about 50% of sleep time and is light sleep. Stages 3 and 4, collectively known as deep sleep or delta sleep, are characterized by the patterns of delta waves, or slow-frequency waves, on the EEG. Rapid eye movement (REM) sleep is neither light nor deep, and the EEG manifests an increase in high-frequency waves. REM sleep is characterized by physiologic activity compared with other sleep stages; skeletal muscle movement is inhibited. The eyes move rapidly from side to side, while blood pressure, heart rate, temperature, respiration, and metabolism are increased.<sup>7,8</sup>

Upon falling asleep, an individual progresses through four stages. The first REM period, usually 5-7 minutes in length, starts in about 70-90 minutes. The time from falling asleep to the first REM period is referred to as REM latency. The sleep cycle then repeats about every 70-120 minutes, with each progressive REM period becoming longer and the time spent in deep sleep becoming shorter. Prolonged suppression of REM sleep can result in psychological and behavioral changes.<sup>7,8</sup>

Sleep physiology changes with increasing age. Among older adults, the total duration of sleep is shorter, the number of nocturnal awakenings increases, and less time is spent in stage 4 and REM sleep. Sleep latency usually remains normal with increasing age. Despite these changes, older adults cannot be assumed to require less sleep.<sup>7</sup> Insomnia can be classified as transient, short term, or chronic according to the duration of sleep disturbance.

Transient insomnia is often self-limiting, lasting less than 1 week. Short-term insomnia usually lasts from 1-3 weeks.<sup>3</sup> Chronic, or long-term, insomnia persists for more than 3 weeks to years and is often the result of medical problems, psychiatric disorders, or substance abuse.<sup>1,3</sup>

Insomnia can also be classified on the basis of an identifiable cause. Primary insomnia is the term used to describe patients who have sleep difficulty for at least 1 month, that affects psychosocial functioning, and that is not caused by another sleep disorder, general medical disorder, psychiatric disorder, or medication (or secondary insomnia).<sup>9</sup> All

underlying causes of insomnia must be identified and managed to relieve the sleep disturbance.<sup>1,3,9</sup> Difficulty falling asleep is often associated with acute life stresses or medical illness, anxiety, and poor sleep habits. The severity of stressful situations can affect the length of insomnia. Travel, hospitalization, or anticipation of an important or stressful event can cause transient insomnia. If more severe stressors, such as the death of a loved one, recovery from surgery, or divorce, are present, transient insomnia can become short-term insomnia. Unless managed appropriately, short-term insomnia can progress to chronic insomnia.

Shift workers often complain of sleep disturbances, excessive sleepiness, or both. Sleep problems occur more frequently in individuals who must rotate shifts. Some nighttime workers adjust to their change in sleep schedule, whereas others never do. Some individuals are extremely sensitive to the stimulant effects of caffeine and nicotine. Drinking caffeinated beverages in the late afternoon or evening hours can cause insomnia. Late-night exercise and late-evening meals as well as environmental distractions, such as noise, lighting, uncomfortable temperatures, or new surroundings, can also interfere with sleep.<sup>7,8</sup>

Several medical disorders, in addition to psychiatric disorders, are associated with chronic insomnia (Table 46-1). Chronic insomnia is a key complaint of patients experiencing pain syndromes. Chronic insomnia can also be secondary to use of medications or other substances, sleep-wake schedule disorders, or primary sleep disorders.<sup>9</sup> Early morning awakening is often associated with depression. Nonprescription hypnotics are generally not helpful in patients with chronic insomnia, and medical referral is indicated.

Medications, including both prescription and nonprescription drugs, can produce either insomnia or withdrawal insomnia (Table 46-2).<sup>1,7,8</sup> Antidepressants, antihypertensive agents, and sympathomimetic amines (e.g., pseudoephedrine, phenylephrine) are commonly associated with causing insomnia. Alcohol can cause insomnia after acute use and as a withdrawal effect after chronic use.

### Clinical Presentation of Insomnia

Patients with insomnia may have varying complaints, such as difficulty falling asleep, frequent awakening, early morning awakening and inability to fall back to sleep, disturbed quality of sleep with unusual or troublesome dreams, or just poor sleep in general. Their actual duration of sleep, as determined by sleep laboratory studies, may or may not differ from that of individuals who report normal sleep. However, these patients usually report that they need more than 30 minutes to fall asleep and/or that their duration of sleep is less than 6-7 hours nightly. Patients who complain of insomnia characterized by frequent nighttime awakenings or early morning awakenings with difficulty going back to sleep or those with symptoms of 4 weeks or longer should be referred to their health care provider for further evaluation.

Sleep-deprived individuals are highly symptomatic, and their quality of life is negatively affected. Some impairment in daytime functioning is necessary for a diagnosis of insomnia, and most untreated patients with insomnia report symptoms of fatigue, drowsiness, anxiety, irritability, depression, decreased concentration, and memory impairment. If untreated, insomnia is associated with an increase in accidents as well as a rise in morbidity and mortality rates from general medical and psychiatric disorders, such as cardiovascular disease, pain syndromes, depression, anxiety, and substance abuse.<sup>1</sup>

### Treatment of Insomnia

#### Treatment Goals

Treatment goals are to improve the patient's presenting symptoms, quality of life, and functioning.

#### General Treatment Approach

For patients with transient or short-term insomnia but no underlying medical or psychiatric conditions that cause insomnia, reestablishing the normal sleep cycle with good sleep hygiene practices, with or without a nonprescription sleep aid, should help normalize sleep patterns. The algorithm in [Figure 46-1](#) outlines the assessment and self-treatment of transient and short-term insomnia, and it lists exclusions for self-treatment.

#### Nonpharmacologic Therapy

The sleep hygiene measures in [Table 46-3](#) are recommended for all patients with insomnia.<sup>10</sup> In many patients with sleep disturbances, these measures should be tried before starting drug therapy. Patients should be encouraged to try one or two measures at a time.

#### Pharmacologic Therapy

When the Food and Drug Administration (FDA) issued its final monograph on nonprescription sleep aids in 1989, diphenhydramine (HCl and citrate salts) was the only sleep aid deemed to be safe and effective for self-administration.<sup>11</sup>

#### Antihistamines

Diphenhydramine and doxylamine are members of the ethanolamine group of antihistamines. Ethanolamines affect sleep through their affinity for blocking histamine<sub>1</sub> and muscarinic receptors.<sup>12</sup> Although the safety and efficacy of doxylamine have not been fully established, FDA has allowed the drug to remain on the market.<sup>13</sup> Few studies

supporting the efficacy of doxylamine as a hypnotic are available.<sup>1,13</sup>

Both diphenhydramine and doxylamine are well absorbed from the gastrointestinal tract with similar times to maximum plasma concentrations (1-4 hours and 2-3 hours, respectively). The elimination half-life of diphenhydramine is 2.4-9.3 hours, whereas that of doxylamine is 10 hours.<sup>11,13</sup> Diphenhydramine is metabolized in the liver through two successive N-demethylations, and its apparent half-life can be prolonged in patients with hepatic cirrhosis.<sup>11</sup> Studies have shown a positive relationship between diphenhydramine plasma concentrations and drowsiness and cognitive impairment. Maximum sedation with diphenhydramine occurs between 3 and 6 hours after a dose.<sup>11</sup>

The primary indication for diphenhydramine in insomnia is the symptomatic management of transient and short-term sleep difficulty, particularly in individuals who complain of occasional problems falling asleep. The efficacy of diphenhydramine in patients with chronic insomnia is poor.<sup>1</sup> Tolerance to the sedative effect of diphenhydramine was reported to develop quickly, within days of repeated use in healthy volunteers.<sup>14</sup>

Although the usual diphenhydramine dosage is 50 mg nightly, some individuals benefit from a 25 mg dosage. Intermittent use for 3 days with an "off" night to assess sleep quality without medication may reduce tolerance to the hypnotic effect. Diphenhydramine should be used for no more than 7-10 consecutive nights because insomnia may be a symptom of an undiagnosed medical or psychiatric illness that requires further evaluation.<sup>11</sup>

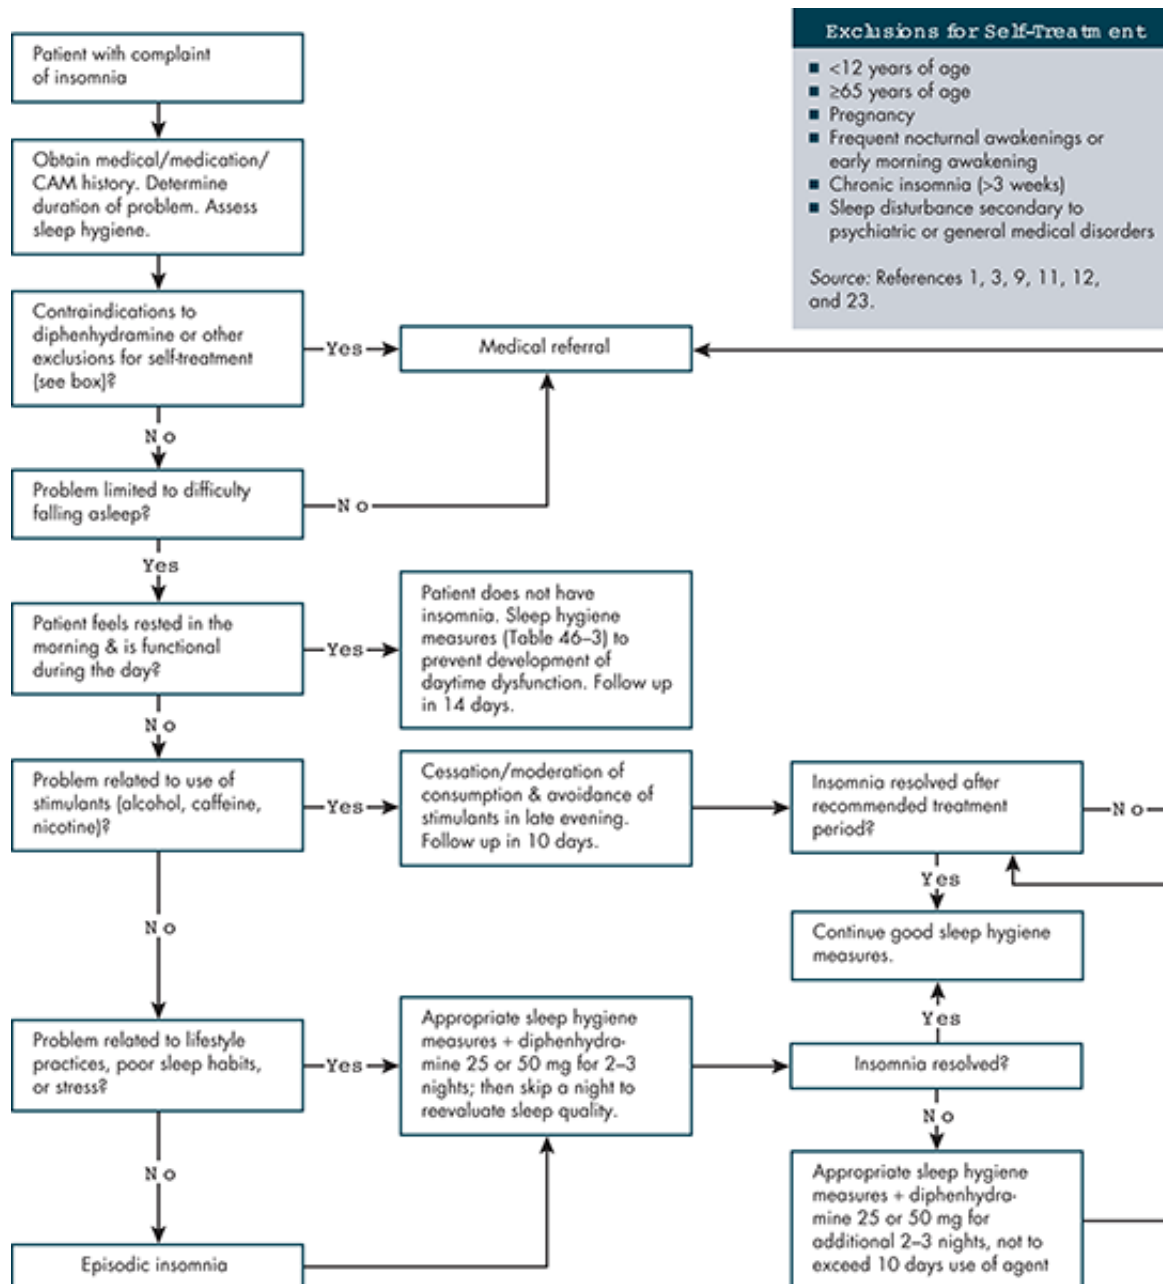

Additive sedation or anticholinergic effects occur when diphenhydramine is used in combination with other medications that have these properties.<sup>12</sup> Diphenhydramine, an inhibitor of the hepatic enzyme CYP2D6, causes more than a twofold decrease in the clearance of metoprolol, especially in women.<sup>15</sup> In patients on multiple medications, particularly older patients, diphenhydramine may reduce the clearance of drugs metabolized by CYP2D6, such as venlafaxine, codeine, or propranolol. These potential interactions should be carefully monitored. Anticholinergic toxicity can result from excessive antihistamine dosages. Other factors, including drug interactions, intentional overdosage, or individual sensitivity, can also lead to toxicity.<sup>12,16</sup> Central nervous system (CNS) anticholinergic toxicity is one of the primary presenting features of antihistamine excess. Patients exhibiting excessive anticholinergic effects can be anxious, excited, delirious, hallucinating, or stuporous. In more severe cases, coma or seizures may occur. Other physical signs of anticholinergic toxicity include dilated pupils, flushed skin, hot and dry mucous membranes, and elevated body temperature. Tachycardia and moderate QTc prolongation on the electrocardiogram are common. In severe cases, rhabdomyolysis, dysrhythmias, cardiovascular collapse, and death can occur.<sup>11,12,16</sup> In the case of diphenhydramine overdose, patients should be referred for emergency treatment, which includes gastric lavage and activated charcoal via gastric tube, and further symptomatic treatment.

The primary adverse effects of diphenhydramine and doxylamine are anticholinergic.<sup>11,13</sup> Dry mouth and throat, constipation, blurred vision, urinary retention, and tinnitus commonly occur. Older patients, patients with comorbid general medical disorders, and patients taking multiple medications are particularly susceptible to developing adverse effects.

Diphenhydramine is contraindicated in several situations. Older men with prostatic hyperplasia and difficulty urinating should not use diphenhydramine because urinary retention can occur. Because anticholinergic agents can increase intraocular pressure, angle-closure glaucoma is another contraindication. Patients with cardiovascular disease, such as angina or arrhythmias, may be particularly susceptible to the anticholinergic adverse effects and should not use these agents.<sup>12</sup> Anticholinergic agents decrease cognition and increase confusion in patients with dementia; diphenhydramine should be avoided in these patients.

Patients should be cautioned to avoid performing tasks that require their full attention or coordination, such as driving, cooking, or operating machinery, until their response is known. They should be discouraged from drinking alcoholic beverages while taking diphenhydramine. Some patients can develop excitation from diphenhydramine and other highly anticholinergic antihistamines.<sup>12</sup> This paradoxical effect occurs more often in children, older patients, and patients with organic mental disorders. Symptoms include nervousness, restlessness, agitation, tremors, insomnia, delirium, and, in rare cases, seizures.

Self-care of transient and short-term insomnia. Key: CAM = Complementary and alternative medication.

Combination products containing diphenhydramine and acetaminophen, ibuprofen, or aspirin are available,<sup>12</sup> although no published studies establish whether these products are of additive benefit in inducing sleep in patients who complain of insomnia caused by pain.

Several case reports have been published of diphenhydramine abuse in patients taking antipsychotic medications.<sup>17</sup> Animal studies indicate that selected antagonists of the histamine<sub>1</sub> receptors enhance dopamine release in the mesolimbic areas similar to that produced by cocaine.<sup>18</sup> Health care providers should carefully assess for abuse in individuals making repeated purchases for diphenhydramine, especially in patients being treated for psychosis.<sup>17</sup>

**TABLE 46-3 Principles of Good Sleep Hygiene**

• Use bed for sleeping or intimacy only.
• Establish a regular sleep pattern. Go to bed and arise at about the same time daily, even on the weekends.
• Make the bedroom comfortable for sleeping. Avoid temperature extremes, noise, and light.
• Engage in relaxing activities before bedtime.
• Avoid using electronic devices (particularly videos, television, and tablets) around bedtime.

• Exercise regularly but not within 2-4 hours of bedtime.
• If hungry, eat a light snack, but avoid eating meals within 2 hours before bedtime.
• Avoid daytime napping.
• Avoid using caffeine, alcohol, or nicotine for at least 4-6 hours before bedtime.
• If unable to fall asleep, do not continue to try to sleep; rather, get out of bed and perform a relaxing activity until you feel tired.
• Do not watch the clock at night.

Source: References 7-10.

## Ethanol

Use of alcohol to induce sleep is common in patients with chronic insomnia and is associated with hazardous drinking behavior.<sup>19</sup> Ethanol, in both low and high quantities, initially improves sleep in people who do not abuse alcohol, but sleep disturbances occur in the second half of the night at high doses. Tolerance quickly develops after the initial beneficial effects, often leading to the use of higher doses. Individuals with heavy or continuous alcohol use usually experience restless sleep, often awaken within 2-4 hours, and have reduced total sleep duration. People who chronically drink alcohol usually have a marked disorganization of the sleep cycle. A worsening of sleep or rebound insomnia can occur when alcohol use ceases.<sup>20</sup>

Alcohol is present in some nonprescription combination cold products, such as NyQuil Liquid, which contains 10% alcohol by volume. Products of this type are marketed to induce sleep. Data are limited, however, regarding the efficacy and safety of these products as hypnotics. The multiple ingredients in these products increase the risk of adverse effects and interactions with other drugs.

## Pharmacotherapeutic Comparisons

Most clinical trials indicate that diphenhydramine is effective in decreasing time to fall asleep (sleep latency) and in improving the reported quality of sleep for individuals with occasional insomnia.<sup>11</sup> Compared with placebo, diphenhydramine improved sleep efficiency for 2 weeks in patients with mild insomnia.<sup>21</sup> In general, diphenhydramine is not as effective as benzodiazepine hypnotics and should not be recommended for a chronic sleep disturbance.<sup>1</sup>

## Product Selection Guidelines

Because the value of doxylamine as a hypnotic is not well established, only diphenhydramine should be recommended to patients for such use. Nonprescription diphenhydramine is available as capsules, gelcaps, tablets, chewable tablets, solutions, and elixirs (Table 46-4), allowing different patient preferences.<sup>12</sup>

**TABLE 46-4 Selected Nonprescription Sleep Aid Products**

<i>Trade Name</i>	<i>Primary Ingredients</i>
<b>Single-Entity Antihistamine Products</b>	
Unisom SleepGels Maximum Strength Capsules, liquid filled	Diphenhydramine HCl 50 mg
Sominex Nighttime Sleep Aid Tablets	Diphenhydramine HCl 25 mg
ZzzQuil Liquid Sleep-Aid Liquid	Diphenhydramine HCL 50 mg
<b>Antihistamine/Analgesic Combination Products</b>	
Advil PM Caplets	Diphenhydramine citrate 38 mg; ibuprofen 200 mg
Bayer PM Caplets	Diphenhydramine citrate 38 mg; aspirin 500 mg
Excedrin PM Geltabs/Caplets/Tablets	Diphenhydramine citrate 38 mg; acetaminophen 500 mg

Tylenol PM Extra Strength Geltabs/Gelcaps/Caplets

Diphenhydramine HCl 25 mg; acetaminophen 500 mg

*Note:* Information is not all inclusive. Products may have changed formulations since time of publication.

## Special Populations

The safety of antihistamines during pregnancy has not been established.<sup>12</sup> Therefore, the benefit-risk ratio of using these drugs to manage insomnia during pregnancy should be carefully evaluated. In April 2013, FDA approved the combination of doxylamine succinate and pyridoxine HCl for treatment of pregnant women experiencing nausea and vomiting. This product has been given a Pregnancy Category A. Diphenhydramine is classified as Pregnancy Category B based on safety studies conducted in animals. Most epidemiologic studies have not demonstrated increased risk of teratogenicity with the use of diphenhydramine during the first trimester, but one trial reported cleft palate alone and with other fetal abnormalities.<sup>11</sup> Nevertheless, rather than recommending a nonprescription product, pregnant women should be referred for further medical evaluation.

An increased risk of CNS adverse effects can occur in breast-fed neonates after maternal intake of a sedating antihistamine. The intermittent use of low doses of diphenhydramine by the mother after the last daytime feeding would lessen potential drug effects in the infant. Use of large dosages for sustained periods of time may inhibit lactation and cause drowsiness in breast-fed infants.<sup>22</sup> Continued use of sedating antihistamines for insomnia are not recommended for use in nursing mothers.<sup>11-13</sup>

Children and adolescents may present with insomnia because of a circadian rhythm disorder. Teenagers should be asked about their use of nonprescription remedies and intake of caffeine, nicotine, or alcohol. Behavioral interventions and good sleep hygiene are first-line treatment for insomnia in children and adolescents.

Diphenhydramine and doxylamine are not indicated to treat insomnia in children younger than 12 years.

Diphenhydramine may cause paradoxical excitation in younger children and is not recommended to induce sleep in infants.<sup>11</sup> Anticholinergic toxicity is common in children, and the symptoms may be more severe. Diphenhydramine toxicity was reported in children using the topical application over large areas of their bodies, as well as in those using both the topical and oral preparations.<sup>11</sup> FDA requires a warning statement advising consumers not to use oral nonprescription diphenhydramine products with any other product containing diphenhydramine, including topical agents.<sup>11</sup>

Treatment of insomnia in older adults consists of behavioral therapy and pharmacotherapy with approved agents.

The Beers criteria recommend avoiding the use of anticholinergic drugs in older adults.<sup>23</sup> Diphenhydramine has caused cognitive impairment and falls in older patients.<sup>1,24</sup> Therefore, nonprescription antihistamines should not be recommended to treat insomnia in this age group, and the patients should be referred to their health care provider for further evaluation.

## Complementary Therapies

Complementary therapies such as melatonin, valerian, and kava are commonly used for insomnia (see chapter 51).

In a representative sample of the U.S. population, 5.2% used melatonin and 5.9% used valerian.<sup>25</sup> The decision to use natural products for insomnia was made in consultation with a health care provider less than 50% of the time.<sup>25</sup>

A report on the safety and effectiveness of melatonin found that, for most sleep disorders, its benefits are limited.<sup>26</sup> Melatonin may be effective in short-term treatment of delayed sleep phase syndrome (i.e., a sleep pattern characterized by a delayed onset of sleep by 2 or more hours from normal, resulting in a later bedtime and wake time).<sup>26</sup> Evidence of its efficacy is conflicting and limited.

Valerian (*Valeriana officinalis*) has limited benefit in insomnia compared with placebo.<sup>27</sup> Clinical trials have used 400-900 mg of the valerian root extract. Continuous nightly use for several days or weeks is required for effect, so valerian is not useful for acute insomnia. Patients using large dosages of valerian over several years can experience severe benzodiazepine-like withdrawal symptoms and cardiac complications.<sup>27</sup> Valerian should be slowly tapered after extended use.

Kava (*Piper methysticum*) has been used in insomnia and has been associated with severe hepatotoxicity.<sup>28</sup> Therefore, kava should not be recommended as a sleep aid.

The American Academy of Sleep Medicine recommends that dietary supplements not be used to treat insomnia or any other sleep problem, unless approved by a health care provider, because of the risk of adverse effects and drug interactions.<sup>29</sup> (See Chapter 51.)

Complementary therapies such as acupuncture, tai chi, and light therapy may be useful in the treatment of insomnia.<sup>1,28</sup> However, these treatments have not been adequately evaluated.

## Assessment of Insomnia: A Case-Based Approach

In assessing whether to recommend a nonprescription sleep aid, the provider should determine whether use of such products is appropriate, what nondrug interventions should be recommended, and whether referral to another health care provider is indicated. Identifying acute causes of insomnia, poor sleep hygiene practices, or underlying medical disorders can assist the provider in making a recommendation.

Case 46-1 illustrates the assessment of a patient with insomnia.

### Patient Counseling for Insomnia

Patients with sleep disorders should be encouraged to practice good sleep hygiene measures. For some patients, these measures alone will resolve insomnia. If use of a nonprescription sleep aid is appropriate, the dosage guidelines and recommended duration of therapy should be reviewed with the patient. Potential adverse effects, drug interactions, and any precautions or warnings should be carefully explained. In addition, patient education should include the signs and symptoms that indicate the need for further visits to the provider. Taking more than one product (i.e., prescription, nonprescription, and dietary supplements) concomitantly to treat insomnia should be discouraged; this approach increases the risk of adverse effects. The box Patient Education for Insomnia lists specific information to provide patients.

### Evaluation of Patient Outcomes for Insomnia

Successful outcomes include decreased time to fall asleep, improved sleep quality, and decreased daytime fatigue and drowsiness. The patient should be advised to seek medical evaluation if sleep has not improved in 10 days.<sup>12</sup>

### Key Points for Insomnia

- Refer patients with chronic insomnia or sleep disturbance caused by an underlying disorder for medical evaluation.
- Advise patients with self-treatable symptoms that if symptoms worsen or do not improve after 10 days, they should contact their health care provider.
- Counsel patients with insomnia on nondrug measures such as good sleep hygiene (Table 46-3).
- Refer children younger than 12 years, pregnant women, and adults older than 65 years with insomnia to their health care provider.
- Advise patients about the different dosage forms of sleep aids so they can select a product that is best suited for them.
- Advise patients that diphenhydramine is the only antihistamine recommended as a sleep aid for occasional insomnia.
- Counsel patients that nonprescription sleep aids can cause next-day sedation.
- Counsel patients on the adverse effects of diphenhydramine and other sleep aids, particularly drowsiness and the additive CNS depressant effects of alcohol and other sedating drugs.
- Advise patients not to take other oral medications that contain diphenhydramine with a nonprescription sleep aid that also contains diphenhydramine.
- Advise patients not to apply topical products that also contain diphenhydramine.
- Advise patients to discuss the potential risks and benefits of complementary therapies with their health care provider before selecting an agent.

### Patient Education for Insomnia

The objectives of self-treatment are to (1) improve the duration and quality of sleep, (2) reduce fatigue and drowsiness during the day, (3) improve daytime functioning, and (4) minimize adverse effects of treatment. Carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes for most patients.

### Disease Information

- Insomnia is difficulty getting enough sleep or trouble sleeping without interruption. Insomnia may be described as difficulty falling asleep, waking up too early, or waking up periodically during the night. Insomnia can cause fatigue and drowsiness during the day. Insomnia is *chronic* when it happens almost nightly for at least 1 month. Insomnia can be caused by medical or psychiatric conditions, mental stress or excitement, or certain daytime and bedtime habits. If prescribed a medication that can exacerbate insomnia, talk with your health care provider about taking the medication in the morning (e.g., corticosteroids).

### Nondrug Measures

- See Table 46-3 for nondrug measures to prevent insomnia.
- Using principles of good sleep hygiene can help improve bad sleep habits and enhance quality sleep.
- If insomnia worsens or continues beyond 2 weeks, seek medical attention.

## Nonprescription Medications

- Do not drive or operate machinery after taking sleep aids, including melatonin and valerian.
- Diphenhydramine is not expected to harm an unborn baby. Tell your doctor if you are pregnant or plan to become pregnant during treatment.
- Diphenhydramine may pass into breast milk and may harm a nursing baby. Antihistamines may also slow breast milk production. Do not use this medicine without medical advice if you are breast-feeding a baby.

### Diphenhydramine

- Establish a regular bedtime and take diphenhydramine 30-60 minutes before you want to go to sleep. Do not take more than 50 mg of diphenhydramine each night.
- After 2-3 nights of improved sleep, skip taking the medication for one night to see if the insomnia is relieved.
- Do not take the medication longer than 10 days. Longer use will cause tolerance to the medication's sleep-inducing effects but not necessarily to its side effects, and you may have an underlying disorder that is causing insomnia.
- Note that diphenhydramine can cause morning grogginess or excessive sedation, dry mouth, blurred vision, constipation, and difficulty urinating (particularly in older men).
- Do not take diphenhydramine with alcohol; alcohol can increase the effects of the medication on the central nervous system. Alcohol also disrupts the sleep cycle.
- Do not take diphenhydramine with prescription sleep aids to improve sleep further.
- Consult your health care provider before taking diphenhydramine with other medications.

### Case 46-1

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of difficulty sleeping for the past 2 weeks. He feels tired and irritable during the day and an overwhelming need for a nap midday.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Difficulty falling asleep began after the patient was laid off from his job as a computer programmer. Previously, he typically slept well.
c. description of the patient's efforts to relieve the symptoms	He tries to stay up until he is sleepy at night. He states that he lies in bed and begins worrying when he cannot fall asleep. He watches the alarm clock, knowing that he has to get up in a few hours to continue a job search. When he can't fall asleep, he usually turns on the television or plays games on his computer.
d. patient's identity	Mitchell Gibbs
e. age, sex, height, and weight	26 years old, male, 5 ft 11 in., 190 lb

f. patient's occupation	Computer programmer; currently unemployed
g. patient's dietary habits	Patient usually eats fast food at least once daily. He drinks 3-4 cups of coffee in the morning, 2-3 Diet Coke sodas through the day, and a 5-hour ENERGY Extra Strength in the afternoon when he feels tired.
h. patient's sleep habits	Stays up late working on his computer or watching television. Often sleeps in on the weekends until noon to "make up for lost sleep." He takes an hour-long nap in the afternoon 2-3 times weekly.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Allergic rhinitis: Allegra D 24-hour allergy and congestion (fexofenadine 180 mg and 240 mg pseudoephedrine) daily; nasal saline prn
j. allergies	Penicillin: throat swelling
k. history of other adverse reactions to medications	None
l. other (describe) _____	Drinks two to three beers every night to help him go to sleep. Denies use of tobacco.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Poor sleep, likely secondary to the stress of loss of job and poor sleep hygiene. Possible use of alcohol on a daily basis, use of a decongestant, and excessive caffeine are disrupting sleep.
3. Identify exclusions for self-treatment (Figure 46-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Mitchell to his health care provider. (2) Recommend diphenhydramine until Mitchell can make an appointment with his health care provider. (3) Recommend diphenhydramine and good sleep hygiene, including limiting daily alcohol and caffeine use and engaging in regular physical activity. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's	Diphenhydramine 50 mg tablets and good sleep hygiene measures, as well as limited alcohol and caffeine consumption.

problem, taking into account patient preferences.	
6. Describe the recommended therapeutic approach to the patient or caregiver.	<p>“Take 1 diphenhydramine 50 mg tablet ½-1 hour before your anticipated bedtime every night for 3 nights. Skip 1 night and evaluate your ability to sleep. If not improved, continue diphenhydramine for 3 more nights, and reevaluate ability to sleep without it. If symptoms persist for 10 days, seek medical evaluation.”</p> <p>“Follow measures for positive sleep hygiene (Table 46-3). Limit alcohol consumption to 1-2 beers or less, consumed no later than 2 hours before bedtime. Limit overall intake of caffeine, and at a minimum, avoid caffeine 6 hours before bedtime.”</p>
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	<p>“A consistent sleep pattern will help resolve your insomnia. Seeing your health care provider may not be necessary if you take the diphenhydramine and follow good sleep hygiene measures. Poor sleep practices are a common cause of insomnia. If these practices are continued, they can create a chronic sleep disturbance. A medicine such as diphenhydramine can facilitate falling asleep, but it must be combined with measures of good sleep hygiene.”</p> <p>“Alcohol in more than modest quantities can disrupt sleep and make insomnia worse. Therefore, alcohol consumption should be limited and avoided before bedtime. In addition, caffeine is a stimulant that promotes wakefulness. Caffeine intake should be limited and not occur within 6 hours of bedtime. Reduce intake of sodas and stop the 5-hour ENERGY Extra Strength drinks. The Diet Coke contains 47 mg of caffeine in each 12-ounce drink. The 5-hour ENERGY Extra Strength contains 242 mg of caffeine, which is equivalent to 2.5 cups of coffee. All dietary (e.g., coffee, sodas, and energy drinks) and hidden sources of caffeine (e.g., chocolate) should be identified.”</p> <p>“The pseudoephedrine in the Allegra-D 24-hour tablets may also contribute to insomnia. You may take Allegra 24-hour tablets without the decongestant for your allergies.”</p>
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	<p>“Take diphenhydramine 50 mg nightly for 3 nights; then reevaluate sleep for 1 night without the medication. Do not exceed this nightly dose. Always use sleep aids in combination with good sleep hygiene measures (Table 46-3). Do not take sleep aids nightly longer than 10 days without seeing your health care provider.”</p> <p>“Avoid drinking alcohol with the diphenhydramine because of the risk of increased sedation and negative effects of alcohol on sleep patterns.”</p> <p>“Adverse effects may include sedation, next-morning hangover, and anticholinergic effects (e.g., dry mouth, urinary retention, blurry vision, and constipation).”</p>
Solicit follow-up questions from the patient or caregiver.	<p>(1) “May I repeat the dose of diphenhydramine if I do not fall asleep within 2 hours?”</p> <p>(2) “May I take diphenhydramine with my Allegra-D allergy medication?”</p>
Answer the patient's or caregiver's questions.	<p>(1) “No. Repeating the dose increases the risk of side effects and will likely not improve sleep.”</p> <p>(2) “You should continue the saline nasal spray while using the diphenhydramine. Do not take the Allegra-D on the days you take diphenhydramine because both are antihistamines.”</p>
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	<p>Contact the patient in 2-3 days to assess efficacy of diphenhydramine and improved sleep hygiene measures. Remind the patient that if the insomnia continues for longer than 10 days he should make an appointment for evaluation with his health care provider.</p>

## Drowsiness and Fatigue

Drowsiness or fatigue may be acute in onset or chronic and can increase the risk of workplace or transport-related accidents, as well as adversely impact productivity, mood, and overall health.<sup>30,31</sup> Evidence indicates an increased incidence of sleep-related crashes in young drivers who report an average of less than 6 hours of sleep per night.<sup>32</sup> Caffeine is the most frequently used CNS stimulant in the world. An estimated 90% of adults report routine caffeine intake, an average of 227 mg daily (1.3 mg/kg), through ingestion of coffee, tea, and soft drinks. Youths consume less caffeine than adults daily; caffeine consumption averaged 69.5 mg (0.55 mg/kg) in those ages 12-17 years and 21 mg (0.4 mg/kg) in those ages 2-11 years.<sup>33</sup> Energy drinks are popular with adolescents and young adults. [Table 46-5](#) lists the caffeine content of common beverages. Caffeine is in many nonprescription, prescription, and dietary supplements. Total daily caffeine intake leads to adverse effects, withdrawal reactions, or, rarely, drug interactions.

## Pathophysiology of Drowsiness and Fatigue

Daytime drowsiness and fatigue are most often caused by inadequate sleep, both insufficient duration and quality of sleep. The degree of sleepiness is determined by two factors that regulate sleep and wakefulness: (1) a homeostatic process involving an increase in sleepiness as time since the most recent period of sleep increases and (2) a circadian process by which the master biologic clock in the suprachiasmatic nucleus varies alertness over the course of the 24-hour day.<sup>34</sup> Other possible contributing factors include the use of CNS depressants, such as antihistamines, antipsychotics, anticonvulsants, and opioids. Dopamine agonists, antibiotics, and antihypertensive agents may also increase the risk of drowsiness. Increased susceptibility to the sedating effects of these agents can be particularly troublesome in older patients. Other etiologies include depression, cancer, anemia, hypothyroidism, and chronic pain, overexertion, or imbalances in diet and exercise.<sup>30,31</sup>

**TABLE 46-5 Caffeine Content in Common Beverages**

<i>Coffees, Teas, and Soft Drinks</i>	<i>Ounces</i>	<i>Caffeine Content (mg)</i>
Coffee	8	108
Coffee, decaffeinated	8	6
Starbucks coffee, tall	12	260
Starbucks coffee, grande	16	330
Espresso	2	100
Instant coffee	8	57
Brewed tea, U.S. brands	8	40
Snapple Iced Tea	8	21
Mountain Dew	12	54
Diet Coke	12	46.5
Coca-Cola	12	34.5
Dr. Pepper	12	41

*Note:* The listed caffeine content for the brewed coffees and teas may vary according to brewing methods.

## Clinical Presentation of Drowsiness and Fatigue

The subjective experience of sleepiness includes yawning, eye rubbing, tendency to fall asleep, and decreased ability to focus and concentrate. Self-reported measures of sleepiness include the Stanford Sleepiness Scale and the Epworth Sleepiness Scale.<sup>35</sup>

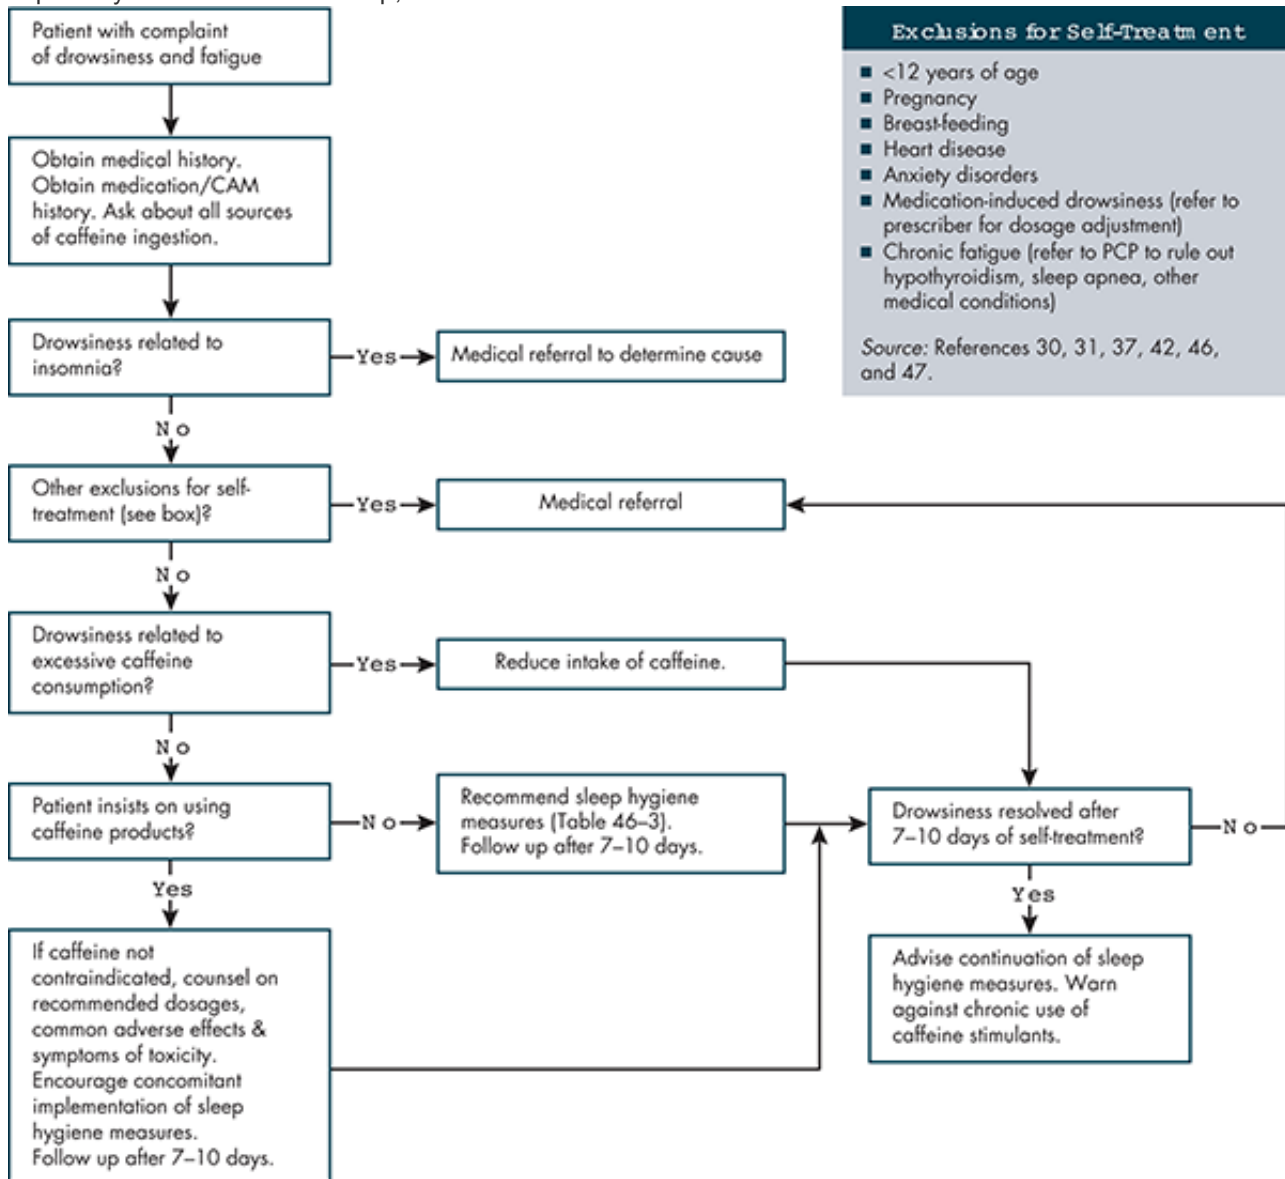

## Treatment of Drowsiness and Fatigue

### Treatment Goals

The goal in treating daytime drowsiness and fatigue is to identify and eliminate the underlying cause to improve mental alertness and productivity. The algorithm in [Figure 46-2](#) outlines the approach to self-treatment.

### General Treatment Approach

Many consumers use dietary sources of caffeine to self-treat occasional symptoms of fatigue and drowsiness. Nonprescription caffeine-containing products may also be used. Caffeine as a supplement, or in dietary form, is not a substitute for adequate sleep. Before recommending any caffeine-containing nonprescription product, the health care provider should rule out any drug-induced cause of daytime drowsiness and fatigue. If symptoms are chronic, especially with 7-8 hours of sleep, referral is indicated.

Self-care of drowsiness and fatigue. Key: CAM = Complementary and alternative medication; PCP = primary care provider.

### Nonpharmacologic Therapy

Good sleep hygiene principles should be emphasized ([Table 46-3](#)).

### Pharmacologic Therapy

Caffeine is a nonselective adenosine antagonist at the A<sub>1</sub> and A<sub>2A</sub> receptors. Adenosine acts centrally to promote sleep. Secondary effects on other neurotransmitters such as dopamine and acetylcholine may also increase alertness.<sup>36</sup>

Low-to-moderate caffeine doses increase arousal, decrease fatigue, and elevate mood; higher doses are associated with anxiety, nausea, jitteriness, and nervousness.<sup>37</sup> Caffeine possesses weak bronchodilatory action and stimulates the sympathetic nervous system. Moderate caffeine doses (250 mg) can cause a transient increase in heart rate and

blood pressure.<sup>38</sup>

Caffeine is completely absorbed, reaching a peak concentration within 30-75 minutes. It is rapidly and widely distributed with an almost immediate effect on alertness. Caffeine is metabolized in the liver by the CYP1A2 isoenzyme; the primary demethylated metabolite is paraxanthine, which predominantly exerts a sympathomimetic effect. Other active metabolites are theobromine and theophylline. Paraxanthine can accumulate with higher dosages and reduce the clearance of caffeine. The elimination half-life is 3-6 hours.<sup>38</sup>

Caffeine is the only FDA-approved nonprescription stimulant, and [Table 46-6](#) lists selected trade-name caffeine-containing products. The labeled dosages of approved nonprescription supplements for adults and children 12 years of age and older is 100-200 mg every 3-4 hours as needed. Caffeine is marketed for occasional use to help restore mental alertness or wakefulness.<sup>39</sup>

Rapid tolerance to the effects of caffeine on the respiratory and cardiovascular systems is common. Habitual caffeine drinkers who routinely consume as little as 1-2 cups of coffee and abruptly discontinue caffeine may experience mild signs and symptoms of withdrawal. Symptoms include headache, fatigue, decreased concentration, and irritability, starting within 12-24 hours after cessation and persisting for 1-5 days.<sup>40</sup>

**TABLE 46-6 Selected Caffeine-Containing Products**

<i>Trade Name</i>	<i>Caffeine Content (mg)</i>
<b><i>Nonprescription Caffeine-Only Products</i></b>	
NoDoz Maximum Strength	200
Vivarin	200
<b><i>Nonprescription Combination Products</i></b>	
Anacin Tablets	32
Excedrin Migraine Caplets	65
Midol Complete Caplets	60
<b><i>Prescription Combination Products</i></b>	
Cafergot	100
Fioricet	40
Fiorinal	40

*Note:* Information is not all inclusive. Products may have changed formulations or caffeine content since time of publication.

An exaggerated pharmacologic effect can occur when nonprescription caffeine is combined with dietary sources, or with prescription or nonprescription medications that contain caffeine ([Table 46-6](#)). Caffeine may increase the absorption of aspirin or reduce the clearance of theophylline to cause additive sympathetic effects such as an increased heart rate.

The CYP1A2 isoenzyme can be induced or inhibited by other drugs. The routine use of high dosages of caffeine (400 mg/day) could theoretically saturate the binding sites and increase the risk of interactions with drugs that share this metabolic pathway, such as clozapine. Cigarette smoking increases the clearance of caffeine by 56%.<sup>41</sup> When quitting smoking, individuals should be counseled to reduce their caffeine intake by half.<sup>42</sup> Conversely, hormonal contraceptives and ciprofloxacin can inhibit the CYP1A2 isoenzyme. The clinical significance of these interactions is unknown, but at-risk patients should be cautioned to moderate their use of caffeine. They should also be monitored for signs of such interactions. Genetic polymorphisms at CYP1A2 and adenosine receptors may also influence response to caffeine.<sup>37</sup>

Patients on monamine oxidase inhibitors or with existing coronary heart disease, uncontrolled hypertension, or preexisting arrhythmias should be counseled to avoid nonprescription caffeine-containing preparations and to moderate their intake of dietary caffeine. The consumption of coffee increases blood pressure. An increase in systolic blood pressure by 2 mm Hg occurred after acute administration of caffeinated coffee for 1-12 weeks.<sup>43</sup> A small increase in blood pressure was demonstrated in healthy individuals and patients with hypertension after chronic consumption of caffeine (4.2 mm Hg systolic; 2.4 mm Hg diastolic).<sup>43</sup>

When taken before sleep, caffeine delays sleep onset, reduces deep sleep, and increases nocturnal awakenings.

After sleep deprivation, caffeine improved psychomotor performance, maintained alertness, and reduced fatigue.<sup>40</sup> In driving simulation tests, caffeine 200 mg was compared with placebo on driving performance and sleepiness during early morning hours.<sup>44</sup> After “restricted sleep,” caffeine reduced early morning sleepiness for 2 hours; after “no sleep,” caffeine delayed sleep by only 30 minutes. Patients should be counseled that caffeine cannot compensate for an inadequate amount of sleep.

The use of caffeinated coffee to counter the effects of excessive alcohol ingestion is a common practice. In a randomized, double-blind study, the effect of caffeine (200 and 400 mg) versus placebo on driving performance was measured in a driving simulator in alcohol-impaired adults.<sup>45</sup> Both doses of caffeine were effective in counteracting “brake latency” but did not counteract other driving impairments caused by the alcohol. In 2010, FDA banned production of caffeinated alcoholic beverages secondary to safety concerns.<sup>46</sup>

Patients should be cautioned about excessive consumption of caffeine in weight-loss supplements and energy sports drinks. Natural caffeine, other methylxanthines, and caffeine-containing herbs, such as guarana, green tea, yerba mate, and cola nut, are common ingredients in products that are marketed to young consumers for energy or weight loss, but the caffeine content is often not listed on the label.<sup>46</sup> Table 46-7 lists the amount of caffeine that is contained in both selected weight-loss dietary supplements and sports energy drinks.

**TABLE 46-7 Caffeine Content in Selected Dietary Supplements and Energy Drinks**

<i>Trade Name</i>	<i>Caffeine Content per Serving (mg)</i>
<b><i>Dietary Supplements</i></b>	
Dexatrim Max Daytime Appetite Control	200
Metabofit Blend	264 <sup>a</sup>
<b><i>Energy Drinks<sup>b</sup></i></b>	
Monster Energy	80 <sup>c</sup>
Red Bull	80 <sup>d</sup>
Rockstar Juiced	80 <sup>e</sup>

*Note:* Information is not all inclusive. Products may have changed formulations or caffeine content since time of publication.

<sup>a</sup> Total amount of methylxanthines from natural sources.

<sup>b</sup> Caffeine content based on serving size sold.

<sup>c</sup> Also contains 1000 mg taurine, 200 mg Panax ginseng, and guarana seed extract.

<sup>d</sup> Also contains 1000 mg taurine.

<sup>e</sup> Also contains 1000 mg taurine, 25 mg Panax ginseng, and 25 mg guarana seed extract.

#### Product Selection Guidelines

#### Special Populations

Nonprescription oral caffeine tablets do not have an FDA Pregnancy Category.<sup>47</sup> Caffeine freely crosses the placenta.<sup>47</sup> The American College of Obstetricians and Gynecologists has concluded that moderate caffeine consumption ( $\leq 200$  mg/day) does not contribute to miscarriages or preterm births.<sup>48</sup> Total daily caffeine intake should be limited to less than 200 mg during pregnancy. The American Academy of Pediatrics considers usual dietary amounts of caffeine compatible with breast-feeding.<sup>48</sup> Infants unable to metabolize caffeine or those who receive large quantities of caffeine through breast milk may have symptoms of nervousness, increased heart rate, sleeplessness, poor feeding, and irritability. Nursing women should consume caffeine only in small-to-moderate amounts, preferably after breast-feeding to minimize effects on the infant.

Children are more susceptible to the cardiovascular and CNS adverse effects of caffeine because of their lower body

weight. In one study of adolescents (ages 12-17 years), dosages of 50 mg, 100 mg, and 200 mg of caffeine per day significantly increased diastolic blood pressure.<sup>49</sup> Nonprescription caffeine products are not indicated in children younger than 12 years.

The elimination half-life of caffeine is prolonged in older adults, increasing their susceptibility to an exaggerated pharmacologic effect and interference with sleep.<sup>42</sup> Older adults should avoid consuming caffeine in the diet or as an ingredient in a medication after dinner.

### Complementary Therapies

Ginseng is frequently used to boost physical and mental energy and a sense of well-being. A review of randomized controlled trials reveals contradictory scientific evidence to support these claims (see [Chapter 51](#)). Caffeine-containing dietary supplements that patients may be using include cola nut, guarana, and yerba mate. Ingredients purported to counteract fatigue that are often found in sports energy drinks include taurine and guarana, although the amounts are unlikely to produce either therapeutic or adverse effects.

### Assessment of Drowsiness and Fatigue: A Case-Based Approach

When assessing a patient with a complaint of daytime drowsiness, the provider should determine the cause of the patient's fatigue. Evaluating the patient's medical or psychiatric problems, current medication use, dietary caffeine consumption, sleep patterns, and lifestyle will help in determining the underlying cause. Given the lack of data supporting the efficacy of caffeine, and the adverse effects associated with recommended and excessive dosages, health care providers should recommend improved sleep hygiene and lifestyle modifications or medical referral before recommending the use of a caffeine-containing product.

Case 46-2 provides an example of the assessment of a patient with drowsiness and fatigue.

### Patient Counseling for Drowsiness and Fatigue

Counseling on the treatment of drowsiness and fatigue should focus on practicing good sleep hygiene and eliminating factors that may interfere with normal sleep. If a caffeine product is indicated, the health care provider should review dosage guidelines with the patient and emphasize the potential adverse effects and drug interactions. The patient should be counseled on symptoms of excessive caffeine ingestion, such as irritability, tremor, rapid pulse, dizziness, or heart palpitations. Regular users of caffeine should also be counseled on withdrawal symptoms such as headache and anxiety, which can occur if caffeine from any source is stopped abruptly. The box Patient Education for Drowsiness and Fatigue lists information to provide patients.

### Evaluation of Patient Outcomes for Drowsiness and Fatigue

Successful outcomes include daytime alertness, increased productivity, and peak performance with respect to psychomotor tasks and cognitive function, including attention and concentration. An individual should seek medical evaluation if, after 7-10 days, drowsiness and fatigue persist despite the limited use of caffeine and the establishment of good sleep hygiene.

### Key Points for Drowsiness and Fatigue

- Advise patients that caffeine appears to be safe and effective in low-to-moderate doses in the diet, as well as for occasional use as a nonprescription supplement during completion of tasks of short duration when enhanced alertness is desired.
- Instruct patients that caffeine is most effective when taken intermittently at dosages of 100 or 200 mg every 3-4 hours as needed.
- Pregnant or nursing women, children younger than 12 years, patients with heart disease, and patients with anxiety disorders should avoid caffeine.
- Health care providers should be aware of the prescription and nonprescription medications and diet supplements that contain caffeine, as well as the patient's dietary consumption of caffeine.
- Adverse effects of caffeine are more likely to occur in occasional users and patients of advanced age.
- Advise patients taking higher daily dosages of caffeine that drug interactions can occur with some medications.
- Counsel patients that dietary supplements should not be used to increase energy or decrease fatigue.

### Case 46-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<i>Information Gathering</i>	

1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient requests help in choosing a product to help her stay awake. She is extremely tired and wants to be more alert during the day. She has become increasingly fatigued with decreased concentration. Her husband has complained that she is "too moody" and wants her to pull herself together, especially regarding housework and cooking. She falls asleep easily but wakes earlier than usual.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient retired 4 years ago and volunteers at her church and a local food bank and belongs to a weekly book club. Over the past month, she either had no energy to volunteer or left early to return home to take a nap. She describes her mood as "low" and lacks the ability to concentrate on reading a book, let alone attend the book club.
c. description of the patient's efforts to relieve the symptoms	The patient recently increased coffee intake from 1 regular cup daily to 2-3 cups spread out over the day.
d. patient's identity	Brenda Loving
e. age, sex, height, and weight	69 years old, female, 5 ft 2 in., 118 lb
f. patient's occupation	Retired mathematics teacher
g. patient's dietary habits	Vegetarian and adheres to a no-added-salt diet. Usually drinks 1 cup of coffee daily but has increased consumption over the past 2 weeks.
h. patient's sleep habits	Falls asleep around 9 pm nightly and has early morning awakening with trouble getting back to sleep. Has trouble getting out of bed in the morning because her arms and legs feel heavy.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Atrial fibrillation: diltiazem extended-release 180 mg daily; atenolol 25 mg daily; aspirin 81 mg daily; urinary incontinence: tolterodine 2 mg twice daily; hot flashes: black cohosh 40 mg daily
j. allergies	Sulfa drugs: rash
k. history of other adverse reactions to medications	Codeine caused severe nausea.
l. other (describe) _____	NA
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly	Daytime fatigue

Identify the patient's primary problem(s).	
3. Identify exclusions for self-treatment ( <a href="#">Figure 46-2</a> ).	OTC stimulants should not be used in patients with heart disease.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Brenda to her health care provider. (2) Recommend an OTC stimulant until Brenda can make an appointment to see her health care provider. (3) Recommend good sleep hygiene and an OTC stimulant to prevent fatigue. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The patient should be referred to her health care provider for evaluation for depression. Patient findings that suggest depression are daytime fatigue, loss of interest in usual activities, decreased concentration, a "low mood," and waking up early in the morning with a heavy feeling in her extremities. Sleep hygiene education ( <a href="#">Table 46-3</a> ) should be offered. Stimulants should not be recommended because a psychiatric condition is the cause of the fatigue and caffeine can prolong the half-life of aspirin.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should make an appointment to see your health care provider."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Because this problem of fatigue may be caused by depression, you should make an appointment with your health care provider for a physical examination. Stimulant medication is not indicated at this time because your provider will have to decide the best method of treatment. Even before you see your health care provider, you should reduce your intake of coffee and begin sleep hygiene measures."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"Can I still drink one cup of coffee a day?"
Answer the patient's or caregiver's questions.	"Yes. Continue with your previous routine."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact the patient in 1-2 days to ensure that she made an appointment and sought medical care.

Key: NA = Not applicable; OTC = over-the-counter.

### Patient Education for Drowsiness and Fatigue

The objective of self-treatment is to maintain wakefulness. For most patients, improved sleep hygiene will help ensure optimal therapeutic outcomes. If the patient insists on taking a caffeine-containing product, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes for most patients.

#### Disease Information

- Symptoms of drowsiness and fatigue often include yawning, a tendency to fall asleep, and decreased ability to focus and concentrate.

#### Nondrug Measures

- Practice principles of good sleep hygiene ([Table 46-3](#).)
- If drowsiness or fatigue persists or recurs, consult your health care provider.

#### Nonprescription Medications

- Do not exceed the recommended dose of 200 mg every 3-4 hours. Note that higher doses of caffeine may cause side effects and that chronic use may result in tolerance as well as withdrawal symptoms upon abrupt discontinuation.
- Do not use caffeine tablets in combination with coffee or other caffeinated products, including dietary supplements.
- Do not use if pregnant or breast-feeding.
- Do not use in children younger than 12 years.
- If you are taking clozapine, hormonal contraceptives, or ciprofloxacin, consult your health care provider before using caffeine-containing products.
- If you have a history of peptic ulcer disease, psychiatric disorders, symptomatic heart disease, or uncontrolled hypertension, consult your health care provider before using caffeine products.

#### When to Seek Medical Attention

- Seek medical attention immediately if the following symptoms of caffeine toxicity occur at the same time:
  - Increases in heart rate and blood pressure
  - Headache
  - Symptoms of anxiety and insomnia
  - Increase in hand tremor

## Handbook of Nonprescription Drugs &gt; Chapter 47. Tobacco Cessation

**Tobacco Cessation: Introduction**

In 1982, the U.S. Surgeon General C. Everett Koop stated that cigarette smoking was the "chief, single, avoidable cause of death in our society and the most important public health issue of our time."<sup>1</sup> This statement remains true over 3 decades later. In the United States, cigarette smoking is the leading known cause of preventable death,<sup>2</sup> responsible for an estimated 443,595 deaths each year.<sup>3</sup> In addition to lives lost, the economic impact of smoking is enormous, costing society approximately \$193 billion annually for smoking-attributable health expenditures and lost productivity.<sup>3</sup> The negative effects of smoking are both well established and well publicized, yet an estimated 42.1 million adult Americans (18.1% overall in 2012; 20.5% of males and 15.8% of females) smoked either every day (77.8%) or some days (22.2%).<sup>4</sup> The prevalence of smoking varies by sociodemographic factors, including gender, race/ethnicity, education level, age, and socioeconomic status. The prevalence of smoking in the United States was highest among non-Hispanic American Indians/Alaska Natives (21.8%) and lowest among non-Hispanic Asians (10.7%). Smoking is more common among people ages 25-44 years (21.6%) and people of lower educational levels and those living below the federal poverty level (27.9%).<sup>4</sup> The median prevalence of smoking varies by state, with Utah exhibiting the lowest prevalence at 11.8% and Kentucky exhibiting the highest at 29.0%.<sup>5</sup> Smoking incidence differs in patients with various medical conditions, with the greatest prevalence among patients with mental illness. This population consumed about 30.9% of all cigarettes sold in the United States during 2009-2011.<sup>6</sup> Despite tobacco control efforts at the state and national levels, tobacco use is a prevailing public health issue of great importance, and only Utah has met the *Healthy People 2020* target goal of a 12% or lower prevalence of smoking.<sup>7</sup> Globally, nearly 6 million deaths attributable to tobacco occur annually; unless tobacco control efforts are able to reverse this trend, the number of annual deaths is likely to exceed 8 million by 2030.<sup>8</sup>

*Editor's Note:* This chapter is based on the 17th edition chapter of the title "Smoking Cessation," written by Karen Suchanek Hudmon, Lisa A. Kroon, and Robin L. Corelli.

**Pathophysiology of Tobacco Use and Dependence**

In 1988, the U.S. Surgeon General released a landmark report that concluded that tobacco products are effective nicotine delivery systems capable of inducing and sustaining chemical dependence.<sup>9</sup> The primary criteria used to categorize nicotine as an addictive substance included its (1) psychoactive effects, (2) use in a highly controlled or compulsive manner, and (3) reinforcement of behavioral patterns of tobacco use. The underlying pharmacologic and behavioral processes associated with tobacco dependence are considered to be similar to those that determine addiction to drugs such as heroin and cocaine.<sup>9</sup> As with other addictive substances (e.g., opiates, cocaine, and amphetamines), nicotine stimulates the mesolimbic dopaminergic system in the midbrain, inducing pleasant or rewarding effects that promote continued use.<sup>10</sup> This effect is also known as the dopamine reward pathway. Nicotine binds to the  $\alpha_4\beta_2$  nicotinic cholinergic receptors in the ventral tegmental area of the brain, triggering the release of dopamine in the nucleus accumbens. Psychosocial, behavioral, genetic, and environmental factors also play an important role in establishing and maintaining dependence.<sup>10,11</sup> For example, smoking commonly is associated with specific activities such as driving, talking on the telephone, eating, drinking coffee or alcohol, and being around others who smoke. Over time, the habitual use of cigarettes under these circumstances can lead to the development of smoking routines that can be difficult to break. Indeed, specific environmental situations can become powerful conditioned stimuli or cues associated with smoking and are capable of triggering "automatic" smoking patterns.<sup>10</sup> Tobacco use dramatically increases one's odds of dependence, disease, disability, and death. Cigarettes are carefully engineered and heavily marketed products. For example, although the design of cigarettes and other tobacco products has evolved over the past five decades (e.g., filtered, menthol, low-tar, "light" cigarettes; e-cigarettes; dissolvable tobacco), overall disease risk has not been reduced among smokers.<sup>11</sup> The tobacco industry spends nearly \$18.50 to market its products for every \$1 that states spend on tobacco control.<sup>12</sup> Cigarettes are the only marketed consumable product that, when used persistently, will kill half or more of its users.<sup>13</sup>

Cigarette smoke, which is classified by the Environmental Protection Agency (EPA) as a Class A carcinogen (i.e., a carcinogen with no safe level of exposure for humans), is a complex mixture of thousands of compounds—including nitrogen, carbon monoxide, ammonia, hydrogen cyanide, benzene, and nicotine—in gaseous and particulate phases. The particulate fraction, excluding the nicotine and water components, is collectively referred to as tar. Numerous carcinogens, including polycyclic aromatic hydrocarbons (PAHs) and nitrosamines, have been identified in the tar fraction of tobacco smoke.<sup>11,14</sup>

Nicotine, the addictive component of tobacco, is distilled from burning tobacco and carried in tar droplets to the small airways of the lung, where it is absorbed rapidly into the arterial circulation and distributed throughout the body. Nicotine readily penetrates the central nervous system and is estimated to reach the brain within seconds after inhalation.<sup>15</sup> Nicotine binds to receptors in the brain and other organs, inducing a variety of predominantly stimulatory effects on the cardiovascular, endocrine, nervous, and metabolic systems.<sup>10,16</sup> Pharmacodynamic effects associated with nicotine administration include arousal and increases in the heart rate and blood pressure. In the brain, smoking leads to the activation of nicotinic cholinergic receptors and release of numerous neurotransmitters, which induce a range of effects such as pleasure (dopamine), arousal (acetylcholine and norepinephrine), cognitive enhancement (acetylcholine), appetite suppression (dopamine, norepinephrine, and serotonin), learning and memory enhancement (glutamate), mood modulation (serotonin), and reduction of anxiety and tension (beta-endorphin and gamma-aminobutyric acid).<sup>10,11,15</sup>

**TABLE 47-1 Health Consequences of Smoking**

<b>Cancer</b> Acute myeloid leukemia Bladder Cervical Esophageal Gastric Kidney Laryngeal Lung Oral cavity and pharyngeal Pancreatic <b>Cardiovascular Diseases</b> Abdominal aortic aneurysm Coronary heart disease (e.g., angina pectoris, ischemic heart disease, myocardial infarction) Cerebrovascular disease (e.g., transient ischemic attacks, stroke) Peripheral arterial disease <b>Pulmonary Diseases</b> Acute respiratory illnesses Upper respiratory tract (e.g., rhinitis, sinusitis, laryngitis, pharyngitis) Lower respiratory tract (e.g., bronchitis, pneumonia) Chronic respiratory illnesses Chronic obstructive pulmonary disease Respiratory symptoms Poor asthma control Reduced lung function	<b>Reproductive Effects</b> Reduced fertility in women Pregnancy and pregnancy outcomes Preterm, premature rupture of membranes Placenta previa Placental abruption Preterm delivery Low infant birth weight Infant mortality Sudden infant death syndrome (SIDS) <b>Other Effects</b> Cataract Osteoporosis (reduced bone density in postmenopausal women, with increased risk of hip fracture) Periodontitis Peptic ulcer disease (in patients infected with <i>Helicobacter pylori</i> ) Surgical outcomes Poor wound healing Respiratory complications

**Clinical Presentation of Tobacco Use and Dependence**

Most chronic tobacco users develop tolerance to the effects of nicotine, and abrupt cessation precipitates symptoms of nicotine withdrawal.<sup>10</sup> The symptoms and their severity vary from person to person but generally include irritability, frustration, anger, anxiety, depression, difficulty concentrating, impatience, insomnia, and restlessness.<sup>17,18</sup> Other symptoms that patients might report include cravings, impaired performance, constipation, cough, dizziness, and increased dreaming. Typically, the physiologic nicotine withdrawal symptoms manifest within the first 1-2 days, peak within the first week, and gradually dissipate over 2-4 weeks.<sup>18</sup> Increased appetite and weight gain may persist for 6 or more months after quitting.<sup>17</sup> According to reports issued by the U.S. Surgeon General in 2004<sup>2</sup> and 2010,<sup>11</sup> smoking adversely affects nearly every organ system in the body and plays a causal role in the development of numerous diseases, including many cancers (Table 47-1). Furthermore, smoking cigarettes with lower machine-measured yields of tar and nicotine provides no clear benefit to health. Involuntary exposure to secondhand smoke, which includes the smoke emanating from a cigarette and that exhaled by the smoker, is associated with adverse health effects in nonsmokers, including cardiovascular disease, respiratory disease, and lung cancer.<sup>19</sup> Even low levels of exposure, such as secondhand smoke exposure, lead to rapid increases in endothelial

dysfunction and inflammation, which lead to acute cardiovascular events and thrombosis.<sup>11</sup> In children, secondhand smoke exposure can increase the risk of ear infections, precipitate more frequent and severe asthma attacks, worsen respiratory symptoms (e.g., coughing, sneezing, shortness of breath), increase the risk of respiratory infections, and increase the risk for sudden infant death syndrome (SIDS).<sup>19</sup> There is no risk-free level of exposure to tobacco smoke.<sup>11,20</sup>

Tobacco smoke interacts with medications through pharmacokinetic or pharmacodynamic mechanisms that can lead to reduced therapeutic efficacy or, less commonly, increased toxicity. Most of the pharmacokinetic interactions are the result of induction of hepatic cytochrome P450 (CYP) enzymes (primarily the CYP1A2 isoenzyme) by PAHs present in tobacco smoke.<sup>21</sup> Induction of the CYP1A2 isoenzyme can increase the hepatic metabolism of certain drugs (Table 47-2), potentially resulting in a reduced therapeutic response or a need for higher dosages in smokers; conversely, the dosages of some drugs might need to be reduced in patients who quit smoking.<sup>21</sup> Similarly, the clearance of caffeine is significantly increased (by 56%) in smokers. Following cessation, ex-smokers who drink caffeinated beverages should be advised to decrease their usual caffeine intake to avoid higher levels of caffeine, which may induce symptoms similar to nicotine withdrawal.

A significant pharmacodynamic drug interaction occurs with tobacco smoke and combination hormonal contraceptives (pills, patch, and ring). Data indicate that cigarette smoking substantially increases the risk of serious adverse cardiovascular events (e.g., stroke, myocardial infarction, and thromboembolism) in women using oral contraceptives.<sup>22-26</sup> This risk is markedly increased in women ages 35 years or older who smoke 15 or more cigarettes per day.<sup>22</sup> Accordingly, most experts consider use of hormonal contraceptives to be a contraindication in smokers; therefore, an alternative form of contraception should be used.<sup>23,26</sup> Additional interactions, with their corresponding underlying mechanisms, are provided in Table 47-2.<sup>21,27</sup> During the course of routine patient care, it is important to assess for potential drug and smoking interactions and to make appropriate adjustments to the medication regimen.

**TABLE 47-2 Drug Interactions with Tobacco Smoke**

<i>Drug/Class (Trade Name)</i>	<i>Mechanism of Interaction and Effects</i>
<b>Pharmacokinetic Interactions</b>	
Alprazolam (Xanax)	Conflicting data on significance, but possible decreased plasma concentrations (up to 50%); decreased half-life (35%).
Bendamustine (Treanda) <sup>a</sup>	Metabolized by CYP1A2. Manufacturer recommends using with caution in smokers owing to likely decreased bendamustine concentrations, with increased concentrations of its two active metabolites.
Caffeine <sup>a</sup>	Increased metabolism (induction of CYP1A2); increased clearance (56%). Caffeine levels are likely increased after cessation.
Chlorpromazine (Thorazine)	Decreased area under the curve (AUC) (36%) and serum concentrations (24%). Decreased sedation and hypotension possible in smokers; smokers may require increased dosages.
Clopidogrel (Plavix) <sup>a</sup>	Increased metabolism (induction of CYP1A2) of clopidogrel to its active metabolite. Clopidogrel's effects are enhanced in smokers (≥10 cigarettes/day): significant increased platelet inhibition, decreased platelet aggregation. Although improved clinical outcomes have been shown, may also increase risk of bleeding.
Clozapine (Clozaril) <sup>a</sup>	Increased metabolism (induction of CYP1A2); decreased plasma concentrations (18%). Increased levels may occur upon cessation; closely monitor drug levels and reduce dose as required to avoid toxicity.
Erlotinib (Tarceva) <sup>a</sup>	Increased clearance (24%); decreased trough serum concentrations (twofold).
Flecainide (Tambocor)	Increased clearance (61%); decreased trough serum concentrations (25%). Smokers may need increased dosages.
Fluvoxamine (Luvox) <sup>a</sup>	Increased metabolism (induction of CYP1A2); increased clearance (24%); decreased AUC (31%); decreased plasma concentrations (32%). Dosage modifications are not routinely recommended, but smokers may need increased dosages.
Haloperidol (Haldol)	Increased clearance (44%); decreased serum concentrations (70%).
Heparin	Mechanism unknown but increased clearance and decreased half-life are observed. Smoking has prothrombotic effects. Smokers may need increased dosages owing to pharmacokinetic (PK) and pharmacodynamic (PD) interactions.
Insulin, subcutaneous	Possible decreased insulin absorption secondary to peripheral vasoconstriction; smoking may cause release of endogenous substances that cause insulin resistance. PK and PD interactions are likely not clinically significant; smokers may need increased dosages and should monitor blood sugar closely.
Irinotecan (Camptosar) <sup>a</sup>	Increased clearance (18%); decreased serum concentrations of active metabolite, SN-38 (~40%; via induction of glucuronidation); decreased systemic exposure resulting in lower hematologic toxicity; may reduce efficacy. Smokers may need increased dosages.
Mexiletine (Mexitil)	Increased clearance (25%; via oxidation and glucuronidation); decreased half-life (36%).
Olanzapine (Zyprexa) <sup>a</sup>	Increased metabolism (induction of CYP1A2); increased clearance (98%). Dosage modifications are not routinely recommended, but smokers may need increased dosages.
Propranolol (Inderal)	Increased clearance (77%; via side-chain oxidation and glucuronidation).
Ropinirole (Requip) <sup>a</sup>	Decreased maximum concentration (30%) and AUC (38%) in study with patients with restless legs syndrome. Smokers may need increased dosages.
Tacrine (Cognex) <sup>a</sup>	Increased metabolism (induction of CYP1A2); decreased half-life (50%); serum concentrations threefold lower. Smokers may need increased dosages.
(Theo Dur, etc.) <sup>a</sup>	Levels should be monitored if smoking is initiated, discontinued, or changed. Maintenance doses are considerably higher in smokers. Increased clearance with secondhand smoke exposure.
Theophylline	Increased metabolism (induction of CYP1A2); increased clearance (58%-100%); decreased half-life (63%).
Tizanidine (Zanaflex)	Decreased AUC (30%-40%) and decreased half-life (10%) observed in male smokers.
Tricyclic antidepressants (e.g., imipramine, nortriptyline)	Possible interaction with tricyclic antidepressants in the direction of decreased blood levels, but the clinical significance is not established.
Warfarin	Increased metabolism (induction of CYP1A2) of R-enantiomer; however, S-enantiomer is more potent, and the effect on the international normalized ratio (INR) is inconclusive. Consider monitoring INR more closely upon smoking cessation.
<b>Pharmacodynamic Interactions</b>	
Benzodiazepines (diazepam, chlordiazepoxide)	Decreased sedation and drowsiness, possibly caused by nicotine stimulation of central nervous system.
Beta-blockers	Less effective antihypertensive and heart rate control effects, possibly caused by nicotine-mediated sympathetic activation.
Smokers may need increased dosages.	
Corticosteroids, inhaled <sup>a</sup>	Smokers with asthma may have less of a response to inhaled corticosteroids.
Hormonal contraceptives <sup>a</sup>	Increased risk of cardiovascular adverse effects (e.g., stroke, myocardial infarction, thromboembolism) in women who smoke and use oral contraceptives. Ortho Evra patch users shown to have twofold increased risk of venous thromboembolism compared with oral contraceptive users, likely owing to increased estrogen exposure (60% higher levels). Increased risk with age and with heavy smoking (≥15 cigarettes per day) that is quite marked in women ≥35 years old.
Opioids (propoxyphene,	Decreased analgesic effect; smoking may increase the metabolism of propoxyphene (15%-20%) and pentazocine (40%). Mechanism is unknown.

pentazocine)

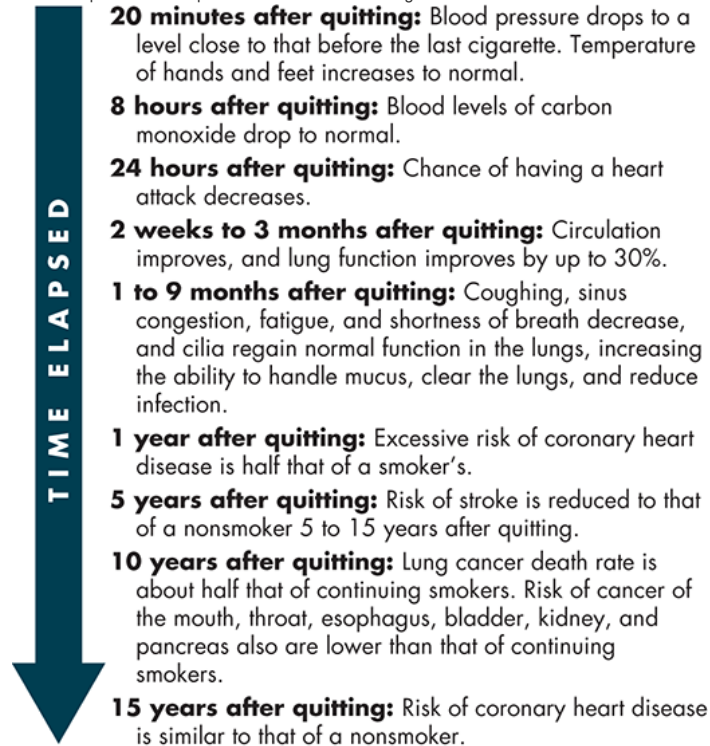

Smokers may need increased opioid dosages for pain relief.

Key: PD = Pharmacodynamic; PK = pharmacokinetic.

**Note:** Many interactions between tobacco smoke and medications have been identified. In most cases, the tobacco smoke—not the nicotine—causes these drug interactions. Tobacco smoke interacts with medications through PK and PD mechanisms. PK interactions affect the absorption, distribution, metabolism, or elimination of other drugs, potentially causing an altered pharmacologic response. The majority of PK interactions with smoking are the result of induction of hepatic cytochrome P450 enzymes (primarily CYP1A2). PD interactions alter the expected response or actions of other drugs. The amount of tobacco smoking necessary to have an effect has not been established, and the assumption is that any smoker is susceptible to the same degree of interaction. Those exposed regularly to secondhand smoke may also be at risk.

<sup>a</sup> Clinically significant interaction.

Health benefits of smoking cessation. (Source: Reference 28.)

#### Benefits of Tobacco Cessation

The 1990 Surgeon General's Report on the health benefits of smoking cessation outlined the numerous and substantial health benefits realized when patients quit smoking.<sup>28</sup> Some health benefits are incurred shortly after quitting (e.g., within 2 weeks to 3 months), and others are incurred over time (Figure 47-1). On average, cigarette smokers die approximately 10 years earlier than nonsmokers; among those who continue smoking, at least half will eventually die of a tobacco-related disease. Quitting at ages 30, 40, 50, and 60 years results in a gain of 10, 9, 6, and 3 years of life, respectively.<sup>13</sup> Thus, although it is important to educate tobacco users that it is never too late to quit and achieve many of the associated health benefits, there are significant benefits to quitting earlier in life.

#### Smoking Cessation Treatment

##### Treatment Goals

Tobacco dependence is a chronic disease characterized by multiple failed attempts to quit before long-term cessation is achieved. Because tobacco use is a complex, addictive behavior, helping patients quit and preventing relapse are best achieved by combining appropriate pharmacotherapy with counseling.<sup>29</sup> For any patient who uses tobacco, the primary goal is complete, long-term abstinence from all nicotine-containing products.

##### General Treatment Approach

Most smokers use no cessation treatments for their quit attempts, also known as quitting "cold turkey,"<sup>30</sup> and approximately 95% of all attempts to quit using this method end in relapse.<sup>29</sup> Yet decades of research clearly show that patients who receive assistance have increased odds of quitting. In 2008, the U.S. Public Health Service published an updated clinical practice guideline for treating tobacco use and dependence,<sup>29</sup> which presents evidence-based recommendations and effective strategies for health care providers who provide tobacco cessation counseling.

Although even brief advice from a provider is associated with increased odds of quitting,<sup>29,31</sup> more intensive counseling (longer and more frequent counseling sessions, or greater overall contact time) and use of pharmacotherapy (excluding patients who should not self-treat with medications, as listed in Figure 47-2) result in increased quit rates. Two particularly effective types of counseling are practical counseling (behavior change counseling, including problem-solving and skills training) and social support delivered as part of treatment.<sup>29</sup> Patients who receive a tobacco cessation intervention from a provider (nonphysician or physician) are 1.7 and 2.2 times as likely to quit (and remain tobacco free at >5 months after cessation), respectively, than are patients who do not receive an intervention from a provider.<sup>29</sup> Self-help materials are only slightly better than no provider intervention. Although the length of an intervention increases effectiveness, even minimal interventions (<3 minutes) increase cessation rates.<sup>29</sup> In a meta-analysis of 46 studies, four or more intervention sessions were found to approximately double cessation rates.<sup>29</sup>

Although the use of pharmacotherapy substantially increases patients' chances of quitting, the addition of counseling further increases cessation rates (1.4 times as likely to quit).<sup>29</sup> Similarly, adding pharmacotherapy to counseling increases cessation rates. Therefore, cessation interventions should consist of pharmacotherapy (one or a combination of medications) and counseling, when medications are not contraindicated (see Special Populations).<sup>29</sup> Figure 47-2 outlines a self-treatment approach for tobacco cessation.

##### Nonpharmacologic Therapy

##### Helping Patients Quit: The 5 A's Approach (Comprehensive Counseling)

As delineated in the Clinical Practice Guideline for Treating Tobacco Use and Dependence,<sup>29</sup> the five key components of comprehensive counseling for tobacco cessation are (1) asking patients whether they use tobacco, (2) advising tobacco users to quit, (3) assessing patients' readiness to quit, (4) assisting patients with quitting, and (5) arranging follow-up care. These steps are referred to as the "5 A's."<sup>29</sup>

##### Ask About Tobacco Use

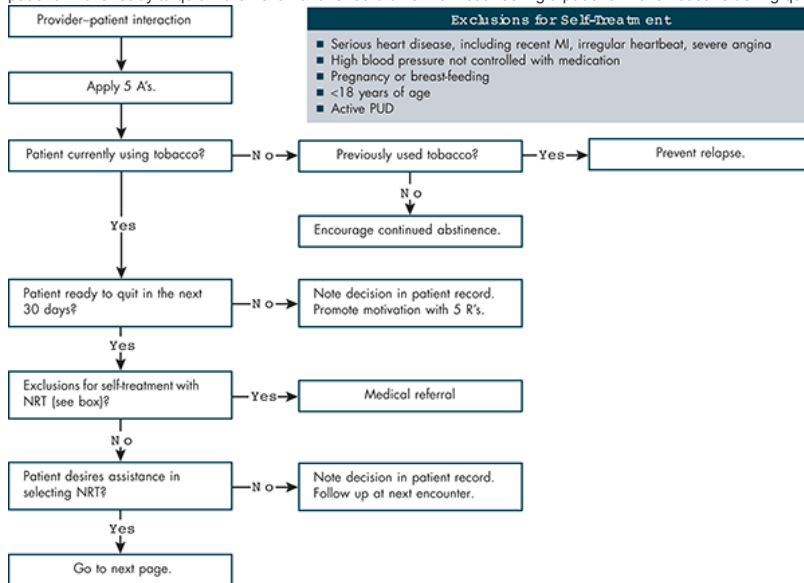

A key first step in the cessation process, and in all patient interactions, is asking about tobacco use. Because tobacco use is the primary known preventable cause of mortality in the United States, and because tobacco smoke interacts with multiple medications, screening for tobacco use is crucial and should be a routine component of care. The following question can be used to identify all types of tobacco use, even for infrequent users: "Do you ever smoke or use any type of tobacco?" In clinic or hospital settings, tobacco use status should be considered a vital sign and collected routinely, along with blood pressure, pulse, weight, temperature, and respiratory rate.<sup>29</sup> In community pharmacies, tobacco use status should be assessed, documented in the patient profile, and reassessed periodically. Asking about exposure to secondhand smoke should also be considered.

**Advise to Quit**

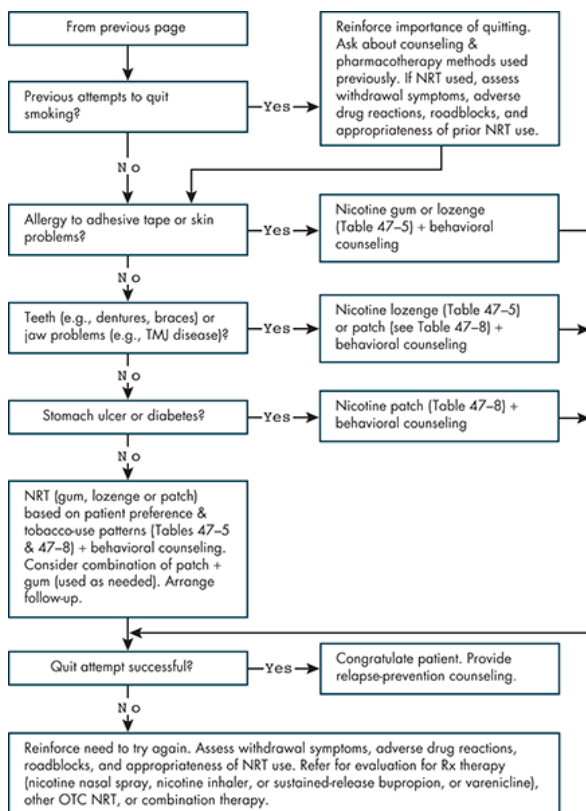

All tobacco users should be advised to quit. The advice should be clear, strong, and personalized, yet be delivered with sensitivity and in a tone of voice that communicates concern for the patient and a willingness to assist the patient with quitting when he or she is ready. When possible, primary care providers should individualize the message by linking their advice to the patient's health status, current medication regimen, personal reasons for wanting to quit, or the effect of tobacco on others. An example of this approach would be "Ms. Bettis, I see that you now are on two different inhalers for your emphysema. Quitting smoking is the single most important treatment for your emphysema and can improve how well your inhalers work. I strongly encourage you to quit, and I would like to help you."

**Assess Readiness to Quit**

Because many patients will not be ready to quit when they are first approached, it is important for providers to gauge each patient's readiness to quit before recommending a treatment regimen. Patients should be categorized as (1) not ready to quit in the next month; (2) ready to quit in the next month; (3) a recent quitter, having quit in the past 6 months; or (4) a former user, having quit more than 6 months ago.<sup>29</sup> This classification defines the provider's next course of action, which is to provide counseling that is tailored to the patient's readiness to quit. The following approach is an example for a current smoker: "Mr. Crosby, what are your thoughts about quitting? Is this something that you might consider doing in the next month?" Counseling a patient who is ready to quit in the next month should differ from counseling a patient who is not considering quitting in the near future.

Self-care of tobacco cessation. Key: 5 A's = Ask, advise, assess, assist, arrange; 5 R's = relevance, risks, rewards, roadblocks, repetition; MI = myocardial infarction; NRT = nicotine replacement therapy; OTC = over-the-counter; PUD = peptic ulcer disease; Rx = prescription; TMJ = temporomandibular joint.

**Assist with Quitting**

Important elements of the assisting component of treatment include (1) helping patients to make the decision to quit and (2) setting a quit date. Providers should be empathetic and acknowledge that quitting is a challenge for most patients. As such, the goal is to help maximize each patient's chances of success by designing an individualized treatment plan. All patients attempting to quit should be encouraged to use pharmacotherapy combined with counseling. This combination will yield higher quit rates than either approach alone, except for special circumstances or specific populations for which there is inadequate evidence of the combined method's effectiveness (pregnant women, smokeless tobacco users, individuals smoking fewer than 10 cigarettes per day, and adolescents).<sup>29</sup> Counseling interventions, which focus on promoting behavior change and enhancing adherence with medication regimens, include

individualized counseling (e.g., in person or by telephone), a group cessation program, an Internet-based program, or a combination of these approaches.

**Arrange Follow-Up Counseling**

Because a patient's ability to quit increases substantially when multiple counseling interactions are provided, arranging follow-up counseling is an important, yet typically neglected, element of treatment for tobacco dependence. Follow-up contact should occur soon after the quit date, preferably during the first week. Follow-up does not have to be done in person and could be performed by telephone or e-mail. A second follow-up contact is recommended within the first month after quitting.<sup>29</sup> Additional follow-up contacts should occur periodically to monitor patient progress (including adherence with pharmacotherapy) and to provide ongoing support. Quit rates at 5 or more months after cessation are associated with the total number of person-to-person contacts (both individual and group): 12.4% for 0-1 contact, 16.3% for 2-3 contacts, 20.9% for 4-8 contacts, and 24.7% for more than 8 contacts.<sup>29</sup> A dose-response relationship has also been seen for length of contact.<sup>29</sup>

**Counseling Interventions for Quitting**

When counseling a patient, a provider's goal is to facilitate the process of change by helping to ready patients for their permanent cessation. It is important that providers convey the view of quitting as a learning process that might take months or even years to achieve, rather than a now-or-never event.

**Counseling Patients Who Are Not Ready to Quit**

When counseling patients who are not ready to quit, an important first step is to encourage the patient to start thinking about quitting and to consider making a commitment to quit sometime in the foreseeable future. Sometimes patients who are not ready truly do not understand the need to quit. In general, most smokers will recognize the need to quit but are not yet ready to make the commitment to quit. Many patients will have tried to quit multiple times and relapsed; thus, they might feel too discouraged to try again.

Strategies for working with patients who are not ready to quit include increasing patient awareness of the available treatment options, having patients identify their reasons for smoking and for wanting to quit, and identifying barriers to quitting. Providers also can engage patients in thinking about quitting by raising awareness of specific drug interactions between medications and tobacco smoke (Table 47-2) and how tobacco use can induce or exacerbate medical conditions (e.g., chronic obstructive pulmonary disease and coronary heart disease). Providers should also discuss the importance of preventive health, such as the recommendation for all adult smokers, ages 19-64, to receive the pneumococcal vaccine to aid in the prevention of invasive pneumococcal disease.<sup>32</sup>

Although it may be useful to provide patients with information about the medications available for quitting, it is not appropriate to recommend a treatment regimen until a patient is ready to quit in the near future (e.g., within the next month). A treatment goal at this stage should be to promote motivation to quit. Providers can encourage patients to seriously consider quitting by asking the following series of three questions:

1. "Do you ever plan to quit?"  
If the patient responds "no," the provider should inquire, "What would have to change for you to decide to quit?" If the patient indicates that nothing would change his or her opinion about quitting, then the provider should offer to assist if or when the patient changes his or her mind. If the patient responds "yes," the provider should continue to question 2.
2. "How would it benefit you to quit now, instead of later?"  
Quitting generally becomes more difficult the longer a patient smokes. Most patients will agree that there is never an ideal time to quit, and that postponing quitting has more negative effects than positive.
3. "What would have to change for you to decide to quit sooner?"  
This question probes patients' perceptions about quitting and can reveal specific barriers to quitting that can be discussed and addressed.

Motivation can also be enhanced by applying the "5 R's": relevance, risks, rewards, roadblocks, and repetition.<sup>29</sup>

**Relevance**

The intervention begins by encouraging patients to think about why quitting is important to them. Because information has a greater effect if it takes on a personal meaning, counseling should be framed to relate to the patient's risk of disease or exacerbation of disease, other health concerns, family or social situation (e.g., having children with asthma), age, and other patient factors such as prior experience with quitting.

**Risks**

This intervention entails asking patients to identify negative health consequences of smoking, such as acute risks (e.g., shortness of breath, exacerbation of asthma, pregnancy complications, or infertility); long-term risks (e.g., cancer and cardiac and pulmonary disease); and environmental risks (e.g., effects of secondhand smoke on others, including children and pets). The risks also include patients demonstrating unhealthy behaviors around children and adolescents such as smoking near them.

**Rewards**

Patients can be asked to identify specific benefits of quitting, such as improved health, enhanced physical performance, acuity of taste and smell, reduced expenditures for tobacco, less time wasted or work missed, reduced health risks to others (e.g., fetus, children, or housemates), and reduced aging of the skin.

**Roadblocks**

This step entails helping patients identify significant barriers to quitting and helping them develop coping skills to address or circumvent each barrier. Common barriers include nicotine withdrawal symptoms, fear of failure, a need for social support while quitting, depression, concern about weight gain, and a sense of deprivation or loss.

**Repetition**

The provider continues to work with patients who are either not motivated to quit or who have been unsuccessful in quitting. Discussing circumstances in which smoking occurs will help identify triggers for relapse and should be viewed as part of the learning process. It is also beneficial to repeat the intervention steps whenever possible.

**Counseling Patients Who Are Ready to Quit**

The goal for patients who are ready to quit in the next month is to achieve cessation by providing an individualized treatment plan that addresses the key issues listed in Table 47-3. The first step is to discuss the patient's tobacco use history by inquiring about levels of smoking (cigarettes/day), number of years smoked, methods used previously for quitting (if any), and reasons for previous failed quit attempts. Providers should understand fully the patient's preferences for the different pharmacotherapies for quitting and work with patients in selecting the quitting methods (e.g., medications or behavioral counseling programs). It is important to recognize that pharmacotherapy might not be desirable or affordable for all patients. However, providers should educate patients that medications, when taken correctly, can substantially increase the likelihood of quitting successfully,<sup>29</sup> and that the costs of continuing smoking far outweigh the costs of the medications.

Ideally, patients will select a quit date that is within the next 2 weeks, allowing ample time to prepare themselves and their environment before the actual quit date. This preparation includes removing all tobacco products and ashtrays from the home, car, and workplace. Patients should be advised to discuss their desire to quit with their family, friends, and coworkers and to request their support and assistance. Having patients think about when and why they smoke can help them anticipate situations that might trigger a desire to smoke and contribute to relapse.

Additional counseling strategies to address with patients during a quit attempt are listed in Table 47-4. Patients should be counseled on proper medication use (including administration), side effects, and adherence, and it is crucial to emphasize the importance of receiving behavioral counseling throughout the quit attempt. Additionally, patients should be advised to adhere to the entire course of pharmacotherapy, even though most withdrawal symptoms subside within 2-4 weeks.<sup>18</sup>

**TABLE 47-3 Key Topics for Individualized Tobacco Cessation Plans**

Topic	Description
Assess tobacco use history	• Current use:
- Type(s) and amount of tobacco used	
• Past use:	
- Duration of smoking	
- Recent changes in levels of use	
• Past quit attempts:	
- Number of attempts, date of most recent attempt, duration of abstinence	
- Previous methods: What did or did not work? Why or why not?	
- Prior experience with cessation pharmacotherapy: agent used, adequacy of dose, adherence, duration of treatment	

- Reasons for relapse	
• Reasons or motivation for wanting to quit (or stay quit)	
• Confidence in ability to quit (or stay quit)	
• Triggers for smoking	
• Routines and situations associated with smoking	
• Stress-related smoking	
• Social support for quitting	
• Concerns about weight gain	
• Concerns about withdrawal symptoms	
Facilitate the quitting process	• Discuss methods for quitting: pros and cons of the different methods
• Set a quit date, ideally within the next 2 weeks	
• Discuss coping strategies	
• Discuss withdrawal symptoms	
• Discuss concept of a slip (occasional smoking) versus full relapse	
• Provide medication counseling: adherence and proper use	
• Offer to assist throughout the quit attempt	
Arrange and provide follow-up counseling	• Monitor the patient's progress throughout the quit attempt
• Evaluate the current quit attempt	
- Status of attempt	
- Slips (occasional smoking) and relapses	
- Medication use:	
• Adherence with regimen	
• Plans for discontinuation	
- Address temptations and triggers; discuss relapse prevention strategies	
- Provide encouragement throughout the quit attempt	
• Follow-up contacts (face-to-face, by telephone, or by e-mail): first contact during first week after quitting, second contact within the first month, additional contacts scheduled as needed

Counseling Patients Who Recently Quit

Patients who recently quit will face frequent, difficult challenges in countering withdrawal symptoms and cravings or temptations to use tobacco. An important step is to help them identify situations that might trigger relapse and to suggest appropriate coping strategies. Because smoking is a habitual behavior, patients should be advised to alter daily routines that were previously associated with tobacco use. These changes help to disassociate the behaviors from the tobacco.

Many people who quit using tobacco will experience cravings for years and even decades after quitting. Thus, relapse prevention counseling should be part of every follow-up contact with patients who have recently or ever quit smoking. Patients who slip and smoke a cigarette (or use any form of tobacco) or experience a full relapse back to habitual smoking should be encouraged to think through the scenario in which smoking first recurred and identify the trigger for relapse. Identifying triggers will provide valuable information for future quit attempts.

Counseling Patients Who Are Former Smokers

The strategies to be applied for former tobacco users are similar but typically less intensive than those to be applied for recent quitters. The goal for former tobacco users is to remain tobacco free for life. Providers should evaluate their patient's resolve for staying tobacco free and ongoing coping strategies; that is, has the patient had any strong temptations to use tobacco or has there been any occasional use of tobacco products? Also, it is important to ensure that patients are appropriately terminating or tapering pharmacotherapy products. Patients who have been tobacco free should be congratulated for their success. For patients who have intermittently used tobacco, situations in which tobacco use occurred should be reviewed, and additional coping strategies should be discussed.

**TABLE 47-4 Cognitive and Behavioral Strategies for Smoking Cessation**

<b>Cognitive strategies focus on retraining of the way a patient thinks. Often, patients mentally deliberate on the fact that they are thinking about a cigarette, and this leads to relapse. Patients must recognize that thinking about a cigarette does not mean they need to have one.</b>	
Review of the commitment to quit, with focus on the downside of tobacco	Remind oneself that cravings and temptations are temporary and will pass. Announce, either silently or aloud, "I want to be a nonsmoker," and the temptation will pass.
Distractive thinking	Practice deliberate, immediate refocusing of thinking when cued by thoughts about tobacco use.
Positive self-talks, pep talks	Say "I can do this," and remember difficult situations in which tobacco use was avoided with success.
Relaxation through imagery	Mentally focus on a scene, place, or situation that is peaceful, relaxing, and positive.
Mental rehearsal, visualization	Prepare for situations that might arise by envisioning how best to handle them. For example, envision what would happen if offered a cigarette by a friend, mentally craft and rehearse a response, and perhaps even practice it by saying it aloud.
<b>Behavioral strategies involve specific actions to reduce the risk of relapse. For maximal effectiveness, patient-specific triggers for smoking should first be identified; then these behavioral strategies should be considered before quitting. Below are some strategies for responding to several common cues or triggers for relapse.</b>	
Stress	Anticipate upcoming challenges at work, at school, or in personal life. Develop a substitute plan for smoking during times of stress (e.g., practice deep breathing, take a break or leave the situation, call a supportive friend or family member, perform self-massage, or use nicotine replacement therapy).

Alcohol	Drinking alcohol can lead to relapse. Consider limiting or abstaining from alcohol during the early stages of quitting.	
Other smokers	Quitting is more difficult when other smokers are around. This is especially difficult if there is another smoker in the household. During the early stages of quitting, limit prolonged contact with individuals who are smoking. Ask coworkers, friends, and housemates not to smoke in your presence.	
Oral gratification needs	Have nontobacco oral substitutes (e.g., gum, sugarless candy, straws, toothpicks, lip balm, toothbrush, nicotine replacement therapy, and bottled water) readily available.	
Automatic smoking routines		Anticipate routines that are associated with tobacco use and develop an alternative plan.
Examples:		
• Smoking with morning coffee: Change morning routine; drink tea instead of coffee; take shower before drinking coffee; take a brisk walk shortly after awakening.		
• Smoking while driving: Remove all tobacco from car; have car interior detailed; listen to an audiobook or talk radio; use oral substitute.		
• Smoking while on the phone: Stand while talking; limit call duration; change phone location; keep hands occupied by doodling or sketching.		
• Smoking after meals: Get up and immediately do dishes or take a brisk walk after eating; call a supportive friend.		
Posts cessation weight gain	Most tobacco users gain weight after quitting. Most quitters will gain less than 10 pounds, but a broad range of weight gain is reported, with up to 10% of quitters gaining as much as 30 pounds. <sup>29</sup> In general, attempting to modify multiple behaviors at one time is not recommended. If weight gain is a barrier to quitting, engage in regular physical activity and adhere to a healthy diet (as opposed to strict dieting). Carefully plan and prepare meals; increase fruit, vegetable, and water intake to create a feeling of fullness; and chew sugarless gum or eat sugarless candy. Consider use of pharmacotherapy shown to delay weight gain (e.g., 4 mg nicotine gum, 4 mg nicotine lozenge, or bupropion).	
Cravings for tobacco	Cravings for tobacco are temporary and usually pass within 5-10 minutes. Handle cravings by using distractive thinking, taking a break, changing activities or tasks, taking deep breaths, or performing self-massage.

#### Helping Patients Quit: The Ask-Advise-Refer Approach (Brief Intervention)

Providers should familiarize themselves with local resources for tobacco cessation, including group programs and telephone quit lines. When time or lack of expertise limits the ability to provide comprehensive cessation counseling, providers are encouraged to apply an abbreviated 5 A's model, whereby they *ask* about tobacco use, *advise* tobacco users to quit, and *refer* patients to other resources, including local services and group counseling programs, for additional assistance. Telephone-based counseling is available throughout the United States. These services provide low-cost interventions that can reach patients who might otherwise have limited access to medical treatment because of geographic location or lack of financial resources. In clinical trials, telephone counseling services for which at least some of the contacts are initiated by the quit line counselor were shown to be effective in promoting abstinence.<sup>29</sup> Combining medication with quit line counseling significantly improves abstinence rates compared with medication alone.<sup>29</sup> The national telephone number for the toll-free tobacco quit line is 1-800-Quit-Now.

#### Pharmacologic Therapy

Although in some situations pharmacotherapy should be used with caution or only under the supervision of a primary care provider (see Special Populations), most patients who are attempting to quit should be advised to incorporate pharmacotherapy in their treatment plan. Currently, seven first-line agents are approved by the Food and Drug Administration (FDA) for smoking cessation<sup>29</sup>: five formulations of nicotine replacement therapy (NRT), sustained-release bupropion, and varenicline. Three NRT formulations (gum, lozenge, and transdermal patch) are nonprescription, but the nicotine inhaler, nicotine nasal spray, bupropion, and varenicline require a prescription.

#### Nicotine Replacement Therapy

NRT is the most commonly used pharmacotherapy for smoking cessation.<sup>30</sup> NRT products are often used to help noncigarette tobacco users to quit, but these products are only FDA labeled to help cigarette smokers quit. Similar to the nicotine present in tobacco, NRT stimulates the release of dopamine in the central nervous system.<sup>10</sup> The rationale underlying the use of NRT for smoking cessation is twofold. First, NRT provides smokers with a nontobacco source of nicotine to reduce the physiologic symptoms of nicotine withdrawal that typically occur after abstinence from tobacco. Second, by attenuating the symptoms of withdrawal, NRT assists quitters by allowing them to focus on the behavioral and psychological aspects of smoking cessation. A key advantage of NRT is that patients, as well as those in the smoker's environment, are not exposed to the carcinogens and other toxic constituents present in tobacco and tobacco smoke. Furthermore, compared with cigarettes, NRT formulations provide lower, slower, and less-variable plasma nicotine concentrations,<sup>15</sup> thereby eliminating the almost immediate reinforcing effects of nicotine obtained through smoking.

Plasma nicotine concentrations for various nicotine delivery systems. (Source: Reproduced with permission from Rx for Change: Clinician-Assisted Tobacco Cessation program. The Regents of the University of California. Copyright © 1999-2015.)

Nicotine is well absorbed (Figure 47-3) from many sites, including the lungs, skin, and nasal and buccal (oral) mucosa. Nicotine absorption is pH dependent, and lower systemic concentrations are achieved under acidic conditions. Nicotine is also well absorbed from the gastrointestinal tract (small intestine) but undergoes extensive first-pass hepatic metabolism, resulting in negligible systemic levels of nicotine.<sup>15</sup>

The main difference between the various NRT formulations is the site and rate of nicotine absorption (Figure 47-3). Compared with cigarettes, all of the NRT formulations deliver nicotine less rapidly and achieve lower serum nicotine levels, thus lowering the likelihood of developing physical dependence. Peak serum concentrations are achieved most rapidly with the nasal spray (11-18 minutes); followed by the gum, lozenge, and inhaler (30-60 minutes); and then by the transdermal patch (3-12 hours). In contrast, significantly higher peak nicotine levels are attained within 10 minutes of smoking a cigarette.<sup>15</sup>

Patients should be instructed not to smoke cigarettes or use other forms of tobacco (e.g., snuff, chewing tobacco, cigars, and pipes) while using NRT. Use of tobacco in combination with NRT may result in serum nicotine concentrations that are higher than those achieved from tobacco products alone, increasing the likelihood of nicotine-related adverse effects, including nausea, vomiting, hypersalivation, perspiring, abdominal pain, dizziness, weakness, and palpitations.

#### Nicotine Polacrilex Gum

Nicotine polacrilex gum is a resin complex of nicotine and polacrillin in a sugar-free (<3 calories/piece) chewing gum base. The product is available as 2 mg and 4 mg strengths, in original (tobacco-like, peppery), cinnamon, fruit, mint (various), and orange flavors (Table 47-5). All gum formulations contain buffering agents (sodium carbonate and sodium bicarbonate) to increase salivary pH, thereby enhancing absorption of nicotine across the buccal mucosa. When the 2 mg and 4 mg gums are used properly, approximately 1.6 mg and 2.2 mg of nicotine is absorbed from each dose, respectively. Peak serum concentrations of nicotine are achieved approximately 30 minutes after chewing a single piece of gum and then slowly decline over 2-3 hours.<sup>15</sup>

The recommended dosage of nicotine gum is based on the "time to first cigarette" (TTFC) of the day. Having a strong desire or need to smoke soon after waking is viewed as a key indicator of nicotine dependence. Therefore, patients who smoke their first cigarette of the day within 30 minutes of waking are likely to be more highly dependent on nicotine and require higher dosages than those who delay smoking for more than 30 minutes after waking. Specifically, if the TTFC is 30 minutes or less, therapy should be initiated with the 4 mg gum. If the TTFC is more than 30 minutes, therapy should be initiated with the 2 mg gum. Table 47-5 provides the manufacturer's recommended dosing schedule. During the initial 6 weeks of therapy, patients should use one piece of gum every 1-2 hours while awake. In general, this amounts to at least 9 pieces of gum daily. Table 47-6 provides specific instructions for proper use of the nicotine gum. The "chew and park" method described in the table allows for the slow, consistent release of nicotine from the polacrillin resin. Patients can use additional pieces of gum (up to the maximum of 24 pieces per day) if cravings occur between the scheduled doses. In general, individuals who smoke heavily will need more pieces to alleviate their cravings.

An important point to note is that patients often do not use enough of the gum to derive its full benefit or they use it incorrectly (e.g., incorrect chewing technique or concurrent consumption of beverages or foods that alter the pH of the mouth). Commonly, patients chew too few pieces per day or shorten the duration of treatment. For this reason, recommending a fixed schedule of administration, tapering over 1-3 months, is preferable to having the patient use the gum as needed to control cravings.<sup>29</sup>

The most common side effects associated with the use of the nicotine gum include unpleasant taste, mouth irritation, jaw muscle soreness or fatigue, hypersalivation, hiccups, and dyspepsia. Many of these side effects can be minimized or prevented by using proper chewing technique.<sup>29</sup> The nicotine polacrillin resin is more viscous than ordinary chewing gum and more likely to adhere to fillings, bridges, dentures, crowns, and braces. Patients should be warned that chewing the gum too rapidly may result in excessive release of nicotine, leading to lightheadedness, nausea, vomiting, irritation of the throat and mouth, hiccups, and indigestion.

Patients with active temporomandibular joint (TMJ) disease should not use the nicotine gum because the highly viscous consistency of the formulation and the need for frequent chewing may exacerbate this condition. In addition, the manufacturer recommends that patients with stomach ulcers or diabetes contact their health care provider before use of the product because these conditions are more serious and might require further monitoring.

**TABLE 47-5 Dosages for Nonprescription Nicotine Polacrilex Gum and Lozenge**

	Gum	Lozenge
Product strength	Nicorette: 2 mg, 4 mg; original, cinnamon, fruit, mint (various) Generic: 2 mg, 4 mg; original, fruit, mint, orange	Nicorette (standard): 2 mg, 4 mg; cherry, mint Nicorette (mini): 2 mg, 4 mg; mint Generic (standard): 2 mg, 4 mg; mint
Dose	First cigarette ≤30 minutes after waking: 4 mg First cigarette >30 minutes after waking: 2 mg Weeks 1-6: 1 piece every 1-2 hours Weeks 7-9: 1 piece every 2-4 hours Weeks 10-12: 1 piece every 4-8 hours	First cigarette ≤30 minutes after waking: 4 mg First cigarette >30 minutes after waking: 2 mg Weeks 1-6: 1 lozenge every 1-2 hours Weeks 7-9: 1 lozenge every 2-4 hours Weeks 10-12: 1 lozenge every 4-8 hours

#### Nicotine Polacrilex Lozenge

The nicotine polacrilex lozenge is a resin complex of nicotine and polacrillin in a sugar-free mint- or cherry-flavored lozenge (Table 47-5). The lozenges are available in 2 mg and 4 mg strengths with two different physical sizes (regular and mini) and should be used similarly to other medicinal lozenges or troches (i.e., suck and rotate it within the mouth until it dissolves). Because the mini-lozenge is smaller, it is more easily concealed and dissolves more quickly. The pharmacokinetics of the nicotine lozenge and gum formulations are comparable, but a nicotine lozenge delivers approximately 25% more nicotine than an equivalent dose of nicotine gum because of complete dissolution of the dosage form.<sup>33</sup> The lozenge form contains buffering agents (sodium carbonate and potassium bicarbonate) to increase salivary pH, enhancing the buccal absorption of nicotine.

**TABLE 47-6 Usage Guidelines for Nicotine Polacrilex Gum**

• Do not smoke cigarettes or use other forms of tobacco (e.g., snuff, chewing tobacco, cigars, and pipes) while on nicotine gum therapy. (Note: In 2013, the FDA recommended labeling changes that will remove this warning. <sup>47</sup> )
• Note that nicotine gum is a nicotine delivery system, not a chewing gum.
• Proper administration technique is necessary when using this product. Nicotine from the gum is released using the "chew and park" method:
- Chew each piece of gum <i>slowly</i> several times.
- Stop chewing at the first sign of a peppery, minty, fruity, or citrus taste, or after experiencing a slight tingling sensation in the mouth. This usually occurs after about 15 chews, but the onset varies.
- Park the gum between the cheek and gum to allow absorption of nicotine across the lining of the mouth.
- When the taste or tingling dissipates (generally after 1-2 minutes), slowly resume chewing.

- When the taste or tingle returns, stop chewing and park the gum in a different place in the mouth. This will decrease the incidence of mouth irritation.
- The chew-and-park steps should be repeated until most of the nicotine is gone, which is when the taste or tingle does not return after continued chewing. On average, each piece of gum lasts 30 minutes.
• To minimize withdrawal symptoms, use the nicotine gum on a scheduled basis rather than as needed.
• Follow the dosage regimen carefully; reduce the dosage at the recommended intervals; if needed for longer than 12 weeks of treatment to keep from smoking, talk to your health care provider.
• Do not chew more than 24 pieces per day.
• Acidic beverages such as coffee, juices, wine, or soft drinks may transiently reduce the salivary pH, resulting in decreased absorption of nicotine across the buccal mucosa. Do not eat or drink anything (except water) 15 minutes before or while using the nicotine gum.
• Note that chewing the gum too quickly will result in an unpleasant taste caused by too much nicotine in the saliva and, if the nicotine is swallowed, may cause effects similar to those produced by excessive smoking (e.g., nausea, throat irritation, light-headedness, and hiccups).
• Have nicotine gum readily available at all times. Keep the nicotine gum in the same place you previously kept your cigarettes (e.g., shirt pocket, purse, or desk).
• Keep this product, including used pieces, out of the reach of children and pets.

As with nicotine gum, dosing for the lozenge is based on the TTFC. If the TTFC is 30 minutes or less, therapy should be initiated with the 4 mg lozenge. If the TTFC is more than 30 minutes, therapy should be initiated with the 2 mg lozenge. During the initial 6 weeks of therapy, patients should use 1 lozenge every 1-2 hours while awake. In general, this amounts to at least 9 lozenges daily. [Table 47-7](#) provides further instructions for proper use of the nicotine lozenge. Patients can use additional lozenges (up to 5 lozenges in 6 hours or a maximum of 20 lozenges per day) if cravings occur between the scheduled doses. The manufacturer recommends that patients with stomach ulcers or diabetes contact their health care provider before using the lozenges because these conditions, which are more serious, may require further monitoring. Side effects associated with the nicotine lozenge include mouth irritation, nausea, hiccups, cough, heartburn, headache, flatulence, and insomnia. Patients who use more than 1 lozenge at a time, continuously use 1 lozenge after another, or chew or swallow the lozenge are more likely to experience heartburn or indigestion.

#### Nicotine Transdermal Systems (Nicotine Patch)

Nicotine transdermal systems deliver continuous, low levels of nicotine through the skin over 24 hours. The patch consists of a waterproof surface layer, a nicotine reservoir, an adhesive layer, and a disposable protective liner. Currently patients can choose from two marketed products ([Table 47-8](#)).

**TABLE 47-7 Usage Guidelines for Nicotine Polacrilex Lozenge**

• Do not smoke cigarettes or use other forms of tobacco (e.g., snuff, chewing tobacco, cigars, and pipes) while using the nicotine lozenge. (Note: In 2013, the FDA recommended labeling changes that will remove this warning. <sup>47</sup> )
• Proper administration technique is necessary when using the nicotine lozenge:
- Place the lozenge in the mouth and allow it to dissolve slowly (20-30 minutes for standard lozenge; 10 minutes for mini-lozenge). As the nicotine is released from the lozenge, you may experience a warm, tingling sensation.
- To reduce the risk of side effects (e.g., nausea, hiccups, and heartburn), do not chew or swallow the lozenge.
- Occasionally rotate the lozenge to different areas of the mouth to decrease mouth irritation.
• To minimize withdrawal symptoms, use the nicotine lozenge on a scheduled basis rather than as needed.
• Follow the dosage regimen carefully; reduce the dosage at the recommended intervals; if needed for longer than 12 weeks of treatment to keep from smoking, talk to your health care provider.
• Do not use more than 5 lozenges in 6 hours or more than 20 lozenges per day.
• Acidic beverages such as coffee, juices, wine, or soft drinks may transiently reduce the salivary pH, resulting in decreased absorption of nicotine across the buccal mucosa. Do not eat or drink anything (except water) 15 minutes before or while using the nicotine lozenge.
• Patients who use more than 1 lozenge at a time, continuously use 1 lozenge after another, or chew or swallow the lozenge are more likely to experience heartburn or indigestion.
• Have nicotine lozenges readily available at all times. Keep the nicotine lozenges in the same place you previously kept your cigarettes (e.g., shirt pocket, purse, or desk).
• Keep this product out of the reach of children and pets.

**TABLE 47-8 Dosages for Nonprescription Nicotine Transdermal Systems (Patch)**

	NicoDerm CQ and Generic Patch
Product strength	7, 14, 21 mg (24 hour)
Dose	>10 cigarettes/day
21 mg/day × 6 weeks (NicoDerm CQ; × 4 weeks for generic);	
14 mg/day × 2 weeks;	
7 mg/day × 2 weeks	
≤10 cigarettes/day	
14 mg/day × 6 weeks;	
7 mg/day × 2 weeks	

The dosing schedules for the nicotine patches vary slightly ([Table 47-8](#)). Before recommending a specific product and a dosing schedule, the caregiver should know how many cigarettes the patient smokes per day. In general, heavier smokers will require higher-strength formulations for a longer duration of therapy. Patients experiencing side effects from the patches, such as dizziness, perspiration, nausea, vomiting, diarrhea, or headache, should consider a lower-strength patch. Additional instructions for proper use of the nicotine patch are listed in [Table 47-9](#). The most common side effects associated with the nicotine patch are local skin reactions (erythema, burning, and pruritus) at the application site, which are generally caused by skin occlusion or sensitivity to the patch adhesives. If this side effect is bothersome, the patient can apply nonprescription hydrocortisone cream to the site or try another manufacturer's product that uses a different adhesive. Other, less common side effects include vivid or abnormal dreams, insomnia, and headache. Sleep disturbances might be caused by nocturnal nicotine absorption. If this side effect becomes troublesome, patients should be instructed to remove the patch at bedtime and apply a new patch as soon as possible after waking the following morning because they may experience increased urges to smoke with the lack of nicotine coverage throughout the night.<sup>29</sup>

#### Prescription Medications for Smoking Cessation

Detailed information about prescription products for tobacco cessation is outside the scope of this publication. The following information is a summary of key information; for more detailed discussion the reader is encouraged to utilize another reference.

**Nicotine Inhaler**

The nicotine inhaler consists of a plastic mouthpiece and a nicotine-containing cartridge that delivers 4 mg of nicotine as an inhaled vapor, 2 mg of which is absorbed across the oropharyngeal mucosa. The inhaler reduces nicotine withdrawal symptoms and may give some degree of comfort by providing a hand-to-mouth ritual that emulates smoking. However, reinforcing the hand-to-mouth ritual can make quitting more difficult. The inhaler has not been evaluated for use in patients with bronchospastic diseases, such as asthma, so it should be used with caution in these patients because of the risk of exacerbation.<sup>34</sup> Side effects of the inhaler include mild mouth and throat irritation, cough, and rhinitis.

**TABLE 47-9 Usage Guidelines for Nicotine Transdermal Systems (Nicotine Patch)**

• Do not smoke cigarettes or use other forms of tobacco (e.g., snuff, chewing tobacco, cigars, and pipes) while using the nicotine patch. (Note: In 2013, the FDA recommended labeling changes that will remove this warning. <sup>47</sup> )
• Apply the patch to a clean, dry, hairless area of the skin on the upper body or the upper outer part of the arm at approximately the same time each day.
• The patch should be applied to a different area of skin each day. To minimize the potential for local skin reactions, the same area should not be used again for at least 1 week.
• During application, apply firm pressure to the patch with the palm of the hand for 10 seconds. Be sure that the patch adheres well to the skin, especially around the edges; this is necessary for a good seal.
• Wash your hands after applying or removing the patch.
• The patch should not be left on the skin for more than 24 hours because prolonged use may lead to skin irritation.
• Any adhesive remaining on the skin after patch removal can be removed with rubbing alcohol.
• Water will not reduce the effectiveness of the nicotine patch if it is applied correctly. You may bathe, swim, shower, or exercise while wearing the patch.
• Do not cut patches in half or into smaller pieces to adjust or reduce the nicotine dosage. Nicotine in the patch may evaporate from the cut edges and the patch may be less effective.
• Local skin reactions (e.g., itching, burning, and redness) are common with the nicotine patch. These reactions are generally caused by adhesives; they can be minimized by rotating patch application sites and, if they occur, treated with nonprescription hydrocortisone cream.
• Remove the nicotine patch before having a magnetic resonance imaging (MRI) procedure. Burns from nicotine patches worn during MRIs have been reported and are likely caused by the metallic component in the backing of some patches.
• Individuals experiencing troublesome dreams or other sleep disruptions should remove the patch before bedtime.
• Discard the removed nicotine patch by folding it onto itself, completely covering the adhesive area.
• Keep new and used patches out of the reach of children and pets.

**Nicotine Nasal Spray**

The nicotine nasal spray is an aqueous solution of nicotine for administration to the nasal mucosa. Each actuation delivers a 0.5 mg bolus of nicotine that is absorbed across the nasal mucosa. Because of its rapid onset of action (relative to other NRT formulations), the spray is a potential option for patients who prefer a medication to manage withdrawal symptoms rapidly; however, in 15%-20% of patients, use of the nasal spray can result in dependence. Some patients with asthma have reported bronchospasm after using the nasal spray, so use of this medication in patients with bronchospastic disease should be avoided.<sup>34</sup> Initially, most patients will experience nose and throat irritation (peppery sensation), watery eyes, sneezing, or coughing when using this product. This product is to be administered without sniffing (i.e., not administered like standard allergy nasal sprays). After the first week, most patients have minimal difficulty with the product, and tolerance generally develops with regular use.

**Sustained-Release Bupropion**

Sustained-release bupropion was the first non-nicotine medication approved for smoking cessation. This agent is a prescription antidepressant medication that is believed to promote smoking cessation by blocking the reuptake of dopamine and norepinephrine in the brain, thereby decreasing the cravings for cigarettes and symptoms of nicotine withdrawal.<sup>29</sup>

Therapy is started with a dose of 150 mg orally every morning for 3 days, followed by 150 mg twice daily for 7-12 weeks. Because steady-state blood levels are reached after approximately 7 days of therapy, patients set their quit date for 1-2 weeks after starting therapy. Insomnia and dry mouth are the most common side effects reported with bupropion. Because seizures have been reported in approximately 0.1% of patients, bupropion is contraindicated in patients who (1) have a seizure disorder, (2) have a current or prior diagnosis of anorexia or bulimia nervosa, (3) are undergoing abrupt discontinuation of alcohol or sedatives (including benzodiazepines), (4) are currently using or have used a monoamine oxidase inhibitor within the past 14 days, or (5) are currently being treated with any other medications that contain bupropion. Other factors that might increase the odds of seizure and are classified as warnings for this medication include history of head trauma or prior seizure, central nervous system tumor, severe hepatic cirrhosis, and concomitant use of medications that lower the seizure threshold. In July 2009, FDA mandated that the prescribing information for all bupropion-containing products include a black-box warning that highlights the risk of serious neuropsychiatric symptoms, including changes in behavior, hostility, agitation, depressed mood, suicidal thoughts and behavior, and attempted suicide.<sup>35</sup> These additional warnings were based on postmarketing adverse event surveillance reports received by FDA.

**Varenicline**

Varenicline (Chantix) is a partial agonist and is highly selective for the  $\alpha_4\beta_2$  nicotinic acetylcholine receptor. The efficacy of varenicline in smoking cessation is believed to be the result of sustained, low-level agonist activity at the receptor site that is combined with competitive inhibition of nicotine binding. The partial agonist activity induces modest receptor stimulation, leading to increased dopamine levels that attenuate the symptoms of nicotine withdrawal. In addition, by competitively blocking the binding of nicotine to nicotinic acetylcholine receptors in the central nervous system, varenicline inhibits the surges of dopamine release that occur immediately after inhalation of tobacco smoke. The latter mechanism may be effective in preventing relapse by reducing the pleasure associated with smoking.<sup>36</sup>

Similar to sustained-release bupropion, treatment with varenicline should be started 1 week before the patient stops smoking. This regimen allows for gradual escalation of the dose to minimize treatment-related nausea and insomnia. Therapy is generally started at 0.5 mg daily on days 1-3; 0.5 mg twice daily on days 4-7; and 1 mg twice daily for weeks 2-12. Nausea, insomnia, abnormal dreams, and headache are the most commonly reported side effects. In July 2009, FDA mandated that the prescribing information for varenicline contain a black-box warning that highlights the risk of serious neuropsychiatric symptoms, including changes in behavior, hostility, agitation, depressed mood, and suicidal events including ideation, behavior changes, and attempted suicide.<sup>37</sup> These additional warnings were based on continued postmarketing adverse event surveillance reports received by FDA. Although these reports are rare in comparison with the total number of patients exposed to varenicline, providers and patients should monitor for changes in mood and behavior during treatment with varenicline.<sup>37</sup>

A small increased risk of cardiac events has been reported in some patients with existing cardiovascular disease.<sup>38</sup> In December 2012, FDA shared results of a meta-analysis conducted by the manufacturer of varenicline, reporting that a higher occurrence of major adverse cardiovascular events was observed in patients using varenicline compared with placebo (although the increased risk was not statistically significant).<sup>38</sup> The warnings and precautions labeling was updated to include the results of the meta-analysis and included instructions to patients to notify their health care providers of new or worsening cardiovascular symptoms and to seek immediate medical attention if they experience signs and symptoms of myocardial infarction or stroke.<sup>37</sup>

**Pharmacotherapeutic Comparison**

Few trials have directly compared the various agents for smoking cessation. In general, most experts believe the risks of placebo, compared with the first-line agents approximately double the long-term quit rates (Table 47-10).<sup>29</sup>

**Product Selection Guidelines**

Because all first-line, FDA-approved cessation medications enhance quit rates, the choice of therapy is based largely on contraindications or precautions, patient preference, tolerability of the available dosage forms, use during prior quit attempts (i.e., what worked well and what did not, regardless of whether medication was being used correctly or not), and cost. Regardless of the regimen selected, the cost of treatment will be insignificant compared with the costs of continued smoking and the costs of managing the resultant complications.

A number of smokeless tobacco products are now on the market, including snuff, snus, and dissolvable tobacco. Currently no guidelines exist for the treatment of tobacco cessation for individuals using these products. A randomized, clinical trial comparing varenicline to placebo showed positive results; however, more studies are needed.<sup>39</sup>

**Special Populations**

NRT should be used with caution in patients with serious underlying cardiovascular disease, including those who have had a recent myocardial infarction (i.e., within the preceding 2 weeks), those with serious arrhythmias, and those with serious or worsening angina pectoris.<sup>29</sup> Nicotine may increase the myocardial workload by increasing the heart rate and blood pressure and may constrict coronary arteries, leading to cardiac ischemia.<sup>40</sup> Although most experts believe the risks of NRT in patients with cardiovascular disease are small relative to the risks of continued smoking,<sup>41-43</sup> patients with serious underlying cardiovascular disease are advised to use NRT only while under the supervision of a health care provider.

**TABLE 47-10 Methods for Smoking Cessation: Estimates of Treatment Efficacy for First-Line Agents Compared with Placebo at 6 Months after Quitting**

Pharmacotherapy	Estimated Odds Ratio <sup>a</sup> (95% CI)	Estimated Abstinence Rate <sup>b</sup> (95% CI)
Placebo	1.0	13.8
<b>Monotherapy (first-line agents)</b>		

Sustained-release bupropion	2.0 (1.8-2.2)	24.2 (22.2-26.4)
Nicotine gum (6-14 weeks)	1.5 (1.2-1.7)	19.0 (16.5-21.9)
Nicotine inhaler	2.1 (1.5-2.9)	24.8 (19.1-31.6)
Nicotine lozenge (2 mg)	2.0 (1.4-2.8)	24.2 <sup>c</sup>
Nicotine patch (6-14 weeks)	1.9 (1.7-2.2)	23.4 (21.3-25.8)
Nicotine nasal spray	2.3 (1.7-3.0)	26.7 (21.5-32.7)
Varenicline (2 mg/day)	3.1 (2.5-3.8)	33.2 (28.9-37.8)
<b>Combination Therapy (first-line agents)</b>		
Nicotine patch (>14 weeks) + as-needed NRT (gum, nasal spray, or lozenge <sup>d</sup> )	3.6 (2.5-5.2)	36.5 (28.6-45.3)
Nicotine patch + bupropion SR	2.5 (1.9-3.4)	28.9 (23.5-35.1)
Nicotine patch + nicotine inhaler	2.2 (1.3-3.6)	25.8 (17.4-36.5)

Key: C, = Confidence interval; NRT = nicotine replacement therapy; SR = sustained release.

<sup>a</sup> Estimated relative to placebo.

<sup>b</sup> Abstinence percentages for specified treatment.

<sup>c</sup> One qualifying randomized trial; 95% CI not reported in the 2008 clinical practice guideline.

<sup>d</sup> A recent trial, not included in the clinical practice guideline, supports the combination of the nicotine patch and nicotine lozenge.<sup>45</sup>

Prescription forms of nicotine are classified by FDA as Pregnancy Category D, meaning there is evidence of risk to the human fetus.<sup>44</sup> Although NRT may pose a risk to the developing fetus, some experts have argued that NRT use during pregnancy is safer than continued smoking.<sup>43,44</sup> However, because data showing effectiveness of NRT in pregnancy are inconclusive and because nicotine has the potential to cause fetal harm, the 2008 clinical practice guideline states that pregnant women should be encouraged to quit without the use of medication. Instead, providers are advised to offer interventions of person-to-person behavioral counseling for their pregnant patients who smoke.<sup>29</sup> The efficacy of NRT, sustained-release bupropion, and varenicline has not been established in pediatric or adolescent smokers, and no NRT product is currently indicated for use in these populations.<sup>29</sup> Accordingly, counseling is the recommended treatment method for smokers younger than 18 years.

People older than 65 years can benefit greatly from quitting smoking. Pharmacologic therapy and counseling are recommended. If mobility is an issue, referral to a quit line may be useful.<sup>13,29</sup> The manufacturers of nicotine gum, lozenge, and patch products recommend that patients taking a prescription medicine for asthma or depression speak with their physician or pharmacist before using nonprescription NRT. Fluvoxamine and theophylline (both now used infrequently) and inhaled corticosteroids have known clinically significant interactions with tobacco smoke (Table 47-2).

For light smokers (those who smoke fewer than 10 cigarettes per day and those who do not smoke every day), counseling is the recommended treatment method for this population.<sup>29</sup> However, the nicotine patch is approved for use in light smokers, and the nicotine lozenge was shown to be effective in individuals smoking 15 or fewer cigarettes daily.<sup>45</sup> Use of smokeless tobacco (e.g., snuff, moist snuff, chewing tobacco, and dissolvable tobacco); cigars; and pipes can produce nicotine addiction and lead to serious health consequences. Behavioral counseling is the recommended treatment method for these tobacco users.<sup>29</sup>

#### Patient Factors

When recommending a nonprescription agent for smoking cessation, health care providers should determine the patient's smoking patterns, lifestyle habits, and coexisting medical conditions. In general, higher levels of smoking will require higher dosages of NRT and longer durations of treatment.

Some patients might need to use their smoking cessation medication longer than the usual recommended treatment duration. Although the general goal is complete, long-term abstinence from all nicotine-containing products, some smokers may benefit from long-term medication use.<sup>29</sup> If continued use helps prevent relapse, this approach is considered preferable to the patient returning to smoking.<sup>29</sup>

Patients who smoke continuously throughout the day might have better success with a nicotine patch because it provides a sustained, steady release of nicotine. Conversely, patients who smoke intermittently throughout the day or who smoke intensely for short periods of time, followed by long periods of abstinence, might prefer a relatively short-acting formulation, such as a nicotine gum or lozenge, to more closely mimic their tobacco use patterns. For some quitters, frequent gum chewing may not be feasible or socially acceptable. The nicotine patch, which can be concealed under clothing, might be a reasonable choice for these individuals. Others may find nicotine lozenges, which can be used more discreetly, to be an acceptable alternative. Patients with underlying dermatologic conditions (e.g., psoriasis, eczema, or atopic dermatitis) or allergy to adhesive tape are more likely to experience skin irritation and should not use the nicotine patch. The nicotine lozenge or patch is more appropriate than the nicotine gum for patients with TMJ disease or dentures. Finally, patients with serious cardiovascular disease, women who are pregnant or nursing, light smokers, and adolescents should be referred for further evaluation by their primary provider before starting treatment with NRT.

#### Patient Preferences

Understanding the patient's perceptions and expectations about pharmacotherapy is particularly important, including the ability to adhere to the regimen, previous experience with smoking cessation medications, and concern about weight gain. Because NRT formulations require frequent dosing or nontraditional routes of administration, patient education about proper use of these products is essential. Patients who have difficulty taking multiple doses of medications throughout the day or those who want a simplified regimen might achieve greater success with the nicotine patch. In contrast, the gum or lozenge may be preferable for patients who want to titrate nicotine levels to manage withdrawal symptoms. Some patients may find they need an oral substitute for tobacco; the oral gratification given by the nicotine gum, lozenge, or inhaler might be beneficial in these patients. Other patients may prefer the idea of using a combination of medications, such as the nicotine patch plus gum or lozenge, on an as-needed basis as discussed later in this section.

All smokers making a repeat quit attempt should be queried about their prior use of pharmacotherapy and their perceptions of the treatment options. For patients reporting a favorable past experience with a given product, repeated treatment with the same agent may be appropriate, with consideration given to increasing the dose, frequency of dosing, or duration of therapy. For patients who report a negative experience with a particular medication (e.g., poor adherence, side effects, palatability issues, or cost), a different regimen should be considered. For example, if a patient had short-term success with the patch but discontinued therapy because of intolerable nightmares, he or she may attempt to quit again by using the patch but may remove it at bedtime. A patient who is unable to tolerate nicotine gum because of jaw muscle ache could be advised to switch to the nicotine lozenge or patch. For patients who express concern about postcessation weight gain, the 4 mg nicotine gum or lozenge or the sustained-release bupropion might be particularly helpful, given that these products were shown to delay weight gain after quitting.<sup>29</sup> Among patients for whom the out-of-pocket expense might be a barrier to pharmacologic treatment, use of the generic formulations is preferable.

Combination therapy should be considered a first-line treatment and might be particularly appropriate in patients who have experienced numerous failed attempts using monotherapy. Combination therapy generally involves the use of a long-acting medication (nicotine patch or sustained-release bupropion) in combination with a short-acting nicotine formulation (nicotine gum, lozenge, inhaler, or nasal spray). The long-acting nicotine formulation, which delivers relatively constant concentrations of drug, is used to prevent the onset of severe withdrawal symptoms, whereas the short-acting nicotine formulation, which delivers nicotine more rapidly, is used as needed to control withdrawal symptoms that may occur during potential relapse situations (e.g., after meals, during episodes of stress, or around other smokers). Research suggests that combination therapy may be somewhat more efficacious than monotherapy.<sup>29,46</sup> Disadvantages of combination therapy are the possibility of more side effects (e.g., nicotine toxicity), difficulty with adherence, and increased cost. In 2013, FDA recommended nonprescription NRT labeling changes that will remove the warning against the concomitant use of nicotine-containing products (including other forms of NRT).<sup>47</sup> For other combination regimens, patients should be referred to their primary care provider to determine the most appropriate option.

#### Complementary Therapies

Although a variety of herbal and homeopathic products are available to aid cessation, data are lacking to support their safety and efficacy. Many herbal preparations for cessation contain lobeline (*Lobelia inflata*), an herbal alkaloid with partial nicotinic agonist properties. A meta-analysis<sup>48</sup> and a multicenter trial<sup>49</sup> found no evidence to support the role of lobeline as an aid for smoking cessation. Similarly, controlled trials did not find hypnosis or acupuncture to be an effective treatment for smoking cessation.<sup>29,50</sup>

#### Electronic Cigarettes

More recently, electronic cigarettes (e-cigarettes) have become available in the United States. These devices are being marketed as a substitute for cigarettes in situations that do not allow smoking. Currently, data are insufficient to support their safety or efficacy in reducing or stopping smoking.<sup>51</sup>

**Assessment of Tobacco Cessation: A Case-Based Approach**

To help patients succeed at tobacco cessation, the provider must assist them in evaluating how they smoke, identify medications and quitting methods they have or have not tried in the past, and determine appropriate cessation therapies. Analysis of the patient's smoking patterns and the triggers for smoking help the provider work with the patient to develop an appropriate treatment plan.

Cases 47-1 and 47-2 illustrate the assessment of patients who want to quit smoking.

**Case 47-1**

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient would like information about the various OTC medications for tobacco cessation. He is noticing that he gets more "winded" when he walks, and he is concerned about the effects of smoking on his health. He has smoked one pack per day (or 20 cigarettes) for 21 years. He smokes 2 cigarettes with his morning coffee and smokes in social situations such as when having a few drinks with coworkers. He has not received cessation counseling from a provider. He has tried the nicotine patch and gum in the past and wants to try Chantix (varenicline).
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	He is in a rush because he has to get back to work. He smokes mostly on work breaks and at home in the morning and in the evenings after dinner.
c. description of the patient's efforts to relieve the symptoms	He has tried to quit smoking about 5 times to date, 3 times using NRT.
d. patient's identity	Kevin Stills
e. age, sex, height, and weight	61 years old, male, 5 ft 8 in., 170 lb
f. patient's occupation	Accountant
g. patient's dietary habits	Reasonably healthy diet; walks 30 minutes daily during his lunch break.
h. patient's sleep habits	Sleeps 7 hours/night during the workweek; does not have trouble sleeping.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Hypertension (controlled on lisinopril 10 mg daily).
j. allergies	NKA
k. history of other adverse reactions to medications	None
l. other (describe)	Married, no kids. His wife is supportive of his attempt to quit. Some close friends and coworkers also smoke.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Patient is a middle-aged male who would like to quit smoking to improve his breathing and overall health.
3. Identify exclusions for self-treatment ( <a href="#">Figure 47-2</a> ).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Recommend pharmacotherapy and counseling. Pharmacotherapy options include: • Nicotine patch. • Nicotine gum. • Nicotine lozenge. • Combination therapy with the nicotine patch plus a short-acting NRT. • Referral to PCP for prescription pharmacotherapy (nicotine inhaler, nicotine nasal spray, bupropion SR, varenicline). (2) Refer Mr. Stills to telephone counseling (1-800-Quit-Now) because he is in a hurry. (3) Recommend that he set a quit date in 1-2 weeks. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Mr. Stills expressed interest in using varenicline. Refer him to his PCP for a prescription. For behavioral counseling, refer him to the quit line. (See <a href="#">Tables 47-3</a> and <a href="#">47-4</a> .)
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Medication is recommended. Although you have no contraindications or precautions for self-care use, varenicline is available only by prescription."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Chantix, or varenicline, is considered a first-line treatment for smoking cessation. Because you would like to use this medication and it is available by prescription only, you will need to contact your primary care provider to obtain a prescription. I can also call your provider for you now if you would like. Receiving counseling, in addition to taking Chantix as directed, will increase your chances of success with quitting."
<b>Patient Education</b>	

8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"What should I do if I am tempted to smoke when I am around my friends?"
Answer the patient's or caregiver's questions.	"The quit line counselor will be able to talk to you about problem-solving and coping skills for your smoking triggers. It is important that your friends and wife support you when you quit. To minimize relapse, reduce or avoid use of alcohol during the first 2 weeks of your quit attempt. The counselor will arrange follow-up contacts after your quit date."
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Mr. Stills plans to contact his PCP and will return to the pharmacy to fill his prescription. He also set a quit date in 2 weeks with plans to follow up with the quit line.

Key: NKA = No known allergies; NRT = nicotine replacement therapy; OTC = over-the-counter; PCP = primary care provider; SR = sustained release.

#### Case 47-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient quit smoking 7 days ago and is using the generic 21 mg nicotine patch. She complains of trouble sleeping and is experiencing disturbing dreams since starting to use the patch. She had been smoking approximately 1.5 packs per day (~30 cigarettes daily) for 10 years before quitting.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Before quitting, patient used to have a cigarette before even getting out of bed, because she had such intense cravings.
c. description of the patient's efforts to relieve the symptoms	Patient has been using the 21 mg nicotine patch for 7 days. She has not previously tried pharmacotherapy for quitting. She purchased the patch after speaking to a pharmacist. She has not received any formal counseling from a provider. She feels a bit agitated and irritable from time to time during the day; she is very tempted to smoke in the morning when she wakes up. Overall, she likes the patch and is not experiencing any significant skin reactions.
d. patient's identity	Kristen Brady
e. age, sex, height, and weight	28 years old, female, 5 ft 6 in., 140 lb
f. patient's occupation	Web designer
g. patient's dietary habits	Tries to eat healthy; drinks approximately 8 cups of caffeinated coffee per day.
h. patient's sleep habits	Sleeps 7-8 hours a night. Since using the patch, she has experienced trouble sleeping and disturbing dreams.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Not pregnant or breastfeeding; temporomandibular joint (TMJ) disease; acetaminophen 325 mg every 6 hours as needed for pain, but uses rarely.
j. allergies	NKA
k. history of other adverse reactions to medications	None
l. other (describe)	Patient is single. Her boyfriend and roommate are supportive of her desire to quit.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Patient quit smoking 1 week ago and is experiencing intolerable side effects from the nicotine patch (i.e., sleep disturbances), daily withdrawal symptoms (i.e., agitation and irritability), and morning cravings.
3. Identify exclusions for self-treatment (Figure 47-2).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Recommend continued pharmacotherapy and counseling. Pharmacotherapy options include: • Removal of nicotine patch at night and addition of a lozenge as needed (particularly in the morning upon waking). • Alternative NRT, such as lozenge alone. • Referral to PCP for prescription pharmacotherapy (nicotine inhaler, nicotine nasal spray, bupropion SR, varenicline). (2) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Because Ms. Brady has expressed that she thinks the patch is working well to manage her withdrawal symptoms, continue the nicotine patch, but advise her to take the patch off before bedtime. This should help reduce the sleep disturbances and disturbing dreams. She can use combination therapy with a nicotine lozenge, as needed. The nicotine gum would not be a good choice because she has TMJ disease. A 2 mg lozenge dose to be used on an as-needed basis is reasonable.

6. Describe the recommended therapeutic approach to the patient or caregiver.	"It's great that the patch is working for you so far. You have no contraindications or precautions for use of the nicotine patch and as-needed 2 mg lozenge. I have some ideas that should help you with your sleep problems and some other information for you, including how to manage morning cravings."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"You do not have any medical conditions for which nicotine replacement medications should be used with caution (e.g., recent heart attack, serious arrhythmias, or angina). The nicotine patch provides a low, constant level of nicotine to help reduce nicotine withdrawal symptoms. By taking it off at night, you should no longer experience sleep disturbances. The nicotine lozenge should be used only when you experience situations in which you are craving a cigarette, such as when you wake up. Receiving counseling, in addition to taking your medications as directed, will increase your chances of quitting."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	"Use the 2 mg nicotine lozenge if you experience situations in which you are craving a cigarette, such as when you wake up." (See Tables 47-5 and 47-8.)
b. maximum number of days the therapy should be employed	See Table 47-8.
c. product administration procedures	See Tables 47-7 and 47-9.
d. expected time to onset of relief	"With the lozenge, nicotine levels will peak 30-60 minutes after you start using it. You are already using the nicotine patch, which provides a steady amount of nicotine throughout the day. The blood nicotine levels from the patch and lozenge are lower than those from smoking but should be sufficient to help control your nicotine withdrawal. Most patients find that nicotine withdrawal symptoms peak in the first few days after the last cigarette; withdrawal symptoms then gradually diminish over the next 2-4 weeks."
e. degree of relief that can be reasonably expected	"Over time, you may find you need to use the lozenge less often. Be sure to stick with the recommended daily dosing schedule for the patch and the duration of use needed for the best chance of success. This will help you to be more comfortable while you are quitting."
f. most common side effects	"The most common side effects of the nicotine patch include skin reactions (redness, burning, itching) at the application site and headaches. The sleep disturbances (vivid dreams, insomnia) that you are currently experiencing from the patch should resolve when you remove it before bedtime. The most common side effects of the nicotine lozenge are nausea, hiccups, and heartburn."
g. side effects that warrant medical intervention should they occur	"If you find that reducing your caffeine intake and using the nicotine lozenge do not help relieve your morning cravings and irritability during the day, contact your PCP. If you experience symptoms of nicotine excess (e.g., nausea, vomiting, dizziness, weakness, or rapid heartbeat), also contact your PCP."
h. patient options in the event that condition worsens or persists	"Contact your PCP for the following reasons: <ul style="list-style-type: none"> <li>• If you experience withdrawal symptoms or severe cigarette cravings, you may need a higher dosage of nicotine.</li> <li>• If you have side effects related to nicotine excess." (see outcome in 8.g.)</li> </ul>
i. product storage requirements	"Store the patches and lozenges at room temperature. Keep unused patches in the closed, protective pouch. Keep all new and used patches and lozenges out of the reach of children and pets."
j. specific nondrug measures	"Reduce caffeine use by half to minimize agitation and trouble sleeping. In addition to the counseling I can provide, other counseling programs are available, including the telephone quit line (1-800-QUIT NOW), group classes, and Internet-based programs. We can discuss which options you feel might be useful to you."
Solicit follow-up questions from the patient or caregiver.	"How often can I use the lozenge?"
Answer the patient's or caregiver's questions.	"You should use the lozenge when you feel a strong craving to smoke, such as when you wake up in the morning. The patch will provide a consistent low level of nicotine to help reduce withdrawal symptoms. You should use the nicotine lozenge only when you feel a need, or urge, to smoke. Even though the box says you can use up to 20 lozenges a day, you should not need this many when you use them with the patch. Also remember to switch to the lower 14 mg strength patch after 6 weeks, use this for 2 weeks, then use the 7 mg patch for 2 weeks."

Key: NKA = No known allergies; NRT = nicotine replacement therapy; PCP = primary care provider; SR = sustained release; TMJ = temporomandibular joint.

### Patient Counseling for Tobacco Cessation

Smoking is the leading cause of preventable morbidity and mortality in the United States. Substantial benefits of quitting can be realized at any age. Although approximately 70% of adult smokers would like to quit,<sup>52</sup> few are able to do so on their own. Research has shown that tobacco cessation rates can be substantially improved with treatment that includes counseling and pharmacotherapy.<sup>29</sup> (See Nonpharmacologic Therapy for a detailed discussion of counseling.) Health care providers are in an ideal position to identify tobacco users and to either provide assistance throughout the cessation attempt or refer the patient to a tobacco cessation resource. The box Patient Education for Tobacco Cessation describes specific information to provide to patients.

### Evaluation of Patient Outcomes for Tobacco Cessation

Follow-up contact is an essential component of treatment for tobacco use and dependence.<sup>29</sup> At each follow-up contact, the provider should do the following:

- Assess a patient's tobacco use status and, if appropriate, evaluate and monitor pharmacotherapy use.
- Congratulate abstinent patients and encourage them to remain tobacco free.
- In cases of relapse, review the specific circumstances; re-assess the commitment to abstinence; encourage the patient to learn from his or her mistakes; and identify strategies to prevent future lapses.
- Determine whether the patient is experiencing nicotine withdrawal symptoms or adverse effects from the pharmacotherapy.
- Offer ongoing support. If providing that level of support is not possible, refer the patient to a specialist for more intensive treatment.

### Key Points for Tobacco Cessation

- Apply the 5 A's approach in providing tobacco cessation counseling: ask, advise, assess, assist, and arrange.
- For a patient who is not ready to quit, provide brief counseling by addressing the 5 R's: relevance, risks, rewards, roadblocks, and repetition.
- For a patient who is ready to quit, offer counseling and pharmacotherapy. If time is limited, ask about tobacco use, advise the patient to quit, and refer the patient to the toll-free quit line

(1-800-Quit-Now).

- Numerous effective medications are available for tobacco dependence; encourage their use by all patients attempting to quit smoking—except when medically contraindicated or with specific populations for which there is insufficient evidence of effectiveness (i.e., pregnant women, smokeless tobacco users, light smokers, and adolescents). If a patient has exclusions for self-treatment with NRT, refer the patient to a primary care provider for further assessment.
- Advise patients that it is never too late for them to quit, but quitting earlier in life is clearly advantageous. Quitting smoking at any age has immediate as well as long-term benefits by reducing the risk for smoking-related diseases and improving health in general.

#### Patient Education for Tobacco Cessation

Tobacco dependence is a chronic disease optimally treated with a combination of counseling and medications. The primary goal of tobacco cessation treatment is to attain complete, long-term abstinence from all nicotine-containing products. For most people, carefully following product instructions and the self-care measures listed here will help ensure optimal treatment outcomes.

#### Nondrug Methods

- Receiving counseling from a health care provider will increase the success of tobacco cessation. A provider can help develop a tailored tobacco cessation treatment plan.
- Telephone quit lines (e.g., 1-800-Quit-Now) are also available to provide comprehensive counseling services at no cost.

#### Nonprescription Medications

##### Nicotine Replacement Therapy (NRT)

- NRT helps relieve and prevent symptoms of nicotine withdrawal by partially replacing the high levels of nicotine that your body is used to obtaining from cigarettes. Use of NRT helps you to focus on changing your smoking routines and to practice new coping skills while decreasing your withdrawal symptoms.
- NRT does not contain any of the harmful tars and other toxins present in tobacco smoke.
- Symptoms of nicotine withdrawal are common and should subside over 2-4 weeks.
- Recommended daily dosages for NRT are shown in [Tables 47-5 and 47-8](#).
- See [Table 47-6](#) for usage guidelines for nicotine gum, [Table 47-7](#) for the nicotine lozenge, and [Table 47-9](#) for the nicotine patch.
- Carefully follow the dosage regimen of the selected product. Failure to do so will increase the chance of having withdrawal symptoms. Discontinuing therapy early might lead to relapse.
- Discontinue the use of any form of NRT if you relapse back to smoking.
- Symptoms of nicotine excess include nausea, vomiting, dizziness, diarrhea, weakness, and rapid heartbeat.
- Do not eat or drink (except water) 15 minutes before or while using the nicotine gum or lozenge.
- Store NRT products at room temperature and protect from light.
- Keep new and used products out of the reach of children and pets.
- For all forms of NRT, consult your primary care provider before use if you have had a recent (in the past 2 weeks) heart attack, experience frequent pain caused by severe angina, have an irregular heartbeat, are pregnant or breast-feeding, are younger than 18 years, or smoke fewer than 10 cigarettes a day.
- You may consider use of the nicotine gum with the patch (gum used only as needed). For other possible medication combinations, speak to your primary care provider first.

#### When to Seek Medical Attention

- For all forms of NRT, stop use and seek medical attention if irregular heartbeat or palpitations occur, or if you have symptoms of nicotine overdose, such as nausea, vomiting, dizziness, diarrhea, or weakness.
- For nicotine gum: Stop use if mouth, teeth, or jaw problems develop.
- For nicotine lozenge: Stop use if mouth problems, persistent indigestion, or severe sore throat develops.
- For nicotine patch: Stop use if the skin swells, a rash develops, or skin redness caused by the patch does not subside with use of nonprescription hydrocortisone cream or does not go away after 4 days.

## Handbook of Nonprescription Drugs > Chapter 48. Home Testing and Monitoring Devices

### Home Testing and Monitoring Devices: Introduction

In 1977, Warner-Lambert introduced the first home pregnancy test kit—an event that had a dramatic effect on the home diagnostics market. Annual sales of home pregnancy tests, excluding Walmart sales, totaled \$227 million in 2010.<sup>1</sup> The market continues to grow, with an expanded array of products that are also more user friendly. Forces driving the growth in home diagnostics include (1) increased public interest in health and preventive medicine; (2) reduced health care costs because patients can avoid unnecessary visits to health care providers and can seek earlier treatment of a medical condition; (3) reduced access and availability of health care resources; (4) increased number of available tests; and (5) important advances in technology that have led to simplified, accurate tests that can be easily performed at home.

Home testing and monitoring kits are designed to detect the presence or absence of a medical or physiologic condition and to monitor disease therapy. The Food and Drug Administration (FDA) requires home tests to perform as well as the professional-use equivalent. However, these products must be used properly to achieve accurate results. This chapter discusses home test kits that aid in detecting the following conditions: pregnancy, female fertility, male fertility, colorectal cancer (fecal occult blood tests), high cholesterol levels, urinary tract infections (UTIs), human immunodeficiency virus (HIV), hepatitis C, and drug abuse. This chapter also covers proper selection and use of blood pressure monitors. In addition, a table of miscellaneous tests is included at the end of the chapter. For other products used in self-monitoring of disorders, see [Chapter 8](#), for vaginal fungal infections, and [Chapter 45](#), for asthma and diabetes mellitus.

### Selection Criteria

With the variety of diagnostic and monitoring products available, deciding which test to recommend to a given patient can be challenging. The major product variables to consider include test complexity, ease of reading results, presence of a control, and cost. [Table 48-1](#) addresses these variables as well as the major patient assessment variables, which fall within three general areas:

1. Appropriateness of testing.
2. Ability to accurately conduct the test and interpret the results.
3. Potential interference with test results.

**TABLE 48-1 Selection and Use of Home Tests and Devices**

<ul style="list-style-type: none"> <li>• Not all available tests are FDA approved for home use. Check the status of a particular test at <a href="http://www.accessdata.fda.gov/scripts/cdrh/cfdocs/cfIVD/Search.cfm">www.accessdata.fda.gov/scripts/cdrh/cfdocs/cfIVD/Search.cfm</a>.</li> </ul>
<ul style="list-style-type: none"> <li>• Always check the expiration date before purchasing a product to ensure that reagents are not outdated. For example, a test that has an expiration date of 07/16 expires at the end of July 2016.</li> </ul>
<ul style="list-style-type: none"> <li>• Follow the manufacturer's instructions for storing the tests to ensure that reagents remain stable.</li> </ul>
<ul style="list-style-type: none"> <li>• When selecting a test, consider simplicity of use. Single-step tests are usually desirable because each step is a potential source of error.</li> </ul>
<ul style="list-style-type: none"> <li>• When considering cost, determine the cost per test unit and whether kits with multiple tests are needed. Generic or store-brand kits may cost significantly less.</li> </ul>
<ul style="list-style-type: none"> <li>• When possible, select a test that includes a control to ensure that the test is functioning correctly.</li> </ul>
<ul style="list-style-type: none"> <li>• Read all instructions carefully and completely before attempting to perform a test.</li> </ul>
<ul style="list-style-type: none"> <li>• Note the time of day that the test is to be conducted, the length of time required, and any necessary supplies or equipment; then schedule the best time and place to conduct the test.</li> </ul>
<ul style="list-style-type: none"> <li>• Follow instructions exactly as described and in the order described. If you have questions about the testing procedure or interpretation of the results, consult a health care provider, or call the test manufacturer's toll-free number, if provided, for customer assistance.</li> </ul>

- Use an accurate timing device that measures seconds to ensure that you wait the specified length of time between steps. In addition, waiting longer than the specified time to read test results could affect test reliability.
- If the selected test requires observation of a color change, read the test in good lighting. If you have color-defective vision or other visual impairment, ask someone without vision problems to observe the color change and/or read the test results.
- If you have physical limitations that could interfere with performing the test, ask someone to help you perform the test.
- If the test requires a fingerstick and you have a medical condition or take medications that may cause excessive bleeding, consult your health care provider before performing the test.
- Food, medications, and certain diseases or conditions can sometimes interfere with test results.

Key: FDA = Food and Drug Administration.

## Pregnancy Detection Tests

In 2010, the birth rate in the United States was 13.0 live births per 1000 population. The female fertility rate in women ages 15-44 years was 64.1 births per 1000 women that year.<sup>2</sup> Women are now able to detect pregnancy earlier, including before the day of the missed period because of the heightened sensitivity of at-home pregnancy tests. Early detection of pregnancy is desirable for many reasons, including allowing the woman to make decisions regarding prenatal care and lifestyle changes to avoid potential harm to the fetus.

## Physiology of the Female Reproductive Cycle

The female reproductive cycle is approximately 28 days and is hormonally controlled. At the beginning of the cycle (day 1 through approximately day 12), low levels of circulating estrogen and progesterone cause the hypothalamus to secrete gonadotropin-releasing hormone (GnRH). GnRH stimulates release of follicle-stimulating hormone (FSH) and low levels of luteinizing hormone (LH) from the anterior pituitary gland. This combination of hormones promotes development of several follicles within an ovary during each cycle. One follicle continues to mature while the others regress. At midcycle (approximately day 14 or 15), circulating and urinary LH levels significantly increase and cause final maturation of the follicle. Ovulation (rupturing of the follicle and release of the ovum) occurs approximately 20-48 hours after the LH surge. Cells in the ruptured follicle form the corpus luteum, which begins to secrete progesterone and estrogen. For approximately 7-8 days after ovulation, the corpus luteum continues to develop and secrete estrogen and progesterone, inhibiting further secretion of FSH and LH.

Once ovulation occurs, the ovum remains viable for fertilization for only 12-24 hours. Sperm may live up to 72 hours; therefore, optimal days for fertilization to occur include the 2 days before ovulation, the day of ovulation, and the day after ovulation. For the greatest chance of achieving pregnancy, intercourse should take place within 24 hours after the LH surge.

If fertilization occurs, trophoblastic cells produce human chorionic gonadotropin (hCG) hormone. This hormone causes the corpus luteum to continue to produce progesterone and estrogen, forestalling the onset of menses while the placenta develops and becomes functional. As early as day 7 after conception, the placenta produces hCG, some of which is excreted in the urine. The concentration of hCG continues to increase during early pregnancy, reaching maximum levels 6 weeks after conception. The levels of hCG decline over the following 4-6 weeks and then stabilize for the remainder of the pregnancy.

If fertilization does not occur during a cycle, the corpus luteum degenerates, circulating levels of progesterone and estrogen diminish, and menstruation occurs (days 1-5). Resulting low levels of progesterone and estrogen cause release of GnRH from the hypothalamus, and the hormonal cycle begins again.

## Usage Considerations

The hormone produced by the trophoblast of the fertilized ovum, hCG, is detectable in the urine within 1-2 weeks after fertilization. It is composed of multiple forms of hCG, including intact hCG, hyperglycosylated hCG (hCG-H), and free alpha and beta subunits. The primary form detected in early pregnancy is hCG-H.<sup>3</sup> However, most pregnancy tests have a decreased sensitivity for hCG-H and beta subunits, so further improvements are needed to detect pregnancies earlier.<sup>4</sup>

Numerous pregnancy tests with different reaction times and hCG sensitivity are available for home use. [Table 48-2](#) lists some available products that have been tested for accuracy.<sup>5-8</sup> Overall, First Response Early Result may be the best test for detecting pregnancy before the fourth week of gestation, when hCG levels are low. After that point, most of the tests are equivalent.

**TABLE 48-2 Selected Nonprescription Pregnancy Tests**

<b>Trade Name</b>	<b>hCG Sensitivity</b>	<b>Product Features</b>
First Response Early Result	<6.3 mIU/mL	Test stick; best combination of sensitivity and reliability; can test up to 4 days before missed period; First Response Rapid Result produces a result in 1 minute
Clearblue +/- Results	25 mIU/mL	Test stick; can test up to 4 days before missed period; Clearblue digital display test also available
Store brands	100 mIU/mL	Test sticks; some CVS samples failed to work <sup>6</sup>
E.P.T.	100 mIU/mL	Test sticks; some samples failed to work <sup>6</sup> ; E.P.T. has digital display test also available
Accu-Clear	>100 mIU/mL	Test sticks or cassettes; 1% of samples failed to work <sup>6</sup>
Fact Plus	>100 mIU/mL	Test sticks or cassettes; can use test sticks to test up to 4 days before missed period

Key: hCG = Human chorionic gonadotropic hormone.

Source: References 5-8.

#### Mechanism of Action

Home pregnancy tests detect hCG in the urine by using monoclonal or polyclonal antibodies in an enzyme immunoassay. The antibodies are bound to a solid surface such as a stick, bead, or filter. If urinary hCG is present, it will form a complex with the antibodies. Another antibody is added, one that is linked to an enzyme and will react with a chromogen to produce a distinctive color. The hCG is sandwiched between the antibody linked to the enzyme and the antibodies bound to the solid surface. Washing or filtering within the testing device removes unbound substances; a chromogen then reacts with the enzyme, causing a color change.

#### Accuracy Rate

A pregnancy cannot be detected before implantation. Because of natural variability in the timing of ovulation, implantation does not necessarily occur before the expected onset of the next menses. One study found that the highest possible screening sensitivity for an hCG-based pregnancy test conducted on the first day of a missed period is 90% because 10% of women may not have an implanted embryo at that point. Although most pregnancy tests are advertised as 99% accurate, studies estimate that the highest possible screening sensitivity of a home pregnancy test by 1 week after the first day of the missed period is 97%.<sup>9</sup> A test sensitivity for hCG of 12.4 mIU/mL is needed to detect 95% of pregnancies on the expected day of a missed period.<sup>10</sup> The actual accuracy rate of these tests is less because users do not carefully follow the directions; formatting changes and improved instructions could help to improve the patient's ability to use home pregnancy tests and accurately interpret results.<sup>11</sup>

#### Interferences

A false-positive result may occur if the woman has had a miscarriage or given birth within the previous 8 weeks because hCG may still be present in the body. Medications such as Pergonal (menotropins for injection) and Profasi (chorionic gonadotropin for injection) can produce false-positive results. Unreliable results may occur in patients with ovarian cysts or an ectopic pregnancy. Oral contraceptive use does not affect test results.

Because hCG levels are very low in early pregnancy and may be below the sensitivity of a particular test, false-negative results may occur with home pregnancy tests if they are performed on or before the first day of a missed period. Erroneous results may also result from not allowing refrigerated urine to warm to room temperature before testing, using waxed cups to collect urine, or collecting urine in household containers that contain soap residue.

#### Usage Guidelines

See the box Patient Education for Pregnancy Tests.

## Patient Education for Pregnancy Tests

### Avoidance of Incorrect Results

- The most accurate results will be obtained by waiting at least 1 week after the date of the expected period. Performing the test too early may produce false-negative results.
- Be sure to use the urine collection device provided in the kit. Wax particles in waxed cups can clog the test matrix, causing false results. Soap residue in household containers can also interfere with test results.
- Try to test the urine sample immediately after collection.
- If the sample must be tested later, store it in the refrigerator but allow the sample to warm to room temperature for 20-30 minutes before testing. Chilled urine may produce false-negative results. Be careful not to redisperse or shake up any sediment present in the sample.

### Usage Guidelines

- Unless package instructions specify otherwise, use the first morning urine because the levels of hCG, if present, will be concentrated at that time.
- If testing occurs at other times of the day, restrict fluid intake for 4-6 hours before urine collection.
- Check the expiration date of the packaging. Remove test stick or cassette from packaging just before use. For test sticks, remove cap, if present, from absorbent tip.
- Apply urine to testing device using whichever of the following methods is specified in package instructions: (1) hold test stick in the urine stream for designated time, (2) urinate into testing well of test cassette, or (3) collect urine in a collection cup and dip the strip in the urine.
- After the urine is applied, lay the testing device on a flat surface. Wait the recommended time (1-5 minutes) before reading the results. Waiting the maximum allowed time may improve the sensitivity of the test.
- After reading the results, discard the testing device. If the test result is negative, test again in 1 week if menstruation has not started.

### When to Seek Medical Attention

- If the second test is negative and menstruation has not begun, consult a health care provider.

Source: References 3, 7, and 8.

### Product Selection Guidelines

Product labeling for most tests states that women may use the test as early as the first day of a missed menstrual period. Some tests that can detect hCG levels at 25 mIU/mL or less can be used 3 days before the missed period. The earlier a pregnancy test is used, the greater the likelihood of a false-negative result. Most pregnancy tests are one-step procedures. Some tests have clear test sticks that allow the woman to see the reaction occurring; this serves as a check that the stick absorbed sufficient urine. Other tests include two devices, which can be helpful if the first test is negative. The newest tests are digital and display the results as “pregnant” or “not pregnant,” or “yes” or “no,” instead of showing colored lines, which eliminates the need to interpret the results. Test results are generally obtained in 3 minutes.

A study of seven nonprescription pregnancy tests found that First Response Early Result was the most sensitive and most reliable test. It detected hCG at concentrations as low as 6.5 mIU/mL. In addition, this product was expected to detect more than 95% of pregnancies on the first day of a missed period.<sup>6</sup>

### Assessment of Pregnancy Test Use

Whether a pregnancy test is appropriate for the patient should be determined first by asking questions about her menstrual cycle and the number of days since intercourse. If product use is appropriate, the patient should be asked about previous use of pregnancy tests and any difficulties the patient had with the tests. Questions about medical disorders and medication use should also be asked to determine whether inaccurate test results are possible or whether special measures may be required to protect the unborn child. Case 48-1 illustrates assessment of a patient who wishes to use a pregnancy test.

#### Case 48-1

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<i>Information Gathering</i>	
1. Gather essential information about the	

patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient thinks that she may be pregnant. She has not had a period in 6 weeks according to her calculations, and she has been feeling a little nauseated. She is not due for her annual OB/Gyn checkup for another couple of months.
b. medical history, including family history	Menstrual cycle: 29 days; regular cycle in the past. She has regular intercourse with her boyfriend of 1 year.
c. patient's identity	Lauren Mason
d. age, sex, height, and weight	21 years old, female, 5 ft 5 in., 155 lb
e. patient's occupation	College student
f. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	No current medical conditions; multivitamin daily
g. prior use of diagnostic/monitoring test	Never used any home diagnostic tests
h. Potential problems with performing/interpreting test	Lauren does not know how to use a pregnancy test.
<b>Assessment and Triage</b>	
2. Determine if self-testing is appropriate.	Self-testing is appropriate.
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Recommend a digital pregnancy test today. Educate the patient to follow all manufacturer's instructions when performing the self-test. (2) Advise the patient to make an appointment with her health care provider to verify test results if the test comes back positive. (3) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Because of financial limitations, the patient could try one of the generic store brand tests.
<b>Patient Education</b>	
6. Describe the testing procedure to the patient:	
a. specific instructions	"When you do perform the test, follow the instructions carefully."

b. how to avoid incorrect results	See the box Patient Education for Pregnancy Tests.
Solicit follow-up questions from the patient or caregiver.	"If the test comes back positive, does this mean I am pregnant?"
Answer the patient's or caregiver's questions.	"Most likely. Your medication and medical histories indicate that you would not have a false-positive test result. The test determines whether you have increased hCG levels in your urine. In addition, symptoms of pregnancy are occurring. If the test comes back positive, you should see a health care provider immediately for follow-up."
<b>Evaluation of Patient Outcome</b>	
7. Assess patient outcome.	"You can call if you have any questions while doing the test or are concerned about the results."

Key: hCG = Human chorionic gonadotropic hormone.

### Patient Counseling for Pregnancy Tests

During counseling on the use of pregnancy tests, the health care provider should emphasize the importance of following package instructions carefully, especially the instruction for when to begin testing. Pregnancy tests are very sensitive; therefore, the patient should be advised of medical and environmental factors that can cause inaccurate test results. The box Patient Education for Pregnancy Tests lists specific information to provide patients.

### Evaluation of Patient Outcomes with Pregnancy Tests

If the pregnancy test result is positive, the woman should assume she is pregnant and contact her health care provider as soon as possible. In addition, if the patient is taking a medication with teratogenic potential (e.g., Accutane or methotrexate) or any medications for chronic conditions, she should be advised to discuss with her health care provider any possible effects the drugs may have on a fetus. If the test result is negative, the woman should review the procedure and make sure she performed the test correctly. She should test again in 1 week if menstrual flow has not begun. If the results of the second test are negative and menses still has not begun, the woman should seek the advice of a health care provider.

### Female Fertility Tests

Women use basal thermometers and ovulation prediction test kits and devices to time sexual intercourse to coincide with optimal fertility. These tests and devices are also useful for women who want to be more aware of their time of ovulation. However, they are not a reliable means of birth control.

It may take several months of attempting pregnancy for a fertile woman to be successful. Infertility, however, is defined as the medical inability to conceive after 1 year of unsuccessful attempts. Infertility is estimated to occur in 6% of married women ages 15-44 years.<sup>12</sup>

Available nonprescription products for ovulation prediction (Table 48-3) include ovulation detection devices, basal thermometers, and urine tests.<sup>13-18</sup> Each detection method has a different mechanism of action and method of use. Women should pick their own preferred method.

**TABLE 48-3 Selected Nonprescription Ovulation Prediction Tests and Devices**

Trade Name	Reaction Time	Product Features
Clearblue EasyDigital Ovulation Test	3 minutes	7-day kit or 1-month kit. Urine test sticks; clear and easy to read with no lines to interpret; digital smiley face technology, highly sensitive and easy to read with 97% of study volunteers correctly reading result and considered most preferred test <sup>14</sup>
Clearblue Easy Fertility Monitor	5 minutes	Reusable monitor. Urine test sticks; typically predicts 2-day window of peak or high fertility; stores daily fertility information; easy to read; tests for LH and E3G, an estrogen metabolite

Clearblue Advanced Digital Ovulation Test	5 minutes	1 or 2 month supply available, Urine test sticks + holder, tests for LH and E3G, an estrogen metabolite; typically identifies 4 fertile days
Answer 1-Step Ovulation	5 minutes	7-day kit. Urine test sticks; predicts ovulation within 24-36 hours
Accu-Clear Early Ovulation Predictor Test	3 minutes	5-day kit. Urine test sticks; predicts ovulation within 24-48 hours
First Response 1-Step Ovulation Predictor Test	5 minutes	7-day kit or 1-month supply kit. Urine test sticks; predicts ovulation within 24-36 hours; digital ovulation test also available
Nexcare Basal Thermometer	1 minute	Digital thermometer. Auto memory for last reading; continuous beep to indicate it is working; signals when done; large lighted display
OV-Watch	Measures chloride ions every 30 minutes up to 12 readings	Lightweight watch that is worn during sleep; detects up to 4 days prior to ovulation; easy to use and read

Key: LH = Luteinizing hormone; E3G = estrone-3-glucuronide.

Source: References 13-19.

Saliva microscopy and home saliva monitors are also available. These two products are not discussed here because the results obtained are not reliable or the data on accuracy are conflicting.<sup>13</sup>

### Basal Thermometry

For many years, women have measured basal body temperature (BBT) to predict the time of ovulation. Resting BBT is usually between 96.0°F (35.5°C) and 97.5°F (36.4°C) during the first part of the female reproductive cycle. Approximately 24-48 hours after ovulation, it rises to a level closer to normal (i.e., 98.6°F [37°C]).<sup>16</sup>

#### Usage Considerations

##### Mechanism of Action

When using basal thermometry, women take their temperature (orally, rectally, or vaginally) with a basal thermometer each morning before arising. These temperature measurements are then plotted graphically. A rise in temperature signals that ovulation has occurred. When the increase occurs, women who want to become pregnant should have intercourse as soon as possible to maximize their chances of conception.

##### Accuracy Rate

The only equipment necessary for monitoring BBT is a basal thermometer, which has smaller gradations than a regular thermometer (i.e., 0.1 degree versus 0.2). Although basal thermometry is a relatively simple method of ovulation prediction, interpreting temperature data can be confusing. The temperature increase that follows ovulation is small (0.4°F-1.0°F [0.2°C-0.6°C]). Women who have trouble reading a thermometer may miss the rise altogether; in this case, a digital model should be used.

##### Interferences

Several factors, such as emotions, movements, and infections, can influence the basal temperature. Eating, drinking,

talking, and smoking should be postponed until after each measurement is obtained.

### Usage Guidelines

See the box Patient Education for Ovulation Prediction Tests and Devices.

Patient Education for Ovulation Prediction Tests and Devices

### Basal Thermometers

#### **Avoidance of Incorrect Results**

- Do not move while taking temperature measurements.
- Emotions can affect temperature measurements.
- If fever is present, discontinue the measurements until resolved. Resume measurements on the first day of the menstrual cycle that occurs after the fever is gone.
- Do not eat, drink, talk, or smoke within 30 minutes before taking temperature measurements.

#### **Usage Guidelines**

- Read and follow the instructions thoroughly before using the thermometer.
- Choose one method of taking temperatures (orally, vaginally, or rectally), and use that method consistently.
- Take temperature readings at approximately the same time each morning. Take temperature just before rising each morning after at least 5 hours of sleep. If using a regular basal thermometer, plot the temperatures on a graph. A rise in temperature indicates that ovulation has occurred.

### Ovulation Prediction Tests

#### **Avoidance of Incorrect Results**

- Fertility medications, PCOS, menopause, and pregnancy can cause false-positive results for ovulation.
- With the Clearblue Easy Fertility Monitor, estrogen-containing medications, impaired liver or kidney function, breast-feeding, tetracycline (but not oxytetracycline or minocycline), and perimenopause can cause false-positive results.
- Recent pregnancy or discontinuation of oral contraceptives or breast-feeding will delay ovulation for one or two cycles. Start testing after two natural menstrual cycles have occurred.

#### **Usage Guidelines (Except Clearblue Easy Fertility Monitor)**

- Start using the test 2-3 days before ovulation is expected.
- Follow the manufacturer's specific directions regarding the timing of urine collection. If the first morning urine is not tested, restrict fluid intake for at least 4 hours before testing, and avoid urinating until ready to test the urine so that the urine will not be diluted.
- Test the urine sample immediately after collection.
- If immediate testing is not feasible, refrigerate urine for the length of time specified in the product's directions. Allow refrigerated sample to stand at room temperature for 20-30 minutes before beginning the test.
- Do not shake up any sediment that may be present in the sample.
- If using a kit designed to be passed through the urine stream, either hold a test stick in the urine stream for the specified time, or collect urine in a collection cup and dip the stick in the urine.
- If using a kit not designed to be passed through the urine stream, collect urine in a collection cup, and then place the urine in the testing well using the dropper provided.
- After the urine is placed on the testing device, read the results in 3 to 5 minutes, depending on the manufacturer's instructions.
- Watch for the test's first significant increase in color intensity or, if using a digital test, the display of the "smiley face." Either result indicates that the surge of LH has occurred and that ovulation will occur within 1 or 2 days.
- Once the LH surge is detected, discontinue testing. Remaining tests can be used later, if necessary.
- If the LH surge is not detected, carefully review the testing instructions to ensure that they were performed properly.
- If the testing procedure was accurate, ovulation may not have occurred or testing may have occurred too late in the cycle. Consider testing for a longer period and earlier in the next cycle to increase the chances of detecting the LH surge.

#### **Usage Guidelines for Clearblue Easy Fertility Monitor Test**

- For the first month, begin testing on the sixth day after menstruation starts; the monitor will indicate how many total days you should test.
- For subsequent months, test the number of days indicated by the monitor.
- Remove test stick from packaging just before use.

- Hold the test stick in the urine stream; insert stick in monitor.
- Discard test stick after use.

### **Ov-Watch Fertility Predictor Device**

#### ***Avoidance of Incorrect Results***

- Fertility medications, hormonal contraceptives, menopause, impaired liver and kidney function, breast-feeding, and PCOS may interfere with results.
- Do not expose the watch to water or excessive moisture. Wait 1 hour after exercising or showering before wearing the watch.

#### ***Usage Guidelines***

- Before using the watch, read thoroughly the manufacturer's instructions for attaching the sensor and programming the device.
- Use the watch on the first, second, or third day of the menstrual period.

Key: LH = Luteinizing hormone; PCOS = polycystic ovarian syndrome.

Source: References 15-19.

#### **Product Selection Guidelines**

Digital thermometers that track multiple temperature readings for the user are available, although they are more expensive than digital thermometers that lack this feature.

### **Urinary Hormone Tests**

Ovulation prediction tests that use urine samples to estimate the time of ovulation are marketed to women who are having difficulty conceiving and need to pinpoint ovulation.

#### **Usage Considerations**

#### **Mechanism of Action**

Urine-based ovulation prediction tests use antibodies specific to luteinizing hormone to detect the surge in LH. An enzyme-linked immunosorbent assay (ELISA) elicits a color change that indicates the amount of LH in the urine.<sup>19</sup> The LH surge is revealed by a difference in color or color intensity from that noted on the previous day of testing. The intensity of color on the test stick is directly proportional to the amount of LH in the urine sample. The standard digital test has a similar mechanism of action; when LH is detected in urine, the test stick shows a blue surge line that is read by the digital device. The digital device will display a smiley face, which means that LH has been detected and a woman's chances for conceiving are increased over the next 48 hours. This device also sets an individualized threshold for measuring the user's LH readings and compares them from baseline. The digital device helps to decrease human error. Generally, early morning collection of urine is recommended because the LH surge usually begins early in the day, and the urine concentration is relatively consistent at this time. Some products do not specify a time of day but require only that a consistent time of day be used.

Testing should begin 2-4 days before the estimated day of ovulation. The kit contains directions to determine when to begin testing; the starting date is based on the average length of the past three menstrual cycles. If the cycle varies by more than 3-4 days each month, the woman should use the shortest menstrual cycle to determine the starting date. The Clearblue Advanced Digital Ovulation Test and Clearblue Fertility Monitor both increase the specificity of ovulation prediction by measuring two hormones, LH and estrone-3-glucuronide (E3G), a component of estrogen. E3G levels rise and fall in a pattern similar to that of LH. The new advanced digital product uses a test holder with disposable test sticks that are designed to detect a user's fertile window. The test holder contains special software that tracks changes in a woman's hormones from baseline in order to display peak and high fertility trends. The Clearblue Fertility Monitor is a small, palm-size device with a light-emitting diode screen that allows the woman to use urine test sticks that she then inserts into the monitor for results. The patient must establish a baseline using data about fluctuations in her hormone levels to accurately predict ovulation. For the first month, the test monitor will instruct the woman to test daily for 10-20 consecutive days, starting on approximately the sixth day after the beginning of menstruation. Using these data, the monitor calculates the time window during which the woman is most likely to conceive. After establishing her baseline, the woman tests for 10-20 days each month, depending on her cycle length. Each day's results are displayed as low, high, or peak fertility. A low result indicates a small chance of conception; a high result indicates an increased chance of conception. This reading is typically displayed for 1-5 days, leading up to the peak fertility period for each cycle. A peak fertility reading indicates the highest chance of conception and is usually observed 2 days before ovulation.<sup>7</sup>

## Interferences

Medications used to promote ovulation (e.g., menotropins) artificially elevate LH and may cause false-positive results in ovulation prediction tests that measure only LH. The true LH surge can be detected in patients receiving clomiphene as long as testing does not begin until the second day after the drug therapy ends. Medical conditions associated with high levels of LH, such as menopause and polycystic ovarian syndrome (PCOS), may cause false-positive results for ovulation. Pregnancy can also cause a false-positive result for ovulation. If the patient has recently discontinued using oral contraceptives, the start of ovulation may be delayed for one to two cycles. Therefore, it would not be appropriate to use a home ovulation prediction test until fertilization has been attempted unsuccessfully for 1-2 months after discontinuation of the oral contraceptives.

PCOS, medications that affect the cycle (e.g., oral contraceptives, certain fertility treatments, and estrogen-containing medications), impaired liver or kidney function (which alters levels of E3G), breast-feeding, tetracycline (not oxytetracycline or minocycline), and perimenopause may produce false-positive results with the Clearblue Fertility Monitor. Women who have recently been pregnant, stopped breast-feeding, or stopped using hormonal contraception should consider waiting until they have at least two consecutive natural menstrual cycles (lasting 21-42 days) before using the Clearblue Fertility Monitor.<sup>7</sup>

## Usage Guidelines

See the box Patient Education for Ovulation Prediction Tests and Devices.

## Product Selection Guidelines

The available ovulation prediction tests vary in the length of time needed to complete the test, method of applying urine to the test stick, number of individual tests provided, and method for reading results. Patients with longer cycles may benefit from purchasing kits that contain more testing sticks.

The Clearblue Fertility Monitor and Clearblue Advanced Digital Ovulation Test have some possible advantages over the traditional ovulation prediction kits, which detect only LH. The traditional kits identify the 24- to 48-hour window around ovulation. Both Clearblue products identify a larger window of several days and do not require that patients interpret color changes. In addition, they measure both LH and E3G, increasing the specificity of ovulation prediction. However, no studies have proved that these advantages increase a woman's chance of accurately identifying ovulation and, ultimately, conceiving. The initial cost of the Clearblue Fertility Monitor is higher than that of the traditional ovulation prediction kits, which detect only LH, but it is reusable for an indefinite period, with only the additional expense of more test sticks.

In an evaluation of 4 ovulation prediction kits, one study found that the Clearblue Digital Ovulation Test was the most preferred by study participants and easiest to read.<sup>14</sup>

## Wristwatch Ovulation Prediction Device

OV-Watch, which is worn on the wrist, uses a specialized biosensor to detect and measure the fluctuation of chloride ions to predict ovulation.

## Usage Considerations

### Mechanism of Action

During a woman's cycle, numerous electrolytes in perspiration fluctuate. One of the electrolytes, chloride, peaks at various times throughout the monthly cycle.<sup>18</sup> Approximately 5 days before ovulation, a chloride ion surge occurs. The OV-Watch has a biosensor that detects the chloride ion surge transdermally. The woman should begin wearing the watch at least 6 hours during sleep, starting on the first, second, or third day of the menstrual cycle. Chloride ion data are recorded every 30 minutes.

### Accuracy Rate

The OV-Watch underwent clinical testing to be cleared as an acceptable device by the FDA. Research concluded that the watch was equivalent to the other products that measured LH. However, compared with the other products, the watch detected fertility up to 4 days prior to ovulation. Finally, the data suggest that approximately two-thirds of patients who used the watch were more likely to become pregnant within 6 months.<sup>18</sup>

## Interferences

Factors such as excessive moisture, hormonal contraceptives, menopause, liver and kidney disease, breast-feeding, and PCOS can affect the accuracy of the watch.

## Usage Guidelines

See the box Patient Education for Ovulation Prediction Tests and Devices.

## Product Selection Guidelines

The OV-Watch uses advanced technology to help predict a woman's fertile window. In addition, the more fertile days that a woman can identify, the greater are her chances of becoming pregnant.

## Assessment of Female Fertility Test Use

The patient should be asked privately about her reasons for using an ovulation prediction test. If the reason is difficulty in conceiving, the patient should be asked whether she has consulted a health care specialist about a possible fertility problem and whether she has previously used ovulation prediction tests or devices. Questions about other possible pathology and medication use are appropriate to determine possible interferences with test results or temperature measurements.

## Patient Counseling for Female Fertility Tests

To use ELISA-based ovulation prediction products effectively, a woman must know approximately when ovulation occurs or be willing to track three menstrual cycles to determine when it occurs. The health care provider should explain hormonal fluctuations during the cycle and how they relate to the use of ovulation prediction tests and devices. The provider should also explain the reason for the number of tests or measurements that must be performed with each type of product. Finally, counseling should emphasize consistent use of the products for at least 3 months to achieve accurate results should. The box Patient Education for Ovulation Prediction Tests and Devices lists specific information to provide patients.

## Evaluation of Patient Outcomes with Female Fertility Tests

Ovulation prediction products should not be used for more than 3 months. If conception does not occur within this period, the woman should see a health care provider.

## Male Fertility Tests

Sperm concentration is one of the many factors used to determine male fertility. Because many additional factors play a role in male infertility, a positive test for sperm count is not a guarantee of fertility. Sperm production is influenced by physical, emotional, and psychological factors. Factors such as concentration of hormones, stress, high fever, exercise, travel, surgery, medication, and changes in diet may result in a decreased sperm concentration.

## Usage Considerations

The male fertility test measures sperm concentration as either above or below the cutoff of 20 million sperm cells per milliliter, which is the World Health Organization criterion for determining low sperm count.<sup>20</sup> Two test results of fewer than 20 million sperm cells per milliliter obtained at least 3 days apart, but not more than 7 days apart, may indicate male infertility.<sup>21</sup>

## Mechanism of Action

The test works by detecting the concentration of a sperm-specific protein (antigen SP-10) in the semen, which is then used to determine the sperm count.<sup>21</sup> The semen is mixed with a buffer to help release the specific protein from the sperm. The mixture then binds to a colloidal gold compound in the test well and flows through the test. If the sample contains more than 20 million cells per milliliter, a reddish line appears, indicating a positive result. The test kit contains all the necessary supplies for the test: a testing device, testing solution, transfer device, and sperm collection cup.

## Accuracy Rate

Testing performed by the manufacturer found the overall accuracy of the test to be 98%.<sup>22</sup>

## Interferences

There are no known interferences.

## Usage Guidelines

See the box Patient Education for Male Fertility Tests.

Patient Education for Male Fertility Tests

### Avoidance of Incorrect Results

- Collect a semen sample between 2 and 7 days after the last ejaculation.
- Test within 3 hours of sample collection.

### Usage Guidelines

- The semen sample is collected by masturbation, with semen directed into the liquefaction cup.
- Because freshly ejaculated semen is gel-like, the sample must be allowed to sit for 20 minutes, during which it will thin to a liquid consistency for testing.
- Gently stir the cup with the semen transfer device at least 10 times.
- Insert the semen-transfer device into the sample cup and withdraw semen to the black line, while trying to avoid any air bubbles.
- Gently add the semen to the upright SpermCheck solution bottle. Gently mix the solution by turning the bottle upside down at least 5-10 times. Let the solution bottle stand for 2 minutes before completing the next step.
- Add 6 drops of the solution to the sample well on the SpermCheck Device that is labeled "S."
- Read results exactly 7 minutes after adding the solution.
- To read the test, make sure there is a reddish line beside the "C" (Control) position on the device. If a control line is not present, the test did not work accurately. If a reddish line appears next to the "T" (Test) position on the device, the result is positive (sperm  $\geq 20$  million/mL). If no line is present at the test position, the sample is negative (sperm  $\leq 20$  million/mL). Do not compare the faintness or darkness of the lines between the control and test positions. The presence of a line is a positive test result.

### When to Seek Medical Attention

- If a negative test is obtained, see a health care provider for evaluation and further testing.

Source: Reference 22.

### Product Selection Guidelines

SpermCheck is the only male fertility test currently on the market. Because this test requires the user to determine visually whether a line is present, patients with visual difficulties should seek assistance in interpreting the test results.

### Assessment of Male Fertility Test Use

The patient should be asked privately whether he has consulted a health care provider about a possible fertility problem, and whether he has previously used male fertility tests. Questions about possible pathology, medication use, stress, and physical activity are appropriate to determine possible interference with test results.

### Patient Counseling for Male Fertility Tests

Because physical, psychological, and emotional factors can affect sperm concentration, the patient should be advised that a positive test does not account for sperm motility, morphology, and other factors that contribute to male fertility. The box Patient Education for Male Fertility Tests lists specific information to provide patients.

### Evaluation of Patient Outcomes with Male Fertility Tests

If a negative result is obtained, the patient should contact his health care provider or a fertility specialist. If a negative result is obtained but the patient is trying to increase his sperm count, he can test his fertility every 3 months.

### Fecal Occult Blood Tests

Colorectal cancer is the second leading cause of cancer death in the United States. In 2013, the American Cancer Society estimated that 149,880 cases of colorectal cancer would be diagnosed and approximately 51,700 people would die from the disease that year.<sup>23</sup> This disorder may be hard to detect. One early and common symptom of colorectal cancer is rectal bleeding. Checking for hidden (occult) blood in the stool is an easy way to screen for a potential colon problem. Fecal occult blood tests (FOBTs) can be used as an adjunct to more-invasive tests to detect colorectal cancer and other causes of gastrointestinal (GI) bleeding.

Colorectal cancer occurs most commonly in patients with a family history of colorectal cancer, intestinal polyps, or ulcerative colitis. The incidence of colorectal cancer has been associated with advancing age and consumption of

high amounts of red and processed meat.<sup>24</sup>

## Usage Considerations

Several nonprescription FOBTs are available. They fall into three categories: toilet tests, manual stool application devices, and collection kits that are sent to a laboratory. They are all noninvasive and easy to use in the privacy of the home.

### Accuracy Rate

The sensitivity of FOBT for colorectal cancer detection varies from 13%-50%.<sup>25</sup>

### Mechanism of Action

The in-home tests detect blood in feces with a colorimetric assay for hemoglobin. The heme portion of hemoglobin acts as an oxidizing agent; it catalyzes oxidation of the test reagent, tetramethylbenzidine, which produces a blue-green color. The appearance of this color indicates a positive test.<sup>26-28</sup>

Blood may be present on the surface or contained within the stool matrix. In general, matrix blood originates in the upper GI tract, whereas surface blood comes from the lower tract. FOBT kits are more likely to detect blood from lower GI abnormalities. The toilet tests use a reagent that is sandwiched between two layers of biodegradable paper. These tests are placed in the toilet bowl after a bowel movement. This type of kit is based on the premise that a significant amount of fecal blood from stool will remain on the surface of the toilet bowl water after a bowel movement. With the stool application device tests, a wooden stick is used to apply stool to two pads or wells. For these tests, the patient should attempt to obtain samples of both surface and inner stool.

### Interferences

Blood in the stool can signify a number of conditions in addition to cancer of the colon and rectum, including ulcers, Crohn's disease, colitis, anal fissures, diverticulitis, and hemorrhoids. Any of these conditions can give a positive result for a FOBT.

Women who are menstruating should delay testing until menses has ceased. Menstrual blood that is present in the toilet bowl water or contaminates the stool sample can produce a positive result.

Aspirin, nonsteroidal anti-inflammatory drugs (NSAIDs), and steroids may cause sufficient gastric bleeding to produce positive results. These medications should be avoided for at least 2-3 days before testing and during the test period. One study, however, found that usual doses of aspirin and NSAIDs did not increase the risk of a false-positive FOBT.<sup>29</sup> The study's authors concluded that little concern exists for a false-positive FOBT in patients who cannot safely discontinue aspirin or NSAIDs before specimen collection. Rectally administered medications should also be avoided. However, patients should always consult a health care provider before discontinuing any prescribed medications.

Vitamin C ingestion in excess of 250 mg/day may interfere with the peroxidase action of hemoglobin, causing false-negative results in the ColonTest-Sensitive product.<sup>27</sup> The FOBTs are not specific for human blood and may produce false-positive results if red meat is consumed. A meta-analysis of dietary restriction studies found no difference in response rates between restricting and not restricting meat consumption before testing.<sup>30</sup> Toilet bowl cleaners may also produce false-positive results. The box Patient Education for Fecal Occult Blood Tests lists measures for avoiding inaccurate test results.

### Patient Education for Fecal Occult Blood Tests

#### Avoidance of Incorrect Results

- Do not perform test during times of known bleeding, such as hemorrhoidal or menstrual bleeding.
- Increase dietary fiber intake for several days before testing. Roughage increases the accuracy of the test by stimulating bleeding from lesions that might not otherwise bleed.
- Because bleeding from cancerous lesions may be intermittent, perform the test on three consecutive bowel movements to increase the chance of detecting a possible lesion.
- Complete all three stool tests, even if the first two produce negative results.
- Do not take nonprescription medications such as aspirin and NSAIDs for 2-3 days before testing and during testing.
- Some prescription medications can cause bleeding and may need to be stopped before testing. Consult a health care provider about which medications to stop before performing the test.
- Chemicals in the toilet can interfere with the test. Following the instructions carefully can prevent this problem.

## Usage Guidelines

- Do not eat red meat 2-3 days before testing and during the test period because undigested meat may produce a false-positive result.
- Do not take more than 250 mg/day of vitamin C for 2-3 days before and during the test period.

### **Toilet Test Products (EZ-Detect and Early Detect Colorectal)**

- Remove toilet tank cleansers or deodorizers, and flush toilet twice before testing.
- Before testing, use one test pad to perform a water quality check. If any trace of blue appears in the cross-shaped area when the pad is placed in the toilet water, use another toilet to complete the testing. Perform this water quality check on the second toilet as well.
- Immediately after a bowel movement, place a pad in the toilet bowl, printed side up. After 2 minutes, check for the appearance of a blue cross on the test pad (positive result).
- If color changes differ from the blue cross, discard the pad and repeat the test after the next bowel movement.
- Repeat the test on the next two bowel movements.
- If results are negative for all three tests, use remaining pad to perform a quality check of the test pads using the positive control chemical package that is provided. Flush the toilet and empty the contents of the package into the bowl as it refills. Float the remaining test pad in the water, printed side up. After 2 minutes, check for a blue cross, which indicates the test pads are working properly. If the blue cross does not appear, call the product manufacturer's assistance line provided with the product.

### **Stool Application Product (ColonTest-Sensitive)**

- Open the test device lid. Apply a stool sample to wells A and B. Try to get both surface and inner stool with each sample.
- Close the device lid and press on the space labeled "press last" to break the test ampule.
- Turn the test device over and hold in a vertical position for 15 seconds.
- The test is positive if wells are partially or completely blue. The test is negative if wells are beige or brown.
- Repeat the test on the next two bowel movements.

### **When to Seek Medical Attention**

- Notify a health care provider if any of the three tests is positive.

Source: References 26-28.

### **Usage Guidelines**

See the box Patient Education for Fecal Occult Blood Tests.

### **Product Selection Guidelines**

Patients who want to avoid restricting their diet or stopping vitamin C may prefer the toilet test products, which do not require a diet or medication change. All tests are similar in cost. All products, except ColonTest-Sensitive, have a card on which the patient records results; the patient then gives the card to the health care provider for evaluation.

### **Assessment of Fecal Occult Blood Test Use**

Because of better sensitivity, the American College of Gastroenterology recommends that colonoscopy rather than FOBT be used to screen for colon cancer.<sup>31</sup> For most patients, colonoscopy screening should start at age 50 and be conducted every 5 years; in African Americans, screening should begin at age 45.<sup>31</sup> The American Cancer Society recommends FOBT yearly, colonoscopy every 10 years, or other screening tests such as a virtual colonoscopy every 5 years as options for people ages 50 and over who are at average risk of colon cancer.<sup>32</sup> For those at increased risk, FOBT is not recommended. Patients seeking FOBT information should be assessed for risk factors for colon cancer. Those with risk factors should be encouraged to have a screening test other than FOBT. Determining the potential for false test results is an important consideration. False-negative tests could delay necessary treatment, whereas false-positive tests could cause unwarranted anxiety and expensive follow-up testing.

### **Patient Counseling for Fecal Occult Blood Tests**

When counseling a patient on the use of FOBTs, the health care provider should emphasize the importance of following package instructions carefully. The box Patient Education for Fecal Occult Blood Tests lists specific information to provide patients.

### **Evaluation of Patient Outcomes with Fecal Occult Blood Tests**

A patient evaluating the results of an FOBT must remember that the test is a screening method and is not specific to a particular disease. A positive test result may indicate any medical condition that causes a loss of blood through the GI system. The primary value of FOBT is to alert patients and health care providers that a thorough workup may be needed. The kits are not intended to replace other diagnostic procedures. Patients should be advised to contact their health care provider if a positive test result is obtained.

### Cholesterol Tests

Elevated levels of low-density lipoprotein cholesterol (LDL-C) and triglycerides and low levels of high-density lipoprotein cholesterol (HDL-C) are major contributors to the development of atherosclerotic heart disease, which can result in heart attack and stroke.<sup>33</sup> Fourteen percent of American adults have high cholesterol.<sup>34</sup> The National Cholesterol Education Program recommends that all adults have a lipid profile measured at least every 5 years, starting at age 20.<sup>33</sup> A home cholesterol test is one means of achieving this critical step to minimize the risk for cardiovascular disease. However, this test should not replace a complete lipid panel conducted by a health care provider.

Because elevated cholesterol is a chronic condition that requires lifestyle modification and, frequently, medication for treatment, adhering to a treatment plan can be difficult for patients. Home cholesterol tests can help monitor the efficacy of and adherence to diet, exercise, and medication plans.

### Usage Considerations

Some nonprescription cholesterol tests (Table 48-4) measure only total cholesterol, whereas others also measure LDL-C, HDL-C, and triglycerides.<sup>35-40</sup> Individuals with diabetes might want to consider a device such as the CardioChek, which measures glucose levels in addition to cholesterol and triglyceride levels. The CholesTrack and First Check kits allow patients to measure their total blood cholesterol levels at home. Check Up America offers a self-collected, laboratory-performed test for a complete lipid profile.

**TABLE 48-4 Selected Nonprescription Cholesterol Tests**

<i>Trade Name</i>	<i>Product Features</i>
CholesTrak AccuMeter Home Cholesterol Test/First Check Home Cholesterol Test	Measures total cholesterol; not reusable; includes test cassette, lancet, and chart for interpreting test results from a drop of blood; chart is specific for test cassette and should not be reused
CardioChek	Measures total cholesterol, HDL-C, and triglycerides; can also measure glucose and ketones; stores results; reusable; separate test strip and corresponding color-coded memory chip required for each type of test
Accutrend Plus and Cholesterol Biometer	Measures total cholesterol; can also measure glucose; stores results; reusable; separate test strip required for each type of test; low and high control solutions (Accutrend Plus only)
Check Up America Cholesterol Panel	Lipid profile (total cholesterol, triglycerides, HDL-C, LDL-C) results are obtained after mailing sample to laboratory; not reusable; contains lancet and sample collection cassette

Key: HDL-C = High-density lipoprotein cholesterol; LDL-C = low-density lipoprotein cholesterol.

Source: References 35-40.

### Mechanism of Action

With the total cholesterol test cassettes, cholesterol present in a blood sample is converted into hydrogen peroxide through a chemical reaction involving cholesterol esterase and cholesterol oxidase.<sup>35,36</sup> The peroxide then reacts with horseradish peroxidase and a dye to produce the color that rises along the cholesterol test's measurement scale. The test cassette has two separate indicator spots that change color to show that the test is functioning properly. One of the indicator spots also indicates completion of the test, signaling that it is time to read the scale. CardioChek, Accutrend Plus, and Q. Steps Cholesterol Biometer all use a reflectance photometer that reads the color intensity of the chemical test reaction.<sup>37-39</sup> Similar to a glucose meter, the results of the test are displayed on a screen. Check Up America's lipid profile is performed by a Clinical Laboratory Improvement Act (CLIA)-certified laboratory.<sup>40</sup>

## Accuracy Rate

The accuracy rate of home cholesterol tests is debated. Except for Check Up America, which is mailed to a laboratory, all products are FDA approved for home use, are CLIA-waived devices, and are rated substantially equivalent to a laboratory-based cholesterol test. A published study of the CholesTrak device found that untrained patients obtained results that correlated well with a laboratory-based cholesterol reference method.<sup>41</sup> Several years ago, *Consumer Reports* tested the CholesTrak, First Check, and CardioChek kits. The first two, which are essentially the same device, gave results that varied no more than 15% from laboratory values. The CardioChek yielded results that were “often wide of the mark.”<sup>42</sup> The report provided no more specifics. The professional version of the CardioChek (CardioChek PA) has been tested against another point-of-care device (Cholestech LDX) and laboratory measurements and did not meet the National Cholesterol Education Program (NCEP) accuracy goal.<sup>43</sup>

## Interferences

Good fingerstick technique is necessary to avoid erroneous results with cholesterol tests. Two or three hanging drops of blood are needed, but excessive squeezing and milking of the finger will negatively affect the quality of the blood sample. If sufficient blood cannot be obtained from the first fingerstick, the patient should use a different finger. A low cholesterol value may result if the blood sample is too small or if it takes longer than 5 minutes to collect the necessary amount of blood.

The patient should avoid doses of 500 mg or more of vitamin C before the test to avoid obtaining an artificially low result. Vitamin C slows the development of the color reaction by slowing the rate of peroxide production by oxidases.

## Usage Guidelines

See the box Patient Education for Cholesterol Tests.

Patient Education for Cholesterol Tests

### Avoidance of Incorrect Results

- If two or three hanging drops of blood cannot be obtained, or if it takes longer than 5 minutes to collect this amount of blood, do not perform the test.
- Do not excessively squeeze or milk the finger.
- If taking vitamin C in doses of 500 mg or more, do not take the dose within 4 hours of testing.
- The lancet is a biohazard; dispose of it in a puncture-resistant container.

## Usage Guidelines

- Before starting the test, wash your hands thoroughly with soap and warm water, and then dry them.
- To stabilize the cholesterol level, sit and relax for 5 minutes before performing the test.
- CardioChek Test: Insert the memory chip corresponding to the desired test into the meter and turn on the meter.
- Lance the outside of one fingertip, and wipe away the first sign of blood with the gauze pad. Then apply blood to the testing device as quickly as possible. Test cassettes (CholesTrak/First Check): Fill the well of the test cassette. Cholesterol meters: Apply enough blood to cover the testing area of a strip. Check Up America Test: Place enough blood to fill the well on the test device and to turn the indicator window red.
- Test cassettes: Wait at least 2 minutes, but no more than 4 minutes, before pulling the clear plastic tab on the right side of the cassette. Pull the tab until it clicks into place and a red line appears. Use a timepiece with a second hand for accurate timing. Wait another 10-12 minutes. When the “END” indicator turns green, measure the height of the purple column against the scale printed on the cassette. Use the result chart included in the kit to interpret the reading.
- Cholesterol Meter: A test strip may need to be inserted before applying blood for the meter to read the bar code. The test strip can be removed to apply the blood sample. The meter displays the test results in approximately 1-3 minutes.
- Check Up America Test: Allow blood to dry on the test cassette. Seal the device in the provided mailing pouch along with the completed paperwork. Mail to the laboratory. Results will be available online in approximately 1 week.
- Dispose of the lancet in a puncture-resistant container.

## When to Seek Medical Attention

- If the total cholesterol reading is 200 mg/dL or greater, HDL-C is 40 mg/dL or less, or triglycerides are 150 mg/dL or greater, see a health care provider for evaluation and further testing.

Key: HDL-C = High-density lipoprotein cholesterol.

Source: References 35-40.

### Product Selection Guidelines

Although significantly more expensive than individual total cholesterol test cassette kits, the cholesterol meters are reusable with the purchase of additional testing materials and will store test results. Some of the meters have the ability to test for HDL-C and triglycerides, whereas the other home tests measure only total cholesterol. Check Up America provides a lipid profile done in a certified laboratory, but results are not immediately available.

### Assessment of Cholesterol Test Use: A Case-Based Approach

Whether the patient has been diagnosed with or has some reason to be concerned about hypercholesterolemia should be determined before a cholesterol test is recommended. Any factors that could affect the test results should also be determined.

Case 48-2 is an example of assessment of a patient who wishes to use a cholesterol test.

#### Case 48-2

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient recently started a new medication and is interested in knowing whether her cholesterol level has gone down.
b. medical history, including family history	She has heart disease, high cholesterol, diabetes, and hypertension. Her health care provider checks her cholesterol level annually.
c. patient's identity	Sue Esposito
d. age, sex, height, and weight	68 years old, female, 5 ft 4 in., 180 lb
e. patient's dietary habits	Patient says that she tries to stick with low-fat, low-cholesterol diet.
f. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Simvastatin 20 mg, ezetimibe 10 mg, metformin 850 mg, losartan 50 mg, clopidogrel 75 mg daily (adherence verified by refill records)
g. prior use of diagnostic/monitoring test	Sue checks her blood pressure at home but does not check her glucose.
h. potential problems with performing/interpreting test	She does have some visual impairment and lives alone.
<b>Assessment and Triage</b>	
2. Determine if self-testing is appropriate.	Self-testing is not appropriate.
3. Identify exclusions for self-treatment.	Visual impairment, no help at home to read test, and

	use of clopidogrel
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer patient for cholesterol testing. (2) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The patient understands why self-testing is not appropriate. She has an appointment with her health care provider in 4 months but will see whether it can be rescheduled to an earlier date.
<b>Evaluation of Patient Outcome</b>	
6. Assess patient outcome.	Contact the patient in a day or two to ensure that she made an appointment and sought medical care for repeat testing.

### Patient Counseling for Cholesterol Tests

Counseling about cholesterol tests should emphasize the importance of properly collecting blood samples. Patients should also be advised to seek assistance with the fingerstick, if needed. As further assurance of accurate test results, patients should be advised of factors that can cause inaccurate test results. The box Patient Education for Cholesterol Tests lists specific information to provide patients.

### Evaluation of Patient Outcomes with Cholesterol Tests

Any patient who obtains a total cholesterol result of 200 mg/dL or greater, an HDL-C of 40 mg/dL or less, or triglycerides of 150 mg/dL or greater should see a health care provider for a full lipid profile and appropriate medical workup. Patients should not adjust their cholesterol-lowering medications based on a home test without consulting their health care provider.

### Urinary Tract Infection Tests

Urinary tract infections (UTIs) are the cause of 4 million visits to health care providers every year.<sup>44</sup> Women have a shorter urethra compared with men and are therefore more likely to contract UTIs because of retrograde migration of bacteria from the skin. Conditions that increase risk of UTIs include pregnancy, diabetes, urinary stones, urinary obstructions such as those caused by an enlarged prostate, presence of urinary catheters, and a history of UTIs.<sup>45</sup>

The gram-negative bacterium *Escherichia coli* is responsible for 80% of UTIs.<sup>44</sup> Other gram-positive and gram-negative bacteria account for the other 20% of causative organisms. Symptoms of a UTI include pain on urination, the sensation of an urgent need to urinate, frequent urination, blood in the urine, and lower abdominal pain or discomfort. Two primary uses for UTI tests are (1) early detection of an infection in patients with a history of recurrent UTIs or risk factors associated with UTIs and (2) confirmation that an infection has been cured by antibiotic therapy.

### Usage Considerations

Two types of UTI tests are available. The mechanism of action is the primary difference between the two.

#### Mechanism of Action

One type of UTI test (UTI Home Test) detects nitrites in the urine on the basis of the principle that gram-negative bacteria reduce nitrate in the urine to nitrite.<sup>46</sup> In the test strip, arsanilic acid reacts with urinary nitrite to form a diazonium compound, which in turn reacts with another chemical on the strip to produce a pink color. A positive test requires a bacterial concentration of  $10^5$  per milliliter of urine. This test also detects protein in the urine, another clinical sign of a UTI.

The other type of test (AZO Test Strips, store brands) detects both nitrite and leukocyte esterase (LE), an enzyme unique to leukocytes (white blood cells).<sup>47</sup> White blood cells may be found in the urine when a UTI is present.

## Accuracy Rate

In general, nitrite-only tests have low sensitivity (45%-60%) and high specificity (85%-98%).<sup>48</sup> Higher levels of accuracy are achieved in elderly, pregnant, and urology patients. Combining nitrite and LE or urinary protein in one test not only increases overall sensitivity and specificity but also decreases the risk of false-negative results.

## Interferences

A strict vegetarian diet that provides insufficient urinary nitrates can cause false-negative nitrite results with a UTI test. Tetracycline may also produce a false-negative reading for nitrites, along with doses of vitamin C in excess of 250 mg because ascorbic acid blocks the nitrite test reaction. The patient should allow 10 hours between the last dose of vitamin C and the test procedure. Doses of vitamin C in excess of 500 mg within 24 hours of testing may result in a false-negative result for the LE test by blocking the development of the color reaction.<sup>47</sup> Dyes or medications such as phenazopyridine, commonly used by patients with UTIs, may cause a false-positive result by changing the sensor pad to pink.

## Usage Guidelines

See the box Patient Education for Urinary Tract Infection Tests.

Patient Education for Urinary Tract Infection Tests

### Avoidance of Incorrect Results

- Persons on a strict vegetarian diet or tetracycline may not obtain accurate results.
- Certain dyes or medications, such as phenazopyridine, may cause a false-positive result by changing the sensor pad to pink.
- If using the UTI Home Test, do not take 250 mg or more of vitamin C within 10 hours of testing.
- If using AZO Test Strips, do not take 500 mg or more of vitamin C within 24 hours of testing.
- Women should not use AZO Test Strips during menses because menstrual blood will cause a false-positive result.

## Usage Guidelines

- Clean the genital area thoroughly before collecting a urine sample.
- Test the first urine of the morning or, for later testing, use urine held in the bladder for at least 4 hours.
- To improve sensitivity, test on 3 consecutive days if the test on the previous day was negative.
- Depending on the test purchased, pass the test strip or stick through the urine stream.
- Do not touch the sensor pad with your fingers because skin oils can interfere with the test reaction. If urine is collected in a cup, immerse the sensor pad in the cup for 1 second.
- Make sure urine completely covers the pad.
- Wait the indicated time (30-60 seconds), then compare the color on the sensor pad with the color chart provided.
- Wait no longer than 3 minutes to read the test strip, and ignore any color changes that occur after that time.

## When to Seek Medical Attention

- Contact a health care provider immediately for evaluation and treatment of any positive test.
- If the test is negative but symptoms persist, see a health care provider immediately for evaluation and treatment.

*Source:* References 46 and 47.

## Product Selection Guidelines

The UTI Home Test is a test stick similar to those used in pregnancy tests. Although the AZO test strips have a small handle attached, the longer test sticks may be easier to hold in the urine stream.

## Assessment of Urinary Tract Infection Tests

The patient's reason for using a UTI test should be determined before a test is recommended. If the patient is testing for a suspected UTI, the patient's symptoms and risk factors for UTIs should be evaluated. If symptoms of a UTI are present, the patient should be referred to his or her health care provider immediately for evaluation and treatment. If the patient is testing to find out whether a treated UTI has been cured, the patient's adherence to the therapy should be assessed. The patient's diet and medication use are important factors to evaluate for possible interference with test results.

## Patient Counseling for Urinary Tract Infection Tests

If the sensor pad is to be immersed in a cup of urine, counseling on the use of UTI tests should emphasize the importance of collecting a clean sample of midstream urine. A patient with visual difficulties should be advised to seek assistance in interpreting test results. As further assurance of accurate test results, patients should be advised of medical and dietary factors that can cause inaccurate test results. The box Patient Education for Urinary Tract Infection Tests lists specific information to provide patients.

## Evaluation of Patient Outcomes with Urinary Tract Infection Tests

Because UTI tests will detect only about 90% of infections, the patient should contact a health care provider if a negative result is obtained but UTI symptoms persist. If a positive result is obtained, the patient should contact a health care provider immediately for evaluation and treatment.

## Human Immunodeficiency Virus Tests

More than 50,000 new cases of human immunodeficiency virus (HIV) infection occur each year in the United States, and an estimated 18% of individuals with HIV are undiagnosed.<sup>49</sup> Home HIV tests allow a person to test for HIV in privacy.

Acquired immunodeficiency syndrome (AIDS) is an incurable disease caused by the HIV virus. The disease destroys the body's immune system. HIV infection can be contracted by contact with infected body fluids such as blood or semen. People at risk for contracting the virus include those who (1) share needles or syringes for the purpose of injecting drugs, including steroids; (2) have sexual intercourse with a person infected with HIV, with someone who injects drugs, or with multiple partners; (3) had a blood transfusion anytime between 1978 and May 1985; and (4) were born to a mother infected with HIV.

## Usage Considerations

Home test kits that require saliva or blood samples for HIV detection are currently available. Home Access HIV Test and Home Access Express HIV Test Systems require a blood sample. A saliva-based kit (OraQuick) was approved for home use in 2012.

### Mechanism of Action

The HIV tests detect antibodies to the virus. Because 3 weeks to 6 months may be required for an exposed individual to develop sufficient antibodies for detection, the time of possible exposure to the virus must be considered in determining when to perform the test.

The saliva test uses technology similar to that used in home pregnancy tests to detect antibodies to both HIV-1 and HIV-2.<sup>50</sup> After collection, the home HIV test blood samples are mailed to a certified laboratory for processing. Positive samples are rescreened twice. Repeated positive samples are confirmed with an immunofluorescent assay.<sup>51</sup>

### Interferences

Providing an inadequate blood sample (i.e., incompletely filling the circle on the blood sample card) or inadequately swabbing the gums to provide an adequate saliva sample may cause inaccurate results.

### Usage Guidelines

See the box Patient Education for HIV Tests.

Patient Education for HIV Tests

### Precautions—Blood Tests

- Do not share the test lancet with other individuals. Do not allow the blood being tested to contact other individuals.
- The lancet is a biohazard; dispose of it in a puncture-resistant container.

### Avoidance of Incorrect Results—Saliva Test

- Do not open any of the packets until you are ready to begin the test.
- Do not eat, drink, or use oral care products (such as mouthwash, toothpaste, or whitening strips) for 30 minutes before starting the test.
- Remove dental products such as dentures or retainers that cover gums.
- To prevent a false-positive result, swab each gum only once.

### Usage Guidelines—Blood Tests

- Call the product manufacturer's toll-free number to register and receive pretest counseling. The manufacturer's customer representative will ask for the confidential code included in the kit.
- Using alcohol, clean the fingertip chosen for puncture. Allow alcohol to dry.
- Prick the cleaned fingertip using the lancet provided, and place a few drops of blood on the blood specimen card. Fill the circle on the card completely to ensure a readable test. Examine the back of the card to ensure that the blood soaked through. If it did not, place more blood on the front of the card. If a second fingerstick is needed, use the second lancet provided in the kit.
- Allow the card to air dry for 30 minutes; place the sample in the specimen return pouch, and seal the pouch in the prepaid and addressed shipping package. Be sure that the processing laboratory receives the specimen within 10 days of sampling.
- To obtain the results, call the manufacturer's toll-free number 3-7 business days after mailing the specimen, depending on which test kit was used.
- Note that counseling is available 24 hours a day, for both negative and positive results, and counseling is included in the cost of the testing unit.

### Usage Guidelines—Saliva Tests

- A timer or watch is needed.
- Remove the test tube from packaging, pop it open, and insert it into the holder. Hold the test tube upright to avoid spilling the liquid that is inside.
- Remove the test stick from packaging. Do not touch the test pad.
- Swipe the test pad along upper and lower gums. Swipe each gum only once.
- Insert the test stick into the test tube with the test window facing forward. Start timing.
- Read the test result in the test window at 20 minutes. After 40 minutes, the results may be invalid.
- The test kit provides guidelines for reading results and what the results mean. One line at C is negative. A line at C and T is positive.
- Note that counseling on performing the test is available 24 hours a day from the company.

### When to Seek Medical Attention

- If the test is positive, see a health care provider immediately for evaluation and treatment. Avoid activities that can result in transfer of blood or other body fluids to other individuals.

*Source:* References 50 and 51.

### Product Selection Guidelines

Many people will prefer to use the saliva test because it gives faster results and does not require a fingerstick. Its price is similar to that of the first Home Access test. For the blood tests, the two available HIV tests differ in price and turnaround time to obtain results. The first test, Home Access, takes approximately 7 business days to obtain the results. The second, Home Access Express, takes approximately 3 business days. The Home Access sample is sent to the testing laboratory by regular mail, whereas the Home Access Express sample is shipped through Federal Express. Consequently, the Home Access Express version costs more.

### Assessment of HIV Test Use

The elapsed time since possible exposure to the HIV virus should be determined before an HIV test is recommended. The patient may not know all the risk factors for HIV infection; therefore, whether the patient has engaged in any activities that increase risk for contracting HIV should be tactfully determined. The patient should be asked about medical disorders that might rule out the use of a fingerstick-based test, such as an anticoagulation or bleeding disorder, or physical limitations that might interfere with performing the test.

### Patient Counseling for HIV Tests

Counseling on the use of HIV blood tests should emphasize the importance of applying enough blood on the specimen card to ensure an accurate reading. Patients should also be advised of the fragility of blood samples and not to delay mailing the specimen card. Counseling for the saliva test should emphasize the importance of adequately swabbing the gums with the test stick. The box Patient Education for HIV Tests lists specific information to provide patients.

### Evaluation of Patient Outcomes with HIV Tests

A patient with a positive result should see a health care provider to be retested for confirmation of HIV infection. Infected patients should be counseled on precautions to avoid infecting others. Patients with negative results should confirm that sufficient time has passed since the potential exposure.

### Hepatitis C Tests

Hepatitis C (HCV) is one of six identified hepatitis viruses. With an estimated 3.2 million chronically infected individuals, HCV infection is the most common blood-borne infection in the United States.<sup>52</sup>

The following are risk factors for hepatitis C<sup>53</sup>:

- Use of injectable drugs
- Receipt of clotting factor concentrate produced before 1987
- Long-term hemodialysis
- Transfusion or organ transplant before 1992
- Sexual intercourse with multiple partners
- Birth by a mother infected with hepatitis C
- Occupational exposure to blood

Hepatitis C induces liver damage by causing hepatic cell necrosis and inflammation, which over time may progress to fibrosis, cirrhosis, and hepatocellular carcinoma. Of people infected with hepatitis C, 75%-85% are likely to progress to the chronic disease state.<sup>52</sup> Clinically, hepatitis C may go undetected for many years; liver disease may be advanced by the time symptoms arise.

### Usage Considerations

Home Access Hepatitis C Check is a single-use test kit containing two lancets, a blood sample card, a gauze pad, an adhesive bandage, and a postage-paid envelope. After collection, the blood sample is mailed to a certified laboratory for processing. Each kit also includes a unique personal identification number, which the purchaser uses to register the kit and access test results.

#### Mechanism of Action

The kit tests for presence of antibodies to the hepatitis C virus, not the virus itself. The Hepatitis C Check uses an ELISA to test for antibodies and then confirms the results with a recombinant immunoblot assay.<sup>53</sup> Because 6 months may be required to develop sufficient antibodies for detection, the time since possible exposure to the virus must be considered in determining when to perform the test.

#### Interferences

Providing an inadequate blood sample (i.e., incompletely filling the circle on the blood sample card) may cause inaccurate results.

#### Usage Guidelines

See the box Patient Education for Hepatitis C Tests.

Patient Education for Hepatitis C Tests

### Precautions

- Do not share the test lancet with other individuals.
- Do not allow the blood being tested to contact other individuals.
- The lancet is considered a biohazard; dispose of it in a puncture-resistant container.

### Usage Guidelines

- Register the PIN (personal identification number) with the manufacturer by calling the provided toll-free telephone number and following the automated directions.
- Remain seated during the testing process to prevent falling if dizziness occurs.
- Before starting the test, wash your hands thoroughly with soap and warm water, and then dry them.
- Date the blood sample card.
- Lance the side of one of your middle fingers.
- Apply a sufficient number of blood drops until both the front and back of the circular area on the testing card are saturated.
- Allow the sample to dry at least 30 minutes before sealing it in the pouch and mailing.
- Within 4-10 business days after mailing the sample, call the toll-free number provided, using the PIN to

access the test results. Test results are available for up to 1 year.

- Note that counseling is included in the cost of the testing unit and is available 24 hours a day, for both negative and positive results.

### When to Seek Medical Attention

- If the test is positive, see a health care provider immediately for evaluation and treatment. Avoid activities that can result in transfer of blood or other body fluids to other individuals.

Source: Reference 53.

### Product Selection Guidelines

Hepatitis C Check is the only test kit currently available for hepatitis C detection.

### Assessment of Hepatitis C Test Use

A patient who recently has been infected may receive a false-negative result because antibodies to the virus have not had sufficient time to form. Clinical studies on file with the manufacturer report no false-positive results.<sup>53</sup> The patient may not know all the risk factors for hepatitis C; therefore, whether the patient has engaged in any activities that can cause the disease should be tactfully determined. The patient should be asked about medical disorders that might rule out use of a fingerstick-based test or physical limitations that could interfere with performing the test.

### Patient Counseling for Hepatitis C Tests

Patients should be advised of the fragility of blood samples and not to delay mailing the specimen card. The box Patient Education for Hepatitis C Tests lists specific information to provide patients.

### Evaluation of Patient Outcomes with Hepatitis C Tests

Patients who test positive should be referred to a health care provider, given that treatment options are available only by prescription. Infected patients should be counseled on precautions to avoid infection of others. These patients should also be advised to avoid alcohol and other drugs that may advance the progression of liver disease. They should also be tested for and vaccinated against other forms of hepatitis, such as the hepatitis A and B viruses.

### Drug Abuse Tests

An estimated 8.7% of Americans abuse drugs, whether legal or illegal.<sup>34</sup> The symptoms of drug use are varied but may include withdrawal from normal activities, fatigue, red eyes, drowsiness, slurred speech, and chronic cough. The National Institute of Drug Abuse ([www.nida.nih.gov](http://www.nida.nih.gov)) is a good resource for specific symptoms for the various drugs of abuse. Drug abuse tests may allow parents and caregivers to detect drug use early enough to affect the course of addiction.

### Usage Considerations

Numerous products for detecting use of drugs are available in retail stores and pharmacies, by telephone, and through the Internet. A number of the tests currently available are not FDA approved for home use. FDA is currently following a policy that the agency proposed and that allows the marketing of non-FDA-approved home test kits if the specimen is mailed to a certified laboratory. Table 48-5 lists some example tests and the substances that each test identifies.

**TABLE 48-5 Selected Nonprescription Home Drug Abuse Tests**

<i>Product (Web site)</i>	<i>Time to Result</i>	<i>Body Site</i>	<i>Testing Location</i>	<i>Substances Detected</i>
At Home Drug Test ( <a href="http://www.phamatech.com">www.phamatech.com</a> )	10 minutes for initial screen; 5-7 days for laboratory confirmation	Urine	Home; send away for confirmation	Depends on kit purchased; one kit tests for amphetamines, marijuana, cocaine, and opiates; other kits test for a single substance
Dr. Brown's Home Drug Testing System ( <a href="http://www.drbrowns.com">www.drbrowns.com</a> )	5-7 days	Urine	Send away	Marijuana, cocaine, amphetamines, phencyclidine, codeine, morphine, heroin

PDT-90 Personal Drug Testing Service ( <a href="http://www.psychemedics.com">www.psychemedics.com</a> )	5-7 days	Hair	Send away	Marijuana, cocaine, opiates, amphetamines, phencyclidine
HairConfirm Regular, Express, and Prescription ( <a href="http://www.hairconfirm.com">www.hairconfirm.com</a> )	5-7 days	Hair	Send away	Marijuana, cocaine, opiates, amphetamines, phencyclidine; in addition to these drugs, Hairconfirm Prescription tests for oxycodone, hydrocodone, hydromorphone; express includes overnight shipping

Source: References 55-58.

Home drug tests are marketed primarily to parents as an aid for determining drug use in their children. These tests are a means of obtaining results anonymously when drug use is suspected. Home drug testing, however, is not a substitute for open communication between parents and children regarding drug use.

Users of these tests may have questions about how soon drugs can be detected after consumption and how long they can be detected after being used. Clearance rates for common drugs of abuse are given in [Table 48-6](#).<sup>54</sup> These are only guidelines, however, and the times can vary significantly from these estimates based on how long the person has been taking the drug, the amount they use, or the person's metabolism.

**TABLE 48-6 Example Estimated Times for Positive Drug Test**

<i>Drug</i>	<i>How soon after taking drug will there be a positive drug test?</i>	<i>How long after taking drug will there continue to be a positive drug test?</i>
Amphetamine, methamphetamine	4-6 hours	2-3 days
Barbiturates	2-4 hours	1-3 weeks
Benzodiazepine	2-7 hours	1-4 days
Cocaine	2-6 hours	2-3 days
Ecstasy	2-7 hours	2-4 days
Marijuana	1-3 hours	1-7 days
Methadone	3-8 hours	1-3 days
Opiates	2-6 hours	1-3 days
Oxycodone	1-3 hours	1-2 days
PCP	4-6 hours	7-14 days
Tricyclic antidepressants	8-12 hours	2-7 days

Source: Reference 54.

Samples of urine or hair are collected at home. The hair tests and some of the urine tests are mailed to a clinical laboratory, with results obtained by telephone or over the Internet. For some of the urine tests, the user conducts a preliminary screening test in the home and then mails positive samples to a laboratory for confirmation. Other urine tests are performed only at home. Saliva tests are available, but they are currently marketed only to drug testing programs and employers.

Some of the test kits include telephone counseling to (1) help parents recognize the signs of drug use, (2) assist in creating a family drug policy, and (3) emphasize that parents should use the test to develop trust and open communication within their families, rather than to intimidate with the threat of random testing. Some telephone counseling programs provide referrals to rehabilitation and counseling services in the family's community.

#### Mechanism of Action

For the home urine tests, an immunochromatographic assay similar to the home pregnancy and ovulation tests is used for initial screening of a sample. Available testing devices include (1) a test cassette to which urine is applied and (2) a test device that is placed in the urine sample. In each test, a positive result for a particular drug is the

absence of a line next to the drug name in the testing area. For a negative test, a line appears by the drug name and in the control area.

The laboratories use an enzyme-multiplied immunoassay technique to detect drugs in the urine samples. Gas chromatography-mass spectrometry is then used to identify the specific drug. Positive home urine samples sent to clinical laboratories for confirmation are checked for evidence of adulteration.<sup>55-57</sup> Substances such as water or household chemicals can be added to urine samples in an attempt to mask drug use.

Home urine tests detect drug use that occurred from several hours before testing to within 2-3 days of testing. The amount of drug found in the urine is affected by the time since consumption, the amount taken, and the amount of water consumed before sampling. Test results are reported as only positive or negative for a drug. Quantity or route of ingestion is not determined.

Hair testing detects trace amounts of ingested drugs that become trapped in the core of the hair shaft as it grows at an average rate of ½ inch per month. Drug use over a 90-day period can be determined from a hair sample of 1½ inches.<sup>58</sup> The presence of drugs is determined by radioimmunoassay techniques, and then gas chromatography-mass spectrometry analysis identifies the specific substance. Hair tests report positive or negative results for a drug. Positive results are reported as a number indicating low, medium, or high levels of use for all drugs except marijuana, which is reported only as positive or negative.

### Usage Guidelines

See the box Patient Education for Drug Abuse Tests.

#### Patient Education for Drug Abuse Tests

##### **Avoidance of Incorrect Results**

- Drug tests on urine samples report only a positive or negative outcome. Neither the quantity of drug taken nor the method in which it was taken is determined.
- Drug tests on hair samples can report a low, medium, or high level of drug use, but the use could have occurred as long as 90 days before testing.
- Cough medications that contain codeine or dextromethorphan, decongestants, antidiarrheals, narcotic analgesics, and possibly poppy seeds may cause false-positive test results.

##### **Usage Guidelines for Urine Drug Abuse Tests**

- Collect urine using the collection device included with the test. Do not take urine from the toilet.
- Check the temperature of the urine sample immediately after collection using the temperature strip, if included. If the sample is not between 90°F (32°C) and 100°F (38°C), adulteration may have occurred.
- Immerse the test card in the urine sample for 10 seconds or until visible migration across the test panels has occurred. Place the device on a flat surface or leave it immersed in the sample. Do not allow urine to exceed the “max line.”
- Read the results when the “results ready” indicator changes to a pinkish red. Do not read the results 15 minutes or more after this indicator changes color or after the “results expired” indicator changes color.
- If no line appears in the control region, the test is invalid and should be repeated with a new card.

##### **Usage Guidelines for Hair Drug Abuse Tests**

- Collect a hair sample, ½-inch wide and one strand deep, from the crown of the head, as close to the scalp as possible.
- Align the cut ends of the hair sample and place the sample in the collection package as directed. Do not collect hair from a hairbrush, comb, or clothing; there is no guarantee that the hair is actually from the person to be tested.
- Results are available approximately 5 days after receipt by the laboratory. To access results, call the manufacturer’s toll-free number and provide the code number accompanying the kit.

##### **When to Seek Medical Attention**

- If the test is positive, seek the services of a drug rehabilitation organization.

Source: References 55-58.

### Interferences

Ingestion of decongestants, dextromethorphan, antidiarrheals, or cough medicines containing codeine may cause false-positive results for home drug abuse tests. These items contain substances structurally related to certain drugs of abuse. Consumption of large quantities of poppy seeds or poppy seed paste may or may not cause a false-positive

result for opiates, depending on the test's sensitivity. Sensitivity standards for opiates have been raised to reduce the possibility of false-positive results.

### Product Selection Guidelines

The criteria for selecting one drug abuse test over another include the drugs that are suspected of being used, the type of suspected use (i.e., casual versus chronic), the length of time since last use, and the possibility that the suspected drug user tampered with the sample. The list of drugs that may be identified varies with each kit. These tests can test for a single drug or up to 12 drugs. Information on FDA approval of a particular drug abuse test for home use is available on the FDA Web site

([www.fda.gov/MedicalDevices/ProductsandMedicalProcedures/InVitroDiagnostics/HomeUseTests](http://www.fda.gov/MedicalDevices/ProductsandMedicalProcedures/InVitroDiagnostics/HomeUseTests)).

In general, urine tests are better for detecting low-level, casual drug use. Hair testing detects longer-term use. It takes at least 5-7 days for hair to grow far enough from the scalp for testing purposes.

Urine samples are subject to tampering by adding chemicals, diluting with water, or substituting someone else's urine sample. Some of the test kits include a temperature strip on the urine collection cup to ensure the sample is at body temperature. Hair samples, if taken directly from the person being tested, are not subject to tampering. Parents should weigh the possibility of tampering when deciding which type of test to choose.

### Assessment of Drug Abuse Test Use

The length of time of suspected drug use and the types of drugs that are suspected will determine which type of drug abuse test to recommend. Whether the suspected user is likely to tamper with urine samples should also be determined. Finally, whether the suspected user takes legal prescription or nonprescription medications that may interfere with the test should be determined.

### Patient Counseling for Drug Abuse Tests

When parents or caregivers ask for assistance in selecting a drug abuse test, health care providers should offer clinical advice and information about family counseling agencies. Counseling should emphasize the limitations of the tests for confirming drug use and, in the case of urine tests, for identifying anything more than the type of drug that is being abused. The box Patient Education for Drug Abuse Tests lists specific information to provide patients.

### Evaluation of Patient Outcomes with Drug Abuse Tests

If a positive result is obtained with a drug abuse test, parents or caregivers need to consider potential problems with the test itself before concluding that drug use is confirmed. In addition, they must not assume that a negative result is accurate. Parents should also consider the testing window when evaluating results.

### Blood Pressure Monitors

Hypertension, defined as either a systolic blood pressure greater than 140 mm Hg or a diastolic blood pressure greater than 90 mm Hg, is often an asymptomatic disease.<sup>59</sup> Table 48-7 lists the classification of blood pressures from the seventh report of the Joint National Committee on Prevention, Detection, Evaluation and Treatment of High Blood Pressure (JNC 7).

**TABLE 48-7 Classification of Blood Pressure**

<i>Category</i>	<i>Systolic BP (mm Hg)</i>		<i>Diastolic BP (mm Hg)</i>
Normal	<120	AND	<80
Prehypertension	120-139	OR	80-89
Hypertension, stage 1	140-159	OR	90-99
Hypertension, stage 2	≥160	OR	≥100

Key: BP = Blood pressure.

Source: Reference 59.

Thirty-two percent of Americans 20 years of age and older have hypertension.<sup>34</sup> Thirty percent of people with hypertension are unaware of their condition; almost 40% are not receiving treatment; and 66% have not achieved national goals for blood pressure control.<sup>59</sup> The reasons for the lack of adequate control are multiple, but a significant factor is lack of patient motivation to take steps to control blood pressure, especially if the patient is asymptomatic,

which leads to nonadherence with treatment strategies.

The consequences of untreated hypertension are well documented. Long-standing elevations in blood pressure can lead to damage to the heart, kidneys, lungs, eyes, and blood vessels, and to an increase in morbidity and mortality. Treatment of high blood pressure often involves significant lifestyle changes (diet and exercise) and the institution of drug therapies. These measures inevitably produce side effects, so the patient who was without symptoms of disease may become symptomatic. Patient education and empowerment play a large role in improving patient adherence with antihypertensive efforts. Adherence, in turn, helps reduce morbidity and mortality, maintains or improves the patient's quality of life, and improves the patient's use of health care resources.

Teaching patients to take their own blood pressure at home is an excellent means of achieving those goals because home blood pressure monitoring gives patients a sense of control over their health and allows them to measure their progress toward a target blood pressure. Three general advantages of measuring blood pressure at home are the ability to (1) distinguish sustained hypertension from "white-coat hypertension" (measurements affected by being in the health care provider's office), (2) assess response to antihypertensive medication, and (3) improve patient adherence to treatment.

### Usage Considerations

Of the three categories of blood pressure monitors (mercury column, aneroid, and digital), the most popular choices for home use are aneroid and digital monitors. Monitors that measure pressure at the wrist and fingers have become popular, but the systolic and diastolic pressures vary substantially in different parts of the arterial tree. Finger monitors have so far been found to be inaccurate and are not recommended.<sup>59,60</sup> Wrist monitors are typically smaller than the arm devices and can be used in obese people because the wrist diameter is little affected by obesity.<sup>60</sup>

### Mechanism of Action

Blood pressure readings include two types of pressures: systolic, which indicates pressure at the time of contraction of the heart cavities, and diastolic, which indicates pressure at the time of dilation of the heart cavities. Blood pressure is measured indirectly by two methods: auscultatory (measurement of sound) and oscillometric (measurement of vibration). Mercury column and aneroid meters involve auscultation with the use of a stethoscope to detect Korotkoff's sounds, which are produced by the motion of the arterial wall in response to changes in arterial pressure.

Oscillometric sensors, which are often used with digital meters, measure blood pressure by detecting blood surges underneath the cuff as it is deflated. The detection device, which is usually indicated on the cuff with a tab or other marking, is placed directly over the brachial artery. The brachial artery can be found by palpating 1-2 inches above and just to the inside of the antecubital space. As cuff pressure increases during the measurement procedure, the brachial artery is compressed and blood flow is obstructed. As cuff pressure is gradually released, blood flow is reestablished and Korotkoff's sounds can be heard in different phases. Phase I, which corresponds to systolic pressure, can be identified when at least two consecutive "beats" are heard as cuff pressure is decreased. The nature of the sounds changes over the next three phases. Diastolic pressure is identified at the point the sounds disappear (Phase V).

### Interferences

Stress, tobacco smoking, and ingestion of caffeine-containing beverages can increase blood pressure. Some medications such as pseudoephedrine may also increase blood pressure.

### Usage Guidelines

The actual measurement of blood pressure is a relatively simple procedure; however, many people consistently do it incorrectly. Blood pressure is naturally variable. Therefore, proper technique is essential to reduce measurement variability and improve the quality of results. The normal range for blood pressure was established in patients seated in the resting state; any variation from this setting can produce inaccurate results.

Using the appropriate size cuff is essential to accurately measure a patient's blood pressure (Table 48-8). If the cuff is too small, blood pressure readings can be overestimated significantly by as much as 20-30 mm Hg. Several monitors are supplied with a large cuff; many others allow a large cuff to be purchased separately. For patients with arms too large for the largest size cuff, a wrist monitor may be a useful alternative. To obtain accurate readings with wrist cuffs, the patient must hold the wrist at heart level during the reading. Because these devices are also highly sensitive to changes in the wrist level, it is best to support the arm on a table with a pillow that will raise the wrist to the appropriate level. For the person who is doing the actual monitoring, following the steps outlined in the box Patient Education for Self-Monitoring of Blood Pressure will help improve the accuracy of blood pressure readings, regardless of whether they are taken in the health care provider's office, the pharmacy, or the home.

#### TABLE 48-8 Arm Circumferences to Determine Appropriate Blood Pressure Cuff Size

--	--

<b>Arm Circumference (adult)<sup>a</sup></b>	<b>Cuff Size</b>
22-26 cm	Small adult cuff
27-34 cm	Regular adult cuff
35-44 cm	Large adult cuff
≥45 cm	Thigh cuff <sup>b</sup>

<sup>a</sup>Determine arm circumference by measuring around the midpoint of the upper arm. Remeasure the patient's arm periodically, especially if he or she has recently gained or lost significant weight.

<sup>b</sup>Consider a wrist monitor for patients whose arm circumference is >45 cm.

Source: Reference 60.

## Patient Education for Self-Monitoring of Blood Pressure

### Precautions and Avoidance of Incorrect Results

- Keep a log of blood pressure readings and any circumstances that might have affected the reading (e.g., feeling nervous or being late for work).
- If home readings are being performed for diagnostic purposes, take readings at different times throughout the day and under different circumstances.
- If readings are being done to determine adequacy of antihypertensive therapy, take the reading at the same time of day, preferably in the early morning soon after arising from bed.
- Allow plenty of time to relax before taking a blood pressure reading. Feelings of stress or pressure can elevate the blood pressure.
- Do not use tobacco products or drink caffeine-containing beverages for at least 30 minutes before taking a measurement. These activities can increase blood pressure.
- Wait 10-15 minutes after a bath and 30 minutes after eating to take a measurement. These activities can lower blood pressure.
- Some medications may increase blood pressure. Be alert for possible changes in readings when starting or stopping medications.

### Usage Guidelines

- Make sure the room is at a comfortable temperature.
- Sit in a comfortable chair, with your back supported and your feet facing straight ahead and placed flat on the floor.
- If using an arm cuff, place the arm to be measured on a table, making sure your upper arm is at heart level. Remove restrictive clothing from the arm.
- If using a wrist cuff, place pillows under the arm to be measured to bring the wrist up to heart level.
- Place the cuff on the arm to be measured. The cuff should be snug but not tight enough to restrict blood flow. Use the guidelines in [Table 48-8](#) for selecting cuff size.
- Rest for at least 5 minutes in this position.
- Measure the blood pressure as directed by the product instructions. If using a stethoscope, listen for the Korotkoff's sounds as defined:
  - Phase 1: Sound begins as a soft tapping. Record the systolic pressure when two taps are heard in sequence.
  - Phase 2: Tapping sound becomes louder and is accompanied by a swishing sound or murmur.
  - Phase 3: Tapping sounds persist, but the swishing or murmur sound stops.
  - Phase 4: There is muffling or softening of tapping sounds.
  - Phase 5: Sound stops. Record the diastolic pressure when the sound stops.
- Using the same arm, take two to three measurements separated by at least 2 minutes.
- Record the results, arm used, time and date of measurement, and name and time of last dose of any medications, including antihypertensive medications.
- Do not adjust blood pressure medications on the basis of home measurements unless specifically instructed to do so by a health care provider.

### When to Seek Medical Attention

- See a health care provider immediately for evaluation and treatment if readings are above limits set by your health care provider or above the limits stated in national guidelines and if you are having symptoms such as headache or blurred vision.

*Source:* Reference 53.

### Product Selection Guidelines

Of the three types of blood pressure-measuring devices, no single one is best for every patient. The choice of device is individualized according to characteristics such as the patient's ability and willingness to learn, physical disabilities, patient preference, and the cost of the device. Mercury column devices are expensive and, as discussed in the next section, have other disadvantages for home use. In general, aneroid devices are the least expensive. Depending on its features, a digital device can cost as much as a mercury column device. A discussion of the pros and cons of all three types of devices follows.

### Mercury Column Devices

The mercury column blood pressure monitor is still the reference standard in blood pressure measurement. This monitor typically comes with a cuff and an inflation bulb. The tubing from the cuff is attached to a column of mercury encased in a calibrated vertical glass tube.

Although mercury monitors are the most accurate and reliable of the devices, their routine use for home measurement is discouraged because they are cumbersome and pose the risk of mercury toxicity should the glass tubing break. They also require good eyesight and hearing for effective use. If the mercury does not rest at zero when the cuff is lying flat and completely deflated, the device needs recalibration.

### Aneroid Devices

Next to mercury column monitors, aneroid devices are the most accurate and reliable. They are light, portable, and very affordable, and they pose no risk from mercury toxicity. They include several features that make patient instruction much easier. First, many devices now come with a stethoscope attached to the cuff, which frees the patient from having to hold the bell of the stethoscope in place. Second, a D-ring on the cuff allows a single user to place the cuff on the arm easily. Third, a few manufacturers offer a gauge attached to the inflation bulb, making it easier to manipulate the equipment because there are fewer pieces to control. These monitors are considered the option of choice for home use, but they do require careful patient instruction and follow-up. Good eyesight and hearing are necessary for accurate readings with standard models. For patients with reduced visual capacity, however, devices with large-type print on the face of the gauge are available.

At the bottom of the face of each aneroid device is a small box. When the cuff is completely deflated and lying on the table, the needle of the gauge should rest in the box. If the needle is outside the box, the gauge needs recalibration. Many manufacturers sell recalibration tools to allow health care providers to adjust the devices.

### Digital Devices

With advancing technology, digital devices have become more accurate, reliable, and easy to use; as a result, they have skyrocketed in popularity. These devices include semiautomatic (manually inflating), fully automatic (autoinflating), wrist, and finger blood pressure monitors. Features such as printouts, pulse monitor, digital clock, automated inflation and deflation, memory, large display, and D-ring for the cuff differentiate many of the devices. These features significantly affect the price.

A major drawback to digital monitors is the user's inability to determine whether the device is out of calibration. As a result, many providers recommend the aneroid devices over the easier-to-use digital products. The JNC 7 report notes that home measurement devices should be checked regularly for accuracy<sup>59</sup>; therefore, patients should be advised to have their monitors checked at least yearly by a health care provider.

If recommending a digital device, the provider should check the manufacturer's specifications to ensure that the monitor meets at least the accuracy standards set by the American National Standards Institute (ANSI). The ANSI standards for digital sphygmomanometers state that blood pressure readings between 20 and 250 mm Hg must not differ by more than 3 mm Hg or 2%, whichever is greater.<sup>61</sup>

### Assessment of Blood Pressure Self-Monitoring

Assessment should include determination of (1) why a patient wants to use a blood pressure monitor, (2) whether the patient has physical impairments that can interfere with proper use of the monitor, and (3) the patient's ability to comprehend and follow instructions.

### Patient Counseling for Blood Pressure Self-Monitoring

The health care provider should emphasize the importance of tracking blood pressure values to monitor control of hypertension. Regular self-monitoring of blood pressure will illustrate positive effects of proper diet, exercise, and medication use in controlling the disorder. This reinforcement can improve patient adherence with prescribed therapies. The patient should be shown the proper technique for blood pressure monitoring and be encouraged to return for a follow-up evaluation of his or her technique. Because of white coat hypertension, patients who measure blood pressure at home usually obtain lower results than those taken at the provider's office. In the home setting, a blood pressure greater than 135/85 mm Hg should be considered elevated.<sup>60</sup> The box Patient Education for Self-Monitoring of Blood Pressure lists specific information to provide patients.

### Evaluation of Patient Outcomes for Self-Monitoring of Blood Pressure

Patients measuring blood pressure for diagnostic and monitoring purposes should be instructed on how to track values and how to discuss the values with a health care provider. Patients monitoring their blood pressure should be cautioned not to adjust their medications unless instructed otherwise. Patients should be instructed to immediately contact their health care provider if they obtain elevated values (Table 48-7) and have any symptoms of high blood pressure, such as headache or blurred vision. Patient counseling and follow-up can improve outcomes in hypertensive patients by (1) motivating them to perform home monitoring of blood pressure, (2) guiding them in product selection, (3) training them to use devices appropriately, and (4) facilitating communication between the patient, the patient's family, and the patient's health care provider regarding any antihypertensive therapy.

### Miscellaneous Home Tests

As the market for home test products and shopping over the Internet have exploded, new tests are becoming available with increasing frequency. Selected miscellaneous home tests are described in Table 48-9. Instructions for use are generally available from the manufacturer's Web site or a site that sells the product. Following the general guidelines given in this chapter will also help patients obtain accurate results.

**TABLE 48-9 Selected Miscellaneous Nonprescription Home Tests**

<i>Test</i>	<i>Purpose</i>	<i>Important Points</i>	<i>Additional Information</i>
Alcohol screening tests (breath and saliva)	Prevent inappropriate alcohol consumption	Put nothing in mouth for 15 minutes before or during the test. Follow timing directions carefully and use a timing device.	Semiquantitative BAC; saliva test strips can be used to detect alcohol in drinks.
Visiderm ( <a href="http://visiderm.com">visiderm.com</a> )	Monitors moles for changes over time	Use a transparent overlay to trace outline of individual moles; record color and other details. Do subsequent examinations of each mole on same overlay.	Test includes transparent overlays, pen, color chart, instructions, and storage box.
Breast Self-Examination Aid	Makes breast self-examination easier and more comfortable	Examine breasts monthly. Self-examination does not take place of mammogram and professional examination.	Two-layer polyurethane breast shield or glove contains a small amount of silicone lubricant to reduce friction. Some kits come with instructional video (Aware, Sensa Touch).
Vagisil Screening Kit ( <a href="http://www.vagisilkit.com">www.vagisilkit.com</a> )	Detects pH of vaginal secretions	pH 4.5 + symptoms suggest yeast. pH $\geq$ 5 + symptoms suggest bacterial vaginosis or trichomoniasis.	Those with first-time yeast infection and those with pH $\geq$ 5 should see HCP for diagnosis. See Chapter 8 for additional information.
TobacAlert/NicAlert ( <a href="http://www.tobacalert.com">www.tobacalert.com</a> , <a href="http://nymox.com">nymox.com</a> )	Detects tobacco use or exposure	Test detects cotine, a metabolite of nicotine; test detects use or exposure in previous 48-72 hours.	Use of nicotine patch or gum can affect results.

		Dip strip in urine (TobaAlert) or saliva (NicAlert) sample and read results in specified time.	
My Allergy Test ( <a href="http://www.immunetech.com">www.immunetech.com</a> )	Detects allergy to 10 most common allergens: dust mites, cat, mold ( <i>Alternaria</i> ), ragweed, mountain cedar (juniper), Timothy grass, Bermuda grass, egg white, milk, wheat	If negative result but positive symptoms, see PCP.	Test measures IgE antibodies but tests for only 10 allergens. Results are available by e-mail in 10 days or by regular mail.
IDENTIGENE DNA Paternity Test Collection Kit	Checks paternity of a child	Collect cheek cell samples from each participant: alleged father, child, and biological mother. Swabs are mailed to laboratory.	Cost includes additional ~\$120 laboratory fee plus price of kit (\$30). Kit is not available in all states. Results are available 3-5 days after sample is received by laboratory. Results are not valid for legal purposes (requires verified collection procedure and additional costs).
EarCheck Middle Ear Monitor ( <a href="http://www.earcheck.com">www.earcheck.com</a> )	Detects middle ear fluid (otitis media with effusion)	Device emits sound waves into the ear canal. Some of the sound reflects off the eardrum and travels back to the built-in microphone. The sound is then analyzed to determine whether middle ear fluid is present.	Device is not validated in patients >19 years and cannot be used in those <6 months of age, or in those with ear tubes, known perforation or rupture of the eardrum, or visible drainage of pus or blood in the outer ear canal. If a negative result + symptoms or a positive result is obtained, see HCP.
Menopause Test	Detects FSH in urine	Positive test = FSH level >25 IU/L, which may indicate a woman is menopausal. FSH levels change during the menstrual cycle so the test should be done twice 1-2 weeks apart to confirm results.	Not a definitive diagnostic test for menopause. The diagnosis would need to be confirmed by the woman's health care provider.

Key: BAC = Blood alcohol concentration; FDA = Food and Drug Administration; Ig = immunoglobulin; IOP = intraocular pressure; HCP = health care provider; FSH = follicle-stimulating hormone.

### Key Points for Home Testing and Monitoring Devices

- To advise patients properly on selecting and using home testing or monitoring products, health care providers must be familiar with the procedures for each available product.
- Manufacturers continually introduce new products and modify current ones to provide more user-friendly versions. To keep up-to-date, providers should request product information from manufacturers by calling their toll-free numbers, visiting their Web sites, or contacting their sales representatives.
- FDA's Web site should also be checked frequently for problem reports, updates, and news on home tests.
- Patients who are using home tests or devices should be encouraged to follow instructions carefully and to contact either their health care provider or the manufacturer's toll-free number for assistance, if needed.

- Health care providers should stress that the patient is self-testing, not self-diagnosing. Positive test results should be reported immediately for definitive diagnosis and management. Negative test results should be questioned when the patient is experiencing symptoms of a suspected condition.
- If there is any question about the results, the patient should seek the advice of a health care provider.

**Handbook of Nonprescription Drugs > Chapter 49. Adult Urinary Incontinence and Supplies****Adult Urinary Incontinence and Supplies: Introduction**

Urinary incontinence (UI) is defined as the complaint of any involuntary leakage of urine.<sup>1</sup> Although often mistakenly thought of as a problem of aging, UI affects people of all ages, socioeconomic backgrounds, and ethnicities. UI is twice as common in women, but men also suffer from the symptoms.<sup>2</sup> An estimated 17 million people in the United States are affected by UI,<sup>3,4</sup> whereas 42.2 million may suffer from overactive bladder (OAB).<sup>5</sup>

UI is an underdiagnosed and underreported condition with major psychosocial and economic effects on society. Feelings of embarrassment, denial, and misinformation prevent many people from seeking help, which may lead to anxiety, depression, and, possibly, social isolation. Severe UI usually results in a loss of self-esteem and the ability to maintain an independent lifestyle. In addition, it is generally recognized as a strong predictor of nursing home admission of older people.<sup>3</sup>

Direct costs associated with UI include the expenses for diagnosis, specific treatment, routine care, rehabilitation, and hospital and nursing home admissions. The direct costs of treating UI in men and women of all ages were estimated at \$19.5 billion in 2000.<sup>4</sup>

Several studies have determined the prevalence of UI in nursing homes and the community.<sup>6,7</sup> The reported prevalence rates are approximately 50% for people in nursing homes and range between 2% and 55% for adults living in the community, depending on the type of UI, population characteristics, and methodological approach.<sup>8</sup> Among adults 30-60 years of age, the prevalence of UI is 12%-42% for women and 3%-5% for men. For older people (>60 years of age), prevalence rates for women have been reported as 17%-55% and rates for men as 11%-34%. Despite the high prevalence of UI, less than half of community-dwelling adults with UI consult with their health care provider.<sup>9</sup> Many accept the symptoms as a natural part of aging and use self-care strategies with little or no health professional guidance. Although they are reluctant to talk about UI, Americans spend \$1.1 billion annually on disposable incontinence products (e.g., pads, shields, guards, undergarments, and briefs).<sup>10</sup>

**Pathophysiology of Urinary Incontinence**

Urination is a complex process, involving a coordinated effort by the bladder, urethra, and muscular components of the lower urinary tract, brain, and spinal cord.<sup>11,12</sup> Urine produced by the kidneys is propelled through the ureters to the bladder. The detrusor muscle, the smooth muscle layer of the bladder, gives tone to the bladder, relaxing as the bladder fills with urine and contracting during urination. The bladder neck, which joins the bladder and the urethra, is surrounded by smooth muscle, referred to as the internal sphincter, which either constricts to hold urine in the bladder or relaxes, permitting urine to flow through the urethra. Voluntary control of urination, or micturition, is maintained by contraction of the external sphincter, a striated muscle located at mid-urethral length. When relaxed, the urethra, which is surrounded by both smooth and striated muscle, allows urine to leave the body.

The bladder and the internal sphincter are innervated by the autonomic nervous system, and the external sphincter is innervated by the somatic or voluntary nervous system. Parasympathetic and sympathetic nerves innervate the smooth muscle of the bladder and urethra. Both alpha-adrenergic and beta-adrenergic receptors are present in the urinary structures. The alpha receptors are located in the base of the bladder and the proximal urethra, and the beta receptors are found primarily in the body of the bladder detrusor. Stimulation of the alpha receptors causes contraction of the smooth muscles in the bladder neck and urethra, thus closing the bladder outlet. Stimulation of the beta receptors results in smooth muscle relaxation and allows the bladder to fill. Thus, sympathetic stimulation causes the bladder to retain urine. Parasympathetic cholinergic receptors are located throughout the bladder. Stimulation of these receptors causes the detrusor to contract, emptying the bladder. The sacral center, lying between vertebrae S2 and S4, acts as the relay center for information to and from the bladder, pelvic floor, and brain.

The capacity of the bladder is approximately 400-500 mL. When the bladder fills, stretch receptors in the detrusor wall transmit signals to the brain through the spinal cord, initiating the urge to urinate when the bladder is approximately half full. Under normal circumstances, adults can delay voiding for 30-60 minutes as a result of the short sacral reflex, which diminishes the urge to urinate by increasing contraction of the external sphincter and relaxing the detrusor muscle of the bladder. Bladder emptying is initiated voluntarily, causing relaxation of the external sphincter and contraction of the detrusor. Normal urination results in complete emptying of the bladder, with little or no residual urine ( $\leq 50$  mL). Any disruption in the integration of musculoskeletal and neurologic function can lead to loss of control of normal bladder function and UI.<sup>13</sup>

## Clinical Presentation of Urinary Incontinence

UI is a symptom that can be caused by external factors and by anatomic, physiologic, and pathologic factors that affect the urinary tract.<sup>2,14-16</sup> In many cases, multiple and interacting factors contribute to UI. The risk of UI is strongly associated with aging. Additional risk factors for UI, some at least partially reversible, have been identified ([Table 49-1](#)).<sup>2,14-16</sup> Identification of the cause(s) of UI is essential for the assessment and successful management of UI.

**TABLE 49-1 Risk Factors for Urinary Incontinence**

<b>Medical Disorders or Procedures</b>
BPH/TURP/prostatectomy
Childhood nocturnal enuresis
Diabetes
Fecal impaction
Immobility/chronic degenerative disease
Impaired cognition: acute or chronic
Metabolic disorders (hyperglycemia, hypercalcemia)
Neurologic disorders (spinal cord injury, neuropathy)
Obesity (moderate-morbid)
Pregnancy/vaginal delivery/episiotomy
Stroke
<b>Physiologic Factors</b>
Estrogen depletion
High fluid intake (leading to polyuria and bladder capacity overload)
Low fluid intake (leading to concentrated urine and bladder irritation that worsens symptoms)
Pelvic floor muscle weakness
<b>Lifestyle Factors</b>
High-impact physical activities
Smoking
<b>Other Factors</b>
Caucasian race
Environmental barriers
Medications ( <a href="#">Table 49-2</a> )

Key: BPH = Benign prostatic hyperplasia; TURP = transurethral resection of the prostate.

Source: Adapted from references 2 and 14-16.

Age-related changes in the bladder and urinary tract may contribute to an older person's vulnerability to UI. With age, the kidney's ability to concentrate urine diminishes, resulting in larger urine volumes. In addition, age-related hypotrophic changes in bladder tissue lead to frequent urination and nocturia, whereas decreased muscle tone of the bladder, as well as the bladder sphincters and pelvic muscles, contributes to the potential for reduced urine control.

This loss of control, combined with diminished mobility and reaction time, predisposes older people to UI.<sup>17</sup> In women, the loss of estrogen causes a decrease in bladder outlet and urethral resistance, as well as a decline in pelvic musculature—all of which increase the likelihood of UI. In addition, estrogen loss results in atrophic changes in

the vaginal and urethral mucosa, disrupting the vaginal flora and leading to atrophic vaginitis and chronic urethritis. These conditions, in turn, may cause urinary frequency and urgency, dysuria, urinary tract infections, and UI. The woman's short urethra exerts less resistance to intravesicular pressure compared with the longer male urethra. Consequently, obesity, chronic cough, and jarring exercise, which all increase intra-abdominal pressure, result in an extra load on the bladder. As such, these factors can overwhelm the relatively low resistance offered by the short female urethra. Childbirth, gynecologic procedures, and muscle atrophy from aging also weaken the woman's pelvic floor muscles, thereby decreasing support for the bladder. Without adequate support, positioning of the bladder becomes distorted (known as cystocele or anterior wall prolapse) and can result in urethral kinking, with subsequent poor bladder emptying. These conditions may result in chronic obstruction of the bladder, again leading to UI from urine volume overload.

Men often develop prostatic enlargement beginning in their middle to late 40s, which results in urethral obstruction, leading to decreased urinary flow rates, increased residual volumes, detrusor instability, and possibly overflow incontinence. Paradoxically, prostatectomy to relieve bothersome symptoms related to benign prostatic hyperplasia (BPH) can result in stress incontinence caused by incidental injury to the internal sphincter.

UI can be described broadly as transient or chronic. Transient UI is usually of sudden onset and secondary to acute illness (e.g., urinary tract infections) or to any disease that causes acute confusion (e.g., respiratory disease, myocardial infarction, or septicemia) or immobility, preventing the person from reaching a toilet independently or in time. Many other conditions and medications can cause or contribute to transient UI (Table 49-2).<sup>2,18</sup> Managing these conditions may resolve UI in some patients but only reduce the severity of symptoms in others. Chronic UI is often related to neurologic or other chronic conditions, such as intrinsic sphincter deficiency, BPH, or cystocele.<sup>19</sup> UI can be classified as OAB, stress incontinence, mixed incontinence (OAB plus stress incontinence), overflow incontinence, or functional incontinence, depending on the underlying etiologies.

**TABLE 49-2 Reversible Conditions That Cause or Contribute to Urinary Incontinence**

<b>Conditions Affecting the Lower Urinary Tract</b>
Urinary tract infections, atrophic vaginitis/urethritis, fecal impaction, pelvic floor prolapse, hyperglycemia, hypercalcemia
<b>Drug Side Effects</b>
Polyuria, frequency, urgency: caffeine, diuretics, alcohol, acetylcholinesterase inhibitors
Urinary retention: anticholinergics, antidepressants, hypnotics/sedatives, antipsychotics, narcotics, muscle relaxants, antihypertensives (calcium channel blockers), beta-adrenergic agonists, alpha-adrenergic agonists
Urethral relaxation: alpha-adrenergic blockers
Urethral pressure imbalance (stress incontinence): cough from ACE inhibitors
<b>Increased Urine Production</b>
Metabolic disorders (e.g., hyperglycemia, hypercalcemia), excessive fluid intake, volume overload, venous insufficiency with edema leading to nocturia
<b>Inability or Unwillingness to Reach a Toilet</b>
Dementia, delirium, illness/injury that interferes with mobility, psychological conditions

Key: ACE = Angiotensin-converting enzyme.

Source: References 2 and 18.

Recognition of signs and symptoms of UI is an essential first step in providing treatment advice. Patients often delay discussion or do not seek medical evaluation of UI with their health care provider. Therefore, it is important for health care providers to inquire about potential UI symptoms when such conditions are suspected on the basis of clinical evidence or patient inquiries. Open-ended questions such as "What problems are you having, if any, with your bladder?" and "How often do you experience urine leakage?" can be used to begin this dialogue. An awareness of signs such as the odor of urine or appearance of wetness is also necessary to identify potential patients suffering from UI. Table 49-3 lists observed and reported symptoms commonly associated with particular types of UI. Encouraging the use of a 24-hour voiding diary, paper or electronic, is a helpful tool in diagnosing and managing UI.<sup>20,21</sup> Voiding dairies permit the patient to document fluid intake, amount of urine voided, episodes of urine leakage, urge to urinate, and activity at the time of leakage or sense of urgency.

**TABLE 49-3 Common Signs and Symptoms of Urinary Incontinence, by Type**

<i>Type of UI</i>	<i>Urgency</i>	<i>Frequency</i>	<i>Volume of Loss</i>	<i>Nocturia</i>	<i>Other</i>
Urge	Frequent	>8 times per day	Large amount of urine loss: >100 mL and may empty completely	>1 time per night	Inability to reach toilet following urge to void
Stress	Occasional	Urine leakage during physical activity, lifting, coughing, sneezing; if severe, urine loss on ambulating	Small-moderate urine loss, depending on level of activity	Rare	Ability to reach toilet in time to complete void
Overflow	Hesitancy	Straining to void	Decreased or incomplete urine stream; dribbling	Frequent	Sensation of bladder or abdominal fullness, and incomplete bladder emptying

*Overactive bladder* occurs in both men and women, and its incidence increases with age. OAB is characterized by sudden and profound urinary urgency (strong desire to void), frequency (urinating more than eight times daily), nocturia (two or more awakenings at night to pass urine), or UI; the condition is often, but not always, accompanied by urge incontinence (involuntary urine leakage with urgency).<sup>2,12,13,17</sup> OAB is usually, but not always, attributable to uninhibited contractions of the detrusor muscle, referred to as detrusor instability. Other terms describing detrusor instability are detrusor hyperreflexia, detrusor hyperactivity with impaired bladder contractility, and bladder instability. Neurogenic causes of detrusor instability include dementia, stroke, parkinsonism, suprasacral spinal cord injury, multiple sclerosis, and medullary lesions. Detrusor instability of neurologic origin is referred to as hyperreflexia. Non-neurogenic causes of detrusor instability include bladder irritation caused by infection or interstitial cystitis (bladder pain syndrome), obstruction (e.g., BPH or cystocele), bladder stones, and tumors. Excessive beverage intake and some therapeutic agents (e.g., diuretics and alcohol) can exacerbate symptoms of urge incontinence as a result of increased filling of the bladder. Bethanechol can also lead to urge incontinence through cholinergically mediated contraction of bladder smooth muscle.

*Stress incontinence* is the most frequently encountered type of UI in women, except in the very old (>75 years), in whom OAB is most common. Symptoms of stress incontinence may occur in some men after transurethral resection of the prostate and radical prostatectomy.<sup>13</sup> Stress incontinence is characterized by involuntary leakage of urine with sudden increases in abdominal pressure associated with sneezing, laughing, coughing, exercising, and lifting. Symptoms are exacerbated with pregnancy and obesity, which also increase intra-abdominal pressure. This involuntary leakage is believed to be caused by hypermobility of the bladder neck or weakness of the urethral sphincter and pelvic floor muscles. Hypermobility refers to displacement of the bladder neck and urethra during physical exertion; it occurs when the supporting pelvic muscles have been weakened as a result of vaginal childbirth and aging. The weakening of the urethral sphincter can be secondary to vaginal or urologic surgery, trauma, aging, or inadequate estrogen, or it may be neurologic in etiology.<sup>22</sup> Drug-related causes of stress incontinence include alpha-adrenergic antagonists such as prazosin, terazosin, doxazosin, tamsulosin, and alfuzosin, which cause urethral relaxation (Table 49-2).

*Overflow incontinence*, an involuntary urine loss associated with overdistention of the bladder, is observed in 7%-11% of incontinent older patients.<sup>2</sup> Symptoms include dribbling, reduced force and caliber of urinary stream, urgency, and a sensation of incomplete voiding. The two main causes are outlet obstruction and/or an underactive bladder (detrusor) muscle. Outlet obstruction can be caused by BPH, urogenital tumors, pelvic organ prolapse, or previous anti-incontinence surgery. Dysfunctional bladder contractility can result from diabetic or alcoholic neuropathy, lower spinal cord injury, radical pelvic surgery, or medications with anticholinergic properties, such as antihistamines, antipsychotics, narcotics, tricyclic antidepressants, muscle relaxants, and medications used to treat urge incontinence. These medications can cause overflow incontinence by blocking cholinergically mediated bladder contractions, thereby inhibiting normal bladder function.

*Mixed incontinence*, most common in women, consists of the combination of OAB and stress incontinence.<sup>2</sup> Although the term *mixed UI* is generally applied to women, men with outlet obstruction resulting from BPH may exhibit mixed symptoms of OAB and overflow incontinence. Men may also exhibit mixed symptoms as a result of stress UI attributable to radical prostatectomy or transurethral resection of the prostate combined with OAB.

*Functional incontinence* is described as urine loss caused by factors such as physical or cognitive impairment, which

interfere with a person's ability to reach toilet facilities in time or to perform toileting tasks.<sup>2,12</sup> Causes of this type of UI are many and include stroke, diminished mobility, impaired cognitive function or perception, environmental barriers, use of sedative and hypotensive agents, poorly controlled severe pain, and psychological unwillingness to release urine in the proper place. Because many functionally impaired people may have other types of UI, functional incontinence should be a diagnosis of exclusion.

The consequences of UI are considerable. Many people are embarrassed by such a condition and refrain from discussing their urinary problems with their primary care providers. Some people with UI believe it is a normal consequence of aging, rather than a symptom of underlying disease or anatomic change. Social isolation occurs because the incontinent patient avoids social interaction to prevent the embarrassment and rejection that often accompany UI. In turn, social isolation leads to depression. Intimate contact and sexual activity with the patient's partner can also decrease. Attempts to limit episodes of involuntary urine loss by restricting fluid intake can cause dehydration and hypotension, whereas skin irritation and ulceration caused by long exposure to urine results in "diaper rash" and possibly pressure ulcers.<sup>2</sup>

The caregivers of incontinent older patients are under stress because of the tedious and time-consuming care needed to deal with the problems of UI at home. Often, the loss of urine control leads to a drastic reduction in quality of life, and in some cases, placement in a nursing home.<sup>2,23</sup> Falls and fractures can result from UI and also with urgency symptoms in the absence of incontinence.

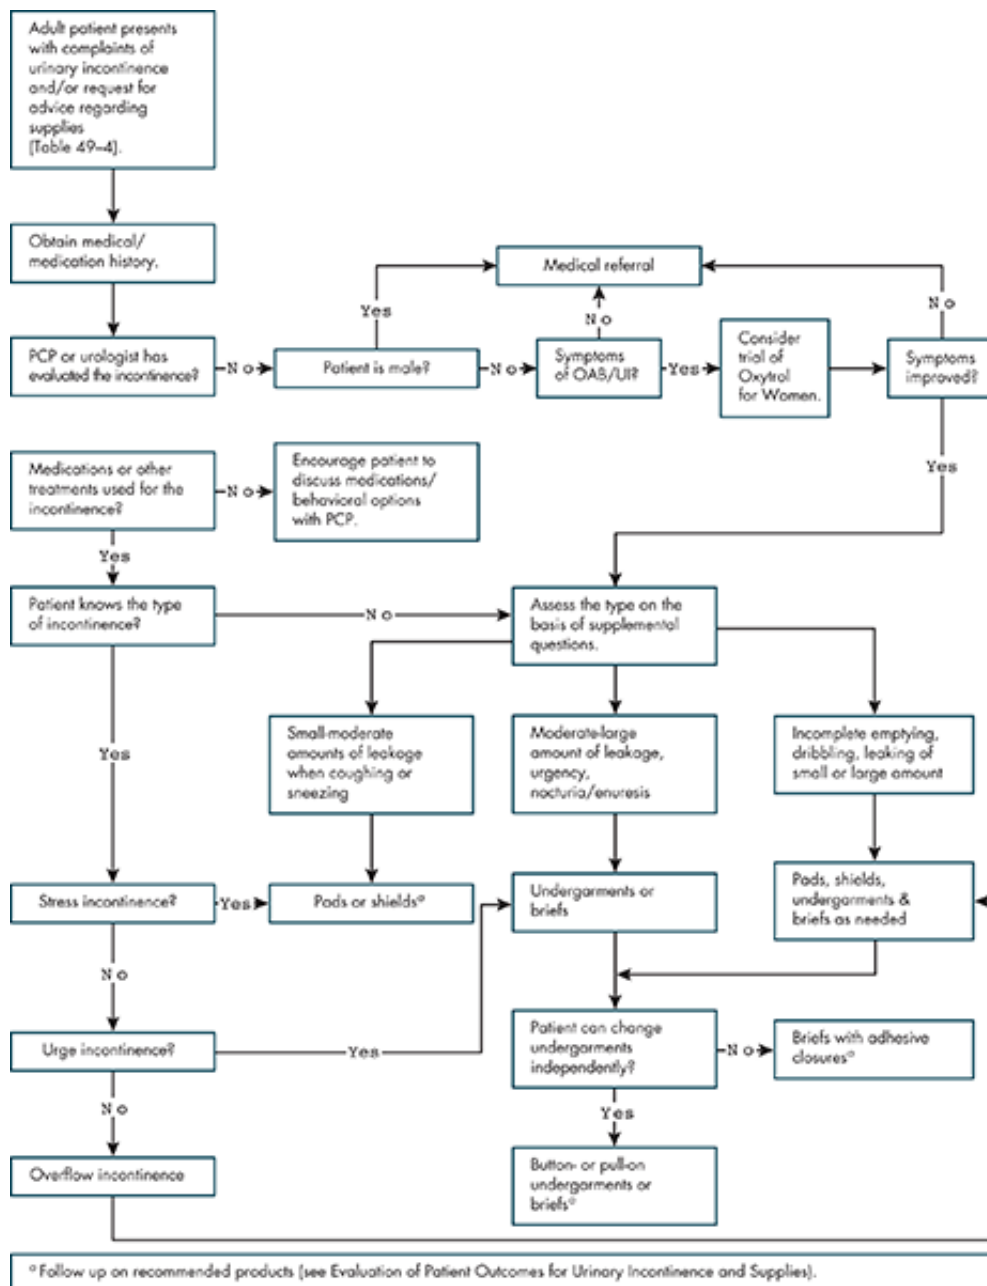

## **Treatment of Adult Urinary Incontinence**

### Treatment Goals

The goals of treatment of UI are to cure incontinence or to reduce the severity of symptoms, avoid complications, and improve the patient's quality of life. When incontinence aids are used as part of self-management in UI treatment, additional goals are to control or treat skin breakdown (diaper rash), control the odor of leaked urine, and contain urine in the undergarment.

### General Treatment Approach

Treatment is individualized for the type of UI. The four major categories of intervention are behavioral modification, use of devices, pharmacologic treatment, and surgical treatment. Nonsurgical treatments for UI in women have been systematically reviewed in a recent publication.<sup>24</sup> [Figure 49-1](#) outlines the self-management of adult UI.

All rights reserved. Any use is subject to the Terms of Use.

Self-care of adult urinary incontinence. Key: OAB = Overactive bladder; PCP = primary care provider; UI = urinary incontinence.

### Nonpharmacologic Therapy

Behavioral techniques decrease the frequency of UI in most patients, have no reported side effects, and do not limit future therapies.<sup>2</sup> To be most successful, these techniques generally require patient and caregiver involvement and continued practice. Three types of behavioral techniques, listed in order of increasing need for patient involvement, are toileting assistance, bladder training, and pelvic floor muscle training. Behavioral techniques are now the accepted first-line therapy in treating all forms of UI except overflow incontinence.<sup>12</sup> A behavioral modification program involving pelvic floor muscle training and behavioral techniques was found to prevent the development of UI in continent older women.<sup>25</sup> Providers should educate patients about the role of behavioral therapy in the prevention and management of UI.

Toileting assistance includes routine or scheduled voiding performed at fixed, regular intervals (every 2-4 hours); habit training, which is voiding scheduled to match patterns in those who have natural voiding patterns; and prompted voiding. In prompted voiding, patients are trained to void only if the need is voiced on direct questioning. They are checked for wetness and praised for maintaining continence and trying to void.

Bladder training consists of education, scheduled voiding with systematic delay, and positive reinforcement. Patients are taught to delay voiding when the urge occurs and to use tactics to increase urine volume and the interval between voids. Bladder training is recommended for urge or mixed incontinence, but it is often difficult to achieve in cognitively impaired or frail older people.

Pelvic floor muscle training aims to improve urethral closure pressure by activating the striated muscles of the urethra and the underlying pelvic floor muscles. Two components of training have been established. Early improvement (reduction of urine leakage within 1 week of beginning pelvic floor muscle exercises) may be achieved by some women who learn “the knack maneuver,” or volitional precontraction. The *knack* describes learning to contract pelvic floor muscles in anticipation of and during increases in intra-abdominal pressure (e.g., coughing). This maneuver alone has demonstrated the capacity to reduce stress incontinence.<sup>26</sup> In addition, pelvic floor muscle training, also known as Kegel exercises or pelvic floor exercises, is designed to strengthen the voluntary periurethral and perivaginal muscles, giving the patient more control of micturition and reducing UI.<sup>2</sup> Kegel exercises, which have been used successfully for stress and OAB, are performed by squeezing the pelvic muscles as if to stop the flow of urine. The contractions should be held for about 10 seconds and then released for 10 seconds; 3-4 sets of 10 contractions per day are generally recommended.<sup>2,27</sup> It is important to advise patients that the response to pelvic muscle exercises is delayed. The exercises may be augmented by the use of vaginal weights or biofeedback techniques. Biofeedback can facilitate learning pelvic muscle exercises. Direct electrical stimulation of the pelvic floor muscles with vaginal or anal probes or surface electrodes has been used with limited success in stress, urge, and mixed UI. Radiofrequency energy treatment (Lyrette, formerly Renessa) is available in a physician’s office and is a nonsurgical approach to stress UI. The treatment, which uses low temperature to cause natural collagen to become firmer, produces improvements in 3 of 4 women and nearly 60% can eliminate the use of pads.<sup>28</sup> Another option available only through a primary care provider’s office is the NeoControl Pelvic Floor Therapy System.<sup>29</sup> This is a pulsating magnetic chair that uses directed magnetic fields to induce pelvic muscle contractions. Patients generally require treatments twice a week for about 20-30 minutes for a total of 8 weeks or more. This option is approved by the Food and Drug Administration (FDA) for the treatment of stress, OAB, and mixed UI. Application of mechanical pressure to support the urethra is evident in the age-old advice to women with stress incontinence to cross their legs before coughing or sneezing to prevent urine leakage.<sup>30</sup> Similarly, various devices have been used for UI, including elevating devices to support the bladder neck (pessary, tampon, or prosthesis); urethral occlusive devices (urethral plug or insert, caps, expandable urethral devices, or urethral shields); external collection systems (condom catheters or female urinals); penile compression devices; and catheterization (intermittent, indwelling, or suprapubic).<sup>2</sup> FemSoft, a small single-use product available by prescription for stress urinary incontinence, is the only urethral insert available in the United States. A recent review of mechanical devices found inconsistent results, insufficient evidence to compare one device with another, and no evidence to compare mechanical devices with other forms of treatment.<sup>18</sup>

Surgery is uncommon in the treatment of OAB; however, both stress and overflow incontinence can be treated successfully by surgery. Surgery is an option when other nonpharmacologic and pharmacologic therapies have failed or the patient wants definitive treatment. The aims of continence surgery are to elevate the bladder neck, support the urethra, and increase urethral resistance.<sup>2,31</sup> Some surgical options include urethral bulking agents (collagen), sling operation, tension-free vaginal tape, artificial sphincter insertion, needle bladder-neck suspension, retropubic suspension, urinary diversion, and bladder denervation. It should be noted that surgical treatment for stress incontinence can instigate or exacerbate symptoms of urgency.

### Pharmacologic Therapy

The type of UI influences the choice of treatments. For that reason, an overview of the pharmacologic measures for specific types of UI is presented here. Most medications used to treat these disorders are prescription products; however, a nonprescription form of oxybutynin, Oxytrol for Women, was approved in 2013. Inappropriate use of systemic nonprescription products and incorrect use of absorbent undergarments and pads before a proper evaluation may result in unnecessary expense, inappropriate treatment, and possibly unnecessary changes in the patient’s lifestyle and psychological well-being.

Overactive bladder or urge incontinence may be treated with anticholinergic medications, which facilitate urine storage by decreasing uninhibited detrusor contractions. Oxytrol for Women provides a nonprescription option for women ages 18 years and older with urinary symptoms consistent with OAB. The patch is applied every 4 days to a clean, dry and smooth area of the skin on the abdomen, hips, or buttocks. Application sites need to be rotated with each patch. Common side effects include skin irritation at the patch application site, constipation, and dry mouth. If symptoms do not improve, women should seek a medical referral.<sup>32</sup> Prescription anticholinergic medications such as darifenacin, oxybutynin chloride, solifenacin, tolterodine, fesoterodine, or trospium are frequently used for OAB and urge UI. Mirabegron, a beta-3 adrenergic agonist approved for the treatment of OAB and urge UI, is an alternative to anticholinergic medications. For patients who do not respond or who cannot take anticholinergic medication, onabotulinumtoxinA offers significant relief from symptoms of OAB and urge UI.<sup>33</sup> Other prescription medications that have less evidence of clinical efficacy and raise concerns about risks of side effects include propantheline, imipramine, hyoscyamine, and nifedipine. Flavoxate, FDA approved for urinary tract symptoms, is not effective

according to the results of four placebo-controlled trials.<sup>31</sup> Diphenhydramine (see [Chapter 11](#)) and dicyclomine are used occasionally. Providers should counsel patients about the potential side effects that occur more frequently with diphenhydramine than with the prescription products. Sedation, dry mouth (a problem for denture users and patients with gastroesophageal reflux disease, dysphagia, or stroke), dizziness, constipation, and confusion can be significant problems in older patients. Contraindications to the use of diphenhydramine (and other anticholinergic medications) include many conditions (e.g., narrow-angle glaucoma, peptic ulcer, urinary tract obstruction, gastroesophageal reflux disease, and uncontrolled hyperthyroidism) that occur more often in older patients than in other patients. Stress incontinence is often treated with agents that increase outflow resistance through alpha-receptor stimulation that enhances contraction of the bladder-neck muscles.<sup>2</sup> A commonly recommended nonprescription drug is pseudoephedrine (see [Chapter 11](#)).<sup>2,22</sup> The dose of pseudoephedrine is 15-30 mg 3 times daily, starting with the lowest dose, especially in older people. Use of nonprescription medications for UI is an off-label indication and must be approved by a primary care provider. Caution should be used, however, when initiating such therapy in patients with hypertension and/or cardiac arrhythmias. The provider should advise patients to monitor their blood pressure and pulse, and to report any new occurrences of heart palpitations or fainting. Common adverse effects of pseudoephedrine include insomnia, headache, tachycardia, elevated blood pressure, dizziness, nervousness, agitation, and tremor.

In women, only topical estrogen should be advised because placebo-controlled studies have shown that oral estrogen therapy is not effective and that systemic therapy is associated with potentially serious adverse effects including venous thromboembolism, heart attack, stroke, and breast cancer. Topical vaginal estrogen therapy is most useful in stress UI with underlying vaginitis and urethritis due to estrogen deficiency; several randomized controlled trials of vaginal estrogen have shown a decrease in urgency and incontinence.<sup>34,35</sup> Therapy with estrogen vaginal cream is usually initiated with daily application and tapered to several times weekly applications; benefits are usually seen in 4-6 weeks. Other vaginal estrogen options include the vaginal ring and vaginal tablets. Estrogen can be used in combination with alpha-adrenergic agonists; however, the combination is only slightly more effective and can be associated with more adverse effects and increased therapy cost. The antidepressant imipramine, which also acts as an adrenergic agonist, has been suggested when alpha-adrenergic agonists and estrogens have failed. Duloxetine, a selective serotonin and norepinephrine reuptake inhibitor currently approved for the treatment of depression, post-herpetic neuropathy, and diabetic neuropathy, is moderately effective in managing stress UI.<sup>36</sup> If medical treatment fails, surgical correction may be possible.

The treatment of overflow incontinence is directed by the underlying cause. In BPH, alpha-adrenergic antagonists (terazosin, doxazosin, tamsulosin, alfuzosin, silodosin, or prazosin) or 5-alpha-reductase inhibitors (finasteride or dutasteride) can be used to reduce the degree of outlet obstruction. Alpha-adrenergic antagonists have a much faster onset of effect (several days) compared with 5-alpha-reductase inhibitors. Because of a relatively high rate of orthostatic hypotension, prazosin is not recommended for therapy of UI. Prescription agents such as bethanechol chloride may be initiated if the bladder has insufficient contractile strength, such as after general anesthesia. Its efficacy is not well established in long-standing hypotonic bladder, however, and it is associated with potentially serious adverse effects. In neurogenic bladder, bethanechol appears to be most effective when starting therapy as soon as possible after the occurrence of incontinence following the neurologic event. Surgery for BPH is often necessary. Catheterization, usually intermittent, is combined with frequent attempts to void as a last resort when medical and surgical corrections have failed.

Treatment of functional and iatrogenic incontinence requires evaluating the patient's entire medical status, medication history, and environment. UI resulting from medications can be resolved by initiating alternative treatments. Underlying dysfunctions such as pain related to rheumatoid arthritis and decreased mobility can be remedied by medical and environmental changes that make using the toilet possible or easier within the limitations of the patient's functional status. Often an assessment by physical or occupational therapists can be useful in enhancing physical function.

### Use of Urinary Incontinence Supplies

Absorbent undergarments and pads are used to protect clothing, bedding, and furniture while allowing the patient to have independence and mobility. Although absorbent products are beneficial, they should be used only after a thorough and complete physical examination. Prematurely initiating the use of absorbent protective products relieves the discomfort and obscures the cause of UI. Because correction of the cause may be possible, the premature acceptance of UI may have significant financial, social, and psychological consequences.

### Product Selection Guidelines

The type of absorbent product selected depends on several factors<sup>2</sup>:

- Type and severity of UI
- Functional status

- Gender
- Availability of caregivers
- Patient preference
- Cost
- Convenience

The health care provider needs to discuss these factors with patients and their caregivers when helping them select absorbent garments and pads, which are available as reusable or disposable products (Table 49-4). This discussion is particularly important for low-income patients, who often do not have the economic flexibility to purchase absorbent products; they may be forced to resort to toilet paper or tissue products, an ineffective substitute. Many people attempt to extend the life of disposable products by layering flushable tissue over the pad. The tissue is also easier to dispose of in public places. However, its reduced wicking capacity can expose the skin to more moisture and thus the potential for breakdown. Some patients may be inclined to use low-cost menstrual pads that may be effective in some cases; however, these products contain materials that are specific to absorbing blood, not urine. Given the wide variety of available products, a resource guide published by the National Association for Continence (NAFC) may be invaluable in helping patients with selection of a product.<sup>37</sup> In 2012, the NAFC recommended the following eight national quality performance standards for disposable adult absorbent products<sup>38</sup>:

1. Rewet rate: a measure of a product's ability to withstand incontinent episodes between changes
2. Rate of acquisition: a measure of the speed at which urine is drawn away from the skin
3. Retention capacity: a measure of a product's capacity to hold fluid
4. Sizing options: sizes ranging from youth and small adult to extra large and XX-large adult
5. Safety: no components, including additives, that are listed in any federal regulatory agency as being considered "unsafe"
6. Presence of a closure system: mechanism that allows the product to be opened and refastened
7. Breathable zones: an acceptable minimum air flow in side "wings" of the product sufficient to release trapped body heat and gaseous body perspiration in the pelvic region
8. Performance of elastics: provision of evidence of fit and the functionality of containment of body waste, without sacrificing comfort

**TABLE 49-4 Selected Adult Incontinence Product Features<sup>a</sup>**

<i>Trade Name</i>	<i>Absorbency</i>	<i>Size</i>	<i>Characteristics</i>
<b>Undergarments</b>			
Assurance Slip-On Protective Undergarment <sup>b</sup>	For moderate-heavy leakage	One size	One-piece design; no buttons or tapes
Attends Undergarments Super Absorbency	For moderate leakage		Reusable elastic belts
Depend Undergarments Easy Fit Elastic Leg/Adjustable Straps Regular & Extra Absorbency	For moderate leakage	One size; fits hip sizes up to 65 inches	Soft, cloth-like outer cover; reusable hook and loop strap tabs
Depend Undergarments Elastic Leg/Button Straps Regular & Extra Absorbency	For moderate leakage	One size; fits hip sizes up to 65 inches	Soft, cloth-like outer cover; reusable button strap tabs
Depend Undergarments Elastic Leg Extra Absorbency	For moderate leakage	One size	Soft, cloth-like outer cover; reusable button strap tabs
Depend Underwear Extra & Super Plus Absorbency	For heavy leakage	S/M, L	Feels and wears like underwear
Depend Refastenable Underwear Extra & Super Plus Absorbency	For heavy leakage	S/M, L/XL	Feels and wears like underwear; four refastenable tabs
Prevail Underwear	For heavy leakage	S, M, L	For men and women; look and feel like

			underwear; pull-on
<b>Briefs</b>			
Attends Briefs	For heavy leakage	Y, S, M, L	Refastenable tapes
Attends Briefs with Waistband	For heavy leakage	M, L	Waistband
Depend Fitted Briefs Regular & Overnight Absorbency	For heavy leakage; overnight absorbency absorbs 30% more urine than regular absorbency	M, L	Six refastenable tapes plus elastic leg and waist; wetness indicator
TENA Briefs	For heavy leakage	Y, S, M, L	Refastenable tabs
<b>Pads</b>			
Attends Pads	For light leakage; medium-, extra-, super absorbency	8.5, 10.5, 12.5 >14.5, 18 inches long	
Poise Pantliners	Very light absorbency	6.5 inches long	
Poise Extra Coverage Pantliners	Very light absorbency	7.5 inches long	
Poise Thin Pads Light Absorbency	For light leakage	8.5 inches long	Elasticized sides
Poise Pads Regular Absorbency	For light leakage	8.5 inches long	Elasticized sides
Poise Pads Extra Absorbency	For light leakage	9.5 inches long	Elasticized sides; one end wider
Poise Pads Extra Plus Absorbency	For light-moderate leakage	11 inches long	Elasticized sides; one end wider
Poise Pads with Side Shields Ultra Absorbency	For light-moderate leakage	11 inches long	
Poise Pads with Side Shields Ultra Plus Absorbency	For moderate leakage	13 inches long	Pad-like comfort with guard-like absorbency; one end wider
Serenity/TENA Dry Active Liners	For light leakage	Regular and long	
Serenity/TENA Active Ultra Thin Pads	For light-moderate leakage	Regular and long	
Serenity/TENA Stylish Ultra Thin Pads with Wings	For light leakage	One size	Form fitting, sleek, and super absorbent
Serenity/TENA Anywhere Ultra Thin Pads	For heavy leakage	Long	
Serenity/TENA Anywhere Ultra Thin Pads	For moderate leakage	Regular	
Serenity/TENA Pads Moderate	For moderate leakage	Regular and long	
Serenity/TENA Pads Heavy	For heavy leakage	Regular and long	
Serenity/TENA Ultimate Pads	For heavy leakage	One size	

Serenity/TENA Overnight Pads	For heavy leakage; overnight	One size	Longest pad
Serenity/TENA Insta-DRY HEAVY Pads	For heavy leakage	One size	Fast-absorbing pad
<b>Guards</b>			
Attends Guards Super Absorbency	For light-moderate leakage	One size	Curved fit
Conveen Drip Collector	For dribbling or light leakage; adheres to underwear; designed for men	3- and 4-ounce capacity	
Depend Guards for Men	For light-moderate leakage	One size	Anatomic design with elasticized pouch and cup-like fit
Serenity/TENA Guards Super Absorbency	For moderate-heavy leakage	One size	
Serenity Guards Super Plus Absorbency	For heavy leakage	One size	

Key: Y = Youth; S = small; M = medium; L = large.

<sup>a</sup> Products change often; for current product availability, refer to Web sites (i.e., [www.depend.com](http://www.depend.com), [www.poise.com](http://www.poise.com), [www.serenity.com](http://www.serenity.com)).

<sup>b</sup> Manufacturer markets other products similar to the Depend line but offers a lower price point.

The disposable product market has been a multimillion-dollar industry since the 1990s. These products work in the same manner as children's disposable diapers. They are designed to absorb urine; provide a moisture barrier to protect clothes, bedding, and furniture; and minimize skin contact with urine. For maximum absorbency, products containing an absorptive gel of superabsorbent polymers may be preferable. Urine is jelled in the matrix of the absorbent layer, minimizing its contact with skin. Reusable incontinence undergarments may offer a more affordable option.<sup>39</sup> These resemble underpants with a waterproof crotch and are designed to hold a reusable panty liner. The newest option is reusable incontinence undergarments that resemble standard underwear but have the absorbency of disposable briefs. These undergarments have a unique crotch design made of several layers of wicking fabric that quickly pulls moisture away from the skin. They are available for men and women in a variety of leakage control levels. Reusable incontinence underwear is constructed of waterproof outer fabrics ranging from lace to nylon floral prints, making them an attractive and affordable option for patients with an active lifestyle. A comparative evaluation of the performance and cost-effectiveness of four key absorbent product designs demonstrated significant and substantial differences between products and considerable individual variability in preference. Cost-effective management with absorbent products may best be achieved by allowing users to choose combinations of designs for different circumstances.<sup>40</sup>

The capacity of each disposable product corresponds to the needs of the patient:

- Guards/shields: 2-12 ounces (60-360 mL), light-heavy capacity
- Undergarments: 12-18 ounces (360-540 mL), moderate-heavy capacity
- Briefs: 28-36 ounces (840-1100 mL), moderate-heavy capacity

Patients with small amounts of leakage (e.g., dribbling), as occurs in stress or overflow incontinence and after urologic surgical procedures, may require only a pad or shield.<sup>41,42</sup> A recent systematic review of absorbent products suggested that disposable insert pads are best for leak-through prevention; they are also the most acceptable and preferred design for women with light UI.<sup>43</sup> In a similar study, guards were a preferred product for light UI in men.<sup>44</sup> If larger amounts of urine are lost with UI, as often occurs with detrusor instability, products with a larger capacity would be more appropriate. Many products designed for overnight (heavy) use tend to have the largest capacities.<sup>37</sup> Booster or doubler pads or inserts are also available to prevent leaks and increase the absorbency of current absorbent products.

Another important issue is the functional capacity of the patient. If the patient needs assistance with absorbent garments, the caregiver may find that briefs or diapers with "roll-on" bed application and adhesive closures are

useful. Securing the product may be an important issue. Close-fitting underwear is recommended. Some garments or shields have adhesive strips or belts to hold them in place. The use of belts may require assistance from a caregiver. Of course, comfort and leg security from urine leakage are important. Many product lines offer elastic legs or contoured shapes. Caregivers and patients should consider products designed for the differences between male and female anatomy when selecting large-capacity products.<sup>41,42</sup>

Protective underpads are often used in conjunction with briefs and undergarments for extended duration activities, such as sleeping and sitting. Both bed and chair pads are available, and the provider should inquire about the need for additional protection. The underpad should have a known capacity, a waterproof duration of several hours, and an ability to remain intact when wet. Bed pads are available in sizes from 16 by 24 inches to 30 by 36 inches. For chairs, a 16- by 18-inch pad should be used.<sup>42</sup>

### Complications from Absorbent Products

Because the use of absorbent products increases the risk of skin irritation and maceration, these products should be checked every 2 hours. With continual urine loss, it is recommended that the absorbent material be changed every 2-4 hours. The use of skin protectants (barrier creams and ointments), as in diaper rash, is appropriate. If a rash occurs, the same treatment as that described for infants is indicated (see [Chapter 35](#)).

Urine odor is an embarrassing problem. Nonprescription products containing chlorophyll (e.g., Derifil, Pals, or Nullo) or vitamin C can be recommended to help decrease urine odor. However, frequent checks and changes are preferable to efforts to mask the odor.

The healing of skin wounds may be delayed in the patient with skin wetted by urine. Any skin breakdown needs to be reported to the primary care provider. This serious complication should not be treated with nonprescription products without medical supervision.

UI products that are not available from the pharmacy or specialty supply store may be obtained by contacting the National Association for Continence, PO Box 1019, Charleston, SC 29402-1019; 1-843-377-0900, 1-800-BLADDER; fax: 1-843-377-0905; or [www.nafc.org](http://www.nafc.org).

### Complementary Therapies

Nutritional deficiencies of protein, calcium, vitamin C, zinc, magnesium, and vitamin B<sub>12</sub> have been proposed as possibly contributing to the development of UI.<sup>45</sup> Of these, the relationship between vitamin B<sub>12</sub> deficiency and UI has been established.<sup>46</sup> A B<sub>12</sub> deficiency may lead to diminished neurosensory input regarding bladder fullness or to inappropriate neurologic stimulation of the bladder, causing detrusor instability. Many factors, such as spicy and acidic foods (e.g., caffeine, alcohol, and tobacco), dyes (e.g., Food Drug and Cosmetic Yellow Dye No. 5), food preservatives, and sugar substitutes (i.e., aspartame), may cause urinary frequency and urgency with the potential for UI.

Several herbal treatments have been suggested for UI, including phytoestrogens (e.g., soybean and flaxseed), saw palmetto and pygeum (African plum), St. John's wort, and bearberry (uva-ursi) teas. Good clinical evidence from recent rigorous studies showed that saw palmetto is not effective in improving lower urinary tract symptoms related to benign prostatic hyperplasia.<sup>47,48</sup> In addition, there is no evidence from controlled studies that other herbal products significantly improve lower urinary tract symptoms of benign prostatic hyperplasia.<sup>49</sup> Patients should be advised to consult with their primary care provider before using any of these products for UI. An in-depth discussion of saw palmetto and pygeum is presented in [Chapter 51](#).

### Assessment of Adult Urinary Incontinence and Supplies: A Case-Based Approach

Because of the public's general lack of sufficient medical knowledge about the different types of UI, some patients (or their caregivers) may attempt self-diagnosis and treatment without consulting their primary care provider. Self-diagnosis obviously could lead to inappropriate assessment and treatment. Therefore, it is imperative that providers inquire about a proper medical evaluation before recommending nonprescription products, including absorbent products. A primary care provider must recommend use of nonprescription medications for off-label indications. Armed with the patient's history and proper diagnosis, the provider can answer questions appropriately and help in the selection and proper use of devices and medications for treating this disorder.

Cases 49-1 and 49-2 illustrate the assessment of adult patients with UI.

#### Case 49-1

<i>Relevant Evaluation Criteria</i>	<i>Scenario/Model Outcome</i>
<i>Information Gathering</i>	

1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of episodes of a "weak bladder," and "I have the urge to go more than 8 times in a day, and sometimes I don't make it to the bathroom in time." The first incident occurred 3 months ago. As a result, she has restricted her fluids and limited her activities. She has not seen her primary care provider.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The "leakage" occurs unexpectedly at no particular time.
c. description of the patient's efforts to relieve the symptoms	"I have been using feminine products. I usually can get to the bathroom in time. When leakage does happen, the urine soaks the pads."
d. patient's identity	Mary Ross
e. age, sex, height, and weight	48 years old, female, 5 ft 4 in., 150 lb
f. patient's occupation	Accountant
g. patient's dietary habits	Balanced diet, 1-2 cups of coffee/tea per day; social alcohol use
h. patient's sleep habits	No nighttime awakenings
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Occasional use of acetaminophen for morning stiffness
j. allergies	NKA
k. history of other adverse reactions to medications	None
l. other (describe) _____	Lives with husband and children.
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Characteristics of Ms. Ross urine leakage are consistent with overactive bladder with urge incontinence.
3. Identify exclusions for self-treatment.	None. However, Ms. Ross should be encouraged to seek a diagnosis for her UI before relying on incontinence products.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a	Options include: (1) Recommend a trial of Oxytrol for Women. If symptoms do not improve, seek medical referral.

medical provider is required, and share this information with the patient or caregiver.	(2) Refer Ms. Ross to her primary care provider or gynecologist for evaluation of urge incontinence. (3) Recommend a pad or shield for light urine leakage. Reusable incontinence underwear may also be an option for her active lifestyle. (4) Suggest avoidance of frequent use of caffeine. (5) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	See <a href="#">Figure 49-1</a> . Ms. Ross should be offered a trial of Oxytrol for Women. She should be advised to consider using pads, shields, or reusable incontinence underwear, as needed, for light urine leakage. These products would offer more protection than feminine pads. She should be counseled on the benefits of caffeine reduction.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Oxytrol for Women is recommended for the self-care of symptoms of overactive bladder, specifically the sudden and urgent need to urinate. If symptoms persist, a medical referral will be necessary."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Oxytrol for Women has been shown to be a safe and effective treatment for overactive bladder. Medical evaluation may be necessary for persistent symptoms to determine the type of incontinence and the need for a prescription medication or device."
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	"Oxytrol for Women is recommended for the self-care of symptoms of overactive bladder, specifically the sudden and urgent need to urinate."
a. appropriate dose and frequency of administration	"Apply 1 Oxytrol for Women to the skin every 4 days. It is a thin clear patch." See the box Patient Education for Adult Urinary Incontinence and Supplies.
b. maximum number of days the therapy should be employed	"Apply the patch no more than 2 days per week. Select 2 days of the week (e.g., Sunday and Wednesday) and maintain a consistent schedule." See the box Patient Education for Adult Urinary Incontinence and Supplies.
c. product administration procedures	"Remove the patch every 4 days and apply a new patch to a different area. The patch may be applied to the abdomen, hip, or buttock. Contact with water when you are bathing, swimming, showering, or exercising will not change the way Oxytrol works." See the box Patient Education for Adult Urinary Incontinence and Supplies.
d. expected time to onset of relief	"Symptoms may improve within 3-4 weeks but could be seen as early as 2 weeks. Results are generally seen by 12 weeks."
e. degree of relief that can be reasonably expected	"Usage may reduce symptoms by as much as 75%." See the box Patient Education for Adult Urinary Incontinence and Supplies.

f. most common side effects	“The Oxytrol for Women patch may cause skin irritation where the patch was applied, dry mouth, and constipation. Incontinence pads may cause skin irritation, rash, maceration, and breakdown.”
g. side effects that warrant medical intervention should they occur	“If skin irritation is severe, discontinue product use. You should check for skin irritation every 2 hours.” See the box Patient Education for Adult Urinary Incontinence and Supplies.
h. patient options in the event that condition worsens or persists	“If symptoms persist, see your primary care provider or urologist for further follow-up. If urine loss is continual, change absorbent undergarments every 2-4 hours.”
i. product storage requirements	NA
j. specific nondrug measures	See the box Patient Education for Adult Urinary Incontinence and Supplies for behavioral measures to reduce and improve incontinence symptoms.
Solicit follow-up questions from patient or caregiver.	(1) “What if the symptoms don’t improve?” (2) “What if the incontinence product does not provide enough protection?”
Answer patient’s or caregiver’s questions.	(1) “If symptoms do not improve, see your primary care provider. Do not increase the dose or frequency of the patch.” (2) “You may select a product with higher absorbency according to the amount of urine leakage (Table 49-4).”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	“If symptoms do not improve within 2 weeks of using Oxytrol, consult your primary care provider for further evaluation and treatment.”

Key: N/A = Not applicable; NKA = no known allergies.

### Case 49-2

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient’s symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient wants to use an herbal product for “dribbling and inability to empty my bladder.” The medication prescribed for this problem 2 weeks ago does not “seem to be working.” He heard about a product for urinary health during a recent radio broadcast.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient’s	The dribbling occurs throughout the day. He often wakes up 2-3 times per night to urinate. These symptoms often make his work deliveries late.

symptom(s)	
c. description of the patient's efforts to relieve the symptoms	Frequent trips to the bathroom
d. patient's identity	Joe Sample
e. age, sex, height, and weight	55 years old, male, 5 ft 8 in., 220 lb
f. patient's occupation	Floral delivery driver
g. patient's dietary habits	2-3 cups of caffeine-containing beverages per day
h. patient's sleep habits	Frequent nighttime awakenings to urinate
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Benign prostatic hyperplasia: Proscar 5 mg daily; hypertension: currently takes lisinopril 10 mg daily
j. allergies	NKA
k. history of other adverse reactions to medications	None
l. other (describe) _____	Married
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Joe's urine leakage is consistent with symptoms of BPH. He is currently on Proscar (finasteride) and has not had symptom relief because of the short duration of the therapy. However, considering his work situation and the impact of BPH, he should see his PCP or urologist for reevaluation of the therapy and prior to starting any dietary supplement or any other nonprescription treatment.
3. Identify exclusions for self-treatment.	Mr. Sample has been evaluated by a PCP or urologist and is currently receiving therapy for BPH.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Joe for further evaluation for BPH therapy. (2) Counsel Joe about options for prescription drug treatment. Because of his symptoms and job requirements, advise him to ask his PCP about alpha-adrenergic antagonists for faster relief of his symptoms. (3) Counsel on the benefits of avoiding frequent use of caffeine. (4) Recommend a guard for persistent urine leakage. (5) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's	Joe should consult a PCP or other health care provider for further evaluation prior to using any nonprescription medication, prescription

problem, taking into account patient preferences.	medication, or incontinence product.
6. Describe the recommended therapeutic approach to the patient or caregiver.	“Once current therapy has been evaluated and other causes eliminated, alternative prescription drug therapy may be suggested for reducing the symptoms of BPH. An absorbent guard may be appropriate for persistent symptoms.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“Medical evaluation is necessary to assess the effectiveness of your current regimen and determine the need for another drug therapy option.”
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	See the box Patient Education for Adult Urinary Incontinence and Supplies.
b. maximum number of days the therapy should be employed	See the box Patient Education for Adult Urinary Incontinence and Supplies.
c. product administration procedures	See the box Patient Education for Adult Urinary Incontinence and Supplies.
d. expected time to onset of relief	NA
e. degree of relief that can be reasonably expected	See the box Patient Education for Adult Urinary Incontinence and Supplies.
f. most common side effects	“You may experience skin irritation, rash, maceration, and breakdown.”
g. side effects that warrant medical intervention should they occur	“You should check for skin irritation every 2 hours.” See the box Patient Education for Adult Urinary Incontinence and Supplies.
h. patient options in the event that condition worsens or persists	“If urine loss is continual, change absorbent undergarments every 2-4 hours. See your primary care provider or urologist for further follow-up.”
i. product storage requirements	NA
j. specific nondrug measures	See the box Patient Education for Adult Urinary Incontinence and Supplies.
Solicit follow-up questions from patient or caregiver.	“What if the incontinence product does not provide enough protection?”
Answer patient’s or caregiver’s	“You may select another product with higher absorbency according to the

questions.	amount of urine leakage (Table 49-4).”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	Contact the patient in a day or two to ensure that he made an appointment and sought medical care

Key: BPH = Benign prostatic hyperplasia; NA = not applicable; NKA = no known allergies; PCP = primary care provider.

### Patient Counseling for Adult Urinary Incontinence and Supplies

The primary care provider's role in self-treatment of UI includes educating patients about UI; recommending medical evaluation, as appropriate, on the basis of an initial evaluation of signs and symptoms; assisting patients and caregivers in selecting products to reduce the risk of urine leaking to outer garments; and avoiding aggravating factors. Patients should be provided with information to help them understand UI. The box Patient Education for Adult Urinary Incontinence and Supplies lists specific information to provide patients regarding the use of incontinence supplies. An excellent resource for patient education is the Simon Foundation for Continence, PO Box 815, Wilmette, IL 60091; 1-800-23Simon; or [www.simonfoundation.org](http://www.simonfoundation.org).

#### Patient Education for Adult Urinary Incontinence and Supplies

The objectives of self-treatment are to (1) reduce or eliminate symptoms of urinary incontinence (UI), (2) control or treat skin irritation caused by contact with urine, (3) control the odor of urine leaked from the bladder, (4) control leakage of urine to outer garments, and (5) prevent other complications such as falls and social isolation. For most patients, carefully following product instructions and the self-care measures listed here will help to ensure optimal therapeutic outcomes.

- Consult a primary care provider or urologist for a thorough examination before resorting to permanent use of absorbent undergarments or shields. Many cases of UI are reversible with treatment.
- These products are designed to absorb urine; to provide a moisture barrier to protect clothes, bedding, and furniture; and to minimize skin contact with urine.
- Base selection of absorbent products on the amount of leaked urine:
  - Guards/shields: 2-12 ounces (60-360 mL), light-heavy capacity
  - Undergarments: 12-18 ounces (360-540 mL), moderate-heavy capacity
  - Briefs: 28-36 ounces (840-1000 mL), moderate-heavy capacity
- Choose briefs or diapers with roll-on bed application and adhesive closures (for patients who are unable to change themselves).
- If additional protection is needed during sleeping and sitting, select absorbent bed or chair pads to use with absorbent undergarments.
- Check skin for irritation or maceration every 2 hours, even when absorbent garments are used.
- If urine loss is continual, change absorbent undergarments every 2-4 hours, and consult your primary care provider or urologist if UI symptoms worsen.
- If desired, use skin protectants labeled for diaper rash to protect the skin.
- If desired, use products containing chlorophyll, such as Derifil, Pals, and Nullo, to help decrease odor. However, continue frequent skin checks and frequent changes of absorbent undergarments.
- If pressure ulcers (open sores) occur in an immobile patient, the caregiver should not attempt to treat the ulcers with nonprescription products and should instead consult a primary care provider.
- Identify and eliminate foods, liquids, or other substances that can irritate the bladder (e.g., coffee, tea, soda, alcohol, chocolate, acidic juices, tomato-based sauces, spicy food, artificial sweeteners, and nicotine).
- Avoid excessive intake of liquid. Drink enough to produce about a cup of urine every 3-4 waking hours on average. Do not drink large amounts of liquid after 5 pm.
- Avoid products that irritate the urethra and bladder. Use cotton underwear, avoid scented powders or bath products, and use white toilet paper.
- Follow instructions for behavioral therapy and medications for incontinence if prescribed by your primary care provider or urologist.

### Evaluation of Patient Outcomes for Adult Urinary Incontinence and Supplies

At follow-up, the provider should find out whether the pharmacologic therapy is effective and the recommended incontinence product is comfortable and easy to use, and whether leakage from the undergarment or odor is a problem. If leakage is occurring, the absorbency and/or type of product should be reassessed. Patients who have problems with odor may need to use deodorizers. The patient or caregiver should also be asked whether the skin,

especially in the perivaginal and perianal areas, is being checked for breakdown. Redness or skin fissures call for the use of skin protectants. Questioning about occurrence of urinary tract or vaginal infections is also appropriate. Such infections may indicate a need to change undergarments more often or to use another type of incontinence product. These measures will prevent prolonged skin contact with urine. In addition, the provider should monitor the effectiveness of other prescription medications and behavioral therapies for UI. The patient should be asked about side effects associated with the specific medication he or she may be prescribed.

Providers should also evaluate whether the use of incontinence products and other treatments has allowed the patient to resume his or her normal lifestyle and social interactions. If these objectives are not being met after an adequate duration of any pharmacotherapy, the medication dose and type should be reviewed. Alternative absorbent products should also be considered. The patient should be encouraged to seek further advice from his or her primary care provider on treatment options.

### Key Points for Adult Urinary Incontinence and Supplies

- UI is a common treatable condition that is often cured or improved with therapy.
- Because the cause of UI may be multifactorial, the patient should receive a comprehensive medical evaluation before a therapy plan is developed.
- A variety of treatment options are available, including drug therapy, behavioral therapies, devices, incontinence aids, and surgery.
- Incontinence aids are designed to absorb urine; to provide a moisture barrier to protect clothes, bedding, and furniture; and to minimize skin contact with urine.
- The selection of absorbent products is based on the amount of urine leakage.
- Providers can play an important role in educating patients about UI; performing assessment and triage and referring for medical evaluation, if needed; counseling on the selection and appropriate use of prescription and nonprescription incontinence products and the avoidance of aggravating factors; and monitoring patient response.

**Handbook of Nonprescription Drugs** > Chapter 50. Introduction to Dietary Supplements**Introduction to Dietary Supplements: Introduction**

The Food and Drug Administration (FDA) defines *dietary supplements* (DS) as vitamins, minerals, herbs or other botanicals, and amino acids; dietary substances used to supplement the diet by increasing dietary intake or concentrates, metabolites, constituents, and extracts; or any combination of these stated ingredients.<sup>1</sup> Many terms have been used to describe DS, including *nutraceuticals*, *natural products*, *supplements*, *herbs*, *botanicals*, and *phytochemicals*. Dietary supplements are most often grouped into the natural products category of Complementary and Alternative Medicine (CAM), according to the National Institutes of Health (NIH).<sup>2</sup> For the purposes of this chapter, herbs, vitamins, and similar products will be referred to as DS. This designation is also used by FDA as it relates to the intended use, namely for oral use only and for supplementing the diet. Indeed, DS are used by consumers not only to supplement the diet but also to maintain health and wellness. Some consumers also use DS to treat symptoms of medical conditions, despite FDA legislation that prohibits DS manufacturers from marketing products for this purpose unless the DS have undergone extensive review and been preapproved by FDA for a specified health claim.

**Use of Dietary Supplements**

## Prevalence and Indications for Use

The 2007 National Health Interview Survey (NHIS) surveyed more than 30,000 U.S. citizens; survey results showed that about 18% of adults older than 18 years and 4% of children had used at least one non-vitamin, non-mineral natural product in the previous 12 months.<sup>3</sup> Importantly, this type of product was the most common form of CAM being used when vitamin and mineral products, the top-selling DS class, were excluded. A 2013 consumer survey of approximately 2000 adults conducted by the Council for Responsible Nutrition estimates that DS use in adults is closer to 68%, with 77% of supplement users taking a multivitamin product. The 2007 NHIS survey reported that use of a multivitamin/mineral product in children is 31%.<sup>4,5</sup> The inclusion of vitamin and mineral products accounts for these higher use estimates.

The 2007-2010 National Health and Nutrition Examination Survey (NHANES) examined motivations for adults to use DS.<sup>6</sup> The primary reasons cited were to improve overall health (45%), maintain health (33%), and promote bone health (25%). Among adults ages 60 years and older, DS were used for site-specific conditions involving the bones, heart, and joints, whereas younger adults, ages 20-39, used DS for energy and immunity. Gender differences also existed: women were frequent users of calcium for bone health, whereas men used DS for heart health and lowering of cholesterol levels.

The 2007 NHIS cited primary indications for CAM use in children, in order of prevalence, as pain, head or chest cold, anxiety or stress, musculoskeletal disorders, and attention-deficit/hyperactivity disorder.<sup>3</sup> When DS were considered as a separate CAM modality, indications of use were less specific and involved diverse health conditions.<sup>5</sup>

## Top-Selling Dietary Supplements

In 2011, Americans spent an average of \$30 billion on DS.<sup>7</sup> Vitamins accounted for 34% of this market, closely followed by specialty products (e.g., products formulated for a specific organ or body function) at 19%, herbs and botanicals at 17%, sports and nutrition products at 12%, meal replacement products at 10%, and minerals at 8%.<sup>7</sup> Although DS sales may be rising, the use of particular DS may be on the decline. Among all DS, multivitamins are the top-selling supplements, primarily because they are used across all life stages. Vitamin D is a market leader, with an increase in sales from \$42 million in 2002 to \$605 million in 2011.<sup>8</sup> Studies correlating low vitamin D levels and poor health outcomes specific to immunity bone and joint health, and heart health are likely to impact sales. Reports of top DS sales differ according to the purchase location.<sup>7</sup> Sales data, however, may differ from actual consumer use data reported in the 2007 NHIS and the 2007-2010 NHANES study. The most commonly used non-vitamin, non-mineral DS among adults in the 30 days prior to completion of the NHIS survey were fish oil, omega-3 fatty acids or docosahexaenoic acid (37%), glucosamine (20%), echinacea (20%), flaxseed (16%), and ginseng (14%).<sup>3</sup> The NHANES study included vitamins and minerals and cited multivitamin/mineral products as the most frequently used DS, followed by calcium and omega-3 or fish oil supplements.<sup>6</sup>

## Attitudes and Predictors of Use

Many studies have measured predictors of CAM use and, more specifically, use of natural products such as DS.<sup>3,6</sup> For most American adults, common predictors for DS use include being a female, ages 50-69 years; having a college education or higher; living in the Western United States (i.e., West North Central, Mountain, and Pacific states); and having a current self-rated health status of very good to excellent.<sup>3,6</sup> Having a higher socioeconomic status, defined as not poor or near poor, and having private health insurance are also predictors of high DS use; individuals who were poor, lacked health insurance, or had public health insurance reported low use of DS.<sup>3</sup> Users of DS are also more likely to have a higher number of physician visits and a greater number of health conditions.<sup>3</sup>

Among children, use of non-vitamin, non-mineral natural products was twice as likely to be reported if the parent also used a CAM modality (9% vs. 4%).<sup>3</sup> When vitamins and minerals were included, predictors of use in children included being from a family with a higher level of parental education, being from a family with private health insurance, living in the western United States, and being of White or Asian ethnicity.<sup>5</sup> DS use was more common in children who have a higher disease burden and ill health than in healthier children.<sup>5</sup>

Older adults, ages 61-69 years, are frequent DS users, according to the NHIS survey. They are more likely to have chronic conditions and to use concomitant prescription medications. Individuals who cited general wellness as their rationale for use were 16 times more likely to consume DS. Other factors that appear to be highly predictive of DS use include having an attitude that the DS will work and having a history of receiving health care from CAM providers.<sup>9</sup> The findings suggest that the most important predictor of use is preservation of health, regardless of an individual's assessment of his or her own health status, medical history, or use of concomitant medications.<sup>9</sup>

Television was the most commonly reported source of DS information (73%), followed by magazines and radio (both 30%), newspapers (13%), friends (8%), and store displays (5%).<sup>9</sup> Consistent across several surveys, users of DS tend not to report this use to their health care providers; this nondisclosure is estimated to be as high as 72%.<sup>3</sup> This tendency is especially concerning among older adults in whom concomitant use of

prescription drugs and DS is estimated to be between 49% and 74%, raising the risk of potential interactions.<sup>10</sup> These data confirm the importance of obtaining a complete medication history, at all patient encounters, that includes use of DS and prescription and nonprescription drugs. The nondisclosure rate is reported to increase if the provider seems disinterested, appears judgmental of CAM use, or appears to lack sufficient knowledgeable about these therapies. Consumers may also feel that CAM therapies are not relevant to medical care and that the coordination of care is a personal choice.

### Legislation and Regulatory Issues

FDA regulates both finished (ready to be sold) DS products and individual dietary ingredients that are used to make a DS product. Importantly, FDA regulates DS under a different set of regulations than those covering conventional foods and medications.

#### Dietary Supplement Health and Education Act

In 1994, the Dietary Supplement Health and Education Act (DSHEA) was approved by Congress and signed into law.<sup>1</sup> This act allowed FDA to regulate DS under the purview of the Center for Food Safety and Applied Nutrition (CFSAN). As a result, DS were excluded from the strict purity and potency standards that are applied to prescription and nonprescription drugs by the Center for Drug Evaluation Research. DS had to meet only the standards that applied to food preparation. Any additional standards regarding purity and potency were the sole responsibility of the manufacturer. The lack of strict good manufacturing practice (GMP) standards created problems with DS content, purity, potency, consistency, and actual identity, as well as contamination, herb misidentification, and sub- and supratherapeutic effects. The lack of strict standards and limited oversight of the manufacturing process created a buyer beware market, placing the consumer at risk and often alienating conventional health care providers to the use of CAM therapies, and also led to the misconception that DS are not regulated by FDA.

Another major difference between DS and prescription and nonprescription drugs is the level of evidence required to demonstrate safety and efficacy. For prescription and nonprescription drugs, clinical trials are required to demonstrate evidence of a drug's safety and efficacy prior to its marketing. Although DS manufacturers are prohibited from marketing unsafe or ineffective products, clinical trials are not generally required to prove the safety and efficacy of DS products prior to their marketing; however, some exceptions exist (e.g., new DS ingredients or DS with health and nutrient content claims). The DS manufacturer is responsible for the product's safety and efficacy; however, FDA assumes a post-marketing surveillance role and must prove that a DS is not safe in order to restrict its use or remove it from the market.

#### New DS Ingredients

DS ingredients that were sold in the United States prior to October 15, 1994, are not required to be reviewed for safety by FDA before being marketed; they are assumed to be safe based on a history of use in humans. For any new DS ingredient (i.e., an ingredient that was not on the market prior to October, 15, 1994), a manufacturer must notify FDA 75 days in advance of its intent to market the product and also provide FDA with evidence that the DS is safe in humans when used as directed.<sup>1</sup> Unfortunately, a comprehensive list of DS ingredients that were sold prior to this date is not available. As a result, the decision whether a product contains a new ingredient is left up to the manufacturer. Since DSHEA was approved by the U.S. Congress, nearly 55,000 DS have come on the market, yet FDA has received only 700 premarket notifications during this period.<sup>11</sup> This stark disparity between newly marketed DS and premarket notifications led to the creation of a guidance document for industry regarding new dietary ingredients. In 2011, FDA issued comprehensive guidance that outlines specific recommendations that must be submitted in new dietary ingredient notifications. The guidance document outlines the specific materials that should be submitted to FDA and makes recommendations for the types of safety evidence that should be submitted for new DS ingredients taken short term, long term, or intermittently. Submission of available information on genotoxicity, teratogenicity, mutagenicity, and toxicology for a dietary ingredient is also recommended.<sup>11</sup>

#### Good Manufacturing Practice

Enactment of DSHEA required establishment of GMP standards for the DS industry. In 2007, FDA issued a final rule on proposed changes to GMP standards for DS.<sup>12</sup> Among the changes, DS must be manufactured in a quality manner without adulterants or impurities, and they must be labeled accurately. These changes have helped to better regulate manufacturing practices, especially with regard to setting limits on the presence of bacteria, pesticides, and heavy metals. DS manufacturers are required to meet GMP standards as outlined in DSHEA. Most achieve this requirement through their manufacturing and production processes. Some manufacturers take extra steps to have their DS products tested by external quality assurance programs so their product can carry a seal of approval verifying compliance with GMP standards. These programs are discussed in the section Quality Assurance Programs.

#### Labeling

FDA has primary responsibility for regulating claims found on packaging, package labeling, inserts, and other promotional materials that are distributed at the point of sale. The Federal Trade Commission (FTC) has primary responsibility for advertising claims made through print and broadcast advertisements, infomercials, catalogs, and other direct marketing materials.<sup>13</sup> FTC requires DS claims of safety and efficacy to be supported by "competent and reliable scientific evidence." This evidence is defined as "tests, analyses, research, studies or other evidence based on the expertise of professionals in the relevant area that have been conducted and evaluated in an objective manner by qualified individuals, using procedures generally accepted to yield accurate and reliable results." Complaints against DS advertising may be filed with FTC online.

All DS marketed in the United States must meet supplement labeling requirements.<sup>1</sup> The labels must list (1) the name of the product as well as the word *supplement*; (2) the net quantity of contents; (3) the manufacturer's, packer's, or distributor's name and place of business; and (4) directions for use. In addition, each label must also contain a supplement facts panel that describes the serving size, the list of dietary ingredients, amount per serving size, and the percent daily value, if one is established. (See [Figure 50-1](#) for the Council for Responsible Nutrition's sample label. The label is also available at [www.cmusa.org/pdfs/CRN\\_How\\_to\\_read\\_a\\_ds\\_label.pdf](http://www.cmusa.org/pdfs/CRN_How_to_read_a_ds_label.pdf).) Plant-based DS should indicate the plant's scientific name, or Latin binomial (i.e., genus and species) and the specific plant part used. Manufacturers may market a combination of DS ingredients as a proprietary blend. Although the individual ingredients in the proprietary blend are listed, the actual quantity of each ingredient is not disclosed. Under DSHEA, the total weight of the blend and the components of the blend, in order of predominance by weight, are required. Fillers, artificial colors, sweeteners, flavors, or binders should also be listed in descending order of predominance. Consistent with the trend in formulating proprietary blends, many multivitamin products are being combined with DS.

## How do you read a supplement label?

Serving size is the manufacturer's suggested serving expressed in the appropriate unit (tablet, capsule, softgel, packet, teaspoonful).

Amount Per Serving heads the listing of nutrients contained in the supplement, followed by the quantity present in each serving.

International Unit (IU) is a standard unit of measure for fat soluble vitamins (A, D and E).

Milligram (mg) and microgram (mcg) are units of measurement for water soluble vitamins (C and B complex) and minerals. A milligram is equal to .001 grams. A microgram is equal to .001 milligrams.

The list of all ingredients includes nutrients and other ingredients used to formulate the supplement, in decreasing order by weight.

All supplements should be stored in a cool, dry place in their original containers, out of the reach of children and should be used before the expiration date to assure full potency.

### Supplement Facts

**Serving Size 1 tablet**  
Suggested Use: Adults, take one tablet per day with meal

Amount Per Serving	% Daily Value
Vitamin A 5000 I.U. 50% as Beta Carotene	100%
Vitamin C 250 mg	417%
Vitamin D 400 I.U.	100%
Vitamin E 200 I.U.	667%
Vitamin K 80 mcg	100%
Thiamin 5 mg	333%
Riboflavin 5 mg	294%
Niacin 20 mg	100%
Vitamin B <sub>6</sub> 5 mg	250%
Folic acid 400 mcg	100%
Vitamin B <sub>12</sub> 6 mcg	100%
Biotin 150 mcg	50%
Pantothenic Acid 10 mg	100%
Calcium 200 mg	20%
Iron 18 mg	100%
Phosphorus 200 mg	20%
Iodine 150 mcg	100%
Selenium 35 mcg	50%
Magnesium 200 mg	50%
Zinc 15 mg	100%
Copper 2 mg	100%
Boron 150 mcg	*

\* Daily Value not established

Ingredients: vitamin A acetate, beta carotene, vitamin D, di-alpha tocopherol acetate, ascorbic acid, thiamin monophosphate, riboflavin, niacinamide, pyridoxine hydrochloride, vitamin B12, biotin, d-calcium pantothenate, potassium chloride, dicalcium phosphate, potassium iodine, ferrous fumarate, magnesium oxide, copper sulfate, zinc oxide, manganese sulfate, sodium selenate, chromium chloride, sodium molybdate, microcrystalline cellulose, calcium carbonate, sodium carboxymethyl cellulose

**Storage:** Keep tightly closed in dry place; do not expose to excessive heat

**KEEP OUT OF REACH OF CHILDREN**  
Expiration date: JUN 2016  
Company V, Cityville, New York 01010

Percent Daily Value (DV) tells what percentage of the recommended daily intake for each nutrient for adults and children ages 4 and up is provided by the supplement.

An asterisk under the "Percent Daily Value" heading indicates that a Daily Value is not established for that nutrient.

The manufacturer's or distributor's name and place of business or phone number are required to appear on the label.

Statutory labeling format for certain dietary supplements. (Source: Food and Drug Administration. Anatomy of the New Requirements for Dietary Supplement Labels. Accessed at [http://www.preventivehealthtoday.com/fda/fdac/fdac\\_9811\\_fdsuppla.pdf](http://www.preventivehealthtoday.com/fda/fdac/fdac_9811_fdsuppla.pdf), May, 18, 2011)

When a DS does not follow labeling requirements, the product is considered misbranded.<sup>1</sup> DS manufacturers are not allowed to make claims that their product will diagnose, cure, mitigate, treat, or prevent disease.<sup>1</sup> These claims would require the product to adhere to the regulations related to a drug, and the product would be subject to all the regulatory processes necessary to demonstrate safety and efficacy. Other examples of misbranding include DS that do not conform to labeling requirements; fail to contain the name or place of business of the manufacturer, packer, or distributor; or fail to include accurate statements regarding the quantity of the contents.

The claims for all DS products fall under one of three types: (1) health claim, (2) nutrient content claim, or (3) structure-function claim.<sup>14</sup> Health claims and nutrient content claims require FDA approval, whereas structure-function claims do not. A manufacturer must notify FDA of the exact wording of any structure-function claim within 30 days after the product is marketed. Product labels that contain these claims must also carry a disclaimer: "This statement has not been evaluated by the FDA. This product is not intended to diagnose, treat, cure or prevent disease." Health claims describe the relationship between a food, food component, or DS ingredient and the resulting reduction in risk of a disease or health-related condition. Claiming that a diet low in saturated fat and cholesterol that includes 25 grams of soy protein daily may reduce the risk of heart disease is an example of an approved health claim. Nutrient content claims describe the relative amount of a nutrient or dietary substance in a product. For example, "very low sodium" means the product is required to have 35 mg or less of sodium per reference amount. Finally, a structure-function claim describes how a product may maintain the normal healthy structure or function of the body without discussing a specific disease state. A supplement manufacturer may claim that the product "supports healthy cholesterol levels" but is prohibited from indicating that the supplement may "reduce high cholesterol levels."

### Dietary Supplement and Nonprescription Drug Consumer Protection Act

One of the most important changes to the supplement industry involves the Dietary Supplement and Nonprescription Drug Consumer Protection Act (Public Law 109-462), which was signed into law on December 22, 2006.<sup>15</sup> This law requires manufacturers, packers, or distributors of DS to submit to FDA reports of serious adverse events that are based on specific information received from the public. Serious adverse events are defined as death, a life-threatening situation, a hospitalization, a persistent or significant disability or incapacity, a congenital anomaly or birth defect, or an adverse event that, based on reasonable medical judgment, requires medical or surgical intervention to prevent such serious outcomes. Increased reporting of adverse events may better characterize the frequency and type of serious adverse events associated with DS. FDA actively evaluates trends in serious adverse events so that appropriate corrective action may be taken. Consumers and health care providers are also encouraged to report DS-related adverse events through FDA's MedWatch adverse event reporting program ([www.fda.gov/medwatch](http://www.fda.gov/medwatch)).<sup>16</sup>

### Production Issues

Plant Species and Parts

A health care provider should explain that herbal products typically carry two names, the common name and the Latin binomial. An example would be a product such as St. John's wort (common name), which is also known as *Hypericum perforatum* (Latin genus and species name). Some product labels may list only the Latin name, which can be confusing to a consumer who is unfamiliar with this terminology. When consumers enter a pharmacy and search for an echinacea product, they may encounter single-ingredient products that contain *Echinacea pallida*, *Echinacea purpurea*, or *Echinacea angustifolia*; products that contain a mixture of two or all of these species; and products that contain echinacea as one of many listed supplement ingredients. In the case of echinacea, single-ingredient products involving the above-ground parts of *E. purpurea*, formulated as an alcohol extract of the fresh pressed juice, have been the most widely studied. According to one meta-analysis, the above-ground parts of *E. purpurea* demonstrate some evidence of efficacy, albeit weak, in reducing cold symptoms in adults when administered at the first sign of symptoms.<sup>17</sup> The other two species of echinacea and combinations involving these species, with or without *E. purpurea*, have not demonstrated consistent benefits in clinical trials for treating colds.<sup>17</sup>

#### Common Product Formulations

The content of any DS is based on the raw starting material and how the material is subsequently processed or formulated. Plant-based DS (e.g., echinacea and ginseng) have greater variability in product composition than single-ingredient nonbotanical DS (e.g., creatine or melatonin). This variability is due to the chemical composition of botanical DS, which is influenced by the plant's growing conditions, the plant species, the specific plant part used, and the time of harvest.

Knowing which plant species is preferred or which part of the plant to use can be based on historical precedent when clinical trial data are lacking. In developing countries, plant-based medicine is common, and information regarding preferred plant species, preferred plant part, and proper use is handed down from generation to generation, setting a historical precedent for use. An estimated 25% of modern drugs are plant derived, and 50% are derived from natural products (e.g., plants, animals, microbes, and their derivatives).<sup>18</sup> In developing countries, such as those in Africa, the use of plants as drugs is as high as 80%.<sup>18</sup> Use of herbs based on historical precedent is also common in the practice of midwifery. Few clinical trials exist on the use of DS in pregnant women, lactating women, and children. The decision to use DS based on historical precedent is something providers must discuss with their patients.

#### Method of Preparation

The method in which a DS is manufactured will ultimately affect its final chemical composition and potential efficacy. Some formulations may be well studied, whereas others may not have been studied at all. The most common herbal formulations that a consumer will encounter are made either directly from the fresh plant (e.g., expressed juice, tincture, or tea) or from the dried plant (e.g., fluid extract/tincture, evaporated extract [capsules, tablets], or tea).<sup>19</sup> Tinctures are most commonly prepared by combining chopped herbs with alcohol. This type of formulation should be avoided in persons taking sedating medications or medications that carry disulfiram reaction warnings. Tinctures should also be used cautiously in special populations such as infants, children, and the elderly. Most of the common non-plant-based DS, such as vitamins, minerals, glucosamine, creatine, coenzyme Q10, melatonin, and S-adenosyl-methionine, are manufactured as tablets or capsules; these DS represent compounds that are structurally similar to or identical to compounds naturally found in the human body.

Freshly pressed juice formulations are prepared by pressing the herb and collecting the liquid that is removed.<sup>19</sup> This type of preparation often takes a large amount of the herb to create a substantial portion of juice. In the case of *E. purpurea*, the best-studied formulation is an alcohol extract of the expressed freshly pressed juice.<sup>17</sup> A potential advantage of the alcohol extract is that the presence of alcohol increases the product's shelf life.

Tea formulations can be prepared from the root, leaf, bark, and/or fruit of a plant. Most often they are prepared as an *infusion* by pouring boiling water over the fresh or dried leaf portions of one or more plant species and then letting the herb steep for a small amount of time.<sup>19</sup> This process releases the water-soluble constituents into the tea. The potency is determined by the steeping time and the amount of herb used. The term *decoction* may be used when the plant parts are placed in cold water, brought to a boil, and then simmered for a period of time.<sup>19</sup> Common single-herb tea formulations include chamomile, ginger, peppermint, green tea, and black tea. Multi-ingredient blends that are customized to a specific person's ailment are commonly used in traditional Chinese medicine and may also be administered as teas.

Extracts are intended to concentrate the effects of an herb and can be prepared by soaking fresh or dried plant parts in alcohol, water, alcohol/water mixtures, or oil.<sup>19</sup> The extraction liquid is then reserved and the plant material discarded. Tinctures are fluid extracts in which alcohol is typically used as the extraction medium.<sup>19</sup> Chemicals that seep into the extraction liquid are specific to the solution used. If the extracted liquid is evaporated and dried, it can be formulated into pills or capsules.<sup>19</sup> Extracts and tinctures may list the extraction ratio on the package label. For example, a 5:1 ratio would indicate that 5 parts of herb were used to prepare 1 part of the extract. *Ginkgo biloba* is prepared as a dried extract in tablet form. Ginkgo is typically standardized to a 50:1 extract ratio, meaning that 50 parts of the ginkgo leaf were used to prepare 1 part of the extract.<sup>19</sup> Garlic is available in multiple formulations, the most popular being a dried powdered extract in tablet or capsule form and an aged garlic extract. The chemical composition of the powdered extract will differ from that of the aged extract because of the differences in method of preparation. This variance in composition, in turn, may influence the efficacy of each product.

#### Standardization

The process of standardization is reserved primarily for plant-based DS because herbs contain many active and inactive constituents. For specific DS, standardization involves identifying specific chemicals or "markers" that may possess therapeutic activity, isolating them, and then formulating them into a final and consistent product. Standardization can occur only if the chemical markers that contribute to the pharmacologic effect have been identified. For example, a *Ginkgo biloba* product may be standardized to contain 6% terpene lactones and 24% flavonoid glycosides, whereas a chastetree berry product may not list any standardized markers at all. The identified active chemical markers may change over time as new research is performed. For example, the active antidepressant marker for St. John's wort was initially thought to be hypericin but is now considered to be hyperforin. Bottles of St. John's wort may list one or both of these standardizations on the package label. Interestingly, no legal or regulatory definition is accepted as it relates to standardization of DS. Claiming that a product is standardized does not necessarily mean a uniform manufacturing process was used. DS verification programs, however, may be helpful in determining compliance with package labeling and actual product composition.

#### Common Quality Control Issue: Adulteration

According to DSHEA, adulteration of a DS occurs when (1) the DS presents a significant or unreasonable risk of illness or injury when used in accordance with the suggested labeling, (2) the DS is a new entity and lacks adequate evidence to ensure its safety of use, (3) the DS has been declared an imminent hazard by the Secretary of the Department of Health and Human Services, or (4) the DS contains a dietary ingredient that is present in sufficient quantity to render the product poisonous or deleterious to human health, as described for adulterated foods in the Food, Drug,

and Cosmetic Act.<sup>1</sup> Adulteration of DS has occurred both intentionally and unintentionally. Examples of unintentional adulterants include heavy metals introduced at the time of cultivation or during the manufacturing process.<sup>20</sup> Heavy metals from environmental pollution can leach from contaminated soil into a plant as the plant grows.<sup>21</sup> In an analysis of 230 Ayurvedic medicines purchased over the Internet, 21% of the Indian-manufactured medicines and 22% of the U.S.-manufactured medicines contained lead, mercury, or arsenic.<sup>20</sup> Heavy metals may also be added to traditional medicine products with the intent of promoting good health. In traditional *rasa shastra* Ayurvedic medicine, addition of heavy metals is standard practice.<sup>21</sup> In this instance, the presence of heavy metals would not be considered adulteration because they were added intentionally and with the intent of promoting good health. However, this practice could still lead to heavy metal contamination of the product user if the content exceeds recommended levels for heavy metal exposure set by state or national health standards.<sup>21</sup> Intentional adulteration can occur when a manufacturer substitutes a different DS for an ingredient that is in short supply or is too expensive (e.g., economic adulteration). It can also occur when a prescription drug is added to the product to enhance its efficacy. A survey of FDA Class I drug recalls performed between 2004 and 2012 found that 50% of all drug recalls involved DS products.<sup>22</sup> A Class I drug recall involves products containing a drug compound that is likely to result in serious health consequences or death.<sup>22</sup> These recalls most commonly involved products manufactured in the United States and marketed for sexual enhancement, body building, and weight loss. In addition, traditional Chinese medicines have frequently been found to contain heavy metals and undeclared drugs.<sup>23</sup> Violations of GMP standards have been documented for nearly half of the DS manufacturing firms inspected by FDA.<sup>22</sup> The agency is addressing this issue by issuing targeted marketing about adulterated supplements to both consumers and health care providers and by creating multinational enforcement groups who target suppliers of commonly adulterated supplements.<sup>22</sup>

### Quality Assurance Programs

Several organizations have developed quality assurance programs to assess analytical reference standards and to certify DS composition. These programs indicate whether the DS product contents match the label contents; unfortunately DS safety or efficacy cannot be ensured. These programs also do not address product quality between different batches or lots because only a single batch is tested at any one time. Most quality assurance programs offer a “voluntary verification program” to manufacturers who pay to have their products tested. Products that pass are then allowed to carry a verification seal on the product label.

#### United States Pharmacopoeia Dietary Supplement Verification Program

In 2002, the U.S. Pharmacopoeia (USP) initiated a voluntary Dietary Supplement Verification Program.<sup>24</sup> The purpose of the program is to provide consumers with a method for identifying DS that have passed rigorous standards for purity, accuracy of ingredient labeling, and GMP. Products earning USP certification carry a distinctive seal of approval on the product label. These products are certified to contain the listed ingredients in the indicated amounts, to be bioavailable and free of contaminants, and to have been manufactured under appropriate conditions. As of 2013, a total of 13 DS manufacturers are regular program participants. The USP will periodically conduct audits of certified products to ensure continuing adherence to quality standards. Approved products can be found at the USP Web site ([www.usp.org/USPVerified/dietarySupplements](http://www.usp.org/USPVerified/dietarySupplements)).

#### Consumerlab.Com

ConsumerLab.com, LLC (CL) is an independent company that tests products related to health, wellness, and nutrition, such as DS.<sup>25</sup> Products are tested on the basis of identity, purity, and consistency with the labeled ingredients. The test results are posted at [www.consumerlab.com/aboutcl.asp](http://www.consumerlab.com/aboutcl.asp), with new results available every 4-6 weeks. Manufacturers are allowed to license the CL seal of approval for a product that passes the review. To continue to carry the approval seal, a product must pass random sample testing every 12 months. The site provides free access to some names of a few products in each category that have passed testing, whereas names of products that fail testing are available only to subscribers. A yearly subscription currently costs \$30. The company is not affiliated with manufacturers of any DS, health, or nutrition products.

#### National Sanitation Foundation International

National Sanitation Foundation (NSF) was established over 66 years ago to standardize sanitation and food safety requirements. Today, NSF International ([www.nsf.org](http://www.nsf.org)) is an independent, nonprofit organization that provides certifications of DS and food and water quality.<sup>26</sup> This organization verifies that the DS product contains the labeled ingredients and that contaminants and unlisted ingredients are not present. Any DS product that meets certification standards is allowed to carry the NSF certification seal of approval on the label. NSF is unique in that it works with professional sports teams to do testing on athletic enhancement supplements.

### Hazards from Dietary Supplements

#### False Advertising/Quackery

Manufacturers who make DS health claims sometimes ignore the regulations established by FDA and FTC and market products using false or misleading claims. FTC requires all advertising to be truthful, not misleading, and based on sound scientific evidence. The weight-loss DS market is one example in which false or misleading health claims are commonly identified.<sup>27</sup> Historically, this type of practice might be considered “quackery,” which implies that the person promoting use of the product knows it to be ineffective and is still promoting its use. In the case of some DS, manufacturers may believe, with or without strong clinical support, that their products are effective for a wide variety of ailments. Consumers and providers should be wary of information found on online sites that market DS products. Compared with non-retail online sites, some retail sites have been shown to be unreliable and may list disease claims, may fail to cite the standard disclaimer, and may lack referenced information.<sup>28</sup>

Consumers should be wary of products that contain any of the characteristics listed in [Table 50-1](#).<sup>27,29</sup> In addition, consumers should consult a reliable drug information resource, as well as their health care provider, to confirm whether the health claims have a scientific basis. Consumers and providers can go to the NIH Office of Dietary Supplements site and sign up to receive FDA and FTC press releases for products that have been identified as containing adulterants (e.g., prescription drugs) or for manufacturers that have been issued warnings or recalls for product quality.<sup>27</sup> This online site also has tips on how to evaluate health information on the Internet.<sup>27</sup> FDA has also created supplement categories that should be viewed with scrutiny because of a history of prior violations or problems.<sup>29</sup> These supplement categories are listed in [Table 50-2](#). A consumer or provider who wishes to file a complaint related to false advertising should contact FTC.<sup>13</sup>

#### TABLE 50-1 Characteristics of Supplements Making Fraudulent or Misleading Claims

- List specific disease states or allude to the product's use for a disease usually treated with prescription drug therapy.
- State that supplement's efficacy is similar to, or supplement can be used as an alternative to, a prescription or nonprescription drug.
- List a wide variety of unrelated clinical conditions for use.
- State only benefits and no harmful effects.
- Neglect to provide expiration date, lot number, and contact information for the manufacturer on the package label.
- Use pseudo-medical terminology such as *detoxify*, *purify*, or *improves body chemistry*.
- Use terms such as *miraculous discovery*, *revolutionary therapy*, or *breakthrough treatment*, which suggest that the product has superior efficacy to standard care.
- Suggest that the product is more expensive because it works so well.
- Use personal testimonials in place of sound scientific evidence to support product claims.
- Promise quick relief of a health condition.
- Promote natural content as being superior to conventional medicine.
- Provide a money back guarantee or satisfaction guarantee but marketers of fraudulent products often relocate their business location.
- Make accusations that pharmaceutical drug manufacturers and health care providers are working together to defraud consumers and steer consumers away from healthier DS options.

**TABLE 50-2 Categories of Supplements That FDA Considers "Clearly Problematic"**

- Treatments for life-threatening diseases (e.g., HIV or cancer) or serious medical conditions (e.g., diabetes, Alzheimer's disease)
- Weight-loss products
- Chelation products
- Treatments for behavioral disorders (e.g., attention-deficit/hyperactivity disorder) or autism
- Treatments for mental retardation or Down syndrome
- Colloidal minerals and silver products
- Supplements for addiction (e.g., smoking, drinking)
- Supplements for body builders
- Supplements for sexual enhancement (e.g., impotence)

Key: FDA = Food and Drug Administration; HIV = human immunodeficiency virus.

### Hazards Introduced by the Consumer

Exceeding the recommended dietary allowance for a vitamin or mineral supplement or taking more of a supplement than is directed on the label can occur intentionally or accidentally. Accidental over-supplementation is more likely to occur when a consumer is taking more than one multi-ingredient product containing similar ingredients. Regardless of how it occurs, over-supplementation should be discouraged because an adverse event may result. Overuse of some DS has serious consequences. For example, overuse of colloidal silver has led to irreversible blue-gray skin discoloration.<sup>30</sup> Overuse of calcium or vitamin D supplements over short periods may cause hypercalcemia. In addition, concern exists that excessive calcium supplementation over long periods of time may contribute to coronary artery calcification.<sup>31</sup> As mentioned previously, adverse events should be reported by consumers and health care professionals to MedWatch.<sup>16</sup> For most DS, individual case reports and postmarketing surveillance provide the best means of identifying adverse events and drug interactions. Consumers should be advised to monitor for acute adverse events for up to 2 weeks after initiating a new DS and to continue the monitoring while using the product.

### Product Hazards: Adverse Effects and Drug Interactions

The fact that herbal DS are derived from a natural source does not guarantee safety. Some plants such as poison oak or ivy were never meant to be ingested. Adverse effects are often linked to the pharmacology of the supplement, as was noted when products containing ephedra were removed from the market because of their association with stroke and myocardial infarction.<sup>32</sup> Other DS may be harmful because they contain chemicals that are toxic when ingested. Pyrrolizidine alkaloids present in comfrey, borage, and life root have been associated with case reports of hepatotoxicity.<sup>33</sup> If an adverse event is suspected, product testing is essential to rule out possible plant misidentification; adulteration with prescription or nonprescription drugs; or contamination with heavy metals, microbial contaminants, and pesticides that can occur during production.<sup>34</sup>

Interactions between DS and conventional medications may have a pharmacodynamic or pharmacokinetic basis. Pharmacodynamic interactions can occur when a supplement's pharmacology is similar to or opposite that of a drug the consumer is taking. For example, both St. John's wort and L-tryptophan have been linked to case reports of serotonin syndrome in persons taking these products with prescription psychotropic drugs.<sup>35,36</sup> Additive effects have occurred, or could theoretically occur, in persons combining central nervous system depressants with DS that have sedative properties (e.g., melatonin or valerian) or in persons combining drugs that have antiplatelet or anticoagulant activity with DS that have antiplatelet properties (e.g., fish oil, flaxseed oil, garlic, ginseng, ginkgo, and ginger).<sup>37</sup> Case reports of a DS opposing the effect of a drug or adversely influencing an existing disease state have been reported infrequently in the literature. Theoretical concerns are cited as a reason to avoid DS that enhance immune system activity (e.g., echinacea) in persons who have autoimmune disorders or require immunosuppressants.<sup>38</sup> Finally, DS may have pharmacokinetic interactions. St. John's wort induces multiple cytochrome P450 isoenzymes, as well as the p-glycoprotein drug transporter system.<sup>37</sup> This herb has been reported to induce metabolism of drugs, including oral contraceptives, indinavir, and cyclosporine, thereby lowering drug levels and overall drug efficacy.

### Communication Issues

#### Counseling on Dietary Supplements

The primary consideration in counseling consumers on DS is to recognize the importance of respecting the person's beliefs and values so that a trusting, nonjudgmental relationship can develop. The person must feel comfortable telling the provider about any use of DS. Providers should ask about all therapies being used, including DS, because consumers may not routinely disclose this information. Providers must also be able to provide recommendations regarding DS, when information is available. The risk of adverse effects versus the potential for positive effects must be considered and clearly explained. As an example, if a consumer wishes to take a DS that has *demonstrated both positive and negative outcomes in clinical trials but lacks* documented side effects or drug interactions, a provider may support DS use with the caveat that it may or may not be of benefit. The consumer should be advised to monitor for perceived benefit and side effects. If no benefits are observed within the time frame expected for the DS's onset of action, the DS should be discontinued. Providers should be less inclined to support use of a DS whose efficacy is

not supported by EBM and should discourage the use of unsafe products and practices. Importantly, providers do not control access to DS, and consumers may choose to use any available DS. In many instances, providers may be in the position of educating a consumer about DS even though they believe that the product should not be used. In these situations, counseling on expectations and adverse events is essential. For example, educating consumers on the early signs of a serious adverse effect will enable them to recognize a problem and discontinue the DS to minimize harm. Consumers should always be advised to seek medical care for serious conditions.

Consumers should read labels carefully and ask questions. Providers should be aware of the potential for confusion related to DS labels and claims, and counsel consumers in a way that lessens confusion. *Thymus* is an example of a term that might be dangerous if misunderstood.

*Thymus vulgaris* is the Latin name for garden thyme. On a supplement label, "*Thymus extract*" may refer to an extract of the herbs thyme, Spanish thyme, or wild thyme, products with relatively few adverse events when used in small doses. However, "thymus extract" may refer to a preparation made from animal thymus gland that is marketed to enhance immune function, a product with considerable quality and safety concerns.

In addition to these broad counseling issues, the following points should be emphasized. First, providers should emphasize that most self-care with DS should be for a limited period. If a problem persists, the consumer should seek medical care. Second, consumers should inform their provider before taking DS for a condition that is also being treated with a prescription drug. Third, consumers should be informed that FDA does not require DS manufacturers to submit data demonstrating efficacy or safety before the product is marketed, unless the product contains a new dietary ingredient (i.e., an ingredient that was not on the market prior to October, 15, 1994). Quality and consistency of DS products remain a concern but may improve with the new GMP standards. The following points should be used in counseling consumers who wish to use a DS:

- Purchase products that have either a seal of quality on the label, acquired through a program such as United States Pharmacopeia's Dietary Supplement Verification Program or NSF International's certification program, or that meet their content claim as assessed by ConsumerLab.com.
- Purchase from large, reputable companies. These companies have the resources to meet strict manufacturing standards, have a reputation to uphold, and are more likely to follow quality assurance procedures. Companies that also manufacture prescription or nonprescription drugs (e.g., Bristol-Myers-Squibb, American Home Products, and drugstore chain store brands) are more likely to have GMP standards in place and to follow these procedures when producing DS.
- Once a quality DS has been selected, continue to use the same brand and formulation. Although this approach does not guarantee a lack of potential quality issues, given that variability between batches can occur, it does increase the likelihood of a consistent product and dose. Providers working with consumers who have not had positive results with use of a DS might consider a trial of a different brand that is appropriate for the specific symptom before determining that the supplement is ineffective for that consumer.
- Know the DS products that you are using and tell your health care provider about them.
- Report any adverse effects related to DS use to your health care provider.

Additional recommendations for counseling can be found in [Table 50-3](#). Cases 50-1 and 50-2 provide examples of how to counsel consumers who wish to treat ailments with DS.

**TABLE 50-3 General Recommendations for Consumers**

<b>Appropriate Use</b>
<ul style="list-style-type: none"> <li>• Read all labels carefully; never take more than the recommended amount.</li> <li>• Never share DS with others.</li> <li>• Do not select a product that lacks dosing recommendations on the label.</li> <li>• Avoid products that do not carry a lot number or expiration date.</li> <li>• Discard products 1 year from date of purchase if no other expiration date is present.</li> <li>• Select products that list the manufacturer's name, address, and telephone number.</li> <li>• Store products in a dry environment out of direct sunlight and away from young children and pets.</li> </ul>
<b>Special Groups</b>
<ul style="list-style-type: none"> <li>• Always seek the advice of a pediatrician before using a DS in children.</li> <li>• Avoid DS if you are pregnant or breast-feeding or are trying to become pregnant.</li> <li>• Speak to your primary care provider if you are trying to treat a life-threatening condition, such as cancer or HIV.</li> </ul>
<b>Adverse Effects</b>
<ul style="list-style-type: none"> <li>• The term <i>natural</i> does not mean safe; be diligent and report any unusual experiences to your health care provider.</li> <li>• If you are allergic to plants, weeds, and/or pollen, ask your provider before using a DS.</li> </ul>
<b>Interactions</b>
<ul style="list-style-type: none"> <li>• If you are taking a prescription medicine, do not take a DS for the same condition.</li> <li>• When possible, avoid taking multi-ingredient preparations; select single-ingredient products that list the strength per dose.</li> <li>• Do not take these products with alcohol.</li> <li>• Check with your primary care provider if you are taking "blood thinning" drugs; some DS may interact with these drugs.</li> <li>• Always inform your primary care provider of the products you are taking; keep a list if necessary or bring them with you to your appointment.</li> </ul>
<b>Expectations</b>
<ul style="list-style-type: none"> <li>• Never use these products in place of proper rest and nutrition; eat a balanced diet.</li> <li>• Do not expect a cure or unrealistic results; these agents are not cure-alls.</li> <li>• If it sounds too good to be true, it probably is; use discretion when evaluating claims.</li> <li>• Keep a diary to track the effectiveness and side effects of DS.</li> </ul>

Key: DS = Dietary supplements; HIV = human immunodeficiency virus.

#### Considerations for Special Population Groups

This section provides a brief overview of issues regarding the use of DS by different consumers. The lack of data on safety and efficacy in these groups, as well as the current regulatory issues, underscores the need for comprehensive assessment of the consumer's health status and knowledgeable counseling.

### Older Adults

Although many older adults are healthy and living independently, some may have a significant burden of disease. The latter may have age- and disease-related physiologic declines such as impaired kidney function. Older individuals may be chronically taking multiple prescription and nonprescription drugs, making a thorough medical history essential. The potential for drug-food and drug-DS interactions, age-related functional declines, and concomitant diseases should be considered in counseling older adults about DS. Products that are likely to be used in older adults include fish oil or omega-3 fatty acids, glucosamine, ginkgo, garlic, saw palmetto in men, and flaxseed and soy supplements in women.

### Children

Use of DS by children presents unique challenges. The central nervous system of a child may be sensitive to many drugs and chemicals. Little research is available regarding the safe and effective use of DS in children, making evidence-based recommendations difficult. In addition, from a practical perspective, an appropriate pediatric dosage of a DS product cannot be determined if the content of the product is in question. Finally, DS should have childproof safety closures because accidental ingestions may occur in young children. The 2007 NHIS found the most commonly used products in children were echinacea, fish oil, flaxseed, pre- or probiotics, and goldenseal.<sup>3</sup>

### Pregnancy and Lactation

Use of DS by a woman who is planning to become pregnant or is already pregnant presents several dilemmas. Throughout the world, herbal DS have been used to maintain health during pregnancy, prevent miscarriages, and induce labor. In the United States, concern has focused on minimizing fetal exposures to prescription and nonprescription drugs, as well as DS. Although many natural products have been used in pregnancy, little published data exist on their safety with regard to the developing embryo and fetus. As part of standard preconception care, a woman should be asked about her use of DS, especially if her nutritional status might be affected at the time of conception (e.g., folic acid intake) or her ability to become pregnant might be affected (e.g., DS affecting ovulation). The most important issue concerning DS use during pregnancy and lactation is the uncertainty about the exact content in any given product batch or brand. Currently, providers should advise women to limit their use of DS to products that have reasonable proof of safety and efficacy for use during pregnancy and lactation. Products that are likely to be used in pregnant women include fish oil, ginger, and tea formulations of raspberry leaf, peppermint, and chamomile.

### Kidney Disease

Many Americans have chronic kidney disease (CKD) caused by diseases such as diabetes mellitus. CKD presents many challenges to the safe use of many prescription and nonprescription drugs. Most commonly, the individual may be unable to eliminate the drug appropriately, potentially resulting in supratherapeutic concentrations. This effect is also true for hepatically metabolized drugs with active, renally eliminated metabolites. When a patient with CKD requires dialysis, the absorption, distribution, and hepatic metabolism of drugs may also be altered. In addition, many herbs possess antiplatelet properties that might increase the risk of bleeding in CKD.<sup>37</sup>

### Liver Disease

The effects of liver disease on DS pharmacokinetics have not been adequately studied. Many DS products contain combination ingredients; studying and evaluating the effects of liver disease on the pharmacokinetics of combination DS presents unique challenges. For this reason, DS should be avoided or used cautiously in patients with compromised liver function. Some DS products can affect the ability of the liver to metabolize other medications, which can lead to drug interactions. DS products containing known hepatotoxic ingredients should be avoided. No DS have been found to be clinically effective in reversing liver disease or in preventing liver damage.

### Surgery

A detailed preoperative history that includes questions related to DS use should be obtained from all patients undergoing surgery. Supplements that are known to affect sedation or platelet function or that may possibly affect the metabolism of anesthetic agents should be discontinued 2 weeks prior to the procedure. Other DS that the patient is taking should be reviewed by the provider to avoid potential harm.

### Case 50-1

<i><b>Patient Complaint/History</b></i>
Mr. Jones is 72 years old and would like to select a glucosamine product for his knee pain. He has knee osteoarthritis that was diagnosed 10 years ago. His knee pain comes and goes; his stiffness and pain usually last a few weeks and then subside. He has been taking acetaminophen 500 mg for his pain every 6 hours when he has flare ups. His doctor told him that he has degraded cartilage and that he should start taking glucosamine to help strengthen his cartilage. He is taking aspirin 81 mg once daily for heart protection and he has no known drug allergies. He is not taking other medicines and is in excellent health. He walks 3 miles every day except when his arthritis flares up. Mr. Jones noticed many glucosamine products on the shelf and is wondering how to select a quality product.
<b>Clinical Considerations</b>
Mr. Jones appears to be a great candidate for glucosamine because his health care provider has confirmed that Mr. Jones has damaged cartilage in his knee, an area where glucosamine may work. Since Mr. Jones is taking only low-dose aspirin, drug interactions with glucosamine are not likely.
Mr. Jones should select a glucosamine supplement that has been approved by one of the three DS quality assurance programs: United States Pharmacopoeia Dietary Supplement Verification Program, ConsumerLab.com, or National Sanitation Foundation International. Some glucosamine products may carry a seal of approval on the label, but others may not. When a seal of approval is not present, a good way to verify the quality of the product is to visit the Web site of each quality assurance program to verify whether the product is approved.
Mr. Jones should also evaluate the supplement facts panel to help him select a product that follows appropriate labeling recommendations. The product he selects should list the name of the DS, its active ingredients, and the strength of each ingredient provided in each pill. The manufacturer's name and address and the recommended daily dose should also be listed. In some cases, the packer's or the distributor's information may be listed instead. He should review and consider all the DS ingredients listed on the label, paying special attention to ingredients that are not necessary, including added salt (e.g., sodium chloride). If the DS makes any statements regarding the structure or function of the body, in this case "strengthening cartilage", the DS product must also carry the following structure-function claim disclaimer: "This statement has not been evaluated by the Food and Drug Administration. This product is not intended to diagnose, treat, cure or prevent any

disease.”

Mr. Jones should follow the dosing recommendations on the label and keep a diary of how he is feeling while taking the supplement. He should document his pain, mobility, and stiffness over time. He should also document any side effects and when they began and disappeared. Keeping a glucosamine diary is important because the supplement may take months to work. He should continue to take acetaminophen as his doctor recommended during his acute flare ups because glucosamine is not an analgesic. Before undergoing any surgical procedures, Mr. Jones should be instructed to let his provider know that he is taking glucosamine. Finally, Mr. Jones should be instructed to purchase his supplements from reputable companies. These companies have the resources to meet strict manufacturing standards, have a reputation to uphold, and are more likely to follow strict quality assurance procedures. Companies that also manufacture prescription and nonprescription drugs are more likely to have good manufacturing practices in place and to follow these procedures when producing DS.

## Case 50-2

### Patient Complaint/History

Ms. McDonald is 22 years old. She approaches the pharmacy counter with two empty DS bottles that she has questions about. She says she is looking for something to boost her mood and hands you an empty bottle of a product that a friend gave her. The products are called “CDF body, life and mood” and “CDF body, life and energy.” You are familiar with Ms. McDonald because she regularly receives her prescription birth control pills and prescription antidepressant medicine (paroxetine) from your pharmacy. Today she looks more tired and disheveled than usual. For the past month, she had been taking two supplements that a friend gave her and was feeling better, but she ran out of pills a week ago. Her friend purchased the supplements when she traveled home to Canada. Ms. McDonald wanted to know if she could buy them in the United States. She would like your help in selecting supplements that are the same or similar to the ones that her friend gave her.

You ask her if anything has happened in her life recently that has made things more difficult for her. She shares that her pet cat died 3 months ago and that graduate school is stressful and she is not performing as well as she would like. She also shares that her mood has been more up and down over the last 6 months and that she has not shared this information with her health care provider because she did not have the time to make an appointment. You ask if she has been eating the same as usual, and she responds that she has lost some weight because she has been eating less over the past 2 months. She sees this as a positive thing, however, because her boyfriend has complimented her on her slimmer figure.

You evaluate the label on the CDF mood supplement and find that it is a proprietary blend with hypericum perforatum listed as the first ingredient. The energy supplement is also a proprietary blend with Panax ginseng listed as the first ingredient.

### Clinical Considerations

The ingredient listed first in a proprietary blend is present in the greatest quantity. In general, the actual amount of each ingredient in a proprietary blend is not listed, but the total weight of the blend is listed. In addition, the contents are listed in the order of the most prevalent to the least prevalent ingredient. Evaluating the first three ingredients in a blend is a good place to start. If the ingredients listed are unfamiliar, one of the drug information resources listed in this chapter can be used to evaluate the ingredients. *Hypericum perforatum* is the Latin binomial name (genus and species) for St John’s wort. Compared with placebo, this DS has been shown to be efficacious in relieving symptoms of mild-to-moderate depression in some clinical trials. The herb’s pharmacology increases the levels of brain neurotransmitters such as norepinephrine, dopamine, and serotonin. If taken with paroxetine, which also increases serotonin levels, the herb may cause an additive effect. Too much serotonin can lead to serotonin syndrome. St John’s wort is also known to enhance the metabolism of several prescription drugs, including oral contraceptives, leading to reduced efficacy. Panax ginseng does not interact with any of her prescription medicines, but, when compared with placebo, it has not shown any consistent benefit in improving energy in clinical trials.

Ms. McDonald has been feeling better after taking the two products, but she has some symptoms that warrant referral. Although she experienced the loss of a pet about 3 months ago and is currently experiencing stress from her graduate studies, her alterations in mood have been occurring for about 6 months. This could be symptomatic of a worsening of her depression. She also presents with a reduced dietary intake accompanied by weight loss and is tired and disheveled in her appearance, which can be symptomatic of depression. Ms. McDonald should be informed that the mood supplement contains St John’s wort as its primary ingredient and that although you sell supplements containing this herb, she should not take this herb in combination with her prescription medications because it can have an additive effect with paroxetine and reduce the efficacy of her birth control pills. She should be informed that taking an energy supplement containing *Panax ginseng* will cause no harm, but this herb has not been shown to have any consistent benefit in improving energy. You should let Ms. McDonald know that you are most concerned that her mood fluctuations and reduced dietary intake may be a sign that her prescription antidepressant needs to be adjusted. You should also advise her not to substitute DS for prescription drug therapy for chronic health conditions without first consulting her provider.

## Reliable Information Resources

The following resources may be used for general information, ongoing research, regulatory updates and alerts, and information on DS composition. Among these, AltMedDex, Natural Standard, Natural Medicine’s Comprehensive Database, and ConsumerLab require a paid subscription.

AltMedDex, Micromedex

AltMedDex provides drug information on all types of DS, including herbs, vitamins, minerals, Chinese medicine, and acupuncture. This resource provides information about DS dosing, pharmacokinetics, interactions, and clinical use, along with primary literature citations. The content undergoes extensive review and is updated quarterly. The database is searchable only by DS ingredient(s) and not by trade name.<sup>39</sup>

CARDS, Office of Dietary Supplements

The Computer Access to Research on Dietary Supplements (CARDS) database contains federally funded research specific to DS. Information found in CARDS is provided from many government agencies that sponsor DS research, including but not limited to the Office of Dietary Supplements. The database is searchable by DS ingredient, health outcome, study type, or names of research investigators. A record of completed and published research studies on DS is maintained within the database.<sup>40</sup>

Cochrane Database of Systematic Reviews

This Cochrane database is accessible through Medline and offers evidence-based analyses of DS. These reports provide detailed information on trials that were included and excluded from the analysis and on the methodology used.<sup>41</sup> One advantage of this database is that statements that support or refute the use of a specific DS are clearly expressed. A disadvantage is that many providers may have difficulty understanding the style and arrangement of the information that supports the analyses.

#### ConsumerLab.Com

This site provides access to a Natural Products Encyclopedia. The information in this encyclopedia is evidence based and well referenced. It is a useful resource for both consumers and health care providers.<sup>25</sup>

#### Dietary Supplement Ingredient Database

The Dietary Supplement Ingredient Database (DSID) was created by a group of federal agencies and research organizations to estimate the levels of ingredients found in DS products. The database provides information on analyzed levels of nutrients found in adult multivitamins and minerals used in the United States. The database is intended for use in research applications that are appropriate for conducting population-based studies on nutrient intake as opposed to assessing individual products. The data are grouped by nutrient levels rather than by product name.<sup>42</sup>

#### Dietary Supplements Labels Database

The Dietary Supplements Labels Database (DSLID) was created by the National Library of Medicine and includes information from the labels of more than 4000 DS products. The database is intended to help consumers and health care professionals identify ingredients found in brand-name DS. Information in this database is based on the ingredients declared by the DS manufacturer and includes both active and inactive ingredients. DS ingredients are linked to MedlinePlus and PubMed to allow users to investigate the dietary ingredients and evaluate the primary literature pertaining to them. For each DS product listed, the database provides the DS manufacturer's name and contact information. The DSLID also provides links to fact sheets published by FDA, the Office of Dietary Supplements, National Center for Complementary and Alternative Medicine (NCCAM), and the National Cancer Institute.<sup>43</sup>

#### MedlinePlus

MedlinePlus, published by NIH, is designed for consumers and contains information regarding diseases, conditions, and wellness. In addition, drug and DS information is provided in consumer-friendly language. The DS content is based on the Natural Medicines Comprehensive Database and includes both plant-based and other DS. Directories, a medical encyclopedia, and a medical dictionary are available in several languages.<sup>44</sup>

#### Natural Medicines Comprehensive Database/Natural Standard<sup>38,45</sup>

The Natural Medicines Comprehensive Database is produced by Therapeutics Faculty, Inc., which also publishes *The Pharmacist's Letter* and *The Prescriber's Letter*. In 2013, Natural Medicines Comprehensive Database merged with Natural Standard. The latter is another electronic DS database that represents an international research collaboration of providers from many disciplines, including those trained in Western- and Asian-based forms of care. Combining the two databases into one platform allows a comprehensive listing of single-ingredient and combination DS products and their associated adverse effects, drug-supplement interactions, and more. Recommendations are graded to reflect the type and quality of the clinical evidence on which they are based. In addition to reviews of DS, the database also includes monographs on other CAM modalities and a dictionary of terms. Each monograph has an accompanying consumer handout.

#### National Center for Complementary and Alternative Medicine

NCCAM is part of NIH and is one of the federal government's leading agencies in promoting evidence-based research on CAM therapies. This online site provides information on clinical trials, opportunities for research and funding, training opportunities for CAM providers, and health information on CAM modalities. DS monographs are in the health information section and provide concise evidence-based summaries.<sup>46</sup>

#### Office of Dietary Supplements, National Institutes of Health

The NIH Office of Dietary Supplements is a comprehensive site for general information on DS. The online site contains information regarding health and nutrition and decision-making approaches for DS treatment options and nutrient recommendations. Importantly, the site provides evidence-based fact sheets on many DS, including vitamins and botanicals. In addition, the site provides resources for researchers of DS and information on DS training and career development opportunities.<sup>47</sup> In 2013, the My Dietary Supplements (MyDS) free mobile application for consumers was launched; it provides an easy way to track vitamin, mineral, and herbal use and to access science-based information on DS.<sup>47</sup>

#### Pubmed Subset for Dietary Supplements

The NIH Office of Dietary Supplements instituted a joint project with the National Library of Medicine to create the PubMed subset for DS. This subset succeeds the International Bibliographic Information on Dietary Supplements database, which was a collaboration between the Office of Dietary Supplements and the U.S. Department of Agriculture National Agricultural Library. The subset was created to help improve access to DS-related literature and incorporates journals indexed in Medline that contain DS-related content.<sup>48</sup>

### Key Points for Dietary Supplements

- DS use is common among consumers, making it essential for all providers to be knowledgeable about the most frequently used products. This education should include information about evidenced-based resources and where to report adverse effects, drug interactions, or suspected fraudulent health claims.
- Regulation under DSHEA has created a marketplace in which product safety, efficacy, and quality can be uncertain.
- Health care providers are in a unique position to counsel consumers on DS and should take an open, nonjudgmental, evidence-based approach.
- Obtaining a DS history should be part of the overall drug history.
- Counseling recommendations should include consideration of overall scientific support, specific patient groups, potential for adverse effects, and potential for interactions with other medications or medical illnesses.

**Handbook of Nonprescription Drugs** > Chapter 51. Natural Products**Natural Products: Introduction**

This chapter uses the organ system approach outlined in [Table 51-1](#). The products discussed were chosen because they have evidence to support their use, are widely promoted either with or without evidence supporting use, or present known or theoretical safety concerns. Some information has been adapted from an earlier version of this chapter.<sup>1</sup>

**Cardiovascular System**

## Coenzyme Q10

Coenzyme Q10 (CoQ10, or ubiquinone) is converted to ubiquinol in the body and is found in every cell, primarily in mitochondria.

## Therapeutic Uses

Consumers use CoQ10 for cardiovascular conditions and as a general antioxidant. It has been investigated for use in Parkinson's disease, breast cancer, migraine prevention, and reduction of chemotherapy-associated adverse effects.<sup>2</sup>

## Physiologic Activity

CoQ10 concentrations are greatest in heart, liver, pancreas, and kidney mitochondria.<sup>2</sup> As the rate-limiting cofactor in mitochondrial adenosine triphosphate (ATP) formation, CoQ10 is involved in many energy production functions and regeneration of other antioxidants such as vitamin E. Statins decrease CoQ10 biosynthesis and lower its serum concentrations, but not always in muscle tissue.<sup>3,4</sup> The extent of the lowering of CoQ10 concentrations differs among statins.<sup>5</sup> CoQ10 stabilizes membranes and may have vasodilatory and inotropic effects.<sup>6</sup>

## Dosage and Product Considerations

For heart failure, cardiomyopathy, or hypertension, the CoQ10 dosage has been 100 mg 1-3 times daily, preferably with meals to aid absorption. The dosage is 30-50 mg once daily for patients taking statins. Products meeting United States Pharmacopeia (USP) standards are available.

## Safety Considerations

Gastrointestinal (GI) effects from CoQ10 use may be minimized by splitting large (>100 mg) doses. Mild increases in liver enzymes have been reported. The use of CoQ10 should be avoided during pregnancy and lactation because safety information is lacking.

Vitamin K-like procoagulant effects have been theorized because of CoQ10's structural similarity to synthetic vitamin K. Case reports of interactions with warfarin exist, although a placebo-controlled crossover study of CoQ10 noted no differences in international normalized ratio (INR) values in patients taking stable dosages of warfarin.<sup>7</sup> Patients taking warfarin should discuss CoQ10 with their health care providers; if used, the INR should be monitored more frequently until CoQ10's effects are determined.

CoQ10 may possibly decrease effectiveness of radiation therapy.<sup>8,9</sup> Information on interactions changes rapidly, so cancer patients should discuss CoQ10 use with their oncologists.

[Table 51-2](#) provides more information on supplement-medication interactions discussed in the chapter.

## Summary of Clinical Evidence

Evidence for CoQ10 in heart failure is contradictory. Studies have shown improvements in markers of cardiovascular health, such as endothelial function and C-reactive protein levels; further, early clinical trials were promising.<sup>10,11</sup> Recent studies have demonstrated contradictory results in overall symptoms, ejection fraction, or oxygen consumption when CoQ10 was added to standard therapy.<sup>12,13</sup> Patients on a heart transplant waiting list experienced significant improvements in multiple symptoms, especially in the 6-minute walk test and in the New York Heart Association functional class, but echocardiography measurements did not change.<sup>12</sup> Although its true efficacy

is unknown, CoQ10 has few adverse effects and so might be an option as adjunctive therapy, if carefully monitored. Preliminary trials have investigated CoQ10 for cardiomyopathy and ischemic heart disease. Risk reduction in adults was minimal, although a 6-month trial in pediatric and adolescent patients with idiopathic cardiomyopathy found improved diastolic function.<sup>14</sup> A 1-year trial examining 120 mg/day CoQ10 in 144 patients who experienced a myocardial infarction (MI) reported a significantly lower rate of cardiac events (24.6% for CoQ10 vs. 45% for B vitamins).<sup>15</sup>

**TABLE 51-1 Discussed Supplements Grouped by Organ Systems**

<b>System</b>	<b>Supplement</b>
Cardiovascular system	Coenzyme Q10 Garlic Fish oil Red yeast rice Resveratrol
Central nervous system	Butterbur Feverfew Huperzine Ginkgo Kava Melatonin St. John's wort Valerian 5-Hydroxytryptophan
Digestive system	Ginger Milk thistle Peppermint
Endocrine system	Alpha-lipoic acid American ginseng Cinnamon DHEA
Immune modulators	Colostrum Echinacea Probiotics Elderberry
Physical and mental performance enhancers	Eleuthero Ginseng Green tea
Kidney, urinary tract, and prostate	African plum Cranberry Saw palmetto
Musculoskeletal system	Glucosamine sulfate Chondroitin sulfate MSM SAmE Devil's claw
Skin and mucous membranes	Melissa (lemon balm) Tea tree oil
Women's health	Black cohosh Chaste tree berry Evening primrose oil Fenugreek Phytoestrogens

Key: DHEA = Dehydroepiandrosterone; MSM = methylsulfonylmethane; SAmE = S-adenosyl-L-methionine.

Although statins can reduce endogenous CoQ10 concentrations, the clinical significance is not well understood. CoQ10, with or without statin discontinuation, may reverse some statin-associated adverse effects.<sup>16</sup> A study in older athletes taking statins noted improved muscle performance, whereas another study found no difference in development of myalgia.<sup>17,18</sup> Genetic differences may be responsible for the diverse findings with CoQ10.<sup>19</sup> CoQ10 has a slight blood pressure-lowering effect in patients with hypertension. Evidence is variable but sufficient to support a trial as adjunctive therapy in patients needing small additional decreases in blood pressure.<sup>20,21</sup>

## Garlic

Garlic supplements are derived from dried or fresh bulbs of *Allium sativum*, the same plant used as a food or spice.

### Therapeutic Uses

Garlic is used to treat hyperlipidemia, hypertension, and type 2 diabetes mellitus, and for improvement of immune function and prevention of various cancers.<sup>22</sup>

### Physiologic Activity

Garlic bulbs contain an odorless sulfur-containing amino acid derivative alliin (S-allyl-L-cysteine sulfoxide). When crushed, the enzyme allinase is released, converting alliin to the pungent allicin, the main component of garlic's volatile oil. For supplements, allicin is used as a quality marker but may not be the primary active compound; other organosulfur-containing or phenolic substances may exert pharmacologic effects. The production of alliin actually occurs after ingestion and is lessened by interference of stomach acid with allinase. In animal and in vitro models, garlic possesses hypotensive, hypolipidemic, antiplatelet, antioxidant, and anti-infective properties.<sup>23</sup> Garlic's prevention of lipid oxidation may be as important to cardiovascular health as its hypolipidemic activity.<sup>24</sup>

### Dosage and Product Considerations

Research on garlic has been conducted primarily with tablets or capsules of powdered, dehydrated garlic standardized to an allicin content of 1%-1.6%, providing 3-5 mg of allicin per day. These dosages should be recommended.

Garlic supplements vary in their chemical composition, which may contribute to the contradictory study results. An enteric coating will help prevent destruction of alliin by gastric acid and may also help to decrease breath odor. The odorless (aged) products are less likely to contain appropriate amounts of allicin but may contain other compounds that have some activity.<sup>22</sup>

### Safety Considerations

Although well tolerated, garlic may cause nausea, vomiting, and heartburn, especially at higher dosages. Bad breath and body odor may also occur. Allergic reactions have been reported.

Garlic should be stopped 10-14 days prior to surgery to reduce the risk of bleeding.<sup>25</sup> Patients taking warfarin or antiplatelet agents should use garlic supplements with caution because of potential bleeding risk; however, dietary amounts do not affect platelet function.<sup>26,27</sup>

Garlic's effect on cytochrome (CYP) P450 isoenzymes is unclear. Garlic decreased concentrations of saquinavir by about 50%. The mechanism may involve P-glycoprotein induction and therefore decreased absorption, rather than increased clearance, because two studies did not find interactions with docetaxel and other CYP3A4 and CYP2D6 substrates.<sup>28,29</sup>

**TABLE 51-2 Selected Herb-Drug Interactions**

<i>Herb</i>	<i>Known Interactions/Results<sup>a</sup></i>	<i>Theoretical Interactions/Results<sup>b</sup></i>
African plum (pygeum)		Potential risk for increased adverse effects when combined with finasteride
Alpha-lipoic acid	Increased bioavailability of valproate	SMBG recommended in patients taking antihyperglycemic drugs Potential chelating activity with minerals and antacids Possible interference with conversion of thyroxine to triiodothyronine

		Possible reduction of effectiveness of some chemotherapy agents
Black cohosh		Possible additive estrogenic activity with ET or OCP May increase toxicity of doxorubicin and docetaxel May decrease effectiveness of cisplatin Possible potentiation of antihypertensive agents Avoid with other hepatotoxic drugs
Butterbur	Substrate of CYP3A4; avoid with known inducers	Possible interaction with anticholinergics or antimigraine medications
Chastetree berry		Minimal evidence for possible interference with hormonal contraceptives Possible interaction with antipsychotics, dopamine agonists, and metoclopramide because of dopaminergic activity
Chondroitin		Possible increased risk of bleeding if taken with antiplatelet agents or warfarin
Coenzyme Q10		Possible vitamin K-like procoagulant effects if taken with warfarin; monitor INR initially
Cranberry		Possible increased INR and risk of bleeding in people taking warfarin Possible CYP2C9 inhibition May alter excretion of weakly alkaline drugs or neutralize effects of antacids
Devil's claw		Possible increased risk of bleeding in patients taking warfarin
DHEA	Triazolam: increased blood levels	Interference with hormonal or antihormonal therapies such as aromatase inhibitors May increase risk of blood clots with OCPs Possible increased levels of CYP3A4 substrates
Echinacea		Possible interaction with immunomodulating therapies CYP3A4 substrates with low oral bioavailability: verapamil, cyclosporine, tacrolimus. Effects on CYP1A2, CYP2C9, or CYP3A4 are likely to be clinically insignificant
Eleuthero ("Siberian ginseng")	Digoxin: possible false elevation in plasma levels (assay dependent)	SMBG recommended in patients taking antihyperglycemic drugs
	Caffeine: increased CNS stimulation	Possible inhibition of CYP1A2, CYP2C9, CYP3A4, and CYP2D6 (although CYP3A4 and CYP2D6 not affected at normal doses)
	Hexobarbital: inhibited metabolism	Variable activity on blood pressure; avoid if taking antihypertensives
Evening primrose oil		Possible additive effects if taken with other antiplatelet agents or herbs Seizure possible if taken with phenothiazines Potential additive effects to antihypertensives
Fenugreek		Possible additive effects if taken with other antiplatelet agents or herbs
Feverfew		Possible additive effects if taken with other

		antiplatelet agents or herbs Avoid with antihyperglycemic drugs because of additive effects
Garlic	Warfarin: increased INR in case reports Saquinavir: 50% decrease in levels OCPs: decreased effectiveness	Contradictory evidence regarding induction of drugs metabolized through CYP3A4 and CYP2D6
Ginger	Antiplatelet agents: possible additive effect at high dosages (>4 g/day)	Avoid with antihyperglycemic drugs because of additive effects
Ginkgo	Antiplatelet agents: possible additive effect (contradictory evidence) Trazodone: case report of coma in patient taking low-dose trazodone Omeprazole: decreased levels	Ingestion associated with seizures; avoid in patients with a history of seizures or on drugs that may lower seizure threshold Potential additive effects with antihypertensive drugs, although paradoxical hypertension has been reported with HCTZ
Ginseng ( <i>Panax ginseng</i> )	Glucose-lowering drugs: possible lowered BG levels in type 2 DM; SMBG levels required Phenelzine: possible headache, tremor, and mania in case report	Unpredictable effect on concurrent anticoagulant and antiplatelet agents Possible interference with antipsychotics and immunosuppressants Inhibition of CYP2D6 (not clinically significant)
Ginseng, American ( <i>Panax quinquefolius</i> )	Warfarin: reduced anticoagulant effect	
Glucosamine	Warfarin: increased bleeding risk in individuals with variant CYP2C9 alleles	SMBG recommended for first few days of use in patients taking antihyperglycemic drugs
Green tea	Decongestants: additive stimulant effects	Possible antagonism of warfarin's effect Possible antagonism of concurrent sedatives related to caffeine content
Fish oil		Possible additive effects if taken with anticoagulant and antiplatelet agents that; occur primarily at dosages > 4 grams daily
5-HTP	SSRIs, tramadol, DM: increased risk of serotonergic adverse effects Carbidopa: decreased peripheral metabolism	
Huperzine A		Possible decreased effectiveness if taken with anticholinergic drugs Possible additive cholinergic effects if taken with acetylcholinesterase inhibitors or cholinergic agents (e.g., bethanechol) Additive effects with drugs causing bradycardia
Kava	Levodopa: reduced efficacy of levodopa Inhibits CYP2E1 Concern over hepatotoxicity contraindicates use with other drugs and supplements that damage liver	Possible increased sedative effect with alcohol and other CNS depressants Possible additive effects with other antiplatelet agents or herbs Preliminary evidence suggests kava may inhibit CYP2C9, CYP2C19, CYP2D6, and CYP3A4 (significance unknown)
Lemon balm (Melissa)		Use of oral lemon balm and sedating supplements and drugs contraindicated
Melatonin	Nifedipine: reduced delivery via the GITS Fluvoxamine, MAOIs, and tricyclic	Caffeine or OCP use has various effects on melatonin levels

	antidepressants: increase melatonin BZDPs and sodium valproate: decrease nighttime levels	Verapamil may decrease melatonin Possible interaction with immunosuppressant drugs related to immunostimulating properties
Milk thistle		Effect on CYP3A4 and CYP2C9 unclear
Peppermint	Decreased absorption of iron salts Premature dissolution of enteric-coated peppermint oil capsules by drugs that increase gastric pH	Decreased activity of CYP3A4 observed during in vitro and in vivo studies; clinical significance is unknown
Phytoestrogens (red clover, others)		Possible increased risk of bleeding in patients taking warfarin with red clover-based products
Probiotics	Separate doses from antibiotics or antifungals by 2 or more hours	
Red yeast rice	Additive activity when used with statins	
SAMe		Possible increased risk of serotonin syndrome if taken with antidepressants and 5-HT <sub>1</sub> agonists Significance on glucocorticoid increases unknown
Saw palmetto		Potential interaction with hormonal or antihormonal therapies Possible additive effects when used with antiplatelet or anticoagulant agents
St. John's wort	CYP3A4 substrates: decreased drug levels and effects (e.g., alprazolam, amitriptyline, atorvastatin, finasteride, imatinib, irinotecan, methadone, nifedipine, simvastatin, tacrolimus, verapamil, warfarin, zolpidem) Antidepressants: increased risk of serotonin syndromes with nefazodone, sertraline, and paroxetine Cyclosporine: decreased blood levels of immunosuppressant, including case reports of transplant graft rejection OCPs and HT: decreased activity Protease inhibitors and nonnucleoside reverse transcriptase inhibitors: decreased serum levels	Possible increased risk of serotonin syndrome if taken with 5-HT <sub>1</sub> agonists, DM, meperidine, pentazocine, and tramadol; interaction possibly similar to conventional antidepressants and MAOIs, with increased potential for hypertension, hyperthermia, agitation, and coma Possible decreased levels and effect of amiodarone Monitoring for fexofenadine toxicity recommended if taken concomitantly Morphine: increased narcotic-induced sleep time in animal studies Use with other photosensitizing agents contraindicated
Valerian		Possible increased sedative effect if taken with alcohol or other CNS depressants (BZDPs) May inhibit CYP3A4 (not usually clinically significant)

Key: BG = Blood glucose; BZDP = benzodiazepine; CNS = central nervous system; CYP = cytochrome P450; DM = dextromethorphan; ET = estrogen therapy; GITS = gastrointestinal therapeutic system; HCTZ = hydrochlorothiazide; HT = hormone therapy; 5-HT<sub>1</sub> = 5-hydroxytryptamine<sub>1</sub>; 5-HTP = 5-hydroxytryptophan; INR = international normalized ratio; MAOI = monoamine oxidase inhibitor; OCP = oral contraceptive pill; SAMe = S-adenosyl-L-methionine; SMBG = self-monitoring of blood glucose; SSRI = selective serotonin reuptake inhibitor.

<sup>a</sup> Based on human studies and/or validated case reports.

<sup>b</sup> Extrapolated from animal or in vitro studies.

## Summary of Clinical Evidence

Garlic supplements slightly reduce total and low-density lipoprotein (LDL-C) concentrations.<sup>30</sup> Reported reductions range from 4% to 12.4% in total cholesterol (TC), 1% to 16.3% in LDL-C, and 18.6% to 22% in triglycerides (TG).<sup>31,32</sup> A meta-analysis concluded that, compared with placebo, garlic has greater effects for hypertension; the effects are larger in individuals with higher blood pressures.<sup>33</sup> Mean decreases were 6-12 mm Hg for systolic pressure and 5-9 mm Hg for diastolic pressure, so garlic's usefulness would generally be for mild hypertension. Aged garlic products may be preferred for this use.<sup>34</sup>

## Fish Oil

Fish oil is a source of omega-3 fatty acids, primarily docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA).

### Therapeutic Uses

Fish oil is used to lower TG levels, improve cardiac health, and relieve inflammatory conditions, such as rheumatoid arthritis. Average American diets tend to be low in omega-3 fatty acids and high in omega-6 fatty acids; consumers who do not eat fish can take fish oil supplements to aid in normalizing the omega-3:omega-6 intake ratio.

### Physiologic Activity

Intake of exogenous EPA and DHA in fish oil influences production and concentrations of inflammatory response cytokines. Competitive inhibition of arachidonic acid decreases production of thromboxane A<sub>2</sub> and leukotriene B<sub>4</sub>, whereas effects at another part of the production cascade increase thromboxane A<sub>3</sub> and prostaglandin E<sub>3</sub>. Overall, the fish oil's actions can be summarized as increasing noninflammatory and decreasing proinflammatory cytokines. Omega-3 fatty acids may decrease intestinal cholesterol absorption and inhibit enzymes involved in synthesis, excretion, and degradation of very low-density lipoproteins (VLDL), thereby decreasing other lipoproteins, including LDL-C.<sup>35</sup> The mechanism of hypotriglyceridemic action through peroxisome proliferator-activated receptors may also be responsible for improvements in glucose concentrations and insulin resistance.<sup>36</sup>

### Dosage and Product Considerations

The usual recommendation for fish oil is 1-2 grams daily; for hyperlipidemia, dosages of 2-4 grams per day in divided doses are used. Available fish oil products have varying amounts of EPA and DHA; most studies have used products with an EPA:DHA ratio of 1.2:1 or 1.5:1. EPA and DHA amounts may not equal the stated dose per capsule because of additional product components, such as small quantities of vitamin E and excipients; however, high-quality products will be close to the total. For example, a "1 gram fish oil" product labeled to contain "480 mg EPA and 370 mg of DHA" per capsule would be within the acceptable ratios, whereas a "1 gram fish oil" product with "250 mg EPA and 180 mg of DHA" per capsule would not contain adequate active components. A prescription omega-3 fatty acid product would be more appropriate for severe hypertriglyceridemia because of ensured quality and insurance coverage. For example, a 1 gram Lovaza capsule contains 465 mg of EPA and 375 mg of DHA, with a dosage of 4 capsules per day, given in 1-2 doses.

Anecdotally, some patients have had success with freezing the capsules to minimize the fish burp. Data on mercury and other toxins in fish have increased concerns about quality of fish oil supplements. Because mercury is insoluble in oil, it collects primarily in flesh, whereas most fish oil is extracted from the skin. Supplements tested have had no or barely detectable concentrations of mercury.<sup>37</sup> Dioxin and pesticides can accumulate in the oil, so the use of a high-quality product meeting USP standards may limit toxin exposure.<sup>38</sup>

### Safety Considerations

Fish oil products are generally safe; the most common adverse effects are belching, fishy halitosis, and GI distress.<sup>39</sup> Patients taking anticoagulants and antiplatelet agents should use no more than 3 g/day and should be monitored closely.

A recent analysis suggested a possible association between high blood levels of polyunsaturated fatty acids and worsened survival or development of prostate cancer.<sup>40</sup> This finding contrasts with other epidemiological data demonstrating a lower risk of prostate cancer with higher dietary intake of omega-3 fatty acids.<sup>41</sup> Until more data are available, patients with, or known to be at high risk for, prostate cancer should avoid taking more than 1 g/day; dietary intake is preferred over supplements.

### Summary of Clinical Evidence

The primary effect of fish oil on lipids and lipoproteins is on TG concentrations. Although some studies have noted 40% reductions in TG concentrations, according to meta-analyses, a decrease of 14%-29% with greater lowering of

VLDL is a more reasonable expectation.<sup>42,43</sup> In general, high-density lipoprotein cholesterol (HDL-C) concentrations do not change or they increase slightly (<10%).<sup>44</sup> Effects on LDL-C are variable, with most studies noting slight decreases.

One gram per day of omega-3 fatty acids, generally as fish oil, reduced the risk of adverse cardiac outcomes (mortality, nonfatal MI, and nonfatal stroke) by 20% in the 1999 GISSI-Prevenzione trial.<sup>45</sup> Similar benefits were shown for primary and secondary prevention in a meta-analysis.<sup>46</sup> A recent study found no difference in cardiovascular mortality and/or morbidity.<sup>47</sup> One potential reason for the differences in outcomes is the increasing use of statins. One large study examined omega-3 fatty acids for secondary prevention in statin users and nonusers and found no differences in outcomes among statin users.<sup>48</sup> Earlier trials of patients with metabolic syndrome noted improvement in cardiovascular and inflammatory markers, whereas recent studies have not demonstrated decreased mortality and/or morbidity.<sup>49</sup>

A large trial is currently evaluating benefits of marine omega-3 fatty acid supplements in the primary prevention of cardiovascular disease and cancer.<sup>50</sup> On the basis of data from the earlier trials before statin use was common, the American Heart Association recommends the intake of 1 g/day of omega-3 fatty acids. The recommendation emphasizes the dietary intake of fatty fish at least twice weekly.<sup>51</sup>

## Red Yeast Rice

*Monascus purpureus*, a yeast that grows on fermented rice, is used in traditional Chinese medicine and gives Peking duck its red hue.

### Therapeutic Uses

Red yeast rice is used to lower lipid concentrations.

### Physiologic Activity

Red yeast rice contains multiple components; monacolin K, a naturally occurring lovastatin analogue, is the most important. The amount of monacolin K component is usually small, with most products containing less than 5 mg/day. As a result, this component cannot be solely responsible for the lipid-lowering effects reported in clinical trials. Other mechanisms such as increased bile acid excretion may also be involved.<sup>52</sup>

### Dosage and Product Considerations

For hyperlipidemia, the dosage is 1.2-2.4 g/day in 2 doses. In the United States, certain red yeast rice products were declared illegal in 2000 because they contained an "unauthorized drug."<sup>53</sup> As a result, although red yeast rice products are available, many manufacturers no longer ensure that their products contain a standardized amount of monacolin K, making choice of a high-quality product difficult.<sup>53</sup>

### Safety Considerations

Adverse effects associated with red yeast rice include allergic reactions, headache, bloating, flatulence, and heartburn. Increased liver function tests and rhabdomyolysis have been reported, so patients taking red yeast rice should have regular liver function monitoring.<sup>53</sup> Patients ingesting more than two alcoholic drinks should not use red yeast rice because of a potentially increased risk of hepatotoxicity. Red yeast rice is considered Pregnancy Category X.<sup>54</sup>

The *Monascus purpureus* yeast can also generate citrinin, a nephrotoxin, during fermentation.<sup>55</sup> Only brands of red yeast rice that have been tested to be free of citrinin should be used; patients with kidney disease should not use red yeast rice.

At least three studies have found that red yeast rice can be safely used in patients unable to take statins.<sup>56-58</sup> Initial increased monitoring for muscle pain is appropriate if used in a patient with prior statin-induced myalgia.

### Summary of Clinical Evidence

Multiple studies have demonstrated that red yeast rice lowers lipid concentrations.<sup>59</sup> A systemic review reported reductions in TC of 10%-44%, in LDL-C of 7%-25%, and in TGs of 13%-44%.<sup>60</sup> In general, increases in the HDL-C concentration have not been significant.

## Resveratrol

Resveratrol is a polyphenol present in grapes and wines, bilberries and blueberries, and pistachios. Interest in resveratrol began with research into the cardioprotective effects hypothesized for red wine. Higher dietary intake of resveratrol has been associated with lower levels of lipids, blood pressure, glucose, and heart rate.<sup>61</sup>

#### Therapeutic Uses

Resveratrol is generally used for cardiovascular health and cancer prevention.

#### Physiologic Activity

Resveratrol is well absorbed but has low bioavailability because of the extensive first-pass effect. Metabolites may be responsible for some effects, and beta-glucuronidase may repeatedly transform metabolites back to *trans*-resveratrol.<sup>62</sup>

Resveratrol is an antioxidant, decreases LDL-C oxidation, and has anti-inflammatory effects.<sup>63</sup> The greatest effects are improved endothelial function; clinically significant flow-mediated dilation of blood vessels occurs through nitric oxide and prostacyclin mechanisms.<sup>64,65</sup> In addition, insulin sensitivity is improved, possibly from increased phosphorylation of protein kinase, part of the signaling mechanism for insulin.<sup>64</sup>

#### Dosage and Product Considerations

The optimal dosage of resveratrol is unknown because studies have used varying preparations or extracts. The most recent clinical trial reporting beneficial effects used 10 mg daily, whereas pharmacokinetic studies have used up to 600 mg daily.<sup>63,66</sup>

#### Safety Considerations

Headache has been reported with the use of resveratrol.<sup>66</sup>

#### Summary of Clinical Evidence

In cardiovascular disease patients on standard drug therapy, a 3-month trial of 10 mg resveratrol resulted in only slight improvement in left ventricular systolic function, but significant improvement in left diastolic function and flow-mediated dilation was seen. Collagen-induced platelet aggregation significantly decreased from 42.61% to 32.89% and LDL-C concentrations from 122 mg/dL to 104 mg/dL.<sup>63</sup>

A 1-year primary prevention trial in patients with cardiac risk factors used 8 mg of resveratrol daily and examined inflammatory markers known to be associated with cardiovascular risk.<sup>67</sup> Significant decreases were reported for tumor necrosis factor- $\alpha$  (-19.8%), high-sensitivity C-reactive protein (-26%), and plasminogen activator inhibitor type 1 (-16.8%); however, interleukin-10 increased by 19.8%.<sup>67</sup> Large-scale studies evaluating clinical outcomes associated with these markers have not been conducted.

### Central Nervous System

#### Butterbur

*Petasites hybridus* (L.) Gaertner, Meyer & Scherb, also known as butterbur, is native to marshy areas in northern Asia, Europe, and parts of North America. It is a member of the Asteraceae/Compositae family.

#### Therapeutic Uses

Butterbur is used to prevent migraines and treat allergic rhinitis and asthma.

#### Physiologic Activity

Petasin and isopetasin are isolated from butterbur's rhizomes, roots, and leaves. Extracts also contain volatile oils, tannins, flavonoids, and pyrrolizidine alkaloids (PAs). Petasin may reduce spasms in smooth muscle and vascular walls and also inhibit leukotriene synthesis. Isopetasin decreases prostaglandin synthesis, thereby reducing inflammation. Both compounds have an affinity for cerebral blood vessels.<sup>68</sup>

#### Dosage and Product Considerations

For migraine prevention, studies have used standardized extracts of butterbur containing a minimum of petasin 7.5 mg and isopetasin 7.5 mg per 50 mg tablet or capsule. Dosages of standardized butterbur ranging from 50 to 75 mg twice daily are used for 4-6 months, then tapered until migraine incidence increases; however, maximum study

duration has been only 12-16 weeks.<sup>68</sup> Standardized petasin (Ze 339) 8-16 mg has been administered 3-4 times daily for allergic rhinitis.<sup>69,70</sup>

### Safety Considerations

Butterbur is generally well tolerated; minor GI complaints are most commonly reported, followed by skin changes and dizziness.<sup>68</sup> PAs and their N-oxides are highly toxic compounds in butterbur extracts that can cause serious hepatotoxicity and carcinogenesis. German manufacturing requirements restrict the content of PAs in butterbur preparations to 1 mcg/day (limited intake to 6 weeks only) or 0.1 mcg/day (no limitations of intake).<sup>71</sup> Patients with an allergy to ragweed and related plants in the Asteraceae/Compositae family should avoid butterbur. Its use should also be avoided during pregnancy and lactation because of the potential for hepatotoxicity.

### Summary of Clinical Evidence

The American Academy of Neurology and the American Headache Society consider butterbur effective for the prevention of migraine, with the highest evidence level of A.<sup>72</sup> Studies including children and adolescents have shown similar results.<sup>73,74</sup> In patients with symptoms related to seasonal allergic rhinitis, studies suggest short-term use for less than 14 days may be as effective as cetirizine and fexofenadine.<sup>69,70</sup> Results of one study indicated that butterbur had similar effects as fexofenadine in patients with perennial allergic rhinitis.<sup>75</sup>

## Feverfew

Feverfew (*Tanacetum parthenium* [L.] Schultz-Bip.) is a member of the Asteraceae/Compositae family. The plant is native to the Balkans and now is found throughout the world.

### Therapeutic Uses

Feverfew is used to prevent migraines and treat dysmenorrhea, arthritis, and psoriasis.

### Physiologic Activity

The activity of feverfew for migraine prevention may involve many mechanisms. Parthenolide, a sesquiterpene lactone, is the most abundant and biologically active component and likely contributes anti-inflammatory benefits. Other active components include flavonoids, volatile oils, and additional sesquiterpene lactones. Feverfew may have effects on prostaglandin synthesis, platelet aggregation, serotonin release, histamine release, and vascular smooth muscle contraction.<sup>76</sup>

### Dosage and Product Considerations

Studies have used feverfew leaf 50-100 mg daily in divided doses or 6.25 mg CO<sub>2</sub>-standardized extract (MIG-99) of 0.2%-0.35% of parthenolide 2-3 times daily.<sup>77,78</sup> Standardization of a product to its parthenolide content does not appear to be necessary. Feverfew must be taken continuously to be effective for migraine prophylaxis and is not effective for treatment of acute migraine attacks.

### Safety Considerations

GI adverse effects may result from ingestion of feverfew. Oral ulcers can occur from chewing fresh leaves. Post-feverfew syndrome has been reported after abrupt withdrawal from chronic use, resulting in anxiety, headaches, insomnia, and muscle stiffness. Patients who are allergic to plants in the Asteraceae/Compositae family should avoid use of feverfew, as should women who are pregnant or breast-feeding.<sup>76</sup> Possible antiplatelet effects have been identified; therefore, patients taking oral anticoagulants and antiplatelet agents or herbs should use feverfew with caution.<sup>25,76</sup>

### Summary of Clinical Evidence

A Cochrane review of feverfew in preventing migraine headache found insufficient evidence from randomized, double-blind trials to suggest an effect.<sup>77</sup> Newer studies that included MIG-99 have been conducted since this publication. From their evaluation of more recent trials, the American Academy of Neurology and the American Headache Society consider MIG-99 probably effective for prevention of migraine, with an evidence level of B.

## Huperzine

Huperzine A is derived from the Chinese club moss (*Huperzia serrata* [Thumb.] Trev.) and is a member of the Lycopodiaceae family. In China, it is approved as a treatment for Alzheimer's disease and vascular dementia.

#### Therapeutic Uses

Huperzine A has been used to treat Alzheimer's disease and dementia and to enhance cognitive function.

#### Physiologic Activity

Huperzine A is a sesquiterpene compound; the levorotatory isomer is the most pharmacologically active. This compound is a potent peripherally and centrally acting reversible acetylcholinesterase inhibitor and may have neuroprotective properties.<sup>79</sup>

#### Dosage and Product Considerations

The dosages for Alzheimer's disease range from 200-400 mcg of huperzine A daily.

#### Safety Considerations

Adverse effects include sweating, blurred vision, nausea, vomiting, diarrhea, dizziness, bradycardia, and loss of appetite. Theoretically, huperzine A should be avoided in patients with bradycardia, peptic ulcer disease, and increased gastric acid secretion. Concurrent use of anticholinergic drugs such as benztropine may decrease the effectiveness of huperzine A. Additive cholinergic effects may occur if huperzine A is taken with other acetylcholinesterase inhibitors (e.g., donepezil), or cholinergic agents (e.g., bethanechol). In addition, huperzine A can have additive effects in the presence of other drugs that cause bradycardia, including beta-blockers. Huperzine should be avoided during pregnancy and lactation because of the lack of safety information.

#### Summary of Clinical Evidence

Systematic Cochrane reviews have been conducted to evaluate the use of huperzine A in mild cognitive impairment, vascular dementia, and Alzheimer's disease. No trials met inclusion criteria for mild cognitive impairment and only one trial of patients with vascular dementia was included; the results were not significant.<sup>80,81</sup> The six clinical trials reviewed concluded that huperzine A has some benefit on cognitive function, global clinical status, behavioral disturbance, and functional performance in patients with Alzheimer's disease. However, only one study was of good quality and sufficient size. Huperzine A should not be used in Alzheimer's disease until additional evidence is available.<sup>82</sup>

### Ginkgo

*Ginkgo biloba* L. is a tree and the only living member of the family Ginkgoaceae.

#### Therapeutic Uses

Ginkgo has been used for Alzheimer's disease, vascular dementia, intermittent claudication, tinnitus, acute mountain sickness, and age-related macular degeneration.

#### Physiologic Activity

The standardized *Ginkgo biloba* L. (EGb 761) concentrated (50:1) leaf extract contains ginkgolides (A, B, C, and M) and bilobalide. These constituents may be responsible for neuroprotective properties reported with the leaf extract. Ginkgolide B is a potent platelet-activating factor antagonist. The extract also contains bioflavonoids and flavone glycosides, such as quercetin, 3-methyl quercetin, and kaempferol. The flavonoid fractions may possess antioxidant and free radical scavenger effects.<sup>83,84</sup>

#### Dosage and Product Considerations

Recommended dosages for dementias and intermittent claudication range between 120 and 240 mg daily of ginkgo leaf extract in 2-3 divided doses. EGb 761 is available as 40, 60, or 120 mg capsules or tablets containing 24% ginkgo flavone glycosides and 6% terpenoids.<sup>83,84</sup> The standardized extract EGb 761 is used in many clinical trials. Many ginkgo supplements may contain subtherapeutic amounts of ginkgolides and bilobalide.

#### Safety Considerations

Mild GI adverse effects, headache, dizziness, and allergic skin reactions have been reported with ginkgo.<sup>85</sup> Recent

concerns have been raised from animal studies that showed an increased rate of cancer in the nose and throat.<sup>86</sup> Single case reports have linked the use of ginkgo with other medications to priapism with risperidone, coma with trazadone, treatment failure of efavirenz, and fatal seizure with valproic acid and phenytoin.<sup>87</sup> Ginkgo has generally been associated with a reduction in blood pressure, although a paradoxical loss of antihypertensive efficacy has also been documented between ginkgo and a thiazide diuretic (Table 51-1).<sup>83</sup> Ginkgo may also increase concentrations of nifedipine.<sup>85</sup> Ginkgo should be avoided during pregnancy and lactation because of the lack of safety information. Several case reports have documented a potential link to hemorrhage in patients taking anticoagulants or antiplatelet agents who used unstandardized ginkgo product.<sup>87,88</sup> In contrast, a meta-analysis of 18 randomized controlled trials comparing EGb 761 against placebo groups found no significant changes in hemostasis outcomes.<sup>89</sup> Patients taking warfarin, antiplatelet agents, and herbs should use ginkgo with caution because of the potential risk for bleeding.<sup>88</sup> The use of ginkgo should also be stopped at least 7-10 days before any surgical procedure.<sup>25</sup>

### Summary of Clinical Evidence

A Cochrane review evaluated 36 studies comparing the efficacy and safety of ginkgo in patients with dementia or cognitive decline. Nine recent studies were of adequate size, totaling over 2000 patients, with duration of at least 6 months and good methodology. Higher-quality trials lacked consistent results that demonstrated benefit on cognition, activities of daily living, mood, depression, and care burden. The subgroup of 925 patients with Alzheimer's disease also showed conflicting results.<sup>90</sup>

Recently, a large randomized placebo-controlled trial, GuidAGE, assessed the prevention of Alzheimer's disease in patients older than 70 years. At 5 years, no significant differences were noted between patients taking 120 mg EGb 761 twice daily or placebo.<sup>91</sup>

The Ginkgo Evaluation of Memory (GEM) study evaluated 120 mg of ginkgo extract twice daily versus placebo in more than 3000 community-dwelling adults ages 72-96 years. At baseline, participants either had no cognitive impairment or only mild disease, and the study had a mean follow-up of about 6 years. The two groups were similar in the rates of change measured by the Modified Mini-Mental State Examination, the cognitive subscale of the Alzheimer Disease Assessment Scale, and the neuropsychological domains of memory, attention, visual-spatial construction, language, and executive functions.<sup>92</sup> Older adults with normal cognition are unlikely to benefit from the use of ginkgo.

## Kava

Kava is derived from the rhizome and roots of *Piper methysticum* G. Forster. A member of the black pepper family (Piperaceae), kava is widely used by Pacific Islanders as a social and ceremonial tranquilizing beverage.

### Therapeutic Uses

Kava is used to treat mild anxiety and sleep disturbances.

### Physiologic Activity

The pharmacologically active constituents of kava are kavalactones and kavapyrones. The mechanism of action affects sodium and calcium channels, inhibiting central monoamine oxidase (MAO)-B, and modulating gamma-aminobutyric acid (GABA) receptors. Kava may also inhibit reuptake of noradrenaline and dopamine.<sup>93</sup>

### Dosage and Product Considerations

The usual daily dosage of kava is equivalent to 60-120 mg of kavapyrones in divided doses or 70-280 mg kavalactones at bedtime. Kava extract is generally standardized to 30% kavalactones. WS 1490 is a standardized kava extract used in many studies at 300 mg per day.<sup>94</sup> Kava-containing products have limited availability because of concerns about the risk of hepatotoxicity as discussed in the next section.

### Safety Considerations

Dizziness and drowsiness are most commonly reported with high doses of kava. The use of kava is discouraged during operation of machinery or motor vehicles. Acute overdoses may result in impaired mental status and ataxia.<sup>95</sup> Mouth ulceration and numbness occurs if the raw plant is chewed. Kava dermatopathy syndrome, a dry, scaly rash primarily on the palms, soles, forearms, shins, and back, can appear in patients chronically using high-dose kava teas, tablets, or the native plant; the rash is reversible upon discontinuation of use. Hematological findings such as thrombocytopenia, leukopenia, increased red blood cells, and reduced serum albumin have been observed. Kava

should be avoided during pregnancy and lactation because of lack of safety information.<sup>94</sup>

In 2002, the Center for Food Safety and Nutrition issued a warning advising consumers and professionals of the risk of severe liver injury associated with kava-containing supplements. Germany, Switzerland, Canada, Australia, and France have restricted the sale of kava products in response to case reports of liver failure associated with use.<sup>96</sup> Several factors are in question as to the origin of liver injury, including aqueous versus acetone or ethanol extracts, continuous high doses, inappropriate raw products, and potential contaminants. No updates to the consumer advisory have been made.<sup>97</sup>

Concomitant use of kava with alcohol and other central nervous system (CNS) depressants (e.g., benzodiazepines, anticonvulsants, opioids, and valerian) could increase the risk of sedation. Kava should not be taken with other hepatotoxic medications, natural products, or alcohol. Kava may interfere with dopamine transmission, resulting in an interaction with levodopa or worsening of symptoms of parkinsonism.<sup>87</sup>

### Summary of Clinical Evidence

Small studies have shown kava extracts to be superior to placebo for short-term treatment of anxiety. A 3-week, placebo-controlled, double-blind crossover study of 60 adults with generalized anxiety accompanied by depression used an aqueous extract of 250 mg/day of kavalactones. Results demonstrated a significant impact on scores for the Hamilton Anxiety (HAM-A) Scale and for the Beck Anxiety Inventory and Montgomery-Asberg Depression Rating Scale.<sup>98</sup> A meta-analysis of kava extract WS 1490 reported efficacy (OR 3.3, 95% CI, 2.09-5.22) compared with the placebo change in HAM-A; however, overall HAM-A scores were not significant. Women and younger patients showed the most improvement.<sup>99</sup>

## Melatonin

### Therapeutic Uses

Melatonin, a hormone produced by the pineal gland, is synthesized from tryptophan via a serotonin pathway. Melatonin has Food and Drug Administration (FDA) orphan drug status for sleep disorders in blind patients. Dietary supplement melatonin is primarily used for insomnia and prevention of jet lag.

### Physiologic Activity

Melatonin regulates sleep and circadian rhythms. Its release is induced by darkness and suppressed by light; exogenous administration increases concentrations to stimulate sleep regulation mechanisms. When taken near bedtime, melatonin does not generally cause drowsiness; instead, it makes attempts to sleep more successful. A potent antioxidant, melatonin has regulatory effects on sexual development and ovulation and may have effects on bone regulation.<sup>100-102</sup>

### Dosage and Product Considerations

For insomnia, 0.3-5 mg can be taken 30 minutes prior to bedtime. For jet lag, the dosage is 2-5 mg the evening (between 5:00 and 10:00 pm) of arrival day at the destination and at bedtime for the following 2-5 days. The dosage for occasional insomnia remains unclear; even 0.3 mg will produce supraphysiologic concentrations and, although higher doses may not be more effective, dosages of 3 mg or 5 mg are most commonly used.<sup>103</sup>

Most melatonin is produced synthetically. Products extracted from bovine pineal glands are available; these products may carry added risk of bacterial contamination and bovine spongiform encephalitis (mad cow disease), so they should be avoided.

### Safety Considerations

Rare adverse effects include nausea and vomiting, headache, tachycardia, irritability, dysthymia and worsening of depressive symptoms, and a morning hangover effect.<sup>100</sup> Long-term use is recommended only under direct supervision of a health care provider.

Melatonin use in children and adolescents is controversial because of potential hormonal effects. Use in children should be discussed first with a health care provider. The use of melatonin should be avoided during pregnancy and lactation.

Several drug interactions are known. Fluvoxamine, MAO inhibitors, and tricyclic antidepressants may increase endogenous melatonin concentrations, whereas benzodiazepines and sodium valproate decrease nighttime concentrations. Oral contraceptives and caffeine have variable effects on melatonin concentrations in women, depending on the reproductive cycle phase.<sup>104</sup> Verapamil may decrease concentrations by increasing melatonin excretion. Nifedipine's effects are reduced, but whether melatonin affects nifedipine or the gastrointestinal

therapeutic system (GITS) delivery method is unclear.<sup>105</sup>

Melatonin may increase effectiveness of some types of chemotherapy or radiotherapy for cancer and help reduce toxicities of doxorubicin and cisplatin.<sup>106,107</sup> Patients should always discuss any melatonin use with their oncologist.

### Summary of Clinical Evidence

Evidence of the effectiveness of melatonin for sleep disturbances in healthy people is inconclusive.<sup>100,108</sup> One meta-analysis concluded melatonin had small but clinically significant benefits, whereas another concluded benefit was only for delayed sleep phase syndrome.<sup>103,109</sup> Individuals with developmental or neurologic disorders have had

more consistent responses to melatonin, with improved sleep and daytime behaviors.<sup>110</sup> Prolonged-release melatonin in elderly patients has improved sleep quality and daytime alertness or psychomotor performance.<sup>111</sup>

Melatonin may benefit depressed patients with sleep disorders.<sup>112,113</sup>

Melatonin can decrease jet lag when crossing five or more time zones; benefit is greater for eastward travel than westward and the amount and timing of exposure to daylight after arrival can decrease the benefit.<sup>114,115</sup> Melatonin may not be as effective as zolpidem for sleep improvement or daytime tiredness.<sup>116</sup>

Despite some positive trial results, evidence does not strongly support melatonin for insomnia caused by shift work, although other delayed sleep phase disorders may benefit.<sup>108</sup>

### St. John's Wort

*Hypericum perforatum* L. is a perennial with more than 400 species that grow wild throughout Europe, Asia, North America, and South America. The yellow flowers and the leaves contain the highest levels of medicinally useful compounds. St. John's wort (SJW) is classified in the Clusiaceae family but may also be listed under the Hypericaceae family.

#### Therapeutic Uses

SJW is used to treat depression, pain, anxiety, obsessive-compulsive disorder, menopause symptoms, and premenstrual syndrome.

#### Physiologic Activity

Although hypericin was previously considered to have antidepressant activity, evidence now indicates that hyperforin and related compounds are mainly responsible. Other potential biologically active constituents include flavonoids and its derivatives, as well as procyanides, tannins, volatile oils, amino acids, phenylpropanes, and xanthenes. SJW appears to modulate serotonin, dopamine, and norepinephrine. Additional data suggest SJW may also activate GABA and glutamate receptors and potentially inhibit MAO.<sup>117,118</sup>

#### Dosage and Product Considerations

The dosage of SJW for adults with mild-moderate depression is 900-1800 mg/day of standardized extract of 0.3% hypericin or 2%-5% hyperforin. It should be taken in three divided doses with meals. LI 160, ZE 117, WS 5570, STW3, and STW3-VI are extracts commonly used in clinical studies. The content of hypericin and hyperforin varies in commercial preparations, and products may not be interchangeable.<sup>119</sup> As with prescription antidepressants, the therapeutic effects of SJW are not evident for several weeks. Depression should never be self-diagnosed or self-treated. Patients should seek appropriate medical care for this serious condition before using SJW.

#### Safety Considerations

An analysis of randomized trials found rates of adverse effects in patients taking SJW that were similar to those for placebo. In addition, rates for SJW were much lower compared with older antidepressants and slightly lower compared with selective serotonin reuptake inhibitors (SSRIs).<sup>120</sup> The most frequently reported adverse effects include paresthesias, headache, nausea, dry mouth, agitation, and skin reactions. SJW should be avoided in patients with bipolar disorder and schizophrenia. Photosensitivity reactions have been reported although evidence is contradictory.<sup>121</sup> Until the potential photosensitivity with SJW is established, patients should limit their exposure to sun and apply sunscreen. As with SSRIs, SJW may cause sexual dysfunction. Abrupt discontinuation after chronic use may result in withdrawal symptoms similar to those of conventional antidepressants. SJW should be avoided during pregnancy and lactation.

Interactions with SJW are well documented and clinically significant (Table 51-2). SJW is a potent inducer of CYP3A4, resulting in significantly lower concentrations of drugs metabolized through this pathway. The extent of

CYP3A4 induction may correlate to hyperforin dose and varies among products.<sup>122</sup> SJW may also induce P-glycoprotein transport proteins, resulting in lower serum concentrations of drugs such as digoxin.<sup>122</sup> Additional evidence suggests possible induction of CYP2C19 and CYP2E1.<sup>122</sup> If taken with other serotonergic agents, SJW may also increase the risk of developing serotonin syndrome.<sup>122</sup>

#### Summary of Clinical Evidence

SJW may be as effective as many antidepressants with fewer adverse effects for mild-moderate depression. A Cochrane review evaluating *Hypericum* extracts for major depression included 18 placebo-controlled trials and 17 studies with an active control. SJW had a significant benefit compared with placebo and similar efficacy to standard antidepressants for mild-moderate depression. The rates for adverse effects and trial discontinuation were also significantly lower with SJW than with older antidepressants, indicating *Hypericum* extract may be more tolerable. In addition, the results vary depending on the country of origin, with German-speaking countries showing more positive outcomes. Conclusions cannot be made regarding severe depression.<sup>123</sup> Similar results have been noted with WS 5572, LI 160, WS 5570, and ZE 117 *Hypericum* extracts when compared with placebo and antidepressants. Evidence supports efficacy for mild-moderate depression, with efficacy comparable to that of fluoxetine, sertraline, and citalopram, but with better tolerability.<sup>124</sup> Preliminary evidence demonstrates potential benefit for treatment of vasomotor symptoms in perimenopausal or postmenopausal women using SJW.<sup>125</sup> (See Women's Health section). However, because of its drug interactions, SJW is not an appropriate choice for many patients.

### Valerian

Native to Europe and Asia, valerian grows in most parts of the world. More than 200 plant species belong to the genus *Valeriana*. The most common plant used for medicinal purposes is *Valeriana officinalis* L. from the Valerianaceae family.

#### Therapeutic Uses

Valerian is used for alleviating insomnia and anxiety.

#### Physiologic Activity

The CNS activity of valerian may be the result of valepotriates and sesquiterpene constituents of the volatile oils. Other active components include alkaloids, furanofuran ligands, and free amino acids, including GABA. Valeric acid and other components likely interact with GABA receptors in the brain, with valeproates and valeric acid producing sedation.<sup>126</sup> Valerian may also have barbiturate-like CNS depressant effects.

#### Dosage and Product Considerations

Most clinical trials for insomnia use valerian root extract in a dosage of 400-900 mg, administered 30-120 minutes before bedtime. Teas can be prepared from dried roots, although they often have an unpleasant taste and smell. Combination products with hops or lemon balm are commonly marketed.

#### Safety Considerations

Valerian is generally well tolerated with headache, excitability, and paradoxical insomnia occurring infrequently. Benzodiazepine-like withdrawal symptoms have been reported after discontinuation of valerian. Residual daytime sedation has been associated with higher dosages. *Valeriana officinalis* preparations are safe despite the known in vitro cytotoxic activity of valepotriates, which are generally not found in products. Chronic administration has been linked to hepatotoxicity, although reports include multi-ingredient products and the role of valerian is unclear. Valerian can potentiate the effects of other CNS depressants and should not be taken concomitantly. Pregnant women should avoid the use of valerian because of potential induction of uterine contractions.

#### Summary of Clinical Evidence

A meta-analysis of 18 randomized, placebo-controlled trials evaluated the effect of valerian on insomnia. Eight trials were of high quality. Subjective improvements were reported for insomnia, although the overall effectiveness of valerian could not be assessed.<sup>127</sup> A study of older adults found *V. officinalis* to be inferior to temazepam or diphenhydramine.<sup>128</sup>

### 5-Hydroxytryptophan

### Therapeutic Uses

5-Hydroxytryptophan (5-HTP) is used for depression, anxiety, and insomnia.

### Physiologic Activity

5-HTP is an intermediary step in the synthesis of serotonin from tryptophan. 5-HTP crosses the blood-brain barrier and can increase levels of several other neurotransmitters, such as dopamine and norepinephrine.<sup>129</sup>

### Dosage and Product Considerations

Patients should be counseled that depression, severe anxiety, and panic disorders are not self-treatable conditions; symptoms should be discussed with health care providers. If 5-HTP is used, close monitoring is necessary, and dosages should not exceed 150-300 mg/day.

### Safety Considerations

5-HTP is marketed as a safer alternative to tryptophan, which was banned in 1989 after more than 1500 cases of eosinophilia myalgia syndrome (EMS), including 38 deaths, were reported. Cases were originally linked to contamination of tryptophan with peak X (4,5-tryptophan-dione).<sup>130</sup> However, doubt exists about the role of peak X because EMS has also occurred with use of uncontaminated tryptophan and 5-HTP products.<sup>131,132</sup> Until more evidence is available, patients should avoid 5-HTP.

Adverse effects include nausea, vomiting, diarrhea, anorexia, belching, flatulence, and serotonergic effects.<sup>132</sup> 5-HTP should not be used during pregnancy or lactation. In addition, the product should not be used with serotonergic agents or MAOIs because of increased risk of serotonin syndrome or mania.<sup>133</sup> Carbidopa may increase 5-HTP adverse effects by decreasing its peripheral metabolism.<sup>134</sup> Use of 5-HTP may increase urinary 5-hydroxyindole acetic acid levels, resulting in misdiagnosis of carcinoid malignancy.<sup>135</sup>

### Summary of Clinical Evidence

Evidence of 5-HTP's efficacy for depression, anxiety, and insomnia is preliminary. Depression studies have been small, and few trials have been conducted in the past decade.<sup>129</sup>

## Digestive System

### Ginger

Ginger (*Zingiber officinale* Roscoe) is a perennial from the Zingiberaceae family whose rhizomes and roots are used medicinally.

### Therapeutic Uses

The primary use of ginger has been to relieve nausea and vomiting associated with pregnancy, motion sickness, chemotherapy, and surgery. Ginger has also been used for indigestion, colic, and arthritis.

### Physiologic Activity

Ginger rhizomes possess a volatile oil that contains sesquiterpene hydrocarbons, including zingiberene and alpha-curcumene with lesser amounts of farnesene, beta-sesquiphellandrene, and beta-bisabolene. Ginger also contains an oleoresin with nonvolatile pungent components, including gingerol, shogaols, and zingerone. Galanolactone, a diterpenoid isolated from ginger, and 6-shogaol have anti-5-hydroxytryptamine activity in the GI tract, which possibly contributes to ginger's antiemetic activity. Ginger does not affect GI motility or increase gastric emptying. The 6-shogaol and 6-gingerol components inhibit cyclooxygenase and lipoxygenase pathways, resulting in anti-inflammatory actions and potential inhibition of platelet thromboxane.<sup>136</sup>

### Dosage and Product Considerations

Dried ginger 250 mg 4 times daily has been used for nausea and vomiting in pregnancy. For motion sickness, a typical dosage is 2 capsules (500 mg) of dried powdered ginger root taken 30 minutes before travel, followed by 1-2 additional 500 mg capsules as needed every 4 hours. Daily dosages greater than 4 grams should be avoided.

### Safety Considerations

Mild heartburn and belching have been reported with ginger.<sup>85</sup> Ginger may increase the risk of hypoglycemia and alter platelet function at dosages greater than 1 g/day. Although findings are mixed, ginger should be used with caution by individuals also taking anticoagulants and antiplatelet agents or natural products.<sup>25,85</sup> Studies have found no significant adverse effects on pregnancy outcomes between ginger and placebo or pyridoxine.<sup>137,138</sup> A large population-based cohort study, with 1020 of 68,522 women in Norway reporting use of ginger during pregnancy, found no increase in malformations, fetal death, premature birth, low birth weight, or Apgar scores below 7. About 45% ingested ginger during the first trimester, although timing of exposure and dosing is lacking. A small, but significant, increase in vaginal bleeding was noted after week 17 (7.8% vs. 5.8%;  $p = 0.007$ ) compared with controls.<sup>139</sup> The American College of Obstetricians and Gynecologists includes ginger as an option with beneficial effects (level evidence B) in treating nausea and vomiting in pregnancy.<sup>140</sup>

#### Summary of Clinical Evidence

Mixed results have been found for ginger's efficacy in the management of postoperative and chemotherapy-induced nausea and vomiting. A meta-analysis evaluated a fixed dose of ginger in the management of postoperative nausea and vomiting.<sup>141</sup> Pooled data from five placebo-controlled trials were included, providing evidence that at least 1 gram of ginger was effective in the management of nausea and vomiting. However, the study with the strongest design did not find a difference between ginger and placebo. A systematic review of five randomized, controlled trials encompassing over 800 subjects compared ginger with metoclopramide or placebo for treatment of chemotherapy-induced nausea and vomiting. Ginger did not control the severity or incidence of acute nausea.<sup>142</sup> However, ginger may be useful as an adjunct in patients receiving highly emetogenic chemotherapy. Both populations, one with children and young adults and the other with only adults, demonstrated a significant delay and reduction in severity of symptoms when ginger powder or oil capsules were used in addition to ondansetron and dexamethasone.<sup>143,144</sup> A systematic review of pregnancy-induced nausea and vomiting evaluated six randomized controlled clinical trials and one observational study. Five studies were of high quality. In early pregnancy, ginger's efficacy was better than that of placebo and similar to that of pyridoxine.<sup>137</sup> A Cochrane review concluded that ginger may have a role in early pregnancy for nausea and vomiting.<sup>145</sup> The effectiveness of ginger for hyperemesis gravidarum is limited, so ginger should not be recommended for this condition.

#### Milk Thistle

Milk thistle (*Silybum marianum* [L.] Gaertn.) is a member of the Asteraceae/Compositae family.

#### Therapeutic Uses

Milk thistle has been used to treat liver disease, including hepatitis and cirrhosis. In Europe, it is used to treat poisoning by the mushroom *Amanita phalloides* (death cap). Milk thistle has been used as a liver protective agent for exposure to alcohol, acetaminophen, and carbon tetrachloride.

#### Physiologic Activity

Milk thistle's seeds and, to a lesser extent, the leaves and stems contain several compounds, collectively referred to as silymarin. The compounds include silybin, isosilybin, dehydrosilybin, silydianin, and silychristin. These biologically active compounds may have antioxidant, antifibrotic, and anti-inflammatory activity, in addition to other beneficial effects such as regulation of cell permeability and inhibition of mitochondrial injury. Stimulation of nucleolar polymerase A, resulting in increased ribosomal protein synthesis, stimulates liver regeneration and the formation of new hepatocytes. The antioxidant properties of silymarin may be the primary beneficial effect.

#### Dosage and Product Considerations

The average dosage is silymarin 150 mg 3 times per day for cirrhosis and silybin (silibinin) 240 mg twice daily for hepatitis. Milk thistle preparations contain varying amounts of a concentrated seed extract, standardized to flavonolignans 70%-80% calculated as silymarin; approximately 70% is silybin. Multiple products of silymarin and silybin have been used in clinical studies, but they may not be available in the United States, even with identical standardization. Liver disease resulting from alcohol, acetaminophen, and other drugs or chemicals is potentially fatal, and patients should be cautioned against self-treatment with milk thistle.

#### Safety Considerations

Neither pregnant women nor patients with an allergy to ragweed and other members of the Asteraceae/Compositae family should use milk thistle. The product may stimulate lactation, although evidence is limited.<sup>146</sup> A potential

inhibitory effect of milk thistle on several CYP isoenzymes and p-glycoprotein has been identified in vitro.<sup>87</sup>

### Summary of Clinical Evidence

Evidence to support the use of milk thistle in liver disease is limited. A Cochrane review of 18 randomized controlled studies investigated the effect of milk thistle on liver disease caused by alcohol or hepatitis B or C viral infection. Reductions in mortality or complications of liver disease or changes in liver histology were not found. Liver-related mortality was significantly reduced with inclusion of all trials but not in the five high-quality trials.<sup>147</sup> In a well-designed, randomized, placebo-controlled trial of patients with chronic hepatitis C virus who did not respond to interferon therapy, patients took 420 mg or 700 mg of silymarin daily for 6 months; the results did not demonstrate reduction in serum alanine aminotransferase levels, hepatitis C virus RNA levels, or changes in quality of life.<sup>148</sup>

### Peppermint

Peppermint (*Mentha piperita* L.) is a member of the mint family Lamiaceae. It has been cultivated for its fragrant volatile oil, which is extracted primarily from its leaves.

### Therapeutic Uses

Both peppermint leaf and oil have been used for many purposes, including treatment of irritable bowel syndrome, nonulcerative dyspepsia, colonic spasm, and tension headache.

### Physiologic Activity

The activity of peppermint may be a result of its 0.5%-4% essential oil. The oil or leaf preparations should be standardized to contain not less than 44% menthol. Menthol stereoisomers are also present, including 3% *d*-neomenthol and menthone, menthofuran, eucalyptol, and limonene. The mechanism of action of peppermint involves direct relaxation of GI smooth muscle.

### Dosage and Product Considerations

The usual dosage of peppermint oil enteric-coated capsules for irritable bowel syndrome is 0.2-0.4 mL (187-374 mg) 3 times a day 15-30 minutes before meals. Enteric-coated preparations reduce risk of heartburn. Clinical trials have studied 8-16 mL of peppermint oil solution as an antispasmodic.<sup>149</sup>

### Safety Considerations

Heartburn may be attributed to relaxation of the lower esophageal sphincter. Patients who have severe preexisting gastroesophageal conditions should avoid use of peppermint oil. Peppermint leaf tea or topical products should be used with caution in infants and small children because of possible laryngeal and bronchial spasms from volatilized menthol. The oil may also irritate mucous membranes. Data suggest that peppermint tea and peppermint oil may decrease activity of CYP3A4.<sup>87</sup> The ingestion of peppermint may decrease absorption of iron.<sup>26</sup> Antacids or other medications that increase stomach pH may affect dissolution of enteric-coated capsules.

### Summary of Clinical Evidence

Studies evaluating peppermint oil have been positive. Pooled data from one meta-analysis included four trials, three with a Jadad score greater than 4, with about 400 patients demonstrating that peppermint was more effective than placebo. The number needed to treat to prevent persistent symptoms of irritable bowel syndrome in 1 patient was 2.5.<sup>150</sup> A Cochrane review revealed similar results, although the authors used a different method of identifying high-quality trials, finding a significant improvement in global assessment (RR 2.25; 95% CI, 1.70-2.98; 225 patients) and symptom scores (RR 1.94; 95% CI, 1.09-3.46; 269 patients).<sup>151</sup> Peppermint's efficacy in reducing colonic spasms during procedures has been investigated with positive results. Studies in patients receiving barium enemas have demonstrated that the incidence of spasms is significantly decreased, compared with placebo, and is similar to that of scopolamine butylbromide.<sup>152,153</sup> Compared with intramuscular hyoscyamine, peppermint has also been shown to significantly increase the opening ratio of the pyloric ring during upper endoscopy with fewer adverse effects.<sup>154</sup> A small study administering delayed-release, enteric-coated capsules prior to colonoscopy decreased colonic spasm and pain in patients, while also decreasing procedure time.<sup>155</sup>

### Endocrine System

## Alpha-Lipoic Acid

### *Therapeutic Uses*

Alpha-lipoic acid (ALA), or thioctic acid, is an endogenous antioxidant promoted for diabetic patients. Intravenous and oral dosage forms have been studied for diabetic peripheral neuropathy.

### *Physiologic Activity*

ALA is a cofactor for glucose metabolism enzymes. Diabetic animals with decreased glucose uptake in muscle tissue have reduced ALA concentrations; theoretically, supplementation would increase enzyme activity and therefore glucose uptake. Animal studies have noted improvements in blood flow and distal conduction of nerves, whereas human studies show improvement in glucose metabolism measurements such as insulin sensitivity.<sup>156</sup>

### *Dosage and Product Considerations*

With oral bioavailability of 30%, 600 mg 3 times daily is comparable to the 600 mg intravenous dosage used in most European trials for diabetic neuropathy.<sup>157</sup> Because food decreases absorption, ALA should be taken on an empty stomach; because of its chelating activity, it should be separated 2-3 hours from antacids or other mineral-containing supplements.<sup>158</sup>

### *Safety Considerations*

Adverse effects include headache, nausea, and rash. Diabetic patients who wish to add ALA to their current regimen should discuss its use with their health care providers because additive hypoglycemic effects may occur. Frequent monitoring of glucose concentrations is necessary, especially during initial weeks of therapy.

ALA can inhibit conversion of thyroxine to triiodothyronine and may displace thyroxine from serum-binding protein. Patients with thyroid conditions should avoid the use of ALA.

### *Summary of Clinical Evidence*

Evidence for oral ALA for diabetic neuropathy is contradictory. Controlled trials have noted improvement in total symptom scores, neuropathy impairment scores, and symptoms of pain and paresthesia in the short term, whereas a 2-year study found improvements in nerve conduction but not neuropathic symptoms.<sup>159-161</sup> The most recent large (n = 460) and rigorous study of 4 years suggests that ALA may be more useful in prevention of progression of neuropathy than in acute treatment.<sup>162</sup>

Reductions in glucose and hemoglobin A1C have not been significant, although studies have noted improvement in insulin sensitivity and glucose disposal rates.<sup>156</sup> Two recent trials documented clinically significant lowering of fasting blood glucose (from 185.4 mg/dL to 156.3 mg/dL) and hemoglobin A1C (-0.6%) when ALA was added to standard antidiabetic medications in poorly controlled patients.<sup>163,164</sup> The 1200 mg daily dosage provided the greatest reduction in the parameters, and body weight was also decreased by 2.1 kg after 8 weeks in one study.<sup>163</sup>

## American Ginseng

### *Therapeutic Uses*

American ginseng, *Panax quinquefolius*, is closely related to Asian ginseng, *P. ginseng*. *P. quinquefolius* is most frequently used to reduce postprandial glucose and to reduce severity of cold and upper respiratory infection symptoms. In traditional Chinese medicine, both ginseng species are considered adaptogens to aid the body in returning to normal function and adapting to stress.

### *Physiologic Activity*

The ginsenosides present in all *Panax* species, triterpene saponins, exert their effects on blood pressure and immune cell function, whereas nonsaponin components are more responsible for hypoglycemic effects.<sup>165,166</sup> The latter compounds are more plentiful in American ginseng.

### *Dosage and Product Considerations*

Trials demonstrating reductions in postprandial glucose concentrations have used 1-9 grams of variously standardized American ginseng products 40-120 minutes before meals.<sup>167-169</sup> The dose should be limited to 1-3 grams taken 40 minutes before meals for safety.

### Safety Considerations

American ginseng is better tolerated than other ginseng species, with mild GI effects reported. Ginsenosides often occur in pairs with opposing pharmacologic actions, so adverse effects include both increased and decreased blood pressure and blood glucose concentrations.<sup>165</sup> The opposing actions may explain why two studies found no effects on blood pressure.<sup>170-172</sup> Use in patients with schizophrenia is contraindicated because of reports of worsening symptoms, although one study has shown memory improvement in patients with schizophrenia.<sup>173</sup> American ginseng may decrease the effectiveness of warfarin. This action may be caused by batch and product variability. As a result, concomitant use should be avoided.

### Summary of Clinical Evidence

Clinically significant reductions in postprandial hyperglycemia have been noted in trials, although most were short term and used glycemic loads of 25 grams, smaller than a typical meal.<sup>167,169,174</sup> Overall, long-term effects and value for glucose management are unknown, so American ginseng cannot be recommended for diabetes.

## Cinnamon

### Therapeutic Uses

Cinnamon, specifically *Cinnamomum cassia* (also called *C. aromaticum*), the type most commonly found in grocery store spice aisles, is used to help lower blood glucose. True cinnamon, *C. verum* (also called *C. zeylanicum*), contains many of the same compounds and has had similar results on blood glucose in rodent studies.<sup>175</sup> However, a human trial of true cinnamon found no effect on glucose or insulin levels, so only *C. cassia* can be recommended as a supplement.<sup>176</sup>

### Physiologic Activity

The flavonoids most responsible for hypoglycemic effects are procyanidin type-A polymers of epicatechin and catechin. Prevalent in water extracts, these flavonoids act to increase insulin sensitivity through increased insulin receptor autophosphorylation and cellular glucose uptake.<sup>177</sup> Consequently, tyrosine phosphatase, which inactivates insulin receptors, is inhibited, and anti-inflammatory actions result through changes in multiple cytokines involved in the inflammatory process.<sup>177</sup>

### Dosage and Product Considerations

The dosage of aqueous extract, the form that may be most effective, is 0.5-1 gram daily. The dosage of ground cinnamon is 2-6 grams given in divided doses, either in capsules or in food. A half-teaspoonful is about 1 gram.<sup>178</sup>

### Safety Considerations

Patients should not confuse cinnamon supplements with cinnamon oil because hypersensitivity reactions to cinnamon oil and pediatric poisoning from its ingestion have occurred.<sup>178</sup> Other than an allergic rash, no adverse events have been reported in supplement trials lasting up to 4 months. Potentiation of hypoglycemic reactions in patients on hypoglycemic medications is possible, so additional glucose monitoring is recommended. Cinnamon supplements may contain varying concentrations of coumarin, a potential hepatotoxin and carcinogen that occurs naturally in cinnamon bark.<sup>179</sup>

### Summary of Clinical Evidence

Clinical trials and meta-analyses have had contradictory results. In general, negative trials used 1-1.5 g/day, whereas positive trials used 3-6 grams or equivalent aqueous extract.<sup>180-182</sup> A well-designed trial of 2 g/day of ground cinnamon added to standard antidiabetic medications reduced mean hemoglobin A1C from 8.22% to 7.86% after 12 weeks, a significantly greater reduction than with placebo.<sup>183</sup> Small decreases in blood pressure were also reported. A recent 3-month trial of cinnamon aqueous extract (120 and 360 mg/day) added to sulfonylurea therapy found both dosages significantly reduced hemoglobin A1C (8.9% to 8.23% and 8%, respectively) compared with placebo.<sup>184</sup> Fasting plasma glucose was also reduced, from 162 mg/dL to 144 mg/dL in the 120 mg group and from 202 mg/dL to 173 mg/dL in the 360 mg group. Cinnamon could be considered for adjunctive therapy in some patients with type 2 diabetes.

## Dehydroepiandrosterone

### *Therapeutic Uses*

Dehydroepiandrosterone (DHEA) is a steroid hormone secreted by the adrenal cortex that declines with advancing age. The dietary supplement form of DHEA is marketed to treat sexual dysfunction or improve sexual performance, to combat physical and mental symptoms of aging, and to enhance athletic performance or increase muscle mass.

### *Physiologic Activity*

In general, the exogenous use of DHEA in women increases testosterone concentrations more than those of estrogen, whereas in men the reverse is true.<sup>185</sup> The extent to which androgen and estrogen transformation occurs depends partly on a patient's baseline hormone concentrations.

### *Dosage and Product Considerations*

For most uses, the dosage is 25-100 mg once daily. Because of greater risk of adverse effects with dosages over 25 mg, patients should use larger dosages only on the recommendation of a health care provider.<sup>186</sup>

Most DHEA is synthetic, but some animal-based products exist; these should be avoided because of contamination risks. Wild yam products are falsely promoted as DHEA or hormone precursors because wild yam contains diosgenin, once used by pharmaceutical manufacturers to produce estrogens and androgens. However, the necessary chemical reactions do not occur in vivo. To further complicate patient education, some wild yam plants do contain very small amounts of naturally occurring DHEA.

### *Safety Considerations*

Adverse effects are related to sex hormones. Women may experience hirsutism, voice deepening (generally irreversible), increased acne, and menstrual changes. Men have reported gynecomastia and testicular changes. If hormone-associated effects appear, DHEA should be discontinued. Other adverse effects include increased levels of liver function enzymes and possibly HDL-C cholesterol, headache, nasal congestion, and insomnia. At least four reports of mania requiring hospitalization exist, so DHEA is contraindicated in bipolar disorder and probably should be avoided in any mood disorder.<sup>186</sup> DHEA should be avoided by patients who have a history of hormone-sensitive cancer, who are taking hormonal or hormone-blocking medications, or who are pregnant or lactating. One study noted increased levels of 5-alpha-androstane-3-alpha-17-beta-diol glucuronide with DHEA supplementation in healthy young men. This substance may function as a prostate growth factor, so long-term use may have negative effects on prostate health.<sup>187</sup>

### *Summary of Clinical Evidence*

Studies of DHEA have evaluated its effects on blood glucose, lipids, and adipose tissue. Results are contradictory, with one small study in men and women over 60 years noting no improvement in glucose metabolism or body fat and small decreases in both TG and HDL-C concentrations.<sup>188</sup> Another study noted slight decreases in visceral fat and significant improvements in oral glucose tolerance; this trial also found a reduction in HDL-C concentrations in women (not men), but the decrease reversed by the end of the second treatment year.<sup>189</sup>

Oral DHEA does not improve sexual arousal or function in healthy premenopausal women.<sup>190</sup> In postmenopausal women, one small study of 10 mg/day DHEA for 1 year found improved McCoy Female Sexuality Questionnaire total scores and increased intercourse frequency equivalent to those of the hormone therapy group.<sup>191</sup> The evidence of the effectiveness of DHEA for erectile dysfunction is also preliminary. In two trials, improvement was noted for erectile dysfunction related to hypertension or unknown causes but not for diabetes-related or neurologically-induced dysfunction. Men with documented declines in DHEA levels did not have benefits for sexuality, lipids, or body composition.<sup>192,193</sup>

Even high dosages of DHEA do not increase strength, lean body mass, or athletic performance in young healthy men, although strength and body composition may be improved in older men and women when supplementation is combined with exercise.<sup>194-196</sup> Some study patients have noted improved skin health, such as increased epidermal thickness and sebum production; topical use may also beneficially affect aging skin.<sup>193,197</sup> Three trials have noted increases in vertebral bone mineral density, although the benefit is limited to women.<sup>198,199</sup>

## **Immune Modulators**

### **Colostrum**

#### *Therapeutic Uses*

Colostrum is the thin, white fluid secreted by mammary glands immediately after birth and prior to milk production. It provides passive immunity against many pathogens until the newborn is able to produce sufficient antibodies. In addition to treatment of different types of diarrhea, colostrum is marketed for general well-being, improved athletic performance, and immune system stimulation.

### *Physiologic Activity*

Colostrum is rich in antibodies, immunoglobulins A and E, and growth factors, which may be the components that provide immune-modulating benefits. Hyperimmune bovine colostrum, which is collected from cows inoculated with pathogens to induce production of specific antibodies and immunoglobulins, has FDA-approved orphan drug status for conditions such as acquired immunodeficiency syndrome (AIDS)-related diarrhea. Dietary supplement bovine colostrum products are generally not collected from inoculated cows. The results of research with hyperimmune colostrum cannot be extrapolated to other types; this section discusses only dietary supplement colostrum products. Human studies have found that bovine colostrum and colostrum extracts can increase serum concentrations of insulin-like growth factor and immune variables such as interleukins, interferons, and immune globulins, as well as inhibit the absorption of lipopolysaccharide endotoxins from the intestine.<sup>200,201</sup> A preliminary study suggested that bovine colostrum may have beneficial effects on blood glucose and lipid levels in diabetic patients.<sup>202</sup>

### *Dosage and Product Considerations*

Trials have used a wide range of dosages and formulations; dosages of colostrum powder of 20-60 grams once daily are common.

A cow never exposed to a pathogen will not produce antibodies to that pathogen, so immune function benefit is general. Patients should be wary of colostrum marketing claims regarding specific diseases or pathogens. Products carry a small risk of contamination from diseased cattle. Risk of bovine spongiform encephalitis is almost nil because colostrum is collected from live cattle and should not come in contact with nerve tissue.

### *Safety Considerations*

Adverse effects include increased liver function enzymes in patients with AIDS and GI upset. Individuals with milk allergies and pregnant or lactating women should avoid the use of colostrum.

### *Summary of Clinical Evidence*

Research on bovine colostrum's effects on strength and endurance do not support improvement in athletic performance. Dietary supplement bovine colostrum is promoted to counteract decreases in immune function seen with intense physical exercise. Trials examining the exercise-related decreases and changes in intestinal permeability have noted both no effects and increases in interleukins, interferons, and immune globulins, as well as both increases and decreases in intestinal permeability.<sup>203,204</sup>

An Italian trial found bovine colostrum combined with influenza vaccination was 3 times more effective at reducing flu sick days compared with vaccination alone.<sup>205</sup> Another study examined patient logbooks from earlier studies that compared concentrated bovine colostrum versus whey protein (as placebo).<sup>206</sup> Upper respiratory symptoms reported in bovine colostrum and whey protein users were 32% and 48%, respectively.

## **Echinacea**

*Echinacea* species used in clinical trials include *E. purpurea*, *E. angustifolia*, and *E. pallida*. Roots, leaves, and flowers are all used medicinally; depending on the species, the above-ground parts may have greater activity.

### Therapeutic Uses

Echinacea is used to prevent and treat colds and other respiratory infections.

### Physiologic Activity

Echinacea has many different components targeting the nonspecific cellular immune system, including alkylamides, caffeic acid derivatives (e.g., chicoric acid), flavonoids, glycoproteins, and polysaccharides. Multiple mechanisms of action may be involved, including increased cytokine secretion, lymphocyte activity, and phagocytosis. Direct inactivation of viruses, bacteria, and fungi has been observed.<sup>207</sup> Anti-inflammatory activities and decreases in mucin production may be more directly responsible for decreased symptoms of upper respiratory infections.<sup>207</sup>

### Dosage and Product Considerations

Products labeled as echinacea may contain chemically different plants or plant parts, making product comparisons difficult. The optimal standardization and dosage for echinacea are unknown. Standardized concentrates, such as Echinaforce, generally perform better in trials. Echinacea is available in single- and multiple-ingredient formulations, such as teas, extracts, juices, throat sprays, capsules, and tablets; each formulation has its own dosing regimen. Many products available in the United States are less concentrated or are labeled for use at dosages much lower than those used in clinical trials. All formulations must be taken at the first sign of illness.

### Safety Considerations

Adverse effects include mild GI discomfort, tingling sensation of the tongue, and headache. Allergic reactions may occur. Patients with a history of asthma or atopy should avoid echinacea; a severe allergy to the Asteraceae/Compositae family, which includes ragweed and chrysanthemums, is a contraindication. Use of echinacea should be avoided in patients with severe systemic illnesses, such as human immunodeficiency virus (HIV) infection or AIDS, multiple sclerosis, tuberculosis, and autoimmune disorders, and in patients taking immunosuppressants; this concern, however, is based on case reports and theory.<sup>208</sup> Echinacea exhibits some effects on P-glycoprotein transport and several intestinal and hepatic CYP450 systems; except for drugs with a narrow therapeutic range, these effects are not likely to be significant.<sup>209</sup> A systematic review of use of echinacea during pregnancy found no differences in rates of major malformations during pregnancy.<sup>210</sup>

### Summary of Clinical Evidence

A Cochrane review analyzed 16 clinical trials that evaluated echinacea for treatment and prevention of the common cold.<sup>211</sup> For treatment, nine studies reported a significant effect on severity and duration compared with placebo, whereas six showed no benefit. *E. purpurea* demonstrated the best results when administered at the first sign of symptoms. A meta-analysis of 14 randomized placebo-controlled studies found a significant reduction in duration of 1.4 days, and the risk of cold development was reduced by 58%.<sup>212</sup> A trial using a low overall dosage and use of echinacea within 36 hours of the onset of cold symptoms demonstrated a shorter duration of symptoms of less than half a day, which is unlikely to be clinically significant.<sup>213</sup>

For prevention of colds, three comparisons showed no benefit over placebo.<sup>211</sup> An additional 8-week study of echinacea prophylaxis found no benefit over placebo for reducing cold frequency.<sup>214</sup> Overall, results have been inconsistent and a review has proposed a more consistent approach to outcomes measurement for future studies.<sup>215</sup> A pilot study in adults with respiratory disease compared the rates of influenza- and parainfluenza-like symptoms and respiratory complications in groups prophylactically given influenza vaccine, a hydroalcoholic root extract of *E. angustifolia* roots, or both. Rate decreases were found in the echinacea-only and echinacea+vaccine groups compared with the vaccine-alone group.<sup>216</sup> Parainfluenza-like symptoms occurred in five patients in the vaccine-only group and in only one patient in each of the echinacea-only and echinacea+vaccine groups. Echinacea throat sprays are commonly sold. A randomized, controlled, double-dummy study compared an echinacea/sage extract spray to a standard lidocaine/chlorhexidine spray. Response rates and symptom decreases were similar between groups, with 50% of patients reaching symptom-free status a half day sooner in the echinacea group than in the lidocaine group; this result was not statistically significant.<sup>217</sup>

## Elderberry

### Therapeutic Uses

Juice or extracts of the *Sambucus nigra* berry are used for prevention or treatment of influenza and other upper respiratory illnesses.

### Physiologic Activity

Elderberries contain many vitamins (e.g., C, B<sub>2</sub>, B<sub>6</sub>, folic acid, beta-carotene) and multiple flavonoids and anthocyanins.<sup>218</sup> Activities include inhibition of replication of viruses, increased production of anti-inflammatory and inflammatory cytokines, strong antioxidant capacity, and inhibition of hemagglutination of the influenza virus, which prevents entry into cells.<sup>219</sup> Liquid extracts have inhibited growth of several gram-positive and gram-negative bacteria.<sup>220</sup> A rigorous in vitro and animal study determined that in vitro activity against influenza A virus was relatively weak, but viral antibodies significantly increased.<sup>221</sup>

### Dosage and Product Considerations

Elderberry is available in multiple dosage forms. Clinical trials have been performed with at least three products: a

spray-dried elderberry juice (400 mg 3 times daily, 10% anthocyanins), a syrup standardized to flavonoid content (Sambucol), and an encapsulated extract (125 mg anthocyanin).<sup>222-224</sup> The optimal standardization and dosage form have not been determined.

### Safety Considerations

Use of appropriate products is important because insufficiently cooked or unripe berries, stems, or leaves contain cyanogenic glycosides metabolized in the GI tract to cyanide; reports exist of not only nausea and vomiting but also dizziness, weakness, and stupor with home-prepared juices and extracts.<sup>218</sup> Commercially available elderberry extracts are well tolerated.

### Summary of Clinical Evidence

The first study of elderberry extract (Sambucol) used 30 mL (15 mL for children) daily for 3 days in patients reporting flu symptoms during an outbreak of influenza B. The duration of fever was 4 days versus 6 days in the treatment and placebo groups, respectively. After 3 days “complete cure” was noted in 46.7% of elderberry-treated patients and 16.7% of placebo-treated patients.<sup>223</sup> The second study (n = 60) of elderberry extract (Sambucol) during an influenza A epidemic used a visual analogue scale to assess symptom improvement and found that elderberry-treated patients reached scores closer to “pronounced improvement” (10 on the 0-10 scale) within 3-4 days, whereas placebo-treated patients reached similar scores after 7-8 days.<sup>225</sup> Rescue medications of a nasal spray and analgesic were used by 21 and 26 patients, respectively, in the placebo group and by 5 and 7 patients, respectively, in the elderberry group. The use of elderberry extracts is an option for patients with flu or upper respiratory symptoms.

## Probiotics

### Therapeutic Uses

The term *probiotics* refers to several types of beneficial bacteria, including *Lactobacillus* spp. and *Bifidobacterium* spp., and one yeast, *Saccharomyces boulardii*. In addition to antibiotic-associated diarrhea and other GI disorders (see [Chapter 23](#)), probiotics are also used for atopic dermatitis and allergies and are being investigated for prevention and treatment of upper respiratory infections.

### Physiologic Activity

The mechanisms by which probiotics reduce allergic symptoms such as rhinitis or dermatitis are not well understood. Probiotics decrease intestinal permeability, which may help to decrease exposure to allergens. The normalization of gut flora decreases inflammatory responses, but probiotics may have immunomodulating activity. Macrophage and lymphocyte activity are both affected, as are various cytokines, such as increased interferon-alpha and immunoglobulin and decreased tumor necrosis factor. (See [Chapter 23](#), [Table 23-8](#) for an in-depth discussion of other potential physiologic effects with probiotics.)

### Dosage and Product Considerations

Many probiotic preparations with one or multiple species and wide dosing ranges are available. Health care providers and consumers should be cautious in selecting products because many species and strains of probiotic bacteria exist; results from studies using one product may not be applicable to different species or strains. (See [Chapter 23](#), [Table 23-9](#).)

For atopy and dermatitis, *Lactobacillus rhamnosus* GG is the most researched and recommended, although *L. acidophilus* and *Bifidobacterium lactis* have also shown benefit.<sup>226,227</sup> *Lactobacillus* and *Bifidobacterium* species are dosed at 1-10 billion colony-forming units per day, given in divided doses. *Saccharomyces boulardii* is dosed at 250-500 mg taken 2-4 times daily. Trials have investigated multiple species, but *Bifidobacterium*-dominant products are generally preferred in infants because they better match the normal flora in this population. Product quality has been a concern because some studies found products containing few or no live cultures; refrigerated products have been recommended as perhaps less likely to have suffered from degrading temperatures.<sup>228</sup> Recent research suggests that dead probiotics may also offer benefit by triggering gut anti-inflammatory responses.<sup>229,230</sup>

### Safety Considerations

GI adverse effects including mild bloating and flatulence subside over time, and titration of doses may minimize these adverse effects. Diarrhea has been reported in children. Although probiotics are being studied in HIV-positive and AIDS patients, immunocompromised patients should avoid their use because of rare reports of systemic infection.<sup>231</sup>

No harmful effects have been observed in women in late-stage pregnancy or in breast-feeding infants during long-term use.<sup>232</sup> Doses of antimicrobial agents should be administered several hours apart from probiotics.

#### Summary of Clinical Evidence

Early trials demonstrated a reduction in the development of eczematous dermatitis, asthma, and atopic sensitization in infants after mothers were treated with probiotics during pregnancy and/or breast-feeding. Several recent trials have not supported any benefit of this practice.<sup>226,233-235</sup> Studies in children with atopic dermatitis have had contradictory results, ranging from no benefit to substantially significant improvement in symptoms and SCORAD (SCORing Atopic Dermatitis) values.<sup>227,236</sup> Adults with atopic dermatitis have also benefitted from probiotic treatments; a recent trial demonstrated significant reductions in SCORAD indices with use of *L. salivarius*.<sup>237</sup> The most recent meta-analysis of probiotics for reduction of respiratory tract infections in children and adults concluded that the results were greater than placebo.<sup>238</sup> Studies used different single and combination therapies, but *Lactobacillus* species were used most often. A combination of *L. rhamnosus* and *B. adolescentis* in a yogurt product demonstrated changes in cytokines but no significant benefits on symptoms or quality of life scores.<sup>239</sup> Children with asthma and allergic rhinitis had improved pulmonary function and decreased rhinitis symptom scores when treated with *L. gasseri* for 2 months.<sup>240</sup> The low cost and safety of probiotics support their use as a treatment option, alone or in conjunction with standard therapies.

### Physical and Mental Performance Enhancers

#### Eleuthero

*Eleutherococcus senticosus* from the Araliaceae family is often referred to as *Acanthopanax senticosus* or Siberian ginseng. The plant is not a genus of *Panax*, as are Asian and American ginseng species. *Eleutherococcus* is found in eastern Siberia, northeastern China, Korea, and Hokkaido Island in Japan.

#### Therapeutic Uses

Eleuthero's traditional use is as an adaptogen for improvement of athletic performance, chronic stress, upper respiratory conditions, and immune deficiency. Other uses include treatment of herpes simplex type 2 infections, blood pressure (hypotension and hypertension), prevention of atherosclerosis, and diabetes mellitus.

#### Physiologic Activity

The active compounds of eleuthero, derived primarily from the root and leaf, are referred to as eleutherosides (subtypes A to M). Flavonoids, hydroxycinnamates, and other constituents such as sesamin, B-sitosterol, hederasaponin B, and isofraxidin may also have biological activity. Animal studies and in vitro analysis suggest these compounds have antiplatelet, immunostimulant, and antioxidant properties.<sup>241</sup>

#### Dosage and Product Considerations

Commercial products are often standardized to eleutheroside B and/or E content at a dosage of 300-400 mg/day. A 33% ethanolic extract 10 mL taken 3 times a day has also been used. After 2 months of daily use, patients should discontinue the product for a minimum of 2 weeks.<sup>241</sup>

#### Safety Considerations

Both drowsiness and stimulant effects have been reported with eleuthero. Because of its variable effects on blood pressure, eleuthero should be avoided in patients with hypertension. Theoretically, patients with diabetes mellitus should be monitored for hypoglycemia. Eleuthero does not affect activity of CYP2D6 and CYP3A4 at normal dosages.<sup>241</sup> Safety data are lacking for use during pregnancy and lactation. In patients taking digoxin, eleuthero may interfere with digoxin assays because of structural likeness of some of its glycosides.<sup>87</sup>

#### Summary of Clinical Evidence

Well-designed, randomized clinical trials documenting the safety and efficacy of eleuthero are lacking. In a small 6-month study, *Eleutherococcus* extract taken once daily demonstrated a beneficial effect on frequency, severity, and duration of herpes simplex type 2 infections.<sup>242</sup> A small trial in elderly patients found improvement in social function measures related to quality of life after 4 weeks of use, but not at 8 weeks.<sup>243</sup>

### Ginseng (Panax Ginseng)

The root and rhizome of Asian ginseng (*Panax ginseng* C.A. Meyer) is from the family Araliaceae and is exported primarily from Korea, China, and Japan.

### Therapeutic Uses

Asian ginseng has been used to improve mental and physical stress, anemia, diabetes mellitus, immune response, insomnia, and impotence, and for cancer prevention.

### Physiologic Activity

The constituents likely responsible for ginseng's adaptogen activity are triterpenoid saponins, including ginsenosides. At least 30 ginsenosides, also referred to as panaxosides, have been identified. Additional constituents include carbohydrates, B vitamins, and flavonoids.<sup>244</sup>

### Dosage and Product Considerations

Ginseng extracts are standardized to 4% ginsenosides administered at 200 mg/day in divided doses. Crude powdered root has been used in dosages of 2-3 g/day. Decoctions and tea preparations are also commonly used.<sup>244</sup>

### Safety Considerations

Adverse effects include insomnia, headache, blood pressure changes, anorexia, rash, mastalgia, and menstrual abnormalities. Large dosages can result in gastric upset and CNS stimulation. Ginseng should be used with caution in patients with cardiovascular disease, diabetes mellitus, or acute illness. Ginseng's effect on anticoagulant and antiplatelet therapy is not predictable. The use of ginseng with phenelzine or other MAOIs, corticosteroids, or large amounts of stimulants, including caffeine-containing beverages, should be avoided.<sup>85,244</sup> Concurrent use with imatinib has resulted in hepatotoxicity.<sup>87</sup> Ginseng abuse syndrome has been described in long-term ginseng users. Although reports have been discredited, prolonged use of ginseng is not recommended.<sup>244</sup> Ginseng should not be used during pregnancy or lactation because of a lack of data and concern about its potential estrogenic effects.<sup>245</sup>

### Summary of Clinical Evidence

Small short-term studies that evaluated Asian ginseng's effect on fasting and postprandial glucose concentrations in patients with type 2 diabetes mellitus yielded mixed results. A systematic review of randomized controlled trials, four of which met inclusion criteria, found a lack of overall effect on fasting blood glucose, hemoglobin A1C, or 2-hour postprandial glucose.<sup>246</sup>

For erectile dysfunction, a systematic review of seven randomized controlled trials found significant benefit with Asian ginseng, although the review noted the limitations of a small sample size and trial quality.<sup>247</sup> A small, randomized, placebo-controlled trial found benefit in improving sexual arousal in menopausal women.<sup>248</sup>

Five trials were included in a Cochrane review of the role of *P. ginseng* for cognition; the majority of subjects were healthy. Because of various dosing regimens, outcomes, and study length, data could not be pooled. Although ginseng benefited some end points related to cognitive function, quality of life, and behavior, available evidence does not support its use.<sup>249</sup>

## Green Tea

Native to southeastern Asia, the tea shrub *Camellia sinensis* (L.) Kuntze belongs to the family Theaceae. Tea leaves are heated immediately after harvesting and then mechanically rolled and crushed before drying to produce green tea. From the same plant as green tea, black tea is produced by allowing the leaves to wilt before they are rolled and left in a humid environment for several hours. This process promotes fermentation and a gradual change in color to reddish-brown. Oolong, another commonly available tea, is a partially fermented tea.

### Therapeutic Uses

Green tea is considered a performance enhancer because of the stimulant effect from caffeine. Green tea has also been used to prevent cardiovascular disease, cancer, and liver disorders. A topical prescription product, Polyphenon E, made from green tea extract is approved for the treatment of condylomata acuminata.<sup>250</sup>

### Physiologic Activity

In addition to caffeine, green tea contains polyphenolic compounds including flavonols (also known as catechins),

flavonoids, and phenolic acids. The most prevalent flavonols include epicatechin, epicatechin-3-gallate, epigallocatechin, and epigallocatechin-3-gallate. These components are thought to have antioxidant and antitumor effects.<sup>251</sup> Catechins and caffeine may each contribute to weight loss.<sup>252</sup>

#### Dosage and Product Considerations

Dosages of green tea in epidemiologic studies vary between 1 and 10 cups daily. The preferred dosage is 3-5 cups per day, or up to 1200 mL/day, including a minimum of 250 mg/day of catechins.<sup>253</sup> Green tea extract supplements standardized to polyphenol content retain effects similar to those of green tea while reducing exposure to caffeine.<sup>251</sup>

#### Safety Considerations

Ingestion of large quantities of green tea can cause adverse GI symptoms as well as CNS and cardiac stimulation attributed to the caffeine content. One 8-ounce cup of green tea contains 24-40 mg of caffeine. In comparison, an 8-ounce cup of black tea has 14-61 mg of caffeine, and an 8-ounce cup of coffee can range from 95 to 200 mg on average.<sup>254</sup> Green tea should be avoided if other stimulating drugs are ingested. Green tea products have been associated with liver toxicity.<sup>255</sup> Serum folate levels have also been reduced by green tea.<sup>87</sup> Green tea should be used cautiously during pregnancy and lactation because of caffeine consumption and potential folic acid concerns. Green tea in large dosages may antagonize the effects of warfarin because of small amounts of vitamin K.<sup>85</sup>

#### Summary of Clinical Evidence

Epidemiologic data suggest that daily consumption of green tea may protect against cardiovascular and metabolic diseases.<sup>256</sup> A randomized placebo-controlled trial demonstrated that standardized green tea capsules lowered blood pressure, serum lipids, and serum amyloid alpha in healthy adults at the end of 3 weeks.<sup>257</sup> Another randomized controlled trial of theaflavin-enriched green tea extract demonstrated mild reductions in LDL-C concentrations in patients on diets low in saturated fats.<sup>258</sup> Green and black teas are currently being reviewed for primary prevention of cardiovascular disease by the Cochrane Heart Group.<sup>259</sup> In obese patients, a Cochrane review found green tea products had no significant effects for weight loss and weight maintenance.<sup>252</sup> Consumption of green tea to reduce the incidence of breast, prostate, lung, bladder, ovarian, digestive, and oral cancers has been studied. A Cochrane review of 51 studies that included 1.6 million subjects was unable to identify a substantive link to green tea consumption and cancer prevention. Most studies were epidemiologic and performed in Asia where green tea consumption is high. The only randomized controlled trial, coupled with higher quality observational studies, found a reduction in prostate cancer risk with consumption of larger quantities. Although data were limited, evidence for prevention of lung, pancreatic, and colorectal cancer was moderate to strong.<sup>253</sup>

### **Kidney, Urinary Tract, and Prostate**

#### African Plum

African plum is derived from the bark of *Prunus africana* (Hook f.) Kalkman (syn. *Pygeum africanum* Hook f.), a member of the Rosaceae family.

#### Therapeutic Uses

Pygeum (African plum tree) bark has been used to treat benign prostatic hyperplasia (BPH).

#### Physiologic Activity

Pygeum bark contains phytosterols; pentacyclic triterpenes, including ursolic and oleanic acids; and ferulic acid esters, including docosanol and tetracosanol. Phytosterols may compete with androgen precursors and inhibit prostaglandin synthesis in the prostate. Triterpenes may have anti-inflammatory properties. Ferulic acid esters reduce concentrations of prolactin and prostate cholesterol, a precursor to testosterone synthesis.<sup>260</sup>

#### Dosage and Product Considerations

Products are standardized to contain 14% triterpenes and 0.5% *n*-docosanol; the average dosage is 50-100 mg twice daily.<sup>261</sup> Demand for pygeum extract has caused the African plum tree to become a threatened species, with current international trade being monitored under the Convention on International Trade in Endangered Species of Wild Fauna and Flora.<sup>260</sup>

## Safety Considerations

Adverse effects include diarrhea, constipation, and gastric pain. Men presenting with prostate symptoms should contact their health care provider before starting pygeum to rule out prostate cancer. It is unclear if pygeum affects prostate-specific antigen concentrations. Adverse effects are increased if pygeum is combined with finasteride.

## Summary of Clinical Evidence

Pygeum has improved urinary flow, void volumes, residual volumes, nocturia, daytime frequency, and subjective symptom assessments of BPH. Larger studies that include standardized dosages, active comparisons, and adequate durations are needed to fully assess its efficacy.<sup>262</sup>

## Cranberry

Cranberry (*Vaccinium macrocarpon* Ait.) is an evergreen bush native to North America and belongs to the family Ericaceae.

## Therapeutic Uses

Cranberry has been used to prevent and treat urinary tract infections (UTIs).

## Physiologic Activity

Cranberry contains proanthocyanidins. Epicatechin is the primary proanthocyanidin found in cranberry extracts. Evidence suggests that cranberry blocks bacteria, *Escherichia coli*, in particular, from adhering to bladder, kidneys, and urethra. Fructose found in cranberry juice may also alter bacterial adhesion.<sup>263</sup>

## Dosage and Product Considerations

Many studies have used unsweetened cranberry juices. Cranberry juice cocktail is about 30% pure cranberry juice and contains sugar; it is unknown if this product will demonstrate the same effects. Efficacy appears to be based on the proanthocyanidins content, although controlling for this variable in studies is inconsistent. For prevention of UTI, the dosage of cranberry juice is 300-900 mL/day. Encapsulated cranberry formulations at a dosage of about 400 mg twice daily may be preferred to avoid the sugar content of juices.

## Safety Considerations

Evidence suggests that regular use of cranberry concentrate tablets might increase risk of kidney stones.<sup>264</sup> Patients may experience diarrhea with large daily doses. Theoretically, cranberry juice may alter excretion of weakly alkaline drugs or neutralize effects of antacids. Case reports have suggested cranberry may cause bleeding in patients taking warfarin; however, pharmacokinetic and pharmacodynamic evidence is lacking.<sup>87,265</sup>

## Summary of Clinical Evidence

A Cochrane review of 24 studies, with 13 included in a meta-analysis, concluded preventive use of cranberry products does not significantly reduce the overall risk of UTIs or in subgroups of women or children with recurrent UTIs, older adults, pregnant women, cancer patients, and catheterized patients. A high dropout rate suggests long-term use of cranberry, specifically juice, is not well tolerated.<sup>266</sup> It is unknown if tablet or capsule products included in studies contain enough proanthocyanidins to be effective.<sup>266</sup> Cranberry should not be used to treat UTIs, and patients should be referred to their health care provider.<sup>267</sup>

## Saw Palmetto

Saw palmetto (*Serenoa repens* [Michx.] G. Nichols), a dwarf palm tree from the Arecaceae family, is native to the southeast coastal region of the United States.

## Therapeutic Uses

Saw palmetto has been used to treat BPH.

## Physiologic Activity

The lipophilic extracts from the ripened fruit contain saturated and unsaturated fatty acids and plant sterols. Although the active compounds have not been identified, they are likely present in the lipophilic extract. Saw palmetto does not

appear to reduce prostate-specific antigen concentrations. Saw palmetto inhibits 5-alpha-reductase and cytosolic androgen receptor binding; it also has local antiestrogenic and anti-inflammatory effects on the prostate.<sup>268</sup>

#### Dosage and Product Considerations

The usual dosage is 160 mg twice daily or 320 mg once daily. Saw palmetto products should contain 80%-95% standardized fatty acids.

#### Safety Considerations

In comparative studies, saw palmetto was better tolerated than finasteride and tamsulosin. GI complaints are most commonly reported. Two reports of pancreatitis have been documented.<sup>269</sup> Significant bleeding has also been reported with saw palmetto; its use in individuals taking other products that might prolong bleeding should be avoided.<sup>85</sup> Patients taking androgenic drugs should also avoid its use. Men with prostate symptoms should contact their provider before starting saw palmetto to rule out prostate cancer. Saw palmetto is occasionally used in multi-ingredient products intended for women. Because of the inhibition of 5-alpha-reductase, it should be considered Pregnancy Category X and also should not be used in lactation.

#### Summary of Clinical Evidence

Evidence does not support use of saw palmetto for symptoms related to BPH. In a Cochrane review that included 32 randomized controlled trials ranging from 4 to 72 weeks with over 5000 male subjects, saw palmetto was not effective for treating urinary symptoms, increasing peak urine flow, or reducing prostate size. In the updated review, two new high-quality trials of scores of 582 men, based on the American Urological Association Symptom Score Index, demonstrated no difference in lower urinary tract symptoms for those taking saw palmetto compared with placebo. One 72-week study with double or triple the usual dose of 320 mg/day found differences in lower urinary tract symptoms, including nocturnal symptoms, remained insignificant. Three high-quality trials assessing peak urine flow in 667 men also found no change compared with placebo. A 12-month trial of 225 men reported no change in prostate size.<sup>270</sup>

### **Musculoskeletal System**

#### Chondroitin Sulfate

##### Therapeutic Uses

Chondroitin sulfate is a glycosaminoglycan found in cartilage. As a dietary supplement, chondroitin sulfate is usually combined with other supplements in osteoarthritis and joint health products.

##### Physiologic Activity

Chondroitin sulfate's primary activity may be inhibition of leukocyte elastase, an enzyme involved in cartilage degradation. Chondroitin also serves as building material for cartilage production, inhibits resorption by osteoclasts, and may stimulate chondrocytes to produce cartilage.<sup>271,272</sup> The supplement also reduces inflammation via inhibition of the translocation of nuclear factor kappa, which is involved in activating B cells, and serves as a sulfur donor, an essential component for creation of the sulfur bonds used in cartilage synthesis.<sup>271,272</sup>

##### Dosage and Product Considerations

For osteoarthritis, the common dosage is 1200 mg daily in 1 or divided doses. Combination products with glucosamine may offer increased benefits, but chondroitin has both less evidence of efficacy and greater cost. Patients should begin therapy with glucosamine sulfate. If, after 4-5 months, a benefit is seen but symptoms are still bothersome, chondroitin may be added. Chondroitin should be taken with food if nausea or GI upset occurs. Chondroitin is often produced from bovine trachea, so a slight microbial contamination risk may exist. Because trachea contains little neural tissue, risk of bovine spongiform encephalitis (mad cow disease) is minimal.

##### Safety Considerations

Adverse effects include mild GI upset and nausea. Allergic reactions, edema, diarrhea, constipation, nausea, heartburn, and hair loss have also been reported.<sup>273</sup> Use during pregnancy or lactation should be avoided because safety information is inadequate. Although no interactions have been reported in humans, patients taking anticoagulants or antiplatelet agents should be monitored carefully because chondroitin and heparin have some structural similarity.

## Summary of Clinical Evidence

Information on the efficacy of chondroitin is limited because few trials have examined monotherapy. A meta-analysis examining three trials with a duration of 2 years concluded that chondroitin alone resulted in a decrease in the rates of knee cartilage degradation.<sup>274</sup> A recent well-designed study using 800 mg/day also noted statistically significant reduction in loss of cartilage volume compared with placebo, although pain and other symptoms were similar to those of the placebo group.<sup>275</sup> Pain, morning stiffness, and the Functional Index for Hand Osteoarthritis scores were all significantly improved over placebo in a 6-month trial using 800 mg/day.<sup>276</sup> Another study examined patients with both knee osteoarthritis and plantar psoriasis; chondroitin demonstrated significant improvement over placebo in pain visual analogue scale, Lequesne index scores, and both patient and physician efficacy ratings after 3 months.<sup>277</sup> Some evidence suggests chondroitin has beneficial effects that persist after discontinuation, and a meta-analysis concluded that long-term use slows radiographic progression of joint space narrowing in osteoarthritis of the knee.<sup>278,279</sup>

## Devil's Claw

### Therapeutic Uses

*Harpagophytum procumbens* is an African desert plant. Both dried ground root and standardized extracts are used for arthritis and back and joint pain.

### Physiologic Activity

Devil's claw has anti-inflammatory, anticonvulsant, analgesic, and hypoglycemic activity.<sup>280</sup> Harpagoside, an iridoid glycoside, is likely the primary active component although beta-sitosterol may contribute. Effects in arthritis may be linked to inhibition of matrix metalloproteinases, which degrade cartilage. Anti-inflammatory effects on pain and osteoarthritis include inhibition of mRNA expression of tumor necrosis factor alpha, interleukin-6, and cyclooxygenase-2, as well as release of prostaglandin E<sub>2</sub>.<sup>281</sup>

### Dosage and Product Considerations

Extracts are often standardized to harpagoside content. The dosage is 100 mg/day of harpagoside in an aqueous extract given in divided doses. Evidence has suggested greater efficacy with aqueous extracts over ethanolic extracts.<sup>280</sup>

### Safety Considerations

Adverse effects include diarrhea, headache, anorexia, and rash. GI disturbances are related to the stimulation of gastric acid.<sup>282</sup> Devil's claw is not recommended for patients with diabetes or cardiac disease because of blood pressure and glucose reductions identified in animal studies. Its use during pregnancy is not recommended because of the potential to induce uterine contractions.<sup>280</sup> Although only one report for anticoagulants and antiplatelet agents exists, devil's claw should not be used with these agents.

## Summary of Clinical Evidence

Several trials have examined the use of devil's claw in osteoarthritis and demonstrated pain relief greater than placebo or equivalent to a prescription analgesic on standard assessment instruments, such as the Western Ontario and McMaster University Osteoarthritis Index (WOMAC) scale.<sup>283</sup> Meta-analyses and systemic reviews support the use of aqueous extracts of devil's claw for osteoarthritis.<sup>280,283</sup>

Devil's claw has been compared with placebo, anti-inflammatory agents, and controls such as massage and acupuncture for treatment of lower back pain. All but one study found greater benefit for devil's claw in pain relief and increased mobility.<sup>280,283</sup> Evidence supports its use for chronic back pain not associated with disk or nerve root conditions.

## Glucosamine

### Therapeutic Uses

Glucosamine is marketed primarily for osteoarthritis.

### Physiologic Activity

Glucosamine is an endogenous mucopolysaccharide. Similar to chondroitin, it increases components available for cartilage synthesis. Glucosamine stimulates chondrocytes to produce cartilage and synoviocytes to produce synovial fluid and hyaluronic acid, inhibits matrix metalloproteinase, and modulates activities of inflammatory cytokines.<sup>284</sup> Glucosamine sulfate and glucosamine hydrochloride have different efficacy profiles, which may be explained by differences in inhibition of gene expression: compared with glucosamine hydrochloride, glucosamine sulfate and combination glucosamine sulfate+chondroitin sulfate stimulate greater increases in the receptor activator of nuclear factor kappa-B ligand to reduce bone resorption by osteoclasts.<sup>285</sup> Glucosamine sulfate may also be a sulfur donor for sulfur bonds used in cartilage production.<sup>286</sup>

### Dosage and Product Considerations

For osteoarthritis, the appropriate dosage is 1500 mg daily of glucosamine sulfate, given in 1 or divided doses. Glucosamine will not provide pain relief as quickly as NSAIDs or acetaminophen can, so concurrent analgesic therapy should be continued as needed. Glucosamine sulfate combined with NSAID therapy has been shown to be more effective than glucosamine sulfate alone in reducing pain symptoms over 3 months.<sup>287</sup> Effects may not be experienced for 6-8 weeks, with full benefits not evident for 4-6 months. If benefits are not observed after 6 months of use, therapy should be discontinued.

Optimal product choice may be difficult, as many supplements use the less expensive glucosamine hydrochloride, which is possibly less effective than the sulfate salt form. Many trials demonstrating the efficacy and safety have used crystalline glucosamine sulfate products from Rotta Laboratories.

### Safety Considerations

Nausea, stomach upset, constipation, and diarrhea are the most common adverse effects for glucosamine. These symptoms are usually alleviated by taking glucosamine in divided doses with meals. Drowsiness, headache, and skin reactions have been infrequently reported.

Glucosamine is manufactured from shellfish chitin or produced synthetically. Some products claim to be allergen free because processing removes allergenic material. Two studies tested this claim using shellfish-derived products and found no reactions in individuals with documented shellfish allergies.<sup>288</sup> Because a manufacturer's source materials may not remain consistent, patients with severe shellfish allergies should avoid glucosamine.

Because of glucosamine's glucose-based chemical structure, older reference texts still contain cautions regarding hyperglycemia. Multiple studies have found no reason for caution beyond having diabetic patients monitor glucose levels more closely for a few days.<sup>289</sup>

Anecdotal cases of cholesterol elevations have been reported, although evidence from long-term clinical trials and a short-term safety trial do not support this concern.<sup>285</sup> Pregnant or lactating women should avoid glucosamine because safety data are lacking. Drug interactions with glucosamine have not been documented.

### Summary of Clinical Evidence

Studies of glucosamine for osteoarthritis can be divided into three general groups: glucosamine sulfate monotherapy, glucosamine hydrochloride monotherapy, and glucosamine of either salt combined with chondroitin sulfate. Conclusions regarding the efficacy of glucosamine have varied, depending on the specific group.

The 2-year Glucosamine/chondroitin Arthritis Intervention Trial (GAIT) funded by the National Institutes of Health is cited both as support that "glucosamine works" and as support that it does not.<sup>290</sup> Five groups in the GAIT compared glucosamine hydrochloride, chondroitin sulfate, glucosamine hydrochloride + chondroitin sulfate, celecoxib, and placebo. The primary outcome measure was a 20% reduction in the WOMAC scale. None of the treatment groups' results were statistically significantly different from those of the placebo group, although patients in the celecoxib and glucosamine hydrochloride groups did achieve slightly better odds of reaching the outcome measure, 1.21 and 1.16, respectively, than did patients in the chondroitin and combination groups. Of the small number of studies evaluating glucosamine hydrochloride alone for knee osteoarthritis, only one demonstrated partial benefit; overall, changes in pain or function scores were not significant.<sup>291</sup> At this time, the overall evidence does not support the use of glucosamine hydrochloride monotherapy.

Trial results for glucosamine hydrochloride + chondroitin sulfate are contradictory, but overall have shown more benefit than glucosamine hydrochloride monotherapy. One example is a study of low doses of 1200 mg glucosamine hydrochloride and 60 mg chondroitin sulfate per day compared with placebo.<sup>292</sup> Outcome measures included Japanese Orthopaedic Association criteria scores and visual analog scales for knee pain. At 16 weeks, the treatment group had significantly improved scores ( $p < 0.5$ ) for both "walking ability and painfulness" and "stairs - ascending/descending ability and painfulness." Both treatment and placebo groups improved from baseline on the visual analog scale scores of pain, but the treatment group had significantly greater improvement at week 16.

Most glucosamine trials in knee osteoarthritis that demonstrated significant efficacy used glucosamine sulfate alone

or with chondroitin sulfate. Multiple early glucosamine sulfate trials found positive results for clinically significant reduction of pain and improvement of movement.<sup>293</sup> Many were criticized for small sample size or association with a glucosamine sulfate manufacturer, although later reviews have supported findings. Outcome measurements differed as well. Early trials often used the Lequesne Index for symptoms, whereas later trials with negative results or smaller effect sizes used the WOMAC scale. This scale was used in the largest (n = 318) trial that compared glucosamine sulfate with placebo and acetaminophen. Glucosamine sulfate was significantly more effective for symptom reduction compared with placebo on both the Lequesne and WOMAC indices, whereas acetaminophen was not.<sup>294</sup> Additional research is needed to identify the effect size expected from this therapy. Although benefit will likely be smaller than early research indicated, evidence is sufficient to support recommendations for glucosamine sulfate use, either alone or in combination with chondroitin sulfate. Currently, osteoarthritis treatment guidelines from the Osteoarthritis Research Society International and the European League Against Rheumatism include glucosamine as initial options, whereas the American College of Rheumatology considers such recommendations to be premature, and the British National Institute for Health and Care Excellence (NICE) guidelines no longer include glucosamine.<sup>285</sup> The evidence at this time ranks the efficacy for knee osteoarthritis as follows: glucosamine sulfate (monotherapy or in combination with chondroitin sulfate) is greater than glucosamine hydrochloride + chondroitin sulfate, which is much greater than glucosamine hydrochloride monotherapy.

Glucosamine is also used for other types of osteoarthritis and joint issues. A recent well-designed trial of glucosamine sulfate versus placebo in patients with lumbar osteoarthritis and chronic low back pain found no difference in pain or disability scores after 6 months of treatment or a 1 year follow-up.<sup>295</sup> Older studies of glucosamine sulfate or glucosamine hydrochloride + chondroitin sulfate noted some benefit for temporomandibular joint pain or joint noise, but the most recent study, well-designed except for a short duration, demonstrated no benefit of 1500 mg/day of glucosamine sulfate over placebo after 12 weeks of treatment.<sup>296</sup>

## Methylsulfonylmethane

### Therapeutic Uses

Methylsulfonylmethane (MSM) is a naturally occurring compound in foods and a major metabolite of dimethylsulfoxide (DMSO), an industrial solvent. Arthritic workers began using DMSO topically, and MSM was developed in an attempt to avoid DMSO's toxicity and adverse effects.<sup>297</sup> MSM is included in arthritis supplements despite little clinical evidence for efficacy.

### Physiologic Activity

Intestinal bacteria break down MSM to release sulfur, which is then incorporated into amino acids such as cysteine. Sulfur is essential for cartilage bonding, and animal studies have found lower sulfur levels in arthritic cartilage. One study of MSM noted decreased joint disease in a rheumatoid arthritis mice model.<sup>298</sup> Studies in mice tissue have demonstrated anti-inflammatory effects such as reduced production of interleukin-6 and tumor necrosis factor- $\alpha$ , decreased cyclooxygenase-2 expression, and inhibition of nuclear factor kappa B.<sup>299</sup>

### Dosage and Product Considerations

The dosages of MSM used in clinical trials have varied from 1500 to 3000 mg/day in 1 or divided doses.<sup>300</sup> A patient choosing to use MSM should not exceed 3000 mg daily. MSM can be destroyed by water or excessive heat during the manufacturing process or storage, so purchasing from a reliable manufacturer and proper storage are essential. Smaller doses of MSM are present in combination products for osteoarthritis than in single-entity products.

### Safety Considerations

Adverse effects of MSM use include headache, pruritus, nausea, and diarrhea. Use during pregnancy and lactation should be avoided because of lack of safety information. No drug interactions are known.

### Summary of Clinical Evidence

For osteoarthritis, one 12-week trial (n = 118) compared MSM with glucosamine sulfate, placebo, and the combination of MSM and glucosamine sulfate. Pain and functioning improved in all groups but the placebo group. Improvement was greater in the combination group than with MSM or glucosamine sulfate alone.<sup>300</sup> Evidence is insufficient to recommend MSM at this time.

## S-Adenosyl-L-Methionine

## Therapeutic Uses

S-Adenosyl-L-methionine (SAME) is an endogenous substance formed from L-methionine and ATP. SAME is used for osteoarthritis and depression.

## Physiologic Activity

SAME is produced primarily in the liver. Liver disease and low vitamin B<sub>12</sub> or folate levels may decrease concentrations.<sup>301</sup> For osteoarthritis, SAME stimulates chondrocytes to produce proteoglycans, may block cartilage degradation enzymes, and has anti-inflammatory effects such as decreased tumor necrosis factor- $\alpha$ .<sup>301,302</sup> SAME donates methyl groups to neurotransmitters and catecholamines, and it increases brain neurotransmitter levels, including those of norepinephrine, dopamine, and serotonin, which may contribute to its antidepressant effects.

## Dosage and Product Considerations

Most osteoarthritis trials used dosages of 400-800 mg/day in divided doses, whereas dosages for depression are 1200-1600 mg/day.<sup>303</sup>

## Safety Considerations

Adverse effects include nausea, diarrhea, and heartburn. Less frequently, dry mouth, headache, dizziness, nervousness, insomnia, cognitive impairment, and a switch to mania in patients with bipolar disorder have been reported.<sup>304</sup> SAME is also associated with hypomania or severe mania in subjects with no personal or family history of mania or bipolar disorder.<sup>305</sup> A report of mixed mania with suicidal ideation occurred within 2 weeks.<sup>306</sup> The CNS effects may be dose related because mania/hypomania has not been reported in lower-dosage osteoarthritis trials. Until more information is available, SAME should not be recommended. Patients who use SAME for osteoarthritis should take the lowest dosage that provides relief and no more than 800 mg/day. SAME should not be used with SSRIs or 5-hydroxytryptamine<sub>1</sub> (5-HT<sub>1</sub>) agonists because of a potentially increased risk of serotonin syndrome. The use of SAME during pregnancy or lactation should also be avoided because of inadequate safety data.

## Summary of Clinical Evidence

Early osteoarthritis studies with SAME that demonstrated positive results were of short duration and poor design, and they used injectable dosage forms or combinations of intravenous and oral therapies.<sup>307</sup> When SAME was compared with NSAIDs or a cyclooxygenase-2 inhibitor, equivalent results in restoration of functionality and decreased pain were seen, although with a slower onset.<sup>308</sup> A meta-analysis concluded that SAME's clinical effects may be small.<sup>307</sup> A more rigorously designed trial compared SAME (1200 mg/day) with nabumetone.<sup>309</sup> Pain on a 40 mm visual analogue scale was significantly decreased to a similar extent in both the SAME (-13 mm) and nabumetone (-15.7 mm) groups at 8 weeks. The WOMAC index also decreased similarly in the SAME and nabumetone groups (-6.9 mm and -9.3 mm, respectively;  $p = 0.459$ ). Changes occurred more slowly in the SAME group; the WOMAC index change was only -3 mm at 4 weeks compared with -6.4 mm for nabumetone. Clinical trials for depression have had methodologic problems, including small sample sizes. Two meta-analyses examining results with both intravenous and oral SAME concluded that SAME does have efficacy for depression that is possibly comparable to that of tricyclic antidepressants.<sup>303</sup> When SAME was added in an open-label fashion to SSRIs or venlafaxine in patients who had not responded to antidepressant therapy alone, significant changes in outcome measures resulted.<sup>310</sup> The Hamilton-D-17 score decreased from 17.7 to 10 ( $p = 0.0001$ ) and the Montgomery Asberg Depression Rating Scale from 23.2 to 13.9 ( $p = 0.0002$ ).

## Skin and Mucous Membrane

### Lemon Balm

Lemon balm is derived from the plant *Melissa officinalis* L. of the family Lamiaceae (mint).

## Therapeutic Uses

Lemon balm is commonly used as a topical cream for cold sores (herpes labialis) and orally for relaxation, agitation related to dementia, insomnia, or GI complaints.

## Physiologic Activity

Lemon balm's effects may be a result of volatile oils extracted from the plant's leaves that are believed to have sedative, antioxidant, and antiviral effects.<sup>311</sup>

#### Dosage and Product Considerations

For cold sores, studies have used a cream or ointment containing 1% of a 70:1 lyophilized aqueous extract applied 2-5 times daily at first sign of symptoms and until all lesions heal. The treatment does not alter the ability to transmit the infection to others.

#### Safety Considerations

Hypersensitivity reactions and skin irritation have been associated with topical application. Theoretically, concomitant use of sedative herbs and drugs should not be combined with oral lemon balm. This natural product has been associated with thyroid inhibition and should be used cautiously in individuals with hypothyroid disease. The use of oral lemon balm should be avoided during pregnancy and lactation because of a lack of safety data.<sup>311</sup>

#### Summary of Clinical Evidence

The application of lemon balm cream has produced significant benefits by reducing the intensity of discomfort and the size and blistering of oral herpes lesions in clinical trials. Chronic use may delay the time to the next herpes flare-up.<sup>312</sup> Combination with valerian has shown efficacy in patients with anxiety and in children with sleep disorders.<sup>313,314</sup>

### Tea Tree Oil

Tea tree oil is derived from leaves of the tree *Melaleuca alternifolia* (Maiden & Betche) Cheel from the family Myrtaceae. The tea tree is not related to the plant used to make black and green teas.

#### Therapeutic Uses

Tea tree oil has been used as a topical anti-infective agent.

#### Physiologic Activity

Tea tree oil has also demonstrated anti-inflammatory properties in decreasing tumor necrosis factor, interleukin-1, interleukin-8, interleukin-10, and prostaglandin E2.<sup>315</sup>

#### Dosage and Product Concerns

The oil is applied topically once or twice daily in concentrations of 0.4%-100%, depending on the condition and area of treatment. For acne, a 5% concentration is applied daily. For athlete's foot, tea tree oil cream 25%-50% is applied twice daily for 4 weeks. For fungal toenail infections, tea tree oil 100% has been used twice daily for 6 months.

#### Safety Considerations

Skin irritation may occur in sensitive patients, especially at higher concentrations. Although the oil can be used safely on oral mucosa, it should not be swallowed; ingesting small amounts may cause confusion, ataxia, and systemic contact dermatitis that resolves slowly.<sup>315</sup> Prepubertal gynecomastia occurred in three boys using topical tea tree and lavender oils and resolved upon discontinuation.<sup>316</sup>

#### Summary of Clinical Evidence

Randomized controlled trials using tea tree oil 5% body wash have demonstrated success in preventing colonization of *Staphylococcus aureus* and clearing methicillin-resistant *S. aureus* in hospitalized patients compared with standard regimens.<sup>317,318</sup> Nasal colonization was also evaluated with 10% tea tree cream, finding that 2% mupirocin was more effective.<sup>318</sup>

Tea tree oil may be effective for athlete's foot and other fungal infections of the skin, hair (dandruff), and nails.<sup>319-321</sup> For onychomycosis, tea tree oil was compared with clotrimazole 1% solution and after 6 months had similar culture and clinical resolutions. Tea tree oil has also been studied in fluconazole-resistant oral *Candida* infections occurring in patients with AIDS, with 60% of patients demonstrating full or partial resolution in an open-label trial.<sup>322</sup> In the treatment of mild-moderate acne, daily application of a tea tree oil gel 5% for 45 days significantly reduced the total acne lesion count and acne severity index compared with placebo.<sup>323</sup> Tea tree oil is an option for individuals who

are not tolerating current therapies for the treatment of athlete's foot, onychomycosis, or acne.

## Women's Health

### Black Cohosh

Black cohosh is made from the dried rhizome and roots of *Cimicifuga racemosa* (L.) Nutt., formerly *Actaea racemosa*. It is a member of the Ranunculaceae (buttercup) family.

### Therapeutic Uses

Black cohosh has been used to treat the symptoms of premenstrual syndrome, dysmenorrhea, menopause, and rheumatoid arthritis.

### Physiologic Activity

The primary active components of black cohosh rhizomes are triterpene glycosides, including acetin, cimicifugoside, and 27-deoxyacetin. Isoflavones such as formononetin are often present, but they may be absent from commercial products. Other constituents include isoferulic and salicylic acids, tannins, resin, starch, and sugars.<sup>324</sup> Black cohosh extract may also act as a partial serotonin agonist.<sup>325</sup> Whether black cohosh has estrogenic activity is controversial; it probably does not exhibit estrogenic activity and has no effect on vaginal epithelium, endometrium, or hormone concentrations.<sup>326</sup>

### Dosage and Product Considerations

Black cohosh, as a standardized extract, is usually taken as 40 mg daily in 1-2 doses. A common proprietary preparation is Remifemin. The extract is standardized to 1 mg of triterpene glycosides, calculated as 27-deoxyacetin, per 20 mg extract tablet.<sup>327</sup>

### Safety Considerations

Adverse effects are mild and include GI complaints, headache, rash, and weight gain. Hepatitis, seizures, and cardiovascular disease have been reported in patients taking multiple herbal products including black cohosh, although causal relationship has not been established.<sup>328</sup> Due to case reports of acute hepatitis with black cohosh, the Dietary Supplement Information Expert Committee recommended a cautionary statement regarding potential hepatotoxicity be placed on product labels.<sup>329</sup> Further evaluations have suggested lack of product quality may have contributed, with the wrong plant being used.<sup>330</sup> The use of black cohosh for longer than 6 months is not recommended because of the lack of long-term safety studies. Data on drug interactions with black cohosh are limited, with the exception of possible additive effects with tamoxifen.<sup>328</sup> Data on concurrent use with estrogens or progestins are not available.<sup>85</sup> The use of black cohosh should be avoided during pregnancy and lactation because of its potential hormonal effects.

### Summary of Clinical Evidence

Several clinical trials have evaluated black cohosh alone and combination products for menopausal symptoms, with mixed results. The largest and most recent systematic review of single-entity black cohosh included 16 randomized controlled trials with 2027 perimenopausal or postmenopausal women.<sup>331</sup> Efficacy was determined against placebo, hormone therapy, red clover, and fluoxetine. Analysis found the median dose of 40 mg per day of black cohosh for a mean of 23 weeks. For hot flashes and menopausal scores, no significant difference was noted between black cohosh and placebo; however, hormone therapy significantly reduced these variables compared with black cohosh (95% CI, 0.13-0.51).<sup>331</sup>

Multi-ingredient product comparisons with placebo, hormonal therapy, and fluoxetine lack standardized dosing and have poor methodologic quality or small differences compared with placebo, making it difficult to establish efficacy. Benefits from other constituents in multi-ingredient black cohosh products and SJW may be responsible for improvement in symptoms.<sup>325</sup> Combination with SJW has demonstrated an impact on climacteric symptoms.<sup>332</sup> Positive results were reported in a meta-analysis, with substantial heterogeneity between studies; six of nine randomized placebo-controlled trials demonstrated a significant improvement of 26% in symptoms related to menopause.<sup>333</sup>

The safety and efficacy of black cohosh in women who have had breast cancer remains controversial. A systematic review in women with a history of breast cancer found inconclusive evidence to support safety and efficacy, although the product did not exert estrogenic effects.<sup>334</sup> The long-term effects on cardiovascular disease, osteoporosis, and

breast cancer are unknown.

### Chastetree Berry

Chastetree (*Vitex agnus-castus* L.), commonly referred to as vitex, is a member of the Verbenaceae family. The dried ripe fruits, or berries, and the leaves are the medicinally useful parts of the plant.

#### Therapeutic Uses

Chastetree berry has been used to treat symptoms of premenstrual syndrome, dysmenorrhea, mastalgia, and menopausal symptoms.

#### Physiologic Activity

The fruits contain essential oils, diterpines, iridoid glycosides, and flavonoids. Effects on menstrual regulation are likely due to the dopaminergic compounds diterpines, which are responsible for suppressing prolactin release by binding to the dopamine-2 receptor. Chastetree berry may have weak estrogenic activity.<sup>335</sup>

#### Dosage and Product Considerations

Clinical trials have used 20-40 mg of the extract daily. The standardization of chastetree berry has not been well established. It is available alone or in combination products.

#### Safety Considerations

GI complaints occur occasionally with use of chastetree berry. Other symptoms include dry mouth, headache, rashes, itching, acne, menstrual disorders, and agitation. The use of chastetree berry should be avoided during pregnancy because of potential effects on the uterus. Chastetree berry potentially may interact with dopaminergic antagonists and oral contraceptives, but these interactions have not been documented.<sup>336</sup>

#### Summary of Clinical Evidence

Clinical evidence for chastetree berry, in combination with other herbals, for menopausal symptoms is mixed. A randomized, double-blind, placebo-controlled parallel trial studied combination SJW (*Hypericum perforatum*) and chastetree berry administered twice daily over 16 weeks in 100 late perimenopausal and postmenopausal women. Symptoms did not differ between the groups regarding the primary end point of hot flashes.<sup>337</sup> A small subgroup analysis of 14 late perimenopausal women found significant improvement in premenstrual syndrome-like symptom scores.<sup>338</sup> Phyto-Female Complex, standardized extracts of black cohosh, dong quai, milk thistle, red clover, American ginseng, and chastetree berry, has been studied in 50 premenopausal and postmenopausal women in a randomized, placebo-controlled trial. Improvements in hot flashes, night sweats, and sleeping quality were reported, with no changes on vaginal ultrasonography, estradiol, follicle-stimulating hormone, liver enzymes, or thyroid-stimulating hormone.<sup>339</sup>

Chaste tree extract may be effective in other reproductive disorders such as premenstrual syndrome, premenstrual dysphoric disorder, and latent hyperprolactinemia. Methodologic quality is a barrier, with limited study sizes and variable treatment measures.<sup>340</sup> A systematic review suggested benefit in cyclic mastalgia, often related to latent hyperprolactinemia, for at least three cycles.<sup>341</sup>

### Evening Primrose Oil

Evening primrose (*Oenothera biennis* L.) is a member of the primrose family Onagraceae and is used for its high content of essential fatty acids. The seed oils of black currant (*Ribes nigrum* L.) and borage (*Borago officinalis* L.) are also used for similar purposes.

#### Therapeutic Uses

Evening primrose oil has been used for mastalgia, premenstrual syndrome, menopause, preeclampsia, diabetic neuropathy, chronic fatigue syndrome, and atopic dermatitis.

#### Physiologic Activity

The oil from evening primrose seeds consists of omega-6 essential fatty acids, primarily 65%-75% linoleic acid and 7%-10% gamma-linolenic acid. These components are thought to be responsible for anti-inflammatory activity.<sup>342,343</sup> The seed oil contains smaller amounts of palmitic, oleic, and stearic acids, as well as the steroids

campesterol and beta-sitosterol.<sup>343</sup>

### Dosage and Product Considerations

In clinical trials, daily dosages of evening primrose oil 2-4 grams have been used as a liquid or capsule. A standardized product, Efamol, a 1 gram capsule is comprised of 0.62 gram linoleic acid, 0.05 gram gamma-linolenic acid, and 0.062 gram oleic acid.<sup>342</sup>

### Safety Considerations

Adverse effects include headache, nausea, diarrhea, and occasional abdominal pain. Evening primrose oil products may possess antiplatelet effects and should be used with caution in patients taking anticoagulants and antiplatelet agents or herbs. Seizures have been reported in people taking evening primrose oil; individuals taking anticonvulsants or medications to lower their seizure threshold should avoid its use.<sup>85,87</sup> Use of evening primrose oil for cervical ripening during labor may be associated with adverse pregnancy outcomes, including prolonged rupture of membranes and vacuum extraction.<sup>343</sup>

### Summary of Clinical Evidence

Data on evening primrose oil for mastalgia and atopic dermatitis have been contradictory. A randomized pilot placebo-controlled study found improvement in cyclical mastalgia with 3 grams of evening primrose oil, taken alone or in combination with vitamin E 1200 IU over 6 months.<sup>344</sup> A large double-blind, randomized, placebo-controlled trial comparing Efamol with or without antioxidant vitamins found no significant changes in reported pain in patients with moderate-severe mastalgia. A large placebo effect was noted, with 40% of subjects reporting improvement without therapy.<sup>345</sup>

A Cochrane review of oral evening primrose oil and borage oil concluded neither was effective for the treatment of atopic eczema. Studies analyzed found no improvement in global eczema symptoms or visual analogue scales.<sup>346</sup> Another meta-analysis of 26 randomized, placebo-controlled trials studying Efamol for use in atopic dermatitis demonstrated promising outcomes regarding itch/pruritus, crusting, edema, and erythema in 4-8 weeks of treatment. Comparisons have not been made to current therapies, and evening primrose oil may not be as effective as high-potency topical steroids.<sup>347</sup>

## Fenugreek

Fenugreek (*Trigonalla foenum-graecum*) has a long history of use as a spice and a medicine in India, China, and Northern Africa. Both leaves and seeds may have medicinal properties.<sup>348</sup>

### Therapeutic Uses

Fenugreek has been used for diabetes, hyperlipidemia, and stimulation of breast milk production.<sup>348</sup>

### Physiologic Activity

An active constituent of fenugreek, 4-hydroxyisoleucine, may contribute to the hypoglycemic effects by stimulating glucose-induced insulin release and reducing insulin resistance. Saponins converted to saponogenins in the GI tract may decrease cholesterol levels through activation of biliary cholesterol secretion. Fenugreek seeds are high in fiber, possibly delaying glucose absorption or binding cholesterol.<sup>348</sup> Lactation effects may be the result of increased sweat production impacting the milk duct or by phytoestrogens and diosgenin found in fenugreek.<sup>146</sup>

### Dosage and Product Considerations

Dosages have varied, with fenugreek seed powder capsules 2.5 grams twice daily or seed powder 25 grams daily in 2 divided doses used in studies. Defatted seeds have also been used at 100 grams daily in 2 equally divided doses. Fenugreek can also be administered in a tea.<sup>349</sup> For increasing milk supply, 2-3 capsules (580-610 mg per capsule) can be administered 3-4 times per day.<sup>146</sup>

### Safety Considerations

Fenugreek is generally safe when used in meal preparation. When fenugreek is consumed, urine, sweat, and breast milk have been noted to smell like maple syrup, which is caused by sotolone excretion. This effect also occurs in breast-feeding infants, which has led to mistaken cases of maple syrup urine disease. Patients with an allergy to

chickpeas should avoid fenugreek because of possible cross-reactivity; inhalation of the powder has resulted in bronchospasm. Fenugreek should be avoided during pregnancy because of potential oxytocic and uterine stimulant effects. Hypoglycemia or hypokalemia may result from use. The high-fiber content can bind with drugs and decrease absorption.<sup>348</sup> Fenugreek may increase risk of bleeding in patients taking warfarin.<sup>87</sup>

### Summary of Clinical Evidence

Although fenugreek is promoted to stimulate production of breast milk, evidence is limited.<sup>146</sup> A small trial of immediate postpartum mothers and nursing newborns compared a treatment group receiving a tea containing fenugreek with placebo and control groups. Infants in the fenugreek group had significantly less weight loss and regained birth weight earlier, and mothers had higher breast milk volume at 3 days compared with placebo and control groups.<sup>350</sup> Other components present in the tea may have contributed to findings as well.

### Phytoestrogens

Phytoestrogens are found in many different plants; supplements have been derived primarily from soy (*Glycine max* [L.] Merrill) and red clover (*Trifolium pratense* L.).

### Therapeutic Uses

Phytoestrogens have been used mainly for symptoms associated with menopause and related bone health. Phytoestrogens may also have a role in preventing prostate cancer.

### Physiologic Activity

Soy-based phytoestrogens may include isoflavones such as genistein, daidzein, and glycitein. Red clover-based products may include biochanin, genistein, daidzein, and formononetin. These compounds have effects including estrogenic, antiestrogenic, antioxidant, and anticancer activity.

### Dosage and Product Considerations

A recommended dosage of phytoestrogen has not been established. Phytoestrogen products contain varying amounts and types of isoflavones. Products derived from soy and red clover sources may have different effects. The benefits from soy are primarily from dietary sources, not from supplements. Soy supplements meeting USP standards are available.

### Safety Considerations

Phytoestrogen products derived from soy or red clover are well tolerated. GI complaints and allergic reactions may occur. The long-term safety of phytoestrogens is not established, especially with respect to the risk of estrogen-dependent cancers and thromboembolic disease. The safety of phytoestrogen supplements in women with hormone-sensitive cancers is unknown, and their use should be avoided.<sup>85</sup> Red clover may increase the risk of bleeding, especially if anticoagulants are taken concomitantly, although clear evidence of this interaction is lacking.<sup>87</sup>

### Summary of Clinical Evidence

Purported benefits of phytoestrogens, especially soy-based products, are derived from population-based observational studies of dietary patterns. It is simplistic to think that the lifetime risk of any given disease is related solely to the presence or absence of one dietary component such as isoflavones. The phytoestrogen content in foods, especially of the biologically active isoflavones, varies significantly even in soy foods, let alone supplements. The most common use of phytoestrogens is for managing vasomotor symptoms. Several meta-analyses and systematic reviews of randomized controlled trials have been conducted to evaluate the effectiveness of phytoestrogens, without finding strong evidence to support their usage. Variations in study design, including dosage and phytoestrogen content, makes it difficult to establish clear benefit. Overall safety is promising because endometrial, uterine, and breast cancer risk does not appear to be increased. Dietary soy intake may even be associated with a decrease in endometrial or uterine cancers; however, it should be used with caution until conclusive data support this finding.<sup>351</sup>

The effect of soy isoflavones on the risk of osteoporosis has yielded mixed findings. A double-blind, placebo-controlled study randomized 389 postmenopausal women with osteopenia to receive placebo or genistein 54 mg/day. Significant changes were observed in the anteroposterior lumbar spine, the femoral neck, and urinary markers, with no documented changes in endometrial thickness.<sup>352</sup> A follow-up study at 3 years continued to show benefit for bone loss, with no significant changes in breast health.<sup>353</sup> Soy isoflavones 120 mg/day did not

demonstrate a benefit on lumbar spine, total proximal femur, and total body bone mineral density in 432 postmenopausal women without osteoporosis in a double-blind, placebo-controlled trial. Improvement was found only at the femoral neck.<sup>354</sup> Another trial of fixed combination genistein and diadzein compared with placebo found no difference in bone mineral density of the lumbar spine or femur after 2 years of use in Taiwanese postmenopausal women.<sup>355</sup>

The ingestion of at least 25 grams of soy protein daily as part of a diet low in saturated fat and cholesterol may reduce the risk of coronary heart disease. The effect of phytoestrogen dietary supplements on the risk of myocardial infarction is unclear.<sup>356</sup>

Epidemiologic research has indicated consumption of soy products has a role in decreasing breast cancer risk; however, concerns exist that estrogenic activity will increase recurrence. The potential effect likely will depend on the specific isoflavone, timing of exposure, genetic factors, and whether estrogen receptors are positive or negative for cancer. Dietary consumption of soy similar to that in Asian populations does not appear to increase cancer recurrence, nor does it interact with tamoxifen or anastrozole.<sup>357</sup> Epidemiologic data analyzed in a meta-analysis suggest that soy food consumption may play a role in reducing prostate cancer risk.<sup>358</sup>

### Assessment of Natural Product Use: A Case-Based Approach

The health care provider should determine the patient's reasons for purchasing a natural product. The appropriateness of supplements must be determined and is essential for a child, a pregnant woman, or an older adult. If a medical condition is being treated and use of a supplement is appropriate, the patient should be encouraged to involve the health care provider in the use of the supplement. Information about possible allergies to plant materials, current drug therapy, and comorbid conditions will identify possible contraindications. For patients who ask about weight loss supplements, the provider can use the information in the box A Word about Weight-Loss Products to counsel them on the safest products to use.

If self-treatment with a natural product is appropriate, the provider should review the length of therapy and recommended dosages with the patient. The efficacy of different dosage forms should also be explained. Cases 51-1 and 51-2 provide examples of assessment of patients who are considering use of a natural product.

#### A Word About Weight-Loss Products

##### Hoodia

*Hoodia gordonii*, a succulent plant found in the Kalahari Desert, is used by the Khoi-San to decrease appetite on long journeys.<sup>359</sup> Animal studies of the P57 glycoside suggest hoodia may affect the hypothalamus to increase satiety and may also affect oral and GI bitter receptors to affect food intake.<sup>359</sup> Drug development of P57 was discontinued because of lack of efficacy and safety concerns over hepatic effects. One human trial with rigorous design, despite a short duration of 15 days, found no significant difference from placebo on caloric intake or weight change but found definite differences in adverse effects.<sup>360</sup> South Africa protects endangered *Hoodia* species with special permits required to grow or harvest plants, so production is very low. One study found 11 of 13 hoodia supplements to contain no hoodia glycosides.<sup>359</sup> Hoodia should be avoided given the lack of efficacy and the potential for adverse effects.

##### Chitosan

Chitosan is claimed to aid weight loss by blocking intestinal fat absorption. A Cochrane review concluded benefits were slight and likely of no clinical significance.<sup>361</sup> A recent well-designed study combined low-molecular-weight chitosan with a mild exercise program (1 hour twice weekly) and noted clinically relevant weight loss and lipid changes compared with the placebo and exercise groups.<sup>362</sup> Whether the available chitosan supplements are helpful is unanswered, but, fortunately, adverse effects are limited to slight GI effects and cross-reactivity with shellfish allergy. Patients using chitosan should take a multivitamin to prevent deficiencies of fat-soluble vitamins and take any medications at least 2 hours apart from a dose of chitosan.

##### Stimulants and "Fat Burners"

After FDA banned ephedrine alkaloids from weight-loss supplements, some manufacturers claimed their supplements were "ephedra free" and simply substituted other sources of the ephedrine alkaloids, such as heartleaf and country mallow. Guarana, yerba maté, cola nut, or other caffeine sources are common in these supplements, as is bitter orange (*Citrus aurantium*), a source of synephrine. Bitter orange has been associated with cardiovascular events and ischemic colitis in case reports, although research has found no cardiovascular effects.<sup>363-365</sup> Even though stimulants may provide a slight weight loss, safety issues outweigh the small benefits.

##### Raspberry Ketone

4-(4-hydroxyphenyl)butan-2-one is similar to synephrine in structure. Mechanistic effects such as increased adiponectin secretion in fat cells seem promising, but two animal studies had contradictory results for weight loss.<sup>366</sup> Raspberry ketone cannot be recommended because human studies and information on adverse effects are lacking.

##### Hydroxycitric Acid

Hydroxycitric acid from the *Garcinia cambogia* plant has been shown in animals to influence satiety through hepatic glucoreceptors, to increase serotonin to affect appetite, and to aid in regulation of leptin and insulin.<sup>367</sup> Short-term human trials have had contradictory results and even positive studies have noted only small benefits compared with placebo.<sup>367</sup> Adverse effects reported in trials have been mild and uncommon. The Hydroxycut brand of weight loss products was reformulated after case reports of hepatotoxicity, although hydroxycitric acid has not been determined to be the actual cause.<sup>367</sup> Until more is known about this possible adverse effect, hydroxycitric acid cannot be recommended; patients should be steered toward other options or closely monitored if they choose to use this supplement.

### Case 51-1

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient's symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient approaches the pharmacy counter in the electric scooter that she uses occasionally instead of her cane. She says, "My left knee has been extra bad this week." The patient exhibits multiple misshapen joints; you can see that her left knee is more swollen than the right and is also slightly reddened.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The patient has severe rheumatoid arthritis affecting all joints. She is under the care of a rheumatologist and follows a daily exercise regimen to preserve mobility and also does water exercise at the local community center several times per week. Her disease state waxes and wanes over time; colder weather and changes in barometric pressure always cause her increased pain and stiffness.
c. description of the patient's efforts to relieve the symptoms	"My regular medicines aren't helping—I feel so bad and I really want to try something else." She holds up a couple of combination glucosamine products and adds, "I have two friends who tell me all that time that these work for their arthritis. Which one would be better for me? I know you told me before that I couldn't take glucosamine, but this one says it's OK for people who are allergic to shellfish."
d. patient's identity	Gwendolyn Gisingham
e. age, sex, height, and weight	54 years old, female, 5 ft 6 in., 138 lb
f. patient's occupation	Schoolteacher, retired for 3 years because of disability
g. patient's dietary habits	Eats a very healthy diet that is high in vegetables, fruits, whole grains, and small portions of low-fat meats.
h. patient's sleep habits	Occasional insomnia when pain is severe.
i. concurrent medical conditions, prescription	Hypothyroidism: levothyroxine; rheumatoid arthritis: methotrexate; mild hypertension: hydroxychloroquine, lisinopril; perennial allergic rhinitis: fexofenadine and fluticasone

and nonprescription medications, and dietary supplements	nasal spray daily; daily multivitamin/mineral, calcium + vitamin D (500 mg/200 IU) twice daily, and 1 gram of enteric-coated fish oil daily. She carries an epinephrine auto injector for allergic reactions and has a prescription for generic Percocet for severe rheumatoid arthritis exacerbations, although she uses it only rarely because of concerns of addiction.
j. allergies	She has many environmental allergies and is highly allergic to bee stings, with severe reactions to strawberries and shellfish as well.
k. history of other adverse reactions to medications	None
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Hypothyroidism, controlled; hypertension, controlled; perennial allergic rhinitis, treated; exacerbation of rheumatoid arthritis; lack of knowledge regarding dietary supplements
3. Identify exclusions for self-treatment.	(1) The patient's symptoms may need additional evaluation and diagnosis. (2) The patient has contraindications to therapies in which she is interested.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a health care provider is required, and share this information with the patient or caregiver.	(1) Continue current prescription and exercise therapy, and refer patient to rheumatologist for further evaluation. (2) Continue current prescription and exercise therapy, and refer patient to rheumatologist for further evaluation. Suggest increasing fish oil dose as an alternative to the products she is interested in. (3) Continue current exercise therapy, and refer patient to rheumatologist for further evaluation. Encourage patient to utilize pain medication as prescribed during episodes of increased pain. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The patient should make an appointment with the rheumatologist right away; use the generic Percocet to help manage the pain; continue the exercise as long as it is helping to decrease the stiffness and/or pain. If movement is making the left knee worse, it may be better to try rest instead of medicating until she can see her primary care provider.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"A visit to the rheumatologist is needed to determine if you are simply having a worsening of the rheumatoid arthritis or if a different problem, such as infection, is developing and needs to be treated." "Patients who use pain medication as prescribed for occasional or short-term use are extremely unlikely to become addicted. Pain can elevate blood pressure, so it's important for your hypertension to keep pain under control."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach	"Your rheumatoid arthritis may simply be getting worse, but because your increased pain and swelling are localized to one knee, it could mean that something else is going on. Your current rheumatoid arthritis medicines might stay the same or be changed." "The arthritis products that your neighbors are recommending are for use in osteoarthritis. They have not been shown to have any benefit for rheumatoid arthritis,

from the considered therapeutic alternatives.	which has a different cause. They also take a very long time to take effect, and you are having pain now. Even though some glucosamine products do seem to be safe for use by patients with shellfish allergy, their use is recommended only when the reaction is fairly mild, such as a mild rash. Your reaction is severe and could be life threatening. Manufacturers can change the source of their products at any time. One batch might be safe to take, but the next one might contain shellfish allergen and trigger a reaction.”
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	“Aren’t there any supplements I can take to help my rheumatoid arthritis?”
Answer the patient’s or caregiver’s questions.	“Yes, if you are still interested in a supplement after seeing the doctor and it turns out that your rheumatoid arthritis is worse, we could talk about increasing the dose of your fish oil. High doses of fish oil have been shown to have some benefit on rheumatoid arthritis symptoms.”
<b>Evaluation of Patient Outcome</b>	
9. Assess patient outcome.	“Call me after you have seen the doctor, and we can talk more about the possibility of using fish oil for your arthritis.”

**Case 51-2**

<b>Relevant Evaluation Criteria</b>	<b>Scenario/Model Outcome</b>
<b>Information Gathering</b>	
1. Gather essential information about the patient’s symptoms and medical history, including:	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient is inquiring about using a “natural” treatment for prevention of migraines. She is holding individual bottles of feverfew and butterbur. She reports developing migraines 2-3 times per month. She currently has no symptoms.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient’s symptom(s)	Her migraines usually present unilaterally with fatigue, nausea, and sensitivity to light. They occur mainly when the patient is fatigued or stressed or prior to her menstrual period.
c. description of the patient’s efforts to relieve the symptoms	The patient has taken divalproex, propranolol, and topiramate for prevention, but she discontinued their use because of adverse events. She would like something “more natural.”

d. patient's identity	Emme Toce
e. age, sex, height, and weight	36 years old, female, 5 ft 5 in., 150 lb
f. patient's occupation	Nurse coordinator for medical practice
g. patient's dietary habits	Healthy diet; tries to avoid migraine triggers, such as caffeine and alcohol.
h. patient's sleep habits	Approximately 6 hours of sleep per night
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Acute migraine: sumatriptan 50 mg as needed, ibuprofen 400 mg every 4-6 hours as needed for migraine pain; vitamin B <sub>2</sub> daily for migraine prevention (she read it may help).
j. allergies	NKDA
k. history of other adverse reactions to medications	Topiramate: parasthesias, memory loss; divalproex: weight gain, hair loss; propranolol: weight gain, fatigue
<b>Assessment and Triage</b>	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Recurrent migraines, approximately 2-3 per month. Symptoms are not severe or intractable.
3. Identify exclusions for self-treatment.	No exclusions for self-treatment at this time. She is under medical care for migraines.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine if triage to a medical provider is required, and share this information with the patient or caregiver.	Options include: (1) Refer Emme to a neurologist to select another medication for prevention of migraines. (2) Educate Emme on nonpharmacologic methods to prevent migraines. (3) Assist in selecting a natural product for prevention of migraines. (4) Take no action.
<b>Plan</b>	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The patient prefers to use feverfew or butterbur to prevent migraines. Confirm that patient does not have an allergy to ragweed (Asteraceae/Compositae family).
6. Describe the recommended therapeutic approach to the patient or caregiver.	"A trial basis of butterbur could be considered in consultation with the health care provider who treats your migraines."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Evidence based on two well-designed trials suggests that butterbur is effective in preventing migraines. Data to support the effectiveness of feverfew are not as strong. Natural product options for prevention of this condition are limited. Long-term data on safety and efficacy are

	available for prescription medications.”
<b>Patient Education</b>	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	
a. appropriate dose and frequency of administration	“Take 50-75 mg twice per day (petasin 7.5 mg and isopetasin 7.5 mg per 50 mg tablet or capsule).”
b. maximum number of days the therapy should be employed	“Long-term data do not exist for efficacy and safety. Studies support use for 12-16 weeks, although some monographs support use for 4-6 months, then taper off.”
c. product administration procedures	“For prevention of migraine headaches, select a high-quality product that does not contain pyrrolizidine alkaloids (PAs).”
d. expected time to onset of relief	“This product is for prevention of migraines.”
e. degree of relief that can be reasonably expected	“Recurrence of migraines will be reduced.”
f. most common adverse effects	“Minor GI upset, possible dermatologic changes, or dizziness are the most common adverse effects.”
g. adverse effects that warrant medical intervention should they occur	“The product is generally well tolerated. See your provider if you suspect liver damage (yellowing of skin, abdominal pain) from the presence of PA.”
h. patient options in the event that condition worsens or persists	“If recurrent migraines continue, seek your provider’s guidance on prescription options to prevent them.”
i. product storage requirements	“Keep product in an appropriate storage area away from excessive heat and moisture and out of reach of children and pets.”
j. specific nondrug measures	“Nonpharmacologic measures to help prevent migraines include avoiding triggers, maintaining regular sleep and eating patterns, and managing stress. Relax in a quiet, dark room when onset occurs. A cool pack or ice pack placed on the forehead or temples may be useful.”
Solicit follow-up questions from the patient or caregiver.	“Can I use butterbur to treat a migraine?”
Answer the patient’s or caregiver’s questions.	“No. Evidence does not support use for an acute migraine. Continue to use medications currently listed for acute migraine.”
<b>Evaluation of Patient Outcome</b>	

9. Assess patient outcome.

“Please discuss using this product with your doctor prior to its use. Call me after a few weeks to tell me how you are tolerating butterbur and whether you are having fewer migraines.”

Key: GI = Gastrointestinal; NKA = no known drug allergies.

## Handbook of Nonprescription Drugs > Chapter 52. Common Complementary and Alternative Medicine Health Systems

### Common Complementary and Alternative Medicine Health Systems: Introduction

The term *complementary and alternative medicine* (CAM) refers to a broad group of healing philosophies, diagnostic approaches, and therapeutic products that do not conform to the conventional Western health system.<sup>1</sup> *Alternative therapies* have been defined as those used in place of conventional practices, whereas *complementary or integrative medicine* is used in combination with mainstream approaches.<sup>2,3</sup> Other terms used to describe CAM include *folkloric, holistic, irregular, nonconventional, non-Western, traditional, unorthodox, and unproven* medicine. Some common CAM therapies and health systems include homeopathy, naturopathy, traditional Chinese medicine (TCM), acupuncture, chiropractic care, Ayurveda, and massage. This chapter presents an overview of common complementary and alternative modalities other than dietary supplements, which are discussed in Chapter 51.

### Overview of Common CAM Health Systems

#### Major Categories

In the United States, the National Center for Complementary and Alternative Medicine (NCCAM) classifies CAM therapies into three broad categories, which are neither formally defined nor exclusive:

1. *Natural Products*. This category includes herbal medicines or botanicals, minerals, vitamins, and other natural products such as probiotics.
2. *Mind-Body Medicine*. According to NCCAM, the CAM modalities in this category are diverse and feature procedures or techniques that are taught or conducted by a trained practitioner or teacher. Examples of mind-body medicine include acupuncture, guided imagery, hypnotherapy, *qi gong, tai chi*, yoga, massage therapy, movement therapies, and spinal manipulation.
3. *Other CAM Practices*.
  - a. *Traditional healers* use “methods based on indigenous theories, beliefs, and experiences handed down from generation to generation,” according to the National Institutes of Health (NIH).<sup>4</sup> Native American healers (e.g., medicine men) and shamans are examples.
  - b. *Energy therapies* use various energy fields to promote health. Veritable energies such as light and magnetism are measurable forces that may be used to treat patients. In contrast, putative energy fields, also known as biofields, are not measurable but are instead based on theories that humans contain vital energies or life forces, which include *qi* in traditional Chinese medicine and *prana* in Ayurveda. Practices such as healing touch, *qi gong*, and reiki are purported to manipulate these forces.
  - c. *Whole medical systems* are “complete systems of theory and practice that have evolved over time in different cultures apart from conventional or Western medicine.”<sup>4</sup> Ancient whole medical systems include Ayurveda and TCM, whereas homeopathy and naturopathy are examples of modern whole medical systems.

Healing systems encompass complete sets of theories and practices. A system centers on a philosophy or lifestyle, such as the power of nature or the presence of energy in the body. Some CAM therapies have become widely integrated into conventional medicine. Many prescription drugs originally came from natural products; examples include digoxin from the foxglove plant, paclitaxel from the bark of the yew tree, yohimbine from yohimbe bark, oseltamivir from Chinese star anise, and artemether from sweet wormwood.<sup>5,6</sup>

#### Potential Risks and Benefits

CAM is often considered a form of preventive medicine and is widely used to maintain health and reduce disease risk.<sup>2</sup> The attraction of CAM includes the potential to treat diseases for which conventional therapies have been ineffective. CAM may also provide an increased sense of patient empowerment and participation, and there is a widespread belief that CAM represents safe and natural therapeutic approaches. Cancer patients have cited the media as influencing their decisions to try CAM therapies.<sup>7</sup> In addition, some patients use CAM techniques such as meditation and prayer to cope with chronic or untreatable illnesses.<sup>3</sup> Although some CAM therapies are supported by basic science and clinical evidence, many CAM therapies have not been subjected to rigorous clinical testing.<sup>5</sup> Because they often contain pharmacologically active constituents,

natural products may potentially cause adverse effects or have clinically significant interactions with drugs, foods, or other dietary supplements.<sup>5,8</sup> Therefore, CAM should not be used concurrently with drugs, or in place of proven conventional therapies, without medical supervision.

### Research Issues

Many CAM approaches have not been fully evaluated. In 1992, the U.S. Congress established the Office of Alternative Medicine within NIH and provided a budget of \$2 million to rigorously evaluate CAM practices. In 1998, after the creation of NCCAM, Congress elevated the status of the Office of Alternative Medicine to a NIH center with a budget of \$50 million for fiscal year 1999. In 2012, the Federal appropriations for NCCAM reached \$128 million. The mission of NCCAM is to “define, through rigorous scientific investigation, the usefulness and safety of complementary and alternative medicine interventions and their roles in improving health and health care.”<sup>9</sup>

In addition, the National Cancer Institute (NCI) established the Office of Cancer Complementary and Alternative Medicine (OCCAM) in October 1998 to coordinate and enhance the activities of NCI and to increase the amount of high-quality cancer research and information on the use of CAM. According to OCCAM, in fiscal year 2010, NCI supported approximately \$114,460,116 in CAM-related research. This represents more than 406 projects in the form of grants, cooperative agreements, supplements, or contracts. Other NIH institutes also contribute funds to CAM research, with estimates of almost \$500 million for all institutes and centers combined.<sup>1</sup>

Evidence on the safety and efficacy of CAM may be difficult to obtain. This challenge may be partly related to the fact that many CAM studies are reported in foreign languages and in journals that are not peer reviewed. To conduct evidence-based assessments on CAM, authors of systematic reviews and meta-analyses often broaden literature searches to include languages other than English. Several databases may be searched in addition to PubMed or MEDLINE. Researchers may also use guides and validated scales, such as the Jadad scale, which has been used to rate the quality of many available studies concerning CAM therapies.<sup>10</sup>

Another issue in evaluating CAM research is the lack of standardization. Many individual therapies involve a variety of techniques or dosages, making comparisons difficult. Some types of CAM such as Ayurveda do not require providers to be licensed or formally trained, which may contribute to the variable research results.

Experimental design is the most problematic issue in CAM research. The metaphysical aspects of some CAM therapies, such as the harmony between the body and the universe in Ayurveda, are difficult to test with scientific methods.<sup>11</sup> Critical elements of clinical research such as placebo control and double blinding are difficult in many CAM studies. For example, the participatory nature of meditation therapy prevents blinding of the subject to the active treatment.<sup>12</sup> Double blinding is a central problem with modalities such as acupuncture because this therapy cannot be easily delivered by a provider blinded to the intervention. The Jadad score is sometimes modified for application to acupuncture studies because of the difficulty in blinding the acupuncturist.<sup>13</sup> In such cases, modified Jadad scoring may include awarding one point if the trial is single blinded or if outcomes are assessed by a blinded investigator rather than the acupuncturist.

With respect to the challenge of a placebo control for CAM therapies such as acupuncture, researchers have developed sham treatments to approximate subject blinding. For acupuncture, sham treatment typically involves placement of needles at non-active sites or at a specific distance, usually about 1 inch, from the active sites in the study, whereas depth and stimulation remain the same. Other sham acupuncture techniques involve treatment at actual acupuncture points but without needle penetration. Critics of this approach argue that even pressure at acupuncture points may elicit effects. Although some studies have demonstrated that sham procedures achieved blinding of subjects, methods used to create sham acupuncture vary widely. Sham acupuncture often is not regarded as a true placebo because the patient is subjected to physical stimulation, and studies have shown this technique to also elicit effects.<sup>14</sup>

### Working with CAM Providers

Ideally, conventional and CAM providers should work collaboratively for the benefit of the patient. Pharmacists and other health care providers should have an objective attitude toward CAM providers, especially given that some techniques are now provided in conventional medical centers. An example of an integrative approach is a clinic that includes both conventional and CAM providers. To meet patient demand, conventional providers may refer patients to CAM therapies, such as therapeutic massage or acupuncture.<sup>15</sup>

Individuals who use CAM may also lack a clear understanding about the therapies. A survey among users of homeopathy in England showed that nearly 10% of users were confused about what constitutes a homeopathic product.<sup>16</sup> Patients should feel comfortable discussing potential CAM therapies with their conventional health care providers, and an increasing number of conventional providers now integrate certain evidence-based CAM techniques into their own practices.

### Homeopathy

Homeopathy is a distinct system of medicine with its own pharmacopoeia and principles of practice. The term *homeopathy* comes from the two Greek words *homoios* (similar) and *pathos* (suffering or disease). Dr. Samuel Hahnemann developed homeopathy in the early 1800s and also coined the term *allopathy* as a synonym for conventional medicine. Homeopathy is based on the principle of “like cures like” or the “law of similars.” This principle maintains that if a substance produces the symptoms of an illness in large doses, that same substance can cure it in very small doses. The more dilute a homeopathic medicine is, the greater is its potency. The efficacy of homeopathic medicines is believed to depend not only on the dilution factor but also on vigorous shaking, or succussion, which is performed with each dilution.

The homeopathic principle of like cures like is often compared with vaccination, which involves administration of antigenic material to induce immunity to infectious agents. However, this comparison is not entirely accurate. Vaccines typically contain measurable levels of attenuated or killed pathogens (or their purified antigens) and are used for prophylaxis. In contrast, homeopathic preparations are often so dilute that they contain statistically negligible amounts of the purported active ingredients. In addition, homeopathic remedies are generally used to treat an existing illness rather than for prophylaxis. One exception is *Oscillococinum*, a homeopathic preparation derived from wild duck heart and liver, which is used to both prevent and treat influenza, although evidence of its efficacy is lacking.<sup>17</sup>

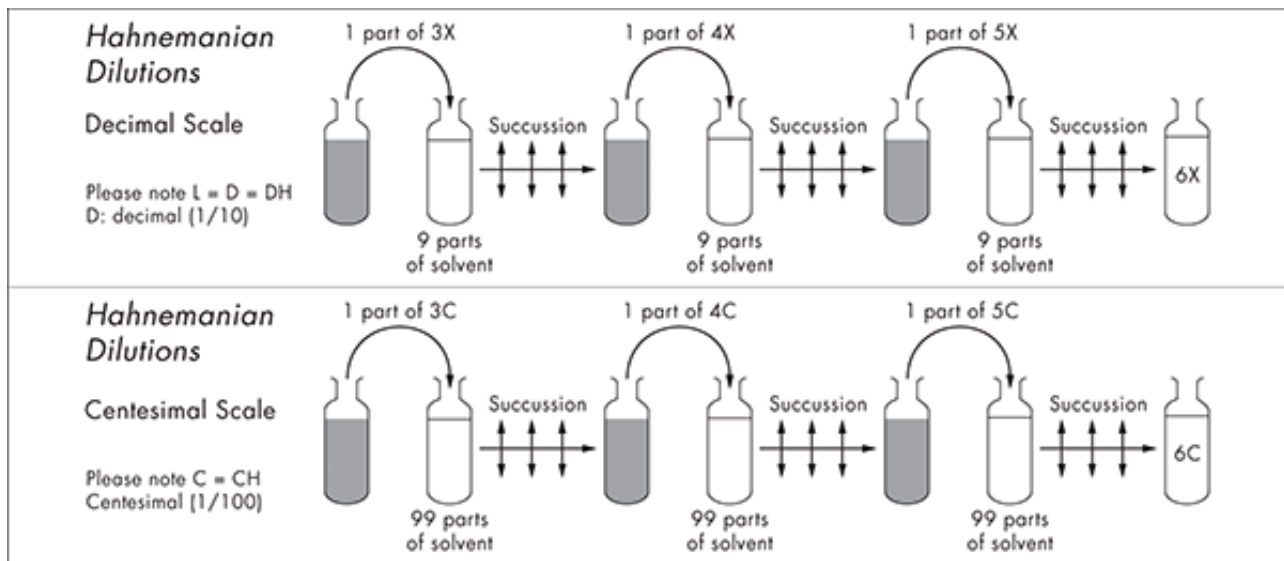

Although homeopathic medicines are generally intended to be ingested, they are not classified as dietary supplements. The Food and Drug Administration (FDA) regulates homeopathic medicines under Sections 201(g) and 201(j) of the Federal Food, Drug, and Cosmetic Act as drugs recognized in the official *United States Pharmacopoeia* (USP), *Homoeopathic Pharmacopoeia of the United States* (HPUS), or *National Formulary* (NF). For homeopathic drugs, the premarket approval process is distinct from the approval process for conventional drugs.<sup>18</sup> Homeopathic drugs are approved with the publication of a monograph by the Homeopathic Pharmacopoeia Convention of the United States (HPCUS) in the HPUS. For a homeopathic drug to be included in the HPUS, it must be manufactured according to approved methods of preparation and determined by HPCUS to be safe and effective. The safety and efficacy of a homeopathic drug is determined by procedures called provings (or research procedures in the HPUS), which determine dosages necessary to induce symptoms in healthy individuals. Evidence from homeopathic provings is subject to verification by conventional clinical research methods; however, according to FDA, “compliance with requirements of the HPUS, USP, or NF does not establish that it has been shown by appropriate means to be safe, effective, and not misbranded for its intended use.”<sup>18</sup>

As with conventional drugs, homeopathic remedies may be sold over the counter if they are intended to treat self-limiting conditions such as headaches and colds. Most homeopathic remedies are available without a prescription, whereas about 5% require prescriptions from medical care providers.<sup>18</sup> Homeopathic medicines are commonly found in integrative pharmacies that stock dietary supplements and alternative remedies along with standard drugs. Chain pharmacies and health food markets may also carry homeopathic medicines, including pediatric and veterinary formulations.

Sales of homeopathic drugs are estimated to be about 0.26% of the U.S. drug market, and their sales increase at a rate of about 8% per year, with estimated sales of \$450 million in 2003.<sup>18</sup> According to the 2007 National Health Interview Survey, nearly 4 million adults and 1 million children used homeopathy in the previous year.<sup>19</sup> Despite the widespread use of homeopathic products, particularly in children, surveys have demonstrated that confusion exists about what constitutes a homeopathic product, which suggests that providers need to dispense better patient education.<sup>16</sup>

## Technique

Medicines used in homeopathy are derived from many substances, including botanical, mineral, pharmaceutical, and zoological sources. These substances are serially diluted and succussed (or triturated) to increase the strength or potency of the medication. This process is called attenuation or potentization. After each attenuation step, the preparation is given a higher number, so a substance that was attenuated 4 times would be designated as 4X, 4C, or LM4 depending on the dilution factor.<sup>18</sup> The decimal (1:10 dilutions) and centesimal (1:100 dilutions) scales of attenuation are used to make X and C potencies, respectively (Figure 52-1). The letter M means 1000C, not the use of 1:1000 dilutions in the attenuation process. A 1:50,000 dilution is represented by the potency LM, which is derived by combining Roman numerals L and M for 50 and 1000, respectively (although the actual Roman numeral LM means 1000 minus 50, or 950). The method for preparing LM potencies is illustrated in Figure 52-2. Although many homeopathic medicines are derived from highly toxic materials such as aconite and arnica, the final preparations are often so dilute that they are well below toxic dosages.

Method for making homeopathic X and C potencies. Decimal scale, designated by an X or D, involves dilutions of 1:10 for each attenuation (dilution with succussion) step taken to make the desired X potency. Centesimal scale, designated by C, involves dilutions of 1:100 for each attenuation step taken to make the desired C potency. Southeastern, PA: The Homeopathic Pharmacopoeia Convention of the United States Revision Service; December 2004:40.)

## Training

More than 30 schools in North America offer training in homeopathy, and the Accreditation Commission for Homeopathic Education in North America (ACHENA, formerly Council on Homeopathy Education [CHE]) continually develops professional standards for homeopathic education. The Council for Homeopathic Certification offers a Certificate in Classical Homeopathy (CCH) and provides listings of certified homeopathic practitioners on their Web sites for use by other health care providers to identify qualified homeopaths.

Certification with CCH is not recognized by any state as a license to practice homeopathy. Arizona, Connecticut, and Nevada require that homeopaths also be licensed allopathic or osteopathic physicians. Health freedom acts in some states, such as Senate Bill 577 of the State of California, protect the rights of professionals without medical licenses to practice homeopathy and other modalities that the state deems harmless. Most other states lack specific regulatory

language for homeopathy; therefore, homeopathy falls under the statutes regulating the practice of medicine.

### Theory/Evidence

Because homeopathic preparations contain little-to-no active ingredient, critics argue that any demonstrated efficacy is simply a placebo effect.<sup>20</sup> Proponents of homeopathy state that trials have demonstrated effectiveness in infants or animals, and that these subjects are unlikely to have preconceived expectations that may influence their perceptions. Overall, the effectiveness of homeopathy has not been demonstrated consistently in randomized controlled trials.<sup>21,22</sup> A 2010 analysis of six reviews in the Cochrane Database of Systematic Reviews concluded that the evidence suggests the effects of homeopathic therapies are similar to those of placebo.<sup>22</sup> Citing the contradictory results of clinical trials and the overall lack of evidence determined by systematic reviews and meta-analyses, NCCAM has stated that homeopathy has not been definitively proven to treat any clinical condition. Similarly, both the American Medical Association and the American Academy of Pediatrics have neither accepted nor rejected homeopathy in the treatment of any medical condition.<sup>23</sup>

### Safety

For most homeopathic medicines, the risk of toxicity is low because of the extremely dilute nature of the homeopathic remedies.<sup>18</sup> Studies have suggested that adverse effects are less frequent in patients receiving homeopathic treatments than in those receiving conventional care.<sup>18,24</sup> The popular cold remedy Zicam has been labeled homeopathic, but some formulations contain significant levels of zinc. The nasal spray formulation containing zinc gluconate is known to cause irreversible damage to human nasal tissue.<sup>25</sup> According to FDA, more than 100 reports of loss of sense of smell have been associated with the use of this product, and this dosage form has since been withdrawn from the U.S. market.

### Naturopathy

The term *naturopathy* was coined in the late 1890s by German priest Sebastian Kneipp, who practiced herbal medicine and water therapies. Dr. Benedict Lust, who studied under Kneipp, purportedly purchased the rights to naturopathic medicine from another of Kneipp's students. In 1902, Dr. Lust opened the American Institute of Naturopathy in New York City. Because he was instrumental in promoting this field of medicine, Dr. Lust is generally credited as the founder of naturopathy.

Traditional naturopathy is a philosophy of life and an approach to living that encourages lifestyles and therapies as close to nature as possible. A system of naturopathic therapy employs natural forces such as light, heat, air, water, and massage. Naturopathy focuses primarily on building health rather than on treating disease.

The practice of naturopathic medicine emerges from six underlying principles of healing that distinguish the profession from other medical approaches. These principles are based on the observation of the nature of health and disease and are continually reexamined in light of scientific analysis. The first principle is that the body has the inherent ability to maintain and restore health. Second, the naturopathic physician aims to identify and treat the cause rather than the symptoms of a disease. The third principle states that methods designed to treat only the symptoms may be harmful and should be avoided or minimized. Fourth, the physician treats the whole person, taking into account the physical, spiritual, mental, and social aspects of the individual. The fifth principle is that the naturopath educates and encourages patients to take responsibility for their own health. Finally, the naturopath assesses risk factors and hereditary susceptibility to disease and makes appropriate interventions to avoid further harm or risk to patients.

### Technique

In most cases of disease or wellness, nutritional counseling and support are major components of naturopathic treatments. Naturopathic physicians use dietetics, fasting, and nutritional supplementation in practice. Botanical medicine and homeopathy may be used in naturopathy.

Naturopathic medicine has its own methods of therapeutic manipulation of the muscles, bones, and spine. Physicians use ultrasound, diathermy (electrically induced heat), exercise, massage, water, heat, cold, air, and gentle electrical pulses. Naturopathic physicians also provide natural childbirth care. They offer prenatal and postnatal care using modern diagnostic techniques. In some states, naturopaths may perform minor outpatient surgeries, such as repair of superficial wounds or removal of foreign bodies or cysts.

Because naturopaths believe that mental attitudes and emotional states may influence or cause physical illnesses, they may incorporate counseling, nutritional balancing, stress management, hypnotherapy, biofeedback, and other therapies to help patients heal on the psychological level.

Naturopaths may prescribe substances that are deemed appropriate by the Naturopathic Formulary Advisory Peer Committee. Listed substances depend on state law and vary among states. Some state-specific regulations, such as

the Naturopathic Physician Practice Act Rule of Utah<sup>26</sup> and those set forth by the Office of Professional Regulation in Vermont,<sup>27</sup> allow naturopaths to prescribe only medicines listed in the *Naturopathic Physician Formulary*.

## Training

In North America, seven schools offer training for the Doctor of Naturopathic Medicine (ND) degree. These include Bastyr University (Seattle, Washington), Boucher Institute of Naturopathic Medicine (Vancouver, British Columbia), the Canadian College of Naturopathic Medicine (Toronto, Ontario), National College of Natural Medicine (Portland, Oregon), National University of Health Sciences (Chicago, Illinois), Southwest College of Naturopathic Medicine (Phoenix, Arizona), and University of Bridgeport College of Naturopathic Medicine (Bridgeport, Connecticut). Similar to allopathic medical schools, admission into a naturopathic training program requires 4 years of undergraduate study that includes premedical coursework. The ND degree consists of 4 years of postgraduate training, which includes about 4500 hours of academic and clinical training. Academic training includes courses such as anatomy, biochemistry, microbiology, and pathology. Clinical training encompasses various alternative modalities, including herbal therapy and homeopathy, in addition to mainstream clinical training such as that in cardiology and nutrition. Naturopathic physicians are educated in modern methods of diagnostic testing and imaging, including X-ray, ultrasound, and other imaging techniques. Some naturopaths may participate in residency programs, including integrative programs that train NDs in conventional medical settings.

In addition to a standard medical curriculum, a naturopath must study holistic therapies with a strong emphasis on preventing disease and optimizing wellness. The ND is required to complete training in clinical nutrition, acupuncture, homeopathic medicine, botanical medicine, psychology, and counseling. Before they can practice, naturopathic physicians must pass board examinations set by the North American Board of Naturopathic Examiners, and most states require NDs to complete continuing education hours to renew their licenses.

The licensing of naturopathic physicians varies among states. According to the Association of Accredited Naturopathic Medical Colleges (AANMC; [aanmc.org/careers/licensure/](http://aanmc.org/careers/licensure/)) and the Council on Naturopathic Medical Education (CNME; [www.cnme.org/faq.html](http://www.cnme.org/faq.html)), NDs are licensed to practice in Alaska, Arizona (where they are known as Natural Medical Doctors, or NMDs), California, Connecticut, Hawaii, Idaho, Kansas, Maine, Minnesota, Montana, New Hampshire, North Dakota, Oregon, Utah, Vermont, and Washington as well as in Alberta, British Columbia, Manitoba, Ontario, and Saskatchewan. In addition, naturopaths are licensed in the District of Columbia, Puerto Rico, and the Virgin Islands. According to the AANMC, legislation for state/province licensing is pending for Colorado, Illinois, Iowa, Massachusetts, New York, North Carolina, Nova Scotia, Wisconsin, and Pennsylvania. Naturopathy is prohibited in the states of South Carolina and Tennessee. In all other states, laws currently do not regulate the practice of naturopathy.

Because of the popularity of naturopathy, more physicians trained in conventional medicine or other CAM fields are incorporating naturopathic treatments into their practices. Health care providers who hold degrees in osteopathy, chiropractic, acupuncture, dentistry, and veterinary medicine may seek additional training in naturopathy; they sometimes use terms such as *holistic*, *natural*, or *integrative* to promote their practices.

## Theory/Evidence

The individual methods used in naturopathic medicine vary in their effectiveness. For instance, a proper diet may help prevent heart disease; this measure is recommended in both conventional and naturopathic medicine. Other forms of naturopathic treatment may not be more effective than conventional medicine. For example, acupuncture may help to reduce pain in some instances, but it is not widely recommended for use in place of standard analgesics for extreme pain or in surgery.<sup>28</sup> On the other hand, compared with psychotherapy, some naturopathic treatments may be more effective than conventional therapies for certain conditions, as shown with a combination naturopathic treatment for anxiety (nutrition counseling, relaxation techniques, and vitamin/herbal supplementation).<sup>29</sup>

## Safety

The safety of naturopathic remedies depends on the treatment and the condition. Naturopathic methods are generally considered safer alternatives to some conventional drugs or treatments. However, herbal remedies are not free from adverse effects, and interactions may occur with drugs, supplements, or foods.<sup>1,5,30</sup> The safety of other naturopathic modalities, such as fasting or other dietary restrictions, depends on the individual. As with all CAM therapies, naturopathic treatments should not be used in place of proven therapies for serious medical conditions. Case 52-1 illustrates assessing the appropriateness of naturopathic treatments in a patient trying to cope with stress and anxiety.

## Traditional Chinese Medicine

*Chinese medicine* is a broad term encompassing many different modalities and traditions of healing, including herbal

medicine and acupuncture.<sup>6,31</sup> These therapies share a common root in Chinese philosophy, including Taoism, Confucianism, and Buddhism, and may date back more than 5000 years.

In the 1940s and 1950s, the Chinese government undertook an effort to coalesce diverse forms of Chinese medicine into a unified system to be officially defined as traditional Chinese medicine (TCM). The intent was to integrate traditional providers into an organized health system and to provide care for a large population by using familiar and inexpensive methods.

Although TCM is considered to be complementary or alternative medicine in most of the Western world, in China the term for TCM literally means “central medicine.” TCM and Western medicine are commonly used side by side in modern China. As a result, compared with Western countries, China is relatively advanced in using integrative medicine. TCM features prominently in the treatment of major illnesses, including cancer and heart disease. According to the World Health Organization, TCM is fully integrated into the Chinese health system and is practiced in 95% of Chinese hospitals.<sup>32</sup>

### Technique

TCM emphasizes herbal medicine. Herbs are usually given as pills, extracts, capsules, tinctures, or powders, which may be used directly or combined with food or other treatments. More than 2000 different types of herbs are used in Chinese medicine, with 400 frequently used and 50 considered “fundamental” herbs.<sup>33,34</sup> Some Chinese herbs have received attention in Western medicine for treating serious disorders. For example, the *Monascus purpureus* fungus, found in red yeast rice, is a natural source of lovastatin. Bevirimat, derived from the Chinese herb *Syzygium claviflorum*, is in a new class of drugs called maturation inhibitors and is being investigated in ongoing clinical trials in HIV.<sup>35</sup>

TCM incorporates not only herbs but also minerals, metals, and animal products into therapeutic preparations. The use of animal products has become more infrequent in recent years, in part because of restrictions on certain species, particularly endangered species.

Acupuncture is also considered a form of TCM, although it is regarded as more of a supportive treatment to herbal therapy. Many varieties of acupuncture exist both in Chinese and Western medicine. Classic acupuncture, also known as five-element acupuncture, uses a different needling technique and relies on acupuncture without the use of herbs. Needles used in Japanese acupuncture are smaller than those of other forms of acupuncture. Medical acupuncture refers to acupuncture practiced by a conventional physician. Auricular acupuncture treats the entire body through acupuncture points in the ears only, and electroacupuncture uses electrical currents attached to acupuncture needles. As with many forms of TCM, acupuncture may require multiple treatments and long-term follow-up for symptom improvement and health maintenance. Case 52-2 illustrates assessing the appropriateness of acupuncture for a patient with lower back pain.

Cupping and moxibustion are commonly used to complement acupuncture, but these techniques may also be used independently in TCM. They share the principle of using heat to stimulate circulation to break up congestion or stagnation of blood and *chi (qi)*, which is the life force central to health and well-being in TCM. Cupping has some relation to the massage technique *tuina*, which uses rapid skin pinching at points on the back to break up congestion and stimulate circulation. Cupping may also be used over acupuncture points or elsewhere. Popular in the United States, moxibustion involves the burning of dried moxa (mugwort), either on or near the skin, and sometimes in conjunction with cupping or acupuncture on specific points.<sup>36</sup>

TCM providers may use other modalities such as meditation and martial arts. *Tai chi chuan* (or *tai chi*) is a meditative form of martial arts that incorporates the theories of *yin* and *yang* from both Taoism and Confucianism. *Tai chi* is practiced to improve balance, coordination, and relaxation, and overall well-being. TCM may also incorporate *feng shui*, which is the art of arranging furniture and objects to increase health and prosperity.

### Training

The Accreditation Commission of Acupuncture and Oriental Medicine (ACAOM) accredits professional acupuncture programs and is recognized by the U.S. Department of Education. According to the ACAOM, acupuncture and Oriental medicine is a 3- or 4-year master's degree program, offered by over 60 accredited or candidate colleges in the United States ([www.naturalhealers.com/natural-health-careers/article/acupuncture-licensure](http://www.naturalhealers.com/natural-health-careers/article/acupuncture-licensure)). The National Certification Commission for Acupuncture and Oriental Medicine (NCCAOM) offers four independent certification programs, including Acupuncture, Chinese Herbology, Oriental Medicine, and Asian Bodywork Therapy ([www.nccaom.org](http://www.nccaom.org); select Certification Brochure). Acupuncturists who pass national examinations administered by NCCAOM are entitled to identify themselves as board certified in their discipline and as diplomates of the NCCAOM. Licenses to practice acupuncture are granted by individual states. Although requirements vary, many states require acupuncturists to pass the NCCAOM examinations and obtain continuing education.

### Theory/Evidence

Taoism, Confucianism, and Buddhism provided the basis for the development of Chinese medical theory. According to these philosophies, nature and the laws that govern the ongoing, harmonious flow of life energy through the natural world also govern the body and health. The person is viewed as an ecosystem that is embedded in the larger ecosystem of nature and is therefore subject to the same laws. The life force called *chi* (or *qi*) circulates through the body and enlivens it. Health is a function of a balanced, harmonious flow of chi, and illness results when there is a blockage or an imbalance in the flow of chi. *Yin* and *yang* are opposite and complementary qualities of life energy (*qi*). *Yin* is regarded as the feminine principle and *yang* the masculine principle. The human being has a system of pathways called meridians, which may also be referred to as channels, through which *chi* flows. Meridians correspond with specific organs or organ systems (organ networks). Health is an ongoing process of maintaining balance and harmony of the circulation of *chi* through all the organs and systems of the body. The body has five organ networks, each corresponding with a particular element.

Despite the growing popularity of TCM in the West, its effectiveness remains debatable. Scientific evidence supports the use of acupuncture for several indications including osteoarthritis and various types of pain and nausea.<sup>5</sup> The American Cancer Society states “clinical studies have found acupuncture may help treat nausea caused by chemotherapy drugs and surgical anesthesia.” Moxibustion, which is traditionally used to turn breech babies, has been used with some success, although systematic reviews and meta-analyses have yielded insufficient evidence to support its efficacy.<sup>36</sup> In general, few well-designed trials of TCM herbal formulas have been conducted,<sup>31</sup> and the need for improving the methodological quality of TCM research has been identified.<sup>37-39</sup>

### Safety

Adverse events with acupuncture are rare, including acupuncture with cupping and moxibustion.<sup>35</sup> Needles must be sterile and disposable needles are often used to reduce the risk of disease transmission. Acupuncture should be avoided or used cautiously in individuals with heart disease, seizures, infections, bleeding disorders, or neurologic disorders, or among individuals using antithrombotic drugs because of theoretical or reported adverse effects.<sup>5</sup> Acupuncture should be avoided on areas that have received radiation therapy and for conditions of unknown medical origin. Caution is advised during pregnancy. Frail older adults or otherwise medically complex patients should use acupuncture with caution. Electroacupuncture should be avoided in patients with an arrhythmia or seizure disorder and in patients with pacemakers.

Cupping commonly leaves a temporary bruising of the skin. Moxibustion may also leave a temporary discoloration on the skin, which may be washed off or will disappear on its own. Historically, some traditional providers of moxibustion have intentionally employed more aggressive use of the technique to an extent that might leave minor scarring, but this aggressive form of practice is not regularly used in the West.

Chinese herbs have been associated with adverse effects. According to a 2004 FDA ruling, more than 1500 cases of serious toxicity, including death related to the use of ephedra or ma huang (*Ephedra sinica*) have been reported. Some Chinese herbal products have contained toxins or heavy metals. In addition, prescription drugs such as corticosteroids have been included in the preparations but not listed as ingredients.<sup>40</sup> Patients should purchase Chinese herbs from trustworthy sources and should be aware that Chinese herbs can interact with other herbs, foods, and drugs.

### Case 52-1

<b>Common CAM Health Systems</b>
<b>Patient Complaint/History</b>
PF is a 43-year-old man who has been experiencing significant amounts of stress and anxiety related to the recent diagnosis of illness in a family member. He comes to your pharmacy and seeks your advice. He likes his primary care provider but thinks the provider is too busy to listen to his concerns and is likely just to prescribe more prescription drugs. The patient states that he does not want to become like his father who takes more than 15 different drugs every day for various chronic illnesses. PF currently takes glipizide for type 2 diabetes (A1C of 6.5%) and low-dose aspirin for prevention of heart disease. He also takes fish oil because his neighbor told him it is good for health. He is interested in any therapies that might ease his anxiety.
<b>Recommendation</b>
Many CAM approaches are available to ease PF's anxiety and stress. He may consider seeing a naturopath to discuss a holistic approach to his anxiety and health. Compared with psychotherapy, some naturopathic treatments may be more effective than conventional therapies for certain conditions, as has been shown with a combination naturopathic treatment for anxiety (nutrition counseling, relaxation techniques, and vitamin/herbal supplementation). Naturopathic methods are generally considered safer alternatives to some conventional drugs

or treatments. However, herbal remedies are not free from adverse effects, and interactions may occur with drugs, supplements, or foods. As with all CAM therapies, naturopathic treatments should not be used in place of proven therapies for serious medical conditions. PF should be encouraged to tell his health care provider about his use of CAM.

Key: A1C = Glycosylated hemoglobin; CAM = complementary and alternative medicine.

### Case 52-2

<b>Common CAM Health Systems</b>
<b>Patient Complaint/History</b>
RA is a 49-year-old man with a history of lower back pain. He has been treated with various modalities, including nonsteroidal anti-inflammatory drugs and chiropractic treatment. He tells you that he previously took Vioxx (rofecoxib), but since it was taken off the market, he has not tried any other drug. He also adds that he does not like the “cracking” sound when he goes to his chiropractor. RA has a history of type 2 diabetes and takes metformin 1000 mg twice daily; he also has depression, for which he takes St. John’s wort. He tells you that his regular (allopathic) primary care provider is also trained in several CAM techniques.
<b>Recommendation</b>
Scientific evidence supports the use of acupuncture for several indications, including various types of pain. Adverse events rarely occur with acupuncture, even with cupping and moxibustion procedures. In normal office practice, acupuncture is commonly used in combination with herbs or supplements. As with many therapies, acupuncture may require multiple treatments and long-term follow-up for symptom improvement and health maintenance. Reassure RA that acupuncture is worth exploring, and provide him with reliable sources of information from which he can acquire more information on which to make an informed decision. After researching the available information, he should discuss his suitability for acupuncture with his allopathic physician.

Key: CAM = Complementary and alternative medicine.

### Chiropractic Care

Chiropractic focuses on the relationship between spinal structure and body function mediated by the nervous system. It originated in 1895 with D. D. Palmer, a popular hands-on healer practicing in Davenport, Iowa. The formulation of *chiropractic* combined the Greek *cheir* (hand) and *praxis* (practice). Palmer’s original philosophy described the approach as connecting “man the spiritual” to “man the physical” by eliminating interference to the flow of “Innate Intelligence” through each individual. This innate intelligence, an almost metaphysical phenomenon, flows through the nervous system. The clearer the nervous system is, the more the innate intelligence can express itself and fully enliven the person’s body and organs.<sup>41</sup>

Important distinctions exist between the profession of chiropractic, chiropractic care, and spinal manipulation. A chiropractor delivers chiropractic care that is a full range of treatment delivered in one or more therapeutic encounters. Treatment includes procedures and techniques of assessment and a tailored mix of therapeutic interventions to improve a patient’s health status. The term *spinal manipulation* or *spinal adjustment* does not operationally define the profession or chiropractic care, although it is a well-known procedure. Chiropractic care also includes other procedures, such as exercise, dietary advice, ergonomic and lifestyle advice, supplements, all forms of physical therapy and rehabilitation intervention, and referral to other providers as necessary.

#### Techniques

Patients usually lie face down on a Cox table, which is similar to a massage table with an open space in which to place the face. Depending on the technique used, chiropractic visits may last 15 minutes to 1 hour or more.

Chiropractors may see clients up to 3 times a week initially and then less frequently over time.

Patients can be diagnosed by different procedures including X-ray, computed tomography, magnetic resonance imaging, electrical current, and ultrasound therapy. Thermography may also be used, followed by treatment with ice packs and heat packs.

More than 100 chiropractic and spinal manipulative adjusting techniques may be employed. Spinal manipulative therapy uses many techniques to apply force to an area of the spine joint. Massage or mobilization of soft tissue is used in techniques such as myofascial trigger point therapy, cross-friction massage, active release therapy, muscle stripping, Rolfing, or other forms of structural integration. Mechanical traction or the use of external resistance on the

spine may also be used. The cracking sound has typically been associated with cavitation in the spinal zygapophyseal (the neural arch between the joint processes) joints. The cracking or popping of a joint has not been proven to be essential to a clinically effective manipulation.

## Training

Chiropractic is one of the largest and best-established professions of CAM in the United States. According to the U.S. Department of Labor, the estimated employment of chiropractors in 2012 was 27,740 practitioners.<sup>42</sup> The Council on Chiropractic Education accredits programs and institutions offering the Doctor of Chiropractic degree, which currently includes 15 schools in the United States and 2 in Canada ([www.cce-usa.org/DCP\\_Representatives.html](http://www.cce-usa.org/DCP_Representatives.html)). According to the Federation of Chiropractic Licensing Boards, all 50 states have formal statutes that recognize and regulate the practice of chiropractic (<http://directory.fclb.org/Statistics.aspx>).

According to the American Chiropractic Association, a typical applicant to a chiropractic college has completed 4 years of undergraduate coursework. The curriculum of a chiropractic college includes didactic coursework and clinical training totaling a minimum of 4200 hours. Clinical training with actual patients typically lasts a minimum of 1 year. Specialty training is available through residency programs, which may require an additional 2-3 years of clinical training. Before they are allowed to practice, doctors of chiropractic must pass national board examinations and become licensed. Chiropractors generally do not prescribe drugs, but those who are also licensed naturopaths or other health care professionals may prescribe remedies according to the respective guidelines in the state in which they practice ([www.acatoday.org/patients/index.cfm](http://www.acatoday.org/patients/index.cfm); select FAQs).

## Theory/Evidence

Designing clinical trials to evaluate the efficacy of chiropractic is difficult, primarily because of the issues in developing an appropriate control. Other major issues include a potentially strong placebo effect and the high rate of spontaneous recovery. In addition, patients often seek chiropractic treatment for conditions with poorly understood pathologies, such as fibromyalgia; available evidence is insufficient to support the use of chiropractic for this condition.<sup>43</sup> For low back pain, sufficient evidence from both blinded and nonblinded trials supports the use of spinal manipulation, although the benefits are modest and of uncertain clinical significance.<sup>44</sup> Chiropractic has been used to treat many conditions including asthma, colic, ear infection, headache, whiplash, and hypertension, although evidence is insufficient to support efficacy for these conditions.<sup>20</sup>

## Safety

The safety of chiropractic is controversial. Some systematic reviews show that spinal manipulation is associated with mild-moderate adverse effects. The most common serious adverse effects with spinal manipulation are vertebral artery dissection and stroke (VADS).<sup>45</sup> A 2010 review revealed 26 deaths associated with chiropractic spinal manipulation, and many more fatalities may be unpublished.<sup>46</sup> However, despite the increasing popularity of chiropractic and its association with potentially fatal adverse events such as VADS, myelopathy, vertebral disc extrusion, and epidural hematoma, few studies have properly evaluated the safety of chiropractic.<sup>47</sup> Whether the adverse effects are directly related to spinal manipulation or to sampling bias of patients is unclear. Case-control studies suggested a causal role,<sup>46</sup> although patients predisposed to VADS may be more likely to seek chiropractic treatment, suggesting a potential sampling bias.<sup>48</sup> A 2009 systematic review showed that adverse events occurred with a frequency of 33%-60.9%, but serious adverse events were rare (as few as 1.46 serious adverse events and 2.68 deaths for every 10 million manipulations).<sup>47</sup> Although this study did not support a strong causal relationship between chiropractic manipulation and the adverse events, the authors stated further high-quality studies are needed to assess its safety.

Patients with osteoporosis or any type of acute arthritis should either avoid chiropractic adjustment or use it cautiously because of the risk of fracture. Caution is also warranted in patients with bleeding disorders, migraines, and tumors or metastases to the spine. Patients with symptoms of vertebrobasilar vascular insufficiency, aneurysms, arteritis, or unstable spondylolisthesis should avoid chiropractic care. Patients receiving anticoagulant therapy should also be advised to avoid chiropractic care.<sup>5</sup>

A final consideration with this health system is that chiropractors have traditionally discouraged the use of routine vaccinations.<sup>49</sup> Although this attitude may be less likely now, Western health care providers, including pharmacists, should be aware of this aspect of chiropractic care.

## Ayurveda

Ayurveda originated in India more than 5000 years ago and is probably the world's oldest system of natural medicine.<sup>50</sup> When translated, *Ayurveda* means science of life, which stems from the spiritual teachings known as the

Vedas. Ayurveda may be the original basis for Chinese medicine and is an integrated system of specific theories and techniques that employ diet, herbs, exercise, meditation, yoga, and massage or bodywork. The goal of Ayurveda is to achieve optimal health on physical, psychological, and spiritual levels.

In India, Ayurveda involves the eight principal branches of medicine: pediatrics, gynecology, obstetrics, ophthalmology, geriatrics, otolaryngology, general medicine, and surgery. In Western countries, the practice of Ayurveda is less focused on its spiritual roots than on its use as a form of CAM. Ayurveda relies on the individual's willingness to participate in lifestyle and behavior changes.

### Technique

Ayurveda teaches that vital energy (*prana*) is the basis of all life and healing.<sup>50</sup> As *prana* circulates throughout the human body, it is governed by the five elements of earth, air, fire, water, and ether. The five elements combine with one another into pairs called *doshas* that include *vata* (ether and air), *pitta* (fire and water), and *kapha* (earth and water). Health is a state of balance and harmony among the five elements, and illness occurs when there is an imbalance or lack of harmony among them.

The regulation of diet as a form of therapy is a central idea in Ayurveda. An individual's temperament and mental and spiritual development can be influenced by the quality and quantity of food consumed. An important principle in Ayurveda is that "there is nothing in the world that is not a medicine or food." Foods and herbs are described in terms of their energetic qualities rather than chemical properties. Sweet foods (called *madhura*) provide nourishment and coolness and also aid in increasing body weight. Sour foods (called *amla*) provide warmth and aid in weight gain. Salty foods (*lavana*) provide warmth, stimulate the senses, and aid weight gain. In contrast, bitter foods (*katu*) provide coolness and help weight loss. Pungent foods (*tikta*) also aid in weight loss but provide warmth and stimulation.

Numerous herbs and spices including turmeric and cumin are used in Ayurveda.<sup>50</sup>

Ayurveda holds that each 24-hour cycle is divided into 4-hour segments governed by the *doshas*. These time periods are believed to correspond with nature. Ayurvedic providers guide patients to plan their activities to be in harmony with these natural principles of timing.<sup>50</sup>

A provider usually interviews the patient about his or her medical history. The provider then palpates the patient's wrist to determine subtle qualities of the pulse. Providers may also evaluate the appearance of the tongue, face, lips, nails, or eyes. Laboratory tests of blood, urine, and stools may be used to help with diagnosis. The initial consultation is usually the longest and lasts from 45 to 90 minutes or longer. Follow-up consultations may be spaced by several weeks or months to monitor the individual's progress. Follow-up will usually be brief office visits involving a diagnostic review and an adjustment of the regimen.<sup>50</sup>

### Training

In India, more than 150 undergraduate and 30 postgraduate institutions for Ayurvedic medicine exist, and according to the NCCAM, the standard length of training is at least 5 years. Despite the abundance of institutions, the standard of Ayurvedic education in India is poorly structured and largely unregulated, which has resulted in a global negative perception of the practice.<sup>51</sup>

According to NCCAM, no national standard for Ayurvedic training or certification exists in the United States. Ayurveda is practiced in Western medicine by health care providers who are licensed in a variety of disciplines.<sup>50</sup> Allopathic and osteopathic physicians, naturopaths, acupuncturists, nurses, massage therapists, and chiropractors may all practice Ayurveda. Health counselors, educators, or consultants may also incorporate Ayurveda into their practices without specific licensing. In Western countries, two major approaches to training and practice exist. The first is offered by diverse teachers and providers, many of whom are either from India or were trained there. The second consists of devotees of Maharishi Mahesh Yogi, the Indian spiritual teacher who introduced Transcendental Meditation (TM) to the West. In 1980, this group coined the term *Maharishi Ayur-Ved*, a practice that incorporates TM as part of an Ayurvedic approach.

### Theory/Evidence

Some of the more metaphysical aspects of Ayurveda, such as harmony between the body and the universe, are difficult to assess with modern scientific methods.<sup>11</sup> Several herbal formulations have been studied in Western-style clinical trials; currently, evidence is inadequate to recommend Ayurveda for any indication.

### Safety

Many different Ayurvedic herbs exist, and they are frequently taken in combination with other herbs and/or minerals. Safety and toxicity will vary depending on the herb and its preparation. In general, Ayurvedic herbal medicines should be used cautiously because their potencies may not be tested or standardized. Therapeutic levels of sildenafil have been detected in Ayurvedic herbal preparations used for aphrodisiac purposes.<sup>52</sup> Patients should purchase

Ayurvedic herbs from trustworthy sources and should be aware that Ayurvedic herbs can interact with other herbs, foods, and drugs. For example, ginger, which is commonly used in Ayurveda, may increase the risk of bleeding when used with anticoagulants or antiplatelet drugs.<sup>8</sup>

Heavy metal contamination continues to be a concern in Ayurvedic medicines. In addition to herbs, Ayurvedic formulas known as *rasa shastra* may also contain metals such as arsenic, mercury, or zinc. Providers claim that these medicines are safe when properly prepared and administered. However, from 1978 to 2009, at least 80 cases of heavy metal poisoning worldwide have been linked to Ayurvedic medicine.<sup>53</sup> According to the U.S. Centers for Disease Control and Prevention, 12 cases of lead poisoning in five states were associated with Ayurvedic medicines from 2000 to 2003. Even herbal Ayurvedic formulas may contain heavy metals; a recent study found that approximately 20% of purported herb-only formulas contained detectable metals compared with 40% of *rasa shastra* medicines.<sup>54</sup> Consequently, patients are advised to use Ayurvedic herbs cautiously. Products that have USP seals of quality approval have been tested and should not contain unacceptable levels of harmful metals. Product testing information is also available from sites such as ConsumerLab (see [Chapter 50](#)).

## Massage

Soft tissue manipulation has been practiced for thousands of years in diverse cultures. Chinese use of massage dates to 1600 BC, and Hippocrates referred to the importance of physicians being experienced with “rubbing” as early as 400 BC.<sup>5</sup>

Massage spread throughout Europe during the Renaissance and was introduced in the United States in the 1850s. By the early 1930s, massage became a less prominent part of Western medicine. Interest in therapeutic massage resurged in the 1970s, particularly among athletes to promote well-being, relaxation, analgesia, stress relief, healing of musculoskeletal injuries, sleep enhancement, and quality of life. Massage is one of the most common forms of CAM therapy used in the United States.<sup>19</sup>

A common goal of massage therapy is to help the body heal itself. Touch is fundamental to massage therapy and is used by therapists to locate painful or tense areas, to determine how much pressure to apply, and to establish a therapeutic relationship with clients. The term *toxic touch* refers to techniques with detrimental effects.

## Technique

Different therapeutic techniques can be classified as massage therapy. Most involve the application of fixed or moving pressure or manipulation of the clients’ muscles and connective tissues. Providers may use their hands or other areas such as forearms, elbows, or feet. Lubricants may be used to aid the smoothness of massage strokes. Examples of massage therapy include Swedish massage, sports massage, deep tissue massage, and trigger point massage.

## Training

Training requirements for massage therapy vary in the United States, but they generally involve 500-1000 hours for certification by the National Certification Board for Therapeutic Massage and Bodywork. Over 1000 massage training programs exist, and some have received accreditation by the Commission on Massage Therapy Accreditation, which is recognized by the U.S. Department of Education as a specialized accrediting agency. Upon fulfilling the necessary requirements, massage therapists receive the designation of Nationally Certified in Therapeutic Massage and Bodywork. A national examination is available from the National Certification Board for Therapeutic Massage and Bodywork. Most states require massage therapists to be certified before practicing.

## Theory/Evidence

Research on massage therapy is limited, and published studies frequently use a variety of techniques and trial designs. The effectiveness of massage has not been established for any health condition, although it remains popular for improving relaxation, mood, and overall well-being, particularly in palliative care.<sup>55</sup>

## Safety

Few adverse effects have been reported with massage.<sup>5</sup> Fractures, discomfort, bruising, swelling of massaged tissues, and liver hematoma have been reported. Vigorous massage should be avoided in patients with bleeding disorders, peripheral vascular disease, or thrombocytopenia, or in those receiving antithrombotic therapy. According to preliminary data, blood pressure may increase in healthy patients following vigorous massage (e.g., trigger point therapy, which focuses on painful muscle knots); however, in patients with hypertension, massage may lower blood pressure. Areas that should not be massaged include those with osteoporotic and other fractures, open/healing skin wounds, skin infections, recent surgery, or blood clots. Massage and other touch-based therapies should be used cautiously in patients with a history of physical abuse. Women who are pregnant should consult their obstetrician

before beginning massage therapy. Allergies or skin irritation can occur with the oils used in massages, such as olive and mineral oil.

**TABLE 52-1 Common Health Issues with Evidence of Benefit from CAM**

<i>Condition</i>	<i>CAM Treatment</i>
Osteoarthritis	Acupuncture
Chronic pain, fibromyalgia, postoperative pain	Acupuncture
Nausea	Acupressure
Low back pain	Chiropractic
Quality of life in cancer patients	Massage
Anxiety and stress	Therapeutic touch

Key: CAM = Complementary and alternative medicine.

Massage has not been evaluated as a method to diagnose medical conditions. Massage should not be used as a substitute for more proven therapies for medical conditions.

### Conclusion

Patients increasingly seek care from CAM providers and health systems. Although some historical and scientific evidence supports the effectiveness of some approaches, general statements are difficult to make on the safety and efficacy of CAM. Important components of clinical trials, such as placebo controls and blinding, are difficult to achieve and, as a result, evidence is limited. Because the use of CAM continues to increase, both patients and providers should be informed about the potential risks and benefits of CAM techniques. (See [Table 52-1](#) for common evidence-based uses of CAM health systems.)

More patients are using the Internet for health information before consulting health care providers. As information has become increasingly available, patients have increased their responsibility for their health decisions and should be encouraged to tell their health care providers whether they are also using any CAM approaches to their health. Similarly, all Western health care providers, including pharmacists, must be knowledgeable about CAM health systems and the evidence that supports or refutes their use.

### Key Points for CAM Health Systems

- The term *complementary and alternative medicine* (CAM) is generally regarded as a broad group of healing philosophies, diagnostic approaches, and therapeutic interventions that do not conform to the conventional Western health system. The most common CAM therapies and health systems include homeopathy, naturopathy, traditional Chinese medicine (TCM)/acupuncture, chiropractic care, Ayurveda, and massage.
- Homeopathy is based on the principle of “like cures like,” which states that if a substance produces the symptoms of an illness in large doses, that same substance can cure it in very minute dosages. The effectiveness of homeopathy currently cannot be determined for any clinical condition, although the risk of toxicity is low.
- Naturopathy employs natural forces such as light, heat, air, water, and massage; this therapy focuses on building health rather than on treating disease. Naturopathy is based on six principles: (1) the healing power of nature, (2) identifying and treating the cause, (3) doing no harm, (4) treating the whole person, (5) the physician as teacher, and (6) preventing disease. The licensing of naturopathic doctors varies depending on state laws.
- TCM includes herbal medicine as well as various techniques such as acupuncture, moxibustion, and cupping. TCM is dependent on the life force (*qi*), which circulates through the body through meridians (channels) connecting all major organs. *Qi* consists of *yin* and *yang*, which are opposite and complementary qualities. Illness results when these forces are unbalanced. An acupuncturist inserts sterilized needles into channels of energy to try to restore balance to the patient’s *qi*.
- Chiropractic focuses on the relationship between spinal structure and body function mediated by the nervous system. The most common adverse event is mild localized discomfort, although adverse events including death have been reported.
- Ayurveda is an integrated system employing diet, herbs, exercise, meditation, yoga, and massage or bodywork. Ayurveda teaches that vital energy (*prana*) is the basis of all life and healing. As *prana* circulates throughout the body, it is governed by the five elements of earth, air, fire, water, and ether. The five elements combine with one another into pairs called *doshas*, which include *vata* (ether and air), *pitta* (fire and water),

and *kapha* (earth and water). Ayurvedic herbs may interact with other drugs, herbs, and foods.

- Touch is fundamental to massage therapy and is used by therapists to locate painful or tense areas, to determine how much pressure to apply, and to establish a therapeutic relationship with clients.

## Handbook of Nonprescription Drugs > Chapter APPENDIX I. FDA Pregnancy Risk Categories for Selected Nonprescription Medications and Nutritional Supplements

### Appendix I

Drug therapy during pregnancy may sometimes be necessary. However, because most drugs cross the placenta to some extent, a mother who takes a drug might expose her fetus to it. Medications should be used during pregnancy only under the supervision of a physician and only when the potential benefits outweigh the potential risks. The table on the following pages contains Food and Drug Administration (FDA) categories for evaluating the safety of drugs during pregnancy for many of the nonprescription medications discussed in this book. The listed categories pertain to the particular strengths or formulations in which the nonprescription medications are available. Prescription strengths or formulations of a medication may have different pregnancy risk categories. Categories that bear a subscript M (e.g., C<sub>M</sub>) were assigned by the manufacturer. The majority of the remaining categories were assigned by drug information sources based on available clinical information. *Drugs in Pregnancy and Lactation: A Reference Guide to Fetal and Neonatal Risk* is the primary information source. The pregnancy risk categories are defined as follows:

- A** Adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.
- B** Animal studies have not demonstrated a risk to the fetus, but there are no adequate studies in pregnant women ... or ... Animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.
- C** Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; the benefits from the use of the drug in pregnant women may be acceptable despite its potential risks ... or ... There are no animal reproduction studies and no adequate studies in humans.
- D** There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.
- X** Studies in animals or humans demonstrate fetal abnormalities, or adverse reaction reports indicate evidence of fetal risk. The risk of use in a pregnant woman clearly outweighs any possible benefit. Use of drugs with this rating is contraindicated in women who are or may become pregnant.

<i>Medication</i>	<i>Pregnancy Risk Category Rating</i>
Acesulfame potassium	No rating <sup>b</sup>
Acetaminophen	B
Alcloxa	No rating <sup>b</sup>
Alpha galactosidase	No rating <sup>b</sup>
Alpha hydroxy acid	No rating <sup>b</sup>
Aluminum acetate	No rating <sup>b</sup>
Aluminum chloride	C <sup>a</sup>
Aluminum hydroxide	C <sup>a</sup>
Aluminum sulfate	No rating <sup>b</sup>
Aminobenzoic acid (PABA)	C <sup>a</sup>
Ammonium chloride	B
Ammonium lactate	B <sub>M</sub>
Antazoline	No rating <sup>b</sup>

Ascorbic acid	See Vitamin C
Aspartame	B (C in women with phenylketonuria)
Aspirin	No rating <sup>b</sup> (D if full doses taken in 3rd trimester)
Avobenzone	No rating <sup>b</sup>
Bacitracin	C
Bentonite	No rating <sup>b</sup>
Benzocaine	C <sub>M</sub>
Benzoyl peroxide	C
Benzyl alcohol	B <sub>M</sub>
Beta-carotene	C
Biotin	B <sup>a</sup> (30 mcg/day recommended during pregnancy)
Bisacodyl	B
Bismuth	C
Brompheniramine	C <sub>M</sub>
Butamben picrate	No rating <sup>b</sup>
Butenafine	C <sub>M</sub>
Butoconazole	C <sub>M</sub>
Caffeine	B
Calamine	No rating <sup>b</sup>
Calcium carbonate	C <sup>a</sup>
Calcium citrate	C <sup>a</sup>
Calcium gluconate	C <sub>M</sub>
Calcium polycarbophil	No rating <sup>b</sup>
Camphor	C
Capsaicin	B <sub>M</sub>
Carbamide peroxide	No rating <sup>b</sup>
Casanthranol	C
Cascara sagrada	C
Castor oil	C (avoid; oxytocic effects)
Cetirizine	B <sub>M</sub>
Charcoal, activated	No rating <sup>b</sup>
Chlophedianol	No rating <sup>b</sup>
Chlorhexidine gluconate	B

Chlorpheniramine	B
Choline	C <sup>a</sup>
Chromium	No rating <sup>b</sup>
Cimetidine	B <sub>M</sub>
Cinoxate	No rating <sup>b</sup>
Clemastine	B <sub>M</sub>
Clotrimazole	B
Coal tar	C <sup>a</sup>
Codeine	C (D if used for prolonged periods or in high doses at term)
Colloidal oatmeal	No rating <sup>b</sup>
Copper	No rating <sup>b</sup>
Cromolyn	B <sub>M</sub>
Cyanocobalamin	See Vitamin B <sub>12</sub>
Cyclizine	B
Dexbrompheniramine	C
Dexchlorpheniramine	B <sub>M</sub>
Dexpanthenol	C <sub>M</sub>
Dextromethorphan	C
Dibucaine	No rating <sup>b</sup>
Dimenhydrinate	B <sub>M</sub>
Dimethisoquin hydrochloride	No rating <sup>b</sup>
Dioxybenzone	No rating <sup>b</sup>
Diphenhydramine	B <sub>M</sub>
Docosanol	B <sup>a</sup>
Docusate calcium	C
Docusate potassium	C
Docusate sodium	C
Doxylamine	A
Dyclonine	C <sub>M</sub>
Ecamsule (terephthalyidene dicamphor sulfonic acid)	No rating <sup>b</sup>
Ensulizole (phenyl benzimidazole sulfonic acid)	No rating <sup>b</sup>
Ephedrine	C

Epinephrine	C
Esomeprazole	C
Ethanol	D (X if used in large amounts or for prolonged periods)
Ethyl alcohol	See Ethanol
Famotidine	B <sub>M</sub>
Fexofenadine	C <sub>M</sub>
Fluoride	C <sup>a</sup> (doses up to 2 mg fluoride/day)
Folic acid	A (C if doses exceed RDA)
Fructose	No rating <sup>b</sup> (natural sources in diet)
Glycolic acid	No rating <sup>b</sup>
Glycerin	C <sub>M</sub>
Homosalate	No rating <sup>b</sup>
Hydrocortisone	C (D if used in the 1st trimester)
Hydrogen peroxide	C <sup>a</sup>
Hydroquinone	C <sub>M</sub>
Ibuprofen	B (D if used in 3rd trimester or near delivery)
Insulin	B (nonprescription insulins only)
Iodine	See Potassium iodide
Ipecac syrup	C <sup>a</sup>
Iron (fumarate, gluconate, and sulfate salts)	A (C if doses exceed RDA) <sup>a</sup>
Isopropyl alcohol in anhydrous glycerin	No rating <sup>b</sup>
Kaolin	C
Ketoconazole	C <sub>M</sub>
Ketotifen	C <sub>M</sub>
Lactic acid	C <sup>a</sup>
Lanolin	B <sup>a</sup>
Lansoprazole	B <sub>M</sub>
Levmetamfetamine (L-desoxyephedrine)	No rating <sup>b</sup>
Lidocaine	B <sub>M</sub>
Loperamide	C <sub>M</sub>
Loratadine	B <sub>M</sub>
Magnesium citrate	C <sup>b</sup>

Magnesium hydroxide	C <sup>b</sup>
Magnesium salicylate	No rating <sup>b</sup>
Manganese	A (RDA during pregnancy is 2 mg/day; no rating if doses exceed RDA <sup>b</sup> )
Meclizine	B <sub>M</sub>
Menthol	No rating <sup>b</sup>
Meradimate (menthyl anthranilate)	No rating <sup>b</sup>
Methylcellulose	No rating <sup>b</sup>
Miconazole	C
Mineral oil	C
Minoxidil	C <sub>M</sub>
Molybdenum	No rating <sup>b</sup>
Naphazoline	C <sub>M</sub>
Naproxen sodium	C (D if used in 3rd trimester or near delivery)
Neomycin	C
Neotame	No rating <sup>b</sup>
Niacin	See Vitamin B <sub>3</sub>
Niacinamide (nicotinamide)	A (C if doses exceed RDA)
Nicotine transdermal system	D <sub>M</sub>
Nicotine polacrilex gum	C <sub>M</sub>
Nizatidine	B <sub>M</sub>
Nonoxynol-9	B <sup>a</sup>
Octoxynol-9	No rating <sup>b</sup>
Octocrylene	C <sup>a</sup>
Octinoxate (octyl methoxycinnamate)	C <sup>a</sup>
Octisalate (octyl salicylate)	No rating <sup>b</sup>
Omeprazole	C <sub>M</sub>
Orlistat	X
Oxybenzone	No rating <sup>b</sup>
Oxymetazoline	C
Padimate O	No rating <sup>b</sup>
Pamabrom	No rating <sup>b</sup>
Pantothenic acid	A (C if doses exceed RDA)

Permethrin	B <sub>M</sub>
Petrolatum	C <sup>a</sup> (poor dermal absorption)
Pheniramine	C
Phenol	No rating <sup>b</sup>
Phenylephrine hydrochloride	C
Phospholipids	No rating <sup>b</sup>
Phosphorus	No rating <sup>b</sup> (an essential nutrient)
Polyethylene glycol	C <sub>M</sub>
Polymyxin B	B
Potassium iodide	D
Povidone-iodine	D
Pramoxine	C <sub>M</sub>
Propylene glycol	C <sup>a</sup>
Propylhexedrine	No rating <sup>b</sup>
Pseudoephedrine	C
Psyllium	No rating <sup>b</sup>
Pyrantel pamoate	C
Pyrethrins	C
Pyridoxine	See Vitamin B <sub>6</sub>
Pyrilamine	C
Pyrithione zinc	B <sup>a</sup>
Ranitidine	B <sub>M</sub>
Resorcinol	B <sup>a</sup>
Riboflavin	See Vitamin B <sub>2</sub>
Saccharin	C
Salicylic acid	No rating <sup>b</sup> (D if full doses used in 3rd trimester)
Selenium	No rating <sup>b</sup> (an essential element)
Selenium sulfide	C <sub>M</sub>
Senna	C
Sennosides	See Senna
Simethicone	C
Sodium bicarbonate	C <sub>M</sub>
Sodium chloride	C <sub>M</sub>

Sodium citrate	No rating <sup>b</sup>
Sodium fluoride	C <sup>a</sup> (doses up to 2 mg fluoride/day)
Sodium phosphate	No rating <sup>b</sup>
Sodium salicylate	C <sup>a</sup>
Sorbitol	C <sub>M</sub>
Sucralose	B <sup>a</sup>
Sulfur	No rating <sup>b</sup>
Sulisobenzone	No rating <sup>b</sup>
Terbinafine	B <sub>M</sub>
Tetracaine	C
Thiamine	See Vitamin B <sub>1</sub>
Tioconazole	C <sub>M</sub>
Titanium dioxide	C <sup>a</sup> (does not cross placenta)
Tolnaftate	No rating <sup>b</sup>
Triethanolamine	No rating <sup>b</sup>
Tripelennamine	B
Trolamine salicylate	No rating <sup>b</sup>
Undecylenic acid	No rating <sup>b</sup>
Urea	C
Vitamin A	A (X if doses exceed RDA)
Vitamin B <sub>1</sub> (thiamine)	A (C if doses exceed RDA)
Vitamin B <sub>2</sub> (riboflavin)	A (C if doses exceed RDA)
Vitamin B <sub>3</sub> (niacin)	A (C if doses exceed RDA; CM for doses used to treat hyperlipidemia)
Vitamin B <sub>6</sub> (pyridoxine)	A
Vitamin B <sub>12</sub> (cyanocobalamin)	A (C if doses exceed RDA)
Vitamin C (ascorbic acid)	A (C if doses exceed RDA)
Vitamin D (calcitriol)	CM (D if used in doses above the RDA)
Vitamin D <sub>2</sub> (ergocalciferol)	A (D if doses exceed RDA)
Vitamin D <sub>3</sub> (cholecalciferol)	C (D if used in doses above the RDA)
Vitamin E (tocopherols)	A (C if doses exceed RDA)
Vitamins, multiple	A (risk factor varies for amounts exceeding RDAs)
Witch hazel	No rating <sup>b</sup>

Xylometazoline	C <sup>a</sup>
Xylitol	No rating <sup>b</sup> (natural sources in diet)
Zinc acetate	No rating <sup>b</sup> (RDA 15 mg/day)
Zinc oxide	C <sup>a</sup> (poor dermal absorption)

<sup>a</sup> Source references did not provide pregnancy risk category. Category is instead based on available clinical information.

<sup>b</sup> Source references did not provide pregnancy risk category. Insufficient clinical information is available to support a rating.

**Handbook of Nonprescription Drugs** > Chapter APPENDIX II. Safety Issues with the Use of Selected Natural Products in Pregnancy

**Appendix II**

<b>Natural Product</b>	<b>Pregnancy Risk Category Rating</b>	<b>Risk Summary</b>
Black cohosh	None	A case report of a woman given a mixture of black cohosh and blue cohosh during labor reported the birth of an infant with severe neurologic impairments. Blue cohosh is unrelated to black cohosh. Black cohosh was associated with estrogenic changes in vaginal cells at 12 weeks in one study and no changes in another. Studies are also mixed for in vitro assays of estrogen activity.
Butterbur	Not recommended	Metabolites of butterbur have been shown to inhibit endocrine function. Butterbur should also be avoided in pregnancy because of its potential hepatotoxicity.
Chastetree berry	Not recommended	Chastetree berry is reported to be a uterine stimulant, so its use in pregnancy should be avoided. Mastodynon (a product containing chastetree berry) was administered to rats at 80 times the human dose, without any noted adverse effects. Teratogenic studies using Mastodynon also found no anomalies in the fetuses. Chastetree berry products may reduce prolactin levels, which has been demonstrated in both animal and human trials.
Chondroitin	C (no human data; probably compatible)	Injection of pregnant mice during gestation produced an increase in cleft palate and tail abnormalities in offspring. In another study, no adverse effects were seen in offspring after administration of chondroitin.
Colostrum	No human data	No studies that document use in humans or animals are available.
Devil's claw	Not recommended	Devil's claw has oxytocic effects in animals; therefore, its use in pregnancy is not recommended.
DHEA	None	DHEA-S (in the sulfated form) has been reported to facilitate midtrimester abortion. It has also been used for the induction of labor at term. No teratogenic effects were observed among the offspring of pregnant rabbits treated with DHEA at doses as high as 125 mg/kd/day. Studies in mice and rats, however, have shown androgenic effects such as masculinization of the external genitalia of female pups. DHEA also inhibits pregnancy development in mice when administered early in the pregnancy.
Echinacea	C (limited human data)	No animal reproductive study has been conducted to examine the effects of echinacea or its components. A prospective cohort study documented the use of echinacea by 206 pregnant women. Of these, 112 women documented use during the first trimester. After matching of data between the study and control arms, no statistically significant differences were observed in live births, spontaneous abortions, induced abortions, gestational age, birth weight, fetal distress, or major malformations. This led the authors to conclude that echinacea posed no major risk of an anomaly.
Eleuthero	None	Secondary resources have not reported teratogenic effects with eleuthero use in mink, sheep, or rats. This effect was determined to be without regard to dose or trimester of pregnancy.
Evening primrose oil	C (probably compatible)	In 2003, a review of pregnancy outcomes in patients taking herbal medications concluded that evening primrose oil (EPO) was safe for use in the induction of

		labor. A randomized, double-blind, placebo-controlled trial compared the effect of evening primrose oil versus placebo on the Bishop score and cervical length. No adverse effects of EPO were observed in fetuses. The effects of EPO in other stages of pregnancy have not been evaluated. Its use during pregnancy has not been recommended.
Fenugreek	No human data	In a study of rats fed fenugreek seeds as 30% of their diets, a reduction in litter size and weight was noted. Male rabbits were also noted to have reduced testes, damaged seminiferous tubules and interstitial tissue, and reduced androgen and sperm production.
Feverfew	Not recommended	A preliminary study found no adverse effects in rats receiving high doses of feverfew. The study, however, was limited by a small sample size. Feverfew has also been rumored to be an abortifacient. Use in pregnancy is not currently recommended.
Ginger	C (compatible, but recent data have suggested concern)	In a reproductive study in rats, consumption of ginger tea was associated with early embryonic loss at a rate double that of the control. Surviving fetuses were heavier and had more advanced skeletal growth. Another study administered ginger extract at a dose of 1000 mg/kg/day during organogenesis in rats; no differences in adverse effects or teratogenicity were noted. The use of ginger for hyperemesis gravidarum was studied in 27 women who reported relief of symptoms. No adverse effects were noted in the women, and no congenital abnormalities were noted in the 25 infants. One woman elected abortion for an unspecified reason, and another had a miscarriage in the 12th week of gestation.
Ginkgo	C (data suggest low risk)	Reproductive studies in animals have revealed no teratogenicity or mutagenicity. Doses as high as 1600 mg/kg were administered to pregnant rats without observing toxic effects. No mutagenic effects were observed in animal or human sperm exposed to <i>Ginkgo biloba</i> . Data are limited, however, and no trials have yet been conducted in humans.
Ginseng (tea)	B (animal data suggest low risk)	A reproductive study examined the effect of <i>Panax ginseng</i> on two generations of rats and noted no differences in behavior and in histopathologic examination at autopsies. Another study examined the use of <i>P. ginseng</i> as a fetal protectant for the compound hexavalent chromium in rats. Rats receiving <i>P. ginseng</i> for protection had better outcomes, such as fewer implantation losses, stillbirths, and skeletal anomalies. Three small reports have described estrogen-like effects such as vaginal bleeding in postmenopausal women taking ginseng. A retrospective study of 88 pregnant women taking ginseng and 88 matched controls found no differences in birthweight, preterm delivery, and stillbirths. No congenital malformations were observed.
Glucosamine	C (probably compatible, although information is limited)	In 1956, a study found no teratogenicity when glucosamine was administered to mice and rabbits. In a brief abstract in 2005, the exposure of pregnant women to glucosamine was documented. The study included 55 women; data are available for 34 subjects. Of the remainder, some pregnancies were still ongoing (20), and no data were provided for 1. For all subjects, a total of 33 live births and 3 spontaneous abortions were reported. The timing of exposures was not noted, and a correlation was not determined. Glucosamine is suspected to inhibit protein, RNA, and DNA synthesis. The percentage of free drug at the maternal/fetal interface is limited, and very little would have the potential to cross into the placenta.
Green tea	None	In two abstracts, tea drinking was associated with neural tube defects, but details on exposure or extent of association have not surfaced. Epigallocatechin gallate is a component of green tea that has some anticancer activity. In rats, this product did not affect embryo development or fertility, despite the subjects receiving very high doses. The caffeine content of green tea should also be considered.
5-HTP	No human data	No studies that document use in humans or animals are available.

Huperzine	No human data	No studies that document use in humans or animals are available.
Juniper tea	X (berries)	Juniper berries are abortifacient; juniper oil stimulates uterine contractions.
Lactobacillus	None	In a study of 127 women, use of <i>Lactobacillus</i> in the third trimester was not associated with adverse effects in fetuses, including congenital anomalies. However, insufficient data are available at this time to rule out fetal risk.
Lemon balm	Not recommended	Lemon balm is contraindicated in pregnancy because it causes menstrual flow. In one study, lemon balm was used as an antimutagen for amino acid pyrolysate and was found to have 100% effect in the Ames test.
Melatonin	C (no human data; animal data suggest moderate risk)	No study in pregnant women that documented the use of melatonin was found. However, there is a trial that documents its use as a human contraceptive. Use was associated with decreased levels of blood luteinizing hormone (LH), estradiol, and progesterone. A study in six rats evaluated their female offspring after the ingestion of melatonin at about 2-10 times the usual human dose. The offspring had lower LH levels and late vaginal opening. Another study in rats during gestation used 143-1400 times the usual human dose and found no increased maternal or fetal risk. The data are limited and somewhat contradictory; the use of melatonin is not recommended and should be avoided.
Milk thistle	Not recommended	A published abstract reported the use of milk thistle by 15 pregnant women, but outcome data on the infants were not reported. In a reproductive teratology study, pregnant rats and rabbits were administered milk thistle at high doses (1000 mg/kg), and no congenital anomalies were noted in the offspring. However, data are inadequate to evaluate the safety of use in pregnancy.
MSM	No human data	MSM was administered to pregnant rats at varying doses during organogenesis. Neither biologically significant alterations in the fetus or maternal weight nor any anomalies were observed.
Red rice yeast	X <sup>a</sup>	No studies that document use of red rice yeast (RRY) in humans or animals are available. The RRY products may contain monacolin K, a naturally occurring lovastatin-like analogue. The use of RRY products should be avoided in pregnancy.
SAMe	Limited data	One study reported the use of SAMe in pregnant women, but the details on use and data on teratogenicity were not available. Adverse effects were not expected because of SAMe's similarity to methionine. SAMe is the naturally occurring methylated form of methionine, an essential amino acid.
Saw palmetto	X <sup>a</sup>	Effects of saw palmetto have not been studied in pregnant women or other species, but the antiandrogenic activity for which it is used is of concern in the development of male fetuses.
St. John's wort	C (limited human data)	There are no data that document the animal or placental transfer of hypericin or other constituents of St. John's wort (SJW). In a randomized, placebo-controlled, reproductive study in mice, the pups exposed to SJW had lower birth weights and lower performance on the negative geotaxis task, which is a measure of behavioral development. The data were driven by a significant effect in male pups. No other differences were noted, and by day 5 all pups were similar in weight and performance. A case report described the use of SJW in a pregnant 38-year-old during her first trimester. Other than late onset thrombocytopenia, the pregnancy was unremarkable. The physical examination and laboratory results of the fetus were normal. Neonatal jaundice developed on day 5 but responded to brief phototherapy. Behavioral assessments were normal. The case study did not report on the presence or absence of physical anomalies. The use of SJW is widespread and dates back many years, with no reports of teratogenicity or other reproductive toxicity.
Valerian	B (limited human data)	Reproductive studies in animals using valerian have shown no negative effects on ovulation, fertility, and embryonic development. Five female mice were bred after

exposure to didrovaltrate, a metabolite of valerian. Each had a normal pregnancy and normal offspring. In humans, two cases of attempted suicide in pregnant women taking valerian are documented, with the women going on to give birth. Of the two infants, one was of normal weight and cognition, whereas the other had impaired cognition and low birth weight after being delivered at 36 weeks gestation. The mother of the second infant attempted suicide during her next pregnancy, with similar results. Two other cases in pregnant women record the use of valerian at weeks 3 and 4 gestation. The infants were born with no abnormalities. Another concern with valerian is its potential to induce uterine contractions. Because of the uncertainty about this risk and the actual content of the products, the use of valerian should be avoided during pregnancy.

Key: DHEA, dehydroepiandrosterone; 5-HTP, 5-hydroxytryptophan; MSM, methyl-sulfonyl-methane; SAME, S-adenosyl-L-methionine.

<sup>a</sup> Rating is based on prescription drugs that contain very similar ingredients: red rice yeast (lovastatin) and saw palmetto (finasteride).
